Abstract

Lyndon factorization and Lempel-Ziv (LZ) factorization are both important tools for analysing the structure and complexity of strings, but their combinatorial structure is very different. In this paper, we establish the first direct connection between the two by showing that while the Lyndon factorization can be bigger than the non-overlapping LZ factorization (which we demonstrate by describing a new, non-trivial family of strings) it is always less than twice the size.

1 Introduction

Given a string (or word) x, a factorization of x partitions x into substrings f₁, f₂, ..., fₜ, such that x = f₁f₂...fₜ. In the past 50 years or so, dozens of string factorizations have been studied, some purely out of combinatorial interest (e.g. [12, 1, 22, 2]) and others because the internal structure that they reveal allows the design of efficient string processing algorithms. Perhaps the two most important factorizations in string processing are the Lempel-Ziv (LZ) factorization [26] and the Lyndon factorization¹ [10].

* This research was partially supported by the Academy of Finland through grant 294143 and by the RFBR grant 16-01-00795.
¹ Also known as the Standard factorization.
The LZ factorization has its origins in data compression, and is still used in popular file compressors\(^2\) and as part of larger software systems (see, e.g., [7, 16] and references therein). More recently it has been used in the design of compressed data structures for indexed pattern matching [13] and other problems [5]. Each factor \(f_i\) in the LZ factorization must be as long as possible and must be either the first occurrence of a letter in \(x\) or occur in \(f_1 \cdots f_{i-1}\).\(^3\) The Lyndon factorization, on the other hand, was first studied in the context of combinatorics on words [20, Sect. 5], and later found use in algorithms; for example, in a bijective variant of the Burrows-Wheeler transform [14, 18], in suffix sorting [21] and in repetition detection [4]. Each factor \(f_i\) in the Lyndon factorization must be a Lyndon word: a string that is lexicographically smaller than all its proper suffixes; and the factors must be lexicographically non-increasing. Lyndon words themselves have deep combinatorial properties [20] and have wide application [6, 9, 11, 15, 18, 19, 20, 23].

For some problems each factorization (Lempel-Ziv or Lyndon) leads to quite different solutions. Perhaps the best known example of this is the computation of all the maximal repetitions – also known as the “runs” – in a string. In 1999 Kolpakov and Kucherov proved that \(\rho(n)\), the number of runs in a string of length \(n\), is \(O(n)\), and showed how to exploit the structure of the LZ factorization to compute all the runs in linear time [17]. Much more recently, Bannai et al. [3] used properties of the Lyndon factorization to obtain a much simpler constructive proof that \(\rho(n) < n\). This later result also leads to a straightforward linear-time algorithm for computing the runs from the Lyndon factorization [4].

Our overarching motivation in this paper is to obtain a deeper understanding of how these two fundamental factorizations – Lempel-Ziv and Lyndon – relate. Toward this aim, we ask: how much can the sizes of the factorizations of the same word differ? Here the size of the Lempel-Ziv factorization \(s = p_1 \cdots p_z\) is \(z\) and the size of the Lyndon factorization \(s = f_1^{e_1} \cdots f_m^{e_m}\), where each \(e_i\) is positive and each \(f_i\) is lexicographically strictly greater than \(f_{i+1}\), is \(m\). For most strings, the number of Lyndon factors is much smaller. Indeed, any string has a rotation with a Lyndon factorization of size one. So the actual question is how big can \(m\) be with respect to \(z\). For a lower bound, we show that there are strings with \(m = z + \Theta(\sqrt{z})\). Our main result is the upper bound: the inequality \(m < 2z\) holds for all strings. This result improves significantly a previous, indirect bound by I et al. [25], who showed that the number of Lyndon factors cannot be more than the size of the smallest straight line program (SLP). Since the smallest SLP is at most a logarithmic factor bigger than the LZ factorization [24, 8], this establishes an indirect, logarithmic factor bound, which we improve to a constant factor two.

## 2 Basic Notions

We consider finite strings over an alphabet \(\Sigma = \{a_1, \ldots, a_n\}\), which is linearly ordered: \(a_1 < a_2 < \cdots < a_n\). For strings, we use the array notation: \(s = s[1..|s|]\), where \(|s|\) stands for the length of \(s\). The empty string \(\varepsilon\) has length 0. Any pair \(i, j\) such that \(1 \leq i \leq j \leq |s|\) specifies a substring \(s[i..j]\) in \(s\). A string \(u\) equal to some \(s[i..j]\) is a factor of \(s\) (a prefix, if \(i = 1\), and a suffix, if \(j = |s|\)). A prefix or suffix of \(s\) is called proper if it is not equal to \(s\). A factor \(u\) may be equal to several substrings of \(s\), referred to as occurrences of \(u\) in \(s\). The occurrences of a given factor \(u\) are totally ordered by their positions in \(s\), so we can speak about “leftmost” or “previous” occurrence. By \(u^k\) we denote the concatenation of \(k\) copies of string \(u\). If \(k = 0\) we define \(u^0 = \varepsilon\).

\(^2\) For example gzip, p7zip, lz4, and snappy all have the LZ factorization at their core.

\(^3\) This is the non-overlapping version of the LZ factorization.
A string \( u \) over \( \Sigma \) is lexicographically smaller or equal than a string \( v \) (denoted by \( u \preceq v \)) if either \( u \) is a prefix of \( v \) or \( u = xav_1 \) and \( v = xbv_2 \) for some strings \( x, v_1, v_2 \) and some letters \( a < b \). In the latter case, we refer to this occurrence of \( a \) (resp., of \( b \)) as the mismatch of \( u \) with \( v \) (resp., of \( v \) with \( u \)). A string \( w \) is called a Lyndon word if \( w \) is lexicographically smaller than all its non-empty proper suffixes. The Lyndon factorization of a string \( s \) is its unique (see [10]) factorization \( s = f_1^{e_1} \cdots f_m^{e_m} \) such that each \( f_i \) is a Lyndon word, \( e_i \geq 1 \), and \( f_i > f_{i+1} \) for all \( 1 \leq i < m \). We call each \( f_i \) a Lyndon factor of \( s \), and each \( F_i = f_i^{e_i} \) a Lyndon run of \( s \). The size of the Lyndon factorization is \( m \), the number of distinct Lyndon factors, or equivalently, the number of Lyndon runs.

The non-overlapping LZ factorization (see [26]) of a string \( s \) is its factorization \( s = p_1 \cdots p_z \) which occurs in \( \text{Lemma 3} \).

### 3 Upper Bound

The aim of this section is to prove the following theorem.

► **Theorem 1.** Every string \( s \) having Lyndon factorization \( s = f_1^{e_1} \cdots f_m^{e_m} \) and non-overlapping LZ factorization \( s = p_1 \cdots p_z \) satisfies \( m < 2z \).

Let us fix an arbitrary string \( s \) and relate all notation \((f_i, e_i, F_i, p_i, m, z)\) to \( s \). The main line of the proof is as follows. We identify occurrences of some factors in \( s \) that must contain a boundary between two LZ phrases. Non-overlapping occurrences contain different boundaries, so our aim is to prove the existence of more than \( m/2 \) such occurrences. We start with two basic facts; the first one is obvious.

► **Lemma 2.** For any strings \( u, v, w_1, w_2 \), the relation \( uw_1 < v < uw_2 \) implies that \( u \) is a prefix of \( v \).

► **Lemma 3.** The inequality \( j < i \) implies \( f_j > F_i \).

**Proof.** We prove that \( f_j > f_i \) for any \( k \), arguing by induction on \( k \). The base case \( k = 1 \) follows from the definitions. Let \( x \preceq f_i \). In the case of mismatch, \( f_j > f_i \) holds trivially. Otherwise, \( f_j = f_i^{e_i-1}x \) for some \( x \neq \varepsilon \). If \( x = f_i \) or \( x < f_i \), then \( x \preceq f_j \), and so \( f_j \) is not a Lyndon word. Hence \( x \preceq f_i \) and thus \( f_j = f_i^{e_i-1}x > f_i \). Thus, the inductive step holds.

The next lemma locates the leftmost occurrences of the Lyndon runs and their products.

► **Lemma 4.** Let \( d \geq 1 \) and \( 1 \leq i \leq m - d + 1 \), and assume that \( F_i F_{i+1} \cdots F_{i+d-1} \) has an occurrence to the left of the trivial one in \( s \). Then:

1. The leftmost occurrence of \( F_i F_{i+1} \cdots F_{i+d-1} \) is a prefix of \( f_j \) for some \( j < i \);
2. \( F_i F_{i+1} \cdots F_{i+d-1} \) is a prefix of every \( f_k \) with \( j < k < i \).

**Proof.** (1) Let \( j \) be the smallest integer such that the leftmost occurrence of \( F_i F_{i+1} \cdots F_{i+d-1} \) in \( s \) overlaps \( F_j \). Suppose first that the leftmost occurrence of \( F_i F_{i+1} \cdots F_{i+d-1} \) is not entirely contained inside a single occurrence of \( f_j \). Then there exists a non-empty suffix \( u \) of \( f_j \) that is equal to some prefix of one of the factors \( f_1, \ldots, f_{i+d-1} \), say \( f_i \). We cannot have \( u = f_j \), because then \( f_j \preceq f_i \), which is impossible since \( j < i' \). Thus \( u \) must be a proper suffix of \( f_j \). But then \( u \preceq f_i < f_j \), which contradicts \( f_j \) being a Lyndon word.

Suppose then that the leftmost occurrence of \( F_i F_{i+1} \cdots F_{i+d-1} \) in \( s \) is entirely contained inside \( f_j \) but is not its prefix, i.e., \( f_j = v F_i F_{i+1} \cdots F_{i+d-1} w \) for some strings \( v \neq \varepsilon \) and \( w \).
Since $f_j$ is a Lyndon word we have $f_j \prec F_i F_{i+1} \cdots F_{i+d-1} w$. Consider the position of the mismatch of $F_i F_{i+1} \cdots F_{i+d-1} w$ with $f_j$. If the mismatch occurs inside $F_i F_{i+1} \cdots F_{i+d-1}$, we can write $f_j = F_i \cdots F_{i-1} f'_j x$ where $i \leq i' < i + d$, $0 \leq e < e_i$, and $x$ is a suffix of $f_j$ that satisfies $x < f'_j < f_j$, which contradicts $f_j$ being a Lyndon word. On the other hand, the mismatch inside $w$ implies that $f_j$ begins with $F_i F_{i+1} \cdots F_{i+d-1}$, contradicting the assumption that the inspected occurrence of $F_i F_{i+1} \cdots F_{i+d-1}$ is the leftmost in $s$.

(2) We prove this part by induction on $d$. Let $d = 1$. By Lemma 3 we have $f_j \succ f_k \succ F_i$. Since $f_j$ begins with $F_i$ by statement 1, so does $f_k$ by Lemma 2. Assume now that the claim holds for all $d' < d$. From the inductive assumption $F_i$ and $F_{i+1} \cdots F_{i+d-1}$ are both prefixes of $f_k$. Let $y, y'$, and $z$ be such that $f_j = F_i F_{i+1} \cdots F_{i+d-1} y$, $f_k = F_i \cdots F_{i+d-1} y' = F_i z$. We have $j < k$ and thus $f_k \prec f_j$ must hold, which, since $F_i$ is a prefix of both $f_j$ and $f_k$, implies $z \prec F_{i+1} \cdots F_{i+d-1} y$. On the other hand, since $f_k$ is a Lyndon word, we have $f_k = F_{i+1} \cdots F_{i+d-1} y' \prec z$. By Lemma 2, $F_{i+1} \cdots F_{i+d-1} y' \prec z \prec F_{i+1} \cdots F_{i+d-1} y$ implies that $F_{i+1} \cdots F_{i+d-1}$ is a prefix of $z$ or equivalently that $F_i F_{i+1} \cdots F_{i+d-1}$ is a prefix of $f_k$. ▲

### 3.1 Domains

Lemma 4 motivates the following definition.

**Definition 5.** Let $d \geq 1$ and $1 \leq i \leq m - d + 1$. We define the $d$-domain of Lyndon run $F_i$ as the substring $\text{dom}_d(F_i) = F_i F_{i+1} \cdots F_{i-1}$, $j \leq i$ of $s$, where $F_j$ is the Lyndon run (which exists by Lemma 4) starting at the same position as the leftmost occurrence of $F_i F_{i+1} \cdots F_{i+d-1}$ in $s$. Note that if $F_i F_{i+1} \cdots F_{i+d-1}$ does not have any occurrence to the left of the trivial one then $\text{dom}_d(F_i) = \varepsilon$. The integers $d$ and $i - j$ are called the order and size of the domain, respectively.

The extended $d$-domain of $F_i$ is the substring $\text{extdom}_d(F_i) = \text{dom}_d(F_i) F_i \cdots F_{i+d-1}$ of $s$.

Lemma 4 implies two easy properties of domains presented below as Lemma 6. These properties lead to a convenient graphical notation to illustrate domains (see Fig. 1).

**Lemma 6.** Let $\text{dom}_d(F_i) = F_j \cdots F_{i-1}$, $j \leq i$. Then:

- For any $d' > d$, $\text{dom}_{d'}(F_i)$ is a suffix of $\text{dom}_d(F_i)$.
- For any $d' \geq 1$, $\text{dom}_{d'}(F_k)$ is a substring of $\text{dom}_d(F_i)$ if $j \leq k < i$.

**Definition 7.** Consider $\text{dom}_d(F_i)$ for some $d \geq 1$, $1 \leq i \leq m - d + 1$, and let $\alpha = F_i \cdots F_{i+d-1}$. We say that the leftmost occurrence of $\alpha$ in $s$ is associated with $\text{dom}_d(F_i)$.

For example, in Fig. 1, $s[7..9]$ is associated with $\text{dom}_2(s[23..24])$; $s[7..17]$ is associated with $\text{dom}_3(s[7..17])$ even though it is not shown, since $\text{dom}_1(s[7..17]) = \varepsilon$. Observe that due
to Lemma 6 this implies that $\text{dom}_d(s[7..17]) = \varepsilon$ for any $d > 1$, and hence for example the substring of $s$ associated with $\text{dom}_2(s[7..17])$ is $s[7..22]$.

A substring $s[i..i+k]$, $k \geq 0$ is said to contain an LZ phrase boundary if some phrase of the LZ-factorization of $s$ begins in one of the positions $i, \ldots, i+k$. Clearly, non-overlapping substrings contain different phrase boundaries. Furthermore, if the substring of $s$ does not have any occurrence to the left (in particular, if it is the leftmost occurrence of a single symbol), it contains an LZ phrase boundary, thus we obtain the following easy observation.

\begin{lemma}
Each substring associated with a domain contains an LZ phrase boundary.
\end{lemma}

3.2 Tandem Domains

\begin{definition}
Let $d \geq 1$ and $1 \leq i \leq m - d$. A pair of domains $\text{dom}_{d+1}(F_i)$, $\text{dom}_d(F_{i+1})$ is called a tandem domain if $\text{dom}_{d+1}(F_i) \cdot F_i = \text{dom}_d(F_{i+1})$ or, equivalently, if $\text{extdom}_{d+1}(F_i) = \text{extdom}_d(F_{i+1})$. Note that we permit $\text{dom}_{d+1}(F_i) = \varepsilon$.
\end{definition}

For example, $\text{dom}_2(s[18..22])$, $\text{dom}_2(s[23..24])$ is a tandem domain in Fig. 1, because we have $\text{extdom}_2(s[18..22]) = \text{extdom}_2(s[23..24]) = s[7..25]$.

\begin{definition}
Let $\text{dom}_{d+1}(F_i)$, $\text{dom}_d(F_{i+1})$ be a tandem domain. Since $F_i \cdot F_{i+d}$ is a prefix of $F_i$ by Lemma 4, we let $F_i = F_{i+1} \cdots F_{i+d}x$. The leftmost occurrence of $F_i \cdots F_{i+d}$ in $s$ can thus be written as $F_{i+1} \cdots F_{i+x}F_{i+1} \cdots F_{i+d}$. We say that this particular occurrence of the factor $xF_{i+1} \cdots F_{i+d}$ is associated with the tandem domain $\text{dom}_{d+1}(F_i)$, $\text{dom}_d(F_{i+1})$.
\end{definition}

\begin{remark}
Note that the above definition permits $\text{dom}_{d+1}(F_i) = \varepsilon$. If $\text{dom}_{d+1}(F_i) \neq \varepsilon$, then $\alpha$, the substring of $s$ associated with $\text{dom}_{d+1}(F_i)$, $\text{dom}_d(F_{i+1})$, is (by Lemma 4) a substring of $F_j$, where $F_j$, $j < i$ is the leftmost Lyndon run inside $\text{dom}_{d+1}(F_i)$. Otherwise, $\alpha$ overlaps at least two Lyndon runs. In both cases, however, $\alpha$ is a substring of $\text{extdom}_{d+1}(F_i)$.
\end{remark}

\begin{lemma}
Each substring associated with a tandem domain contains an LZ phrase boundary.
\end{lemma}

\begin{proof}
Let $\text{dom}_{d+1}(F_i)$, $\text{dom}_d(F_{i+1})$ be a tandem domain and let $u = xF_{i+1} \cdots F_{i+d}$ be the associated substring of $s$. Suppose to the contrary that $u$ contains no LZ phrase boundaries. Then some LZ-phrase $p_t$ contains $u$ and the letter preceding $u$. Since we consider a non-overlapping LZ variant, the previous occurrence of $p_t$ in $s$ must be a substring of $p_{t-1} \cdots p_{t-1}$. Note, however, that $u$ is preceded in $s$ by the leftmost occurrence of $F_{i+1} \cdots F_{i+d}$, which is the prefix of $F_j$ (see Definition 10). Thus, the leftmost occurrence of $u$ in $s$ either immediately precedes the associated substring, or overlaps it, or coincides with it. This, however, rules out the possibility that the previous occurrence of $p_t$ occurs in $p_{t-1} \cdots p_{t-1}$, a contradiction.
\end{proof}

We say that a tandem domain $\text{dom}_{d+1}(F_i)$, $\text{dom}_d(F_{i+1})$ is disjoint from a tandem domain $\text{dom}_{e+1}(F_k)$, $\text{dom}_e(F_{k+1})$ if all $i, i+1, k, k+1$ are different, i.e., $i+1 < k$ or $k+1 < i$.

\begin{lemma}
Substrings associated with disjoint tandem domains do not overlap each other.
\end{lemma}

\begin{proof}
Let $\text{dom}_{d+1}(F_i)$, $\text{dom}_d(F_{i+1})$ and $\text{dom}_{e+1}(F_k)$, $\text{dom}_e(F_{k+1})$ be tandem domains called the $d$-tandem and $e$-tandem, respectively. Without the loss of generality let $i+1 < k$.

Case 1: $\text{dom}_{d+1}(F_i) \neq \varepsilon$ and $\text{dom}_{e+1}(F_k) \neq \varepsilon$. First observe that if the $d$-tandem and $e$-tandem begin with different Lyndon runs, then the associated substrings trivially do not overlap by the above Remark. Assume then that all considered domains start with $F_j$, $j < i$. By Definition 10 we can write $F_j$ as $F_j = F_{i+1} \cdots F_{i+d}xF_{i+1} \cdots F_{i+dy}$, where $|F_{i+1} \cdots F_{i+d}| = |F_i|$ and $xF_{i+1} \cdots F_{i+d}$ is the substring of $s$ associated with the $d$-tandem.
Similarly we have $F_j = F_k x' F_{k+1} \cdots F_{k+e} y'$ where $|F_{k+1} \cdots F_{k+e} x'| = |F_k|$ and $x' F_{k+1} \cdots F_{k+e}$ is the substring of $s$ associated with the $e$-tandem. However, by Lemma 4, $F_k \cdots F_{k+e}$ is a prefix of $F_{i+1}$ and thus $|F_{k+1} \cdots F_{k+e} x' F_{k+1} \cdots F_{k+e} | \leq | F_{i+1} |$, i.e., the substring of $s$ associated with the $e$-tandem is inside the prefix $F_{i+1}$ of $F_j$ and thus is on the left of the substring associated with the $d$-tandem.

Case 2: dom$_{d+1}(F_i) = F_j \cdots F_{i-1}$, $j < i$, and dom$_{e+1}(F_k) = \varepsilon$. In this case the substring associated with the $e$-tandem begins in $F_k$ by the above Remark and thus is on the right of the substring associated with the $d$-tandem.

Case 3: dom$_{d+1}(F_i) = \varepsilon$ and dom$_{e+1}(F_k) = F_j \cdots F_{k-1}$, $j < k$. Then, the substring of $s$ associated with $e$-tandem is a substring of $F_j$. If $i > j$, then clearly extdom$_{d+1}(F_i)$ does not overlap $F_j$. On the other hand, if $i < j$, it must also hold $i + d < j$ since otherwise $F_j$ (and thus also $F_{k+1} \cdots F_{k+e}$) occurs in $F_i$, contradicting dom$_{e+1}(F_k) = F_j \cdots F_{k-1}$, and thus again, extdom$_{d+1}(F_i)$ does not overlap $F_j$. In both cases the Remark above implies the claim. Finally, if $i = j$, we must also have $i + 1 < k$ from the assumption about the disjointness of $d$- and $e$-tandem. By Lemma 4 we can write $F_i = F_{i+1} \cdots F_{i+d} x$, $F_{i+1} = F_k \cdots F_{k+e} x'$ and hence also $F_i \cdots F_{i+d} = F_k \cdots F_{k+e} x' F_{i+2} \cdots F_{i+d} x F_{i+1} \cdots F_{i+d}$. In this decomposition, the substring associated with the $e$-tandem occurs inside the prefix $F_k \cdots F_{k+e}$, and the substring associated with the $d$-tandem is the suffix $x F_{i+1} \cdots F_{i+d}$, which proves the claim.

### 3.3 Groups

We now generalize the concept of tandem domain.

**Definition 13.** Let $d \geq 1$, $2 \leq p \leq m$, and $1 \leq i \leq m - d - p + 2$. A set of $p$ domains dom$_{d+p-1}(F_i)$, dom$_{d+p-2}(F_{i+1}), \ldots$, dom$_d(F_{i+p-1})$ is called a $p$-group if for all $t = 0, \ldots, p-2$ the equality dom$_{d+p-1-t}(F_{i+t}) \cdot F_{i+t} = $ dom$_{d+p-2-t}(F_{i+t+1})$ holds or, equivalently, extdom$_{d+p-1}(F_i) = \ldots = $ extdom$_d(F_{i+p-1})$. Note that we permit dom$_{d+p-1}(F_i) = \varepsilon$.

**Lemma 14.** Substrings associated with tandem domains from the same group do not overlap each other.

**Proof.** Consider a $p$-group, $p \geq 3$ and assume first that $p = 3$. By Lemma 4 we have $F_i = F_{i+1} \cdots F_{i+d+1} x'$ and $F_{i+1} = F_{i+2} \cdots F_{i+d+1} x$ for some words $x'$ and $x$. We can thus write the leftmost occurrence of $F_i \cdots F_{i+d+1}$ in $s$ as $F_{i+2} \cdots F_{i+d+1} x F_{i+2} \cdots F_{i+d+1} x' F_{i+1} \cdots F_{i+d+1}$. It is easy to see that those occurrences of $x F_{i+2} \cdots F_{i+d+1} x'$ and $x' F_{i+1} \cdots F_{i+d+1}$ are associated with (resp.) tandem domains dom$_{d+1}(F_{i+1})$, dom$_{d}(F_{i+2})$ and dom$_{d+2}(F_{i+1})$, dom$_{d+1}(F_{i+1})$, and thus the claim holds.

For $p > 3$ it suffices to consider all subgroups of size three, in left-to-right order, to verify that the substrings associated with all tandem domains occur in reversed order as a contiguous substring and thus no two substrings overlap each other.

The above Lemma is illustrated in Fig. 2. It also motivates the following definition which generalizes the concept of associated substring from tandem domains to groups.

**Definition 15.** Consider a $p$-group dom$_{d+p-1}(F_i)$, dom$_{d+p-2}(F_{i+1})$, $\ldots$, dom$_d(F_{i+p-1})$ for some $p \geq 2$. From Lemma 4, $F_{i+p-1} \cdots F_{i+p+d-2}$ is a prefix of $F_i$. Thus, the leftmost occurrence of $F_i \cdots F_{i+p+d-2}$ in $s$ can be written as $F_{i+p-1} \cdots F_{i+p+d-2} x F_{i+1} \cdots F_{i+p+d-2}$.
We say that this particular occurrence of the substring \( xF_{i+1} \cdots F_{i+p+d-2} \) is associated with the \( p \)-group \( \text{dom}_{d+p-1}(F_i), \ldots, \text{dom}_d(F_{i+p-1}) \).

It is easy to derive a formal proof of the following Lemma from the proof of Lemma 14.

▶ **Lemma 16.** The substring associated with a \( p \)-group is the concatenation, in reverse order, of the \( p-1 \) substrings associated with the tandem domains belonging to the \( p \)-group.

Our consideration of groups culminates in the next two results.

▶ **Corollary 17.** The substring associated with a \( p \)-group contains at least \( p-1 \) different LZ phrase boundaries.

We say that a \( p \)-group \( \text{dom}_{d+p-1}(F_i), \ldots, \text{dom}_d(F_{i+p-1}) \) is disjoint from a \( p' \)-group \( \text{dom}_{d'+p'-1}(F_k), \ldots, \text{dom}_d(F_{k+p'-1}) \) if \( i + p - 1 < k \) or \( k + p' - 1 < i \). By combining Lemma 12 and Lemma 16 we obtain the following fact.

▶ **Lemma 18.** Substrings associated with disjoint groups do not overlap.

### 3.4 Subdomains

The concept of \( p \)-group does not easily extend to \( p = 1 \). If we simply define the 1-group as a single domain and extend the notion of groups to include 1-groups then Lemma 18 no longer holds (e.g. in Fig. 1 the substring associated with tandem domain \( \text{dom}_3(s[18..22]) \), \( \text{dom}_2(s[23..24]) \) is \( s[10..14] \) and the substring associated with domain \( \text{dom}_1(s[7..17]) \) is \( s[7..17] \)). Instead, we introduce a weaker lemma (Lemma 20) that also includes single domains.
Definition 19. We say that a domain $\text{dom}_e(F_k)$ is a subdomain of a domain $\text{dom}_d(F_i) = F_j \cdots F_{i-1}$, $j \leq i$ if $k = i$ and $e = d$ (i.e., the domain is its own subdomain), or $j \leq k < i$ and $\text{extdom}_e(F_k)$ is a substring of $\text{extdom}_d(F_i)$ (or equivalently, if $k + e \leq i + d$). In other words, $F_k$ has to be one of the Lyndon runs among $F_j$, $\ldots$, $F_{i-1}$ and the extended domain of $F_k$ cannot extend (to the right) beyond the extended domain of $F_i$.

Lemma 20. Consider a tandem domain $\text{dom}_{e+1}(F_k)$, $\text{dom}_e(F_{k+1})$ such that $\text{dom}_e(F_k)$ and $\text{dom}_e(F_{k+1})$ are subdomains of $\text{dom}_d(F_i)$. Then, the substring associated with the tandem domain $\text{dom}_{e+1}(F_k)$, $\text{dom}_e(F_{k+1})$ does not overlap the substring associated with $\text{dom}_d(F_i)$.

Proof. First, observe that in order for a tandem domain consisting of two subdomains to exist, $\text{dom}_d(F_i)$ has to be non-empty. Thus, let $\text{dom}_d(F_i) = F_j \cdots F_{i-1}$ for some $j < i$. This implies (Lemma 4) that the substring associated with $\text{dom}_d(F_i)$ is a prefix of $F_j$.

Assume first that $\text{dom}_{e+1}(F_k) = F_j \cdots F_{k-1}$, $j < j' \leq k$. The substring associated with the tandem domain is a substring of $\text{extdom}_{e+1}(F_k)$ thus it trivially does not overlap $F_j$.

Assume then that $\text{dom}_{e+1}(F_k) = F_j \cdots F_{k-1}$. If $k + 1 < i$ then by Lemma 4, $F_i \cdots F_{i+d-1}$ is a prefix of $F_{k+1}$. By Definition 10 the leftmost occurrence of $F_k \cdots F_{k+e}$ in $s$ can be written as $F_k \cdots F_{k+e}$ if $F_{k+e}$ is not overlapped by $F_k \cdots F_{k+e}$. Thus clearly the leftmost occurrence of $F_1 \cdots F_{i+d-1}$ (associated with $\text{dom}_e(F_i)$) occurs in a prefix $F_{k+1}$ not overlapped by $xF_{k+1} \cdots F_k$ (which is a substring associated with the tandem domain).

The remaining case is when $k + 1 = i$. Then by Definition 19 we must have $e = d$ and again the claim holds easily from Definition 10.

For any domain $\text{dom}_d(F_i) = F_j \cdots F_{i-1}$, $j < i$ we define the set of canonical subdomains as follows. Consider the following procedure. Initialize the set of canonical subdomains to contain $\text{dom}_d(F_i)$. Then initialize $\delta = d$ and start scanning the Lyndon runs $F_j$, $\ldots$, $F_{i-1}$ right-to-left. When scanning $F_i$ we check if $\text{dom}_{e+1}(F_i) = F_j \cdots F_{i-1}$.

- If yes, we include $\text{dom}_{e+1}(F_i)$ into the set, increment $\delta$ and continue scanning from $F_{i-1}$.
- Otherwise, i.e., if $\text{dom}_{e+1}(F_i) = F_j' \cdots F_{i-1}$ for some $j' > j$, we include the domain $\text{dom}_{e+1}(F_i)$ into the set. Then we set $\delta = 0$ and continue scanning from $F_{j'-1}$. All domains that were included into the set of canonical subdomains in this case are called loose subdomains.

See Fig. 3 for an example. The above procedure simply greedily constructs groups of domains, and whenever the candidate for the next domain in the current group does not have a domain that starts with $F_j$, we terminate the current group, add the loose subdomain into the set and continue building groups starting with the next Lyndon run outside the (just included) loose subdomain.

Note that the current group can be terminated when containing just one domain, so it is not a group in this case. Hence we call the resulting sequences of non-loose domains clusters, i.e., a cluster is either a single domain, or a p-group, $p \geq 2$. Note also that during the construction we may encounter more than one loose subdomain in a row, so clusters and loose subdomains do not necessarily alternate, but no two clusters occur consecutively.

Finally, observe that the sequence of clusters and loose subdomains always ends with a cluster (possibly of size one) containing $\text{dom}_{e'}(F_{i'})$ for some $d'$ ($d' = 3$ for the example in Fig. 3), since $\text{dom}_{e'}(F_{i'}) = \varepsilon$ for all $d'$.

3.5 Proof of the Main Theorem

We are now ready to prove the key Lemma of the proof. Recall that the size of $\text{dom}_d(F_i) = F_j \cdots F_{i-1}$, $j \leq i$ is defined as $i - j$. 
Figure 3 An example showing the set of canonical subdomains of $\text{dom}_2(F_{15})$. Using notation from Lemma 21, the set has $p = 4$ clusters of size (left-to-right): $\ell_1 = 3, \ell_2 = 1, \ell_3 = 2, \ell_4 = 3$, and $t = 3$ loose subdomains: $\text{dom}_2(F_5) = F_4F_5$, $\text{dom}_3(F_6) = F_5$, $\text{dom}_5(F_{12}) = \varepsilon$ of size $k_1 = 2$, $k_2 = 1$, $k_3 = 0$. Note how the extended domains of loose subdomains do not overlap each other. Furthermore, note that $\text{extdom}_2(F_{15}) = F_1 \cdots F_{16}$ can be factorized as $F_1 \cdots F_2 \cdots F_3$ concatenated with the extended domains. By Corollary 17 and Lemmas 18 and 20, $F_1 \cdots F_2$, contains $1 + \sum_{h=1}^{t}(\ell_h - 1) = 6$ LZ phrase boundaries, while the extended domains $\text{extdom}_2(F_{16})$, $\text{extdom}_3(F_5)$, $\text{extdom}_5(F_{12})$ contain $\sum_{h=1}(\lfloor k_h/2 \rfloor + 1) = 5$ LZ phrase boundaries by Lemma 21.

Lemma 21. Let $\text{dom}_d(F_i)$ be a domain of size $k \geq 0$. Then $\text{extdom}_d(F_i)$ contains at least $\lceil k/2 \rceil + 1$ different LZ phrase boundaries.

Proof. Let $\text{dom}_d(F_i) = F_j \cdots F_{i-1}$, $j \leq i$ and $k = i - j$. The proof is by induction on $k$. For $k = 0$, $\text{extdom}_d(F_i)$ is the substring of $s$ associated with $\text{dom}_d(F_i)$ (see Definition 7) and thus by Lemma 8, $\text{extdom}_d(F_i)$ contains at least one LZ phrase boundary.

Let $k > 0$ and assume now that the claim holds for all smaller $k$. Consider the set $C_{i,d}$ of canonical subdomains of $\text{dom}_d(F_i)$. If $C_{i,d}$ contains no loose subdomain, it consists of a single cluster which is a $(k + 1)$-group. By Corollary 17, the substring associated with this group contains $k$ phrase boundaries; by Lemma 20, one more boundary is provided by the domain $\text{dom}_d(F_i)$ itself. We have $1 + k \geq 1 + \lceil k/2 \rceil$, which concludes the proof of this case.

For the rest of the proof assume that $C_{i,d}$ contains $t \geq 1$ loose subdomains, denoted, left to right, by $\text{dom}_{d_1}(F_{i_1}), \ldots, \text{dom}_{d_t}(F_{i_t})$. Note that $d_t > d$. Let $k_h$ be the size of $\text{dom}_{d_h}(F_{i_h})$, $h = 1, \ldots, t$. Further, let $\ell \geq 1$ be the size of the leftmost cluster (the one that contains some domain of $F_j$). By the construction of the canonical set we have

$$\text{extdom}_{d}(F_i) = F_j \cdots F_{j+t-1}\text{extdom}_{d_1}(F_{i_1})\text{extdom}_{d_2}(F_{i_2}) \cdots \text{extdom}_{d_t}(F_{i_t}).$$ (1)

Both clusters and loose subdomains contribute some number of LZ phrase boundaries into their total. The boundaries contributed by clusters are all different by Lemma 18; let $S$ be their number. These boundaries are also different from the boundary inside the substring associated with $\text{dom}_d(F_i)$ by Lemma 20. Furthermore, it is easy to see from the proof of Lemma 20 that all these phrase boundaries are located inside $F_j \cdots F_{j+t-1}$. The number of phrase boundaries inside the extended domains of loose subdomains can be estimated by the inductive assumption (by Eq. 1, these external domains do not overlap each other or
On the Size of Lempel-Ziv and Lyndon Factorizations

So we obtain that \( \text{extdom}_d(F_i) \) contains at least

\[
1 + \sum_{h=1}^{t} \left( \left\lceil \frac{k_h}{2} \right\rceil + 1 \right) + S
\]

(2)

different LZ phrase boundaries. Let us evaluate \( \sum_{h=1}^{t} k_h \). By the construction, a loose \( d_h \)-subdomain is followed by exactly \( d_h \) Lyndon runs which are outside loose subdomains; then another loose subdomain follows (cf. Fig. 3). The only exception is the rightmost loose subdomain, which is followed by \( d_t - d \) Lyndon runs outside loose subdomains (note that we only count Lyndon runs inside \( \text{dom}_d(F_i) \)). Then

\[
\sum_{h=1}^{t} k_h = k - \ell - \sum_{h=1}^{t} d_h + d.
\]

(3)

Next we evaluate \( S \). By Corollary 17, a cluster of size \( r \) contributes \( r - 1 \) phrase boundaries. Then the leftmost (resp., rightmost) cluster contributes \( \ell - 1 \) (resp., \( d_t - d - 1 \)) boundaries. Each of the remaining clusters is preceded by a loose \( d_h \)-subdomain, where \( d_h > 1 \), and contributes \( d_h - 2 \) boundaries. Using Knuth’s notation \([\text{predicate}]\) for the numerical value (0 or 1) of the predicate in brackets, we can write

\[
S = \ell - 1 + \sum_{h=1}^{t} d_h - t - d - \sum_{h=1}^{t-1} [d_h > 1].
\]

(4)

Finally, we estimate the number in Eq. 2 using Eq. 3 and Eq. 4:

\[
1 + \sum_{h=1}^{t} \left( \left\lceil \frac{k_h}{2} \right\rceil + 1 \right) + S 
\geq 1 + t + \frac{k - \ell - \sum_{h=1}^{t} d_h + d}{2} + \ell - 1 + \sum_{h=1}^{t} d_h - t - d - \sum_{h=1}^{t-1} [d_h > 1]
\]

\[
= \frac{k}{2} + \frac{\ell}{2} + \sum_{h=1}^{t} \frac{d_h}{2} - \sum_{h=1}^{t-1} [d_h > 1] = \frac{\ell + d_t - d}{2} + \frac{k}{2} + \sum_{h=1}^{t-1} \left( \frac{d_h}{2} - [d_h > 1] \right) \geq 1 + \frac{k}{2}.
\]

The obtained lower bound for an integer can be rounded up to \( 1 + \lceil k/2 \rceil \), as required. ◀

Using the above Lemma we can finally prove the main Theorem.

**Proof of Theorem 1.** Partition the string \( s \) into extended domains as follows: take the string \( s' \) such that \( s = s' \cdot \text{extdom}_1(F_m) \) and partition \( s' \) recursively to get

\[
s = \text{extdom}_1(F_{i_1}) \cdots \text{extdom}_1(F_{i_t}), \text{ where } i_t = m.
\]

By Lemma 21, each extended domain \( \text{extdom}_1(F_{i_h}) \) contains at least \( \lceil k_{i_h}/2 \rceil + 1 \) phrase boundaries, where \( k_{i_h} \) is the size of the domain \( \text{dom}_1(F_{i_h}) \). Clearly, \( \sum_{h=1}^{t} k_{i_h} = m - t \); hence the total number \( z \) of the boundaries satisfies

\[
z \geq \sum_{h=1}^{t} \left( \left\lceil \frac{k_{i_h}}{2} \right\rceil + 1 \right) \geq \left\lceil \frac{m - t}{2} \right\rceil + t = \left\lceil \frac{m + t}{2} \right\rceil > \frac{m}{2},
\]

as required. ◀
4 Lower Bound

The upper bound on the number of factors in the Lyndon factorization of a string, given in of Theorem 1, is supported by the following lower bound. Consider a string $s_k = B_0 \cdots B_ka$, $k \geq 0$, where:

- $B_0 = b$,
- $B_1 = ab$,
- $B_2 = a^2baba^2b$,
- $B_k = (a^kbba^1b) \cdots (a^kba^{k-1}b)a^kb$.  

For example, $s_3 = (b)(ab)(a^2baba^2b)(a^3baba^2ba^3b)(a)$.

**Theorem 22.** Let $f_1 \cdots f_m$ and $p_1 \cdots p_k$ be the Lyndon factorization and the non-overlapping LZ factorization of the string $s_k$, $k \geq 2$. Then $m_k = k^2/2 + k/2 + 2$, $z_k = k^2/2 - k/2 + 4$, and thus $m_k = z_k + \Theta(\sqrt{z_k})$.

**Proof.** First we count Lyndon factors. All factors will be different, so their number coincides with the number of Lyndon runs. By the definition of Lyndon factorization, the block $B_i$ ($0 < i \leq k$) is factorized into $i$ Lyndon factors:

$$B_i = a^iba^1b \cdot a^iba^2b \cdots a^iba^{i-1}b \cdot a^i b.$$  

(5)

For any suffix $u$ of $B_0 \cdots B_{i-1}$ and any prefix $v$ of $B_i$, $u \succ v$ holds since $a^i$ is a prefix of $B_i$ and this is the leftmost occurrence of $a^i$. Thus there is no Lyndon word that begins in $B_0 \cdots B_{i-1}$ and ends in $B_i$. This implies that the factorization of $s_k$ is the concatenation of the first $b$, then $k$ factorizations Eq. 5, and the final $a$, $k^2/2 + k/2 + 2$ factors in total.

Let $LZ(s_k)$ denote the LZ factorization of $s_k$. The size of $LZ(s_2) = b \cdot a \cdot ba \cdot aba \cdot baaba$ is 5. For $k \geq 3$, we prove by induction that

$$LZ(s_k) = LZ(s_{k-1}) \cdot a^{k-1}baba^{k-1} \cdot aba^2ba^{k-1} \cdots aba^{k-2}ba^{k-1} \cdot aba^{k-1}ba^kba.$$  

(6)

For $k = 3$ we have $LZ(s_3) = LZ(s_2) \cdot aababaabaaababaababaaba$ and thus the claim holds. If $k > 3$, by the inductive hypothesis the last phrase in $LZ(s_{k-1})$ is $p = aba^{k-2}ba^{k-1}ba$. The factor $p$ has only one previous occurrence: it occurs at the boundary between $B_{k-2}$ and $B_{k-1}$, followed by $b$. So, $p$ remains a phrase in $LZ(s_k)$. Each of subsequent $k - 2$ phrases of $LZ(s_k)$ also has a single previous occurrence (inside $B_{k-1}$), and this occurrence is followed by $b$ because $B_{k-1}$ has no factor $a^k$. Thus, $LZ(s_k)$ correctly represents $LZ(s_k)$. Direct computation now gives $z_k = k^2/2 - k/2 + 4$.  

\[\square\]
