This study of the spatial distribution and ecology of the flying squirrel during the turn of the 20th century provides a description of new methods and techniques for detecting and accounting flying squirrels in the forest zone of Eurasia. The flying squirrel population area covers the territory of 61 regions of Russia, including Kamchatka Krai and Chukotka Autonomous District. The number of flying squirrels in Karelia especially to the east – in the Arkhangelsk region and Western Siberia – significantly exceeds that of Finland, but considerable spatial variability in the number is obvious through all the regions: there are areas where this animal is quite abundant, or inhabits all the territory rather evenly, and there are areas where it is completely absent in vast territories even with seemingly favourable conditions. The flying squirrel is quite difficult to study and the reasons of its absence in obviously favourable areas are still to be explained. Some reasons are: the specificity of favourable landscape, forest coverage pattern, trophic relationships with predators and genetic aspect. A number of hypotheses are supposed to be tested in the nearest future.

Key words: accounting, flying squirrel, forest zone, home range, spatial distribution.

Introduction

The Siberian flying squirrel (Pteromys volans L.) is a specialized dendraobiont, adapted to life in the top layers of the forest (Fig. 1), the only member of the family (according to other sources – subfamily) of Old World flying squirrels in the territory of Russia. It is included in the Red Data Book of East Fennoscandia (Hokkanen & Fokin, 1998), the Baltic region (Ingelög et al., 1993), Finland (Rassi et al., 2001), Estonia (Red Data Book of Estonia, 2008), the Republic of Belarus (Grihich, 2006). On the IUCN Red List it has currently the status of LC (Least Concern – Lowest Risk, 2008), in the previous version – LR/NT (Lower Risk / Near Threatened, 1996). Pteromys volans was originally described as Sciurus volans (Linnaeus, 1758) based on a specimen from Sweden. In the first half of the XX century Ognev (1940) distinguished 9 subspecies of P. volans, and referred flying squirrels, common in the north of European Russia and in the Urals, to the subspecies P. v. volans. Despite the great interest of researchers, until recently the ecology of flying squirrels in the wild has been studied quite poorly. This work is to partly fill this gap, as we have accumulated additional material since the release of our latest publication (Ivanter et al., 2009a; Kurhinen et al., 2010). We believe that the lack of data on this species distribution is associated with the complexities of its detection in the wild. The Siberian flying squirrel is a small and extremely agile animal, mainly crepuscular or nocturnal. Meanwhile, techniques suggested here can quite accurately determine the abundance of the species in the investigated territory.

Material and Methods

To study the flying squirrel’s spatial distribution we used the discount areas method by Hanski (1998) and Hanski et al., (2000), based on telemetry research of female flying squirrel’s home ranges size and location. It was successfully tested in Finland and on the Karelian Isthmus in the early 21st century (Hanski et al., 2004, 2006). Using telemetry Hanski (1998) collected reliable data on the territo-
cially trained fieldworking students to inspect 927 discount areas. Due to the fact that the home ranges of adult female flying squirrels are separate and quite constant in size we were able to develop the cartographic basis for accounting areas system optimization. This accounting method was previously described in more detail (Hanski et al., 2006; Ivanter et al., 2009b; Kurhinen et al., 2010).

Results and Discussion

RANGE AND LEGAL STATUS OF FLYING SQUIRRELS IN RUSSIA. Being quite extensive in the past, the flying squirrel range has significantly changed over the past 100–200 years, mainly on boundaries. In the Russian Federation the flying squirrel range extends to most of the area, covering forest zone and taiga. The flying squirrel range includes the territory of 61 regions of Russia, including the Kamchatsky Krai and Chukotka Autonomous District, where the species is found in very limited territories, as well as the cities of federal status: Moscow and St. Petersburg. In 2014 we confirmed flying squirrels inhabiting the territory of New Moscow (due to changes in the city boundaries the animal world objects shifted from the territory of Moscow region, to the city and changed protected status according to the Red Book of Moscow); within the boundaries of St. Petersburg the flying squirrel occurs in the reserve «Lake Shchuchye» (Volobuev, pers. comm.). However, data for some regions are still to be confirmed, especially at the outskirts of the range. Material on the flying squirrel in the Urals for the period 1956–2014 include data of direct observations, occasional prey by hunters, incidental catch and specimens stored in the museums of the Institute of Plant and Animal Ecology, Ural Branch of Russian Academy of Sciences and the Zoology Department of the Ural State University. In total there were registered more than 80 range spots of this species in the Middle and Northern Urals. The largest number (more than 60) was recorded in the Sverdlovsk region, sporadically they occur on the territory of Permsky Krai, Komi Republic and Chelyabinsk region. The flying squirrel obviously prefers the old dark coniferous forests, especially those directly along the Ural Mountains.

Information on flying squirrels in Central Siberia comprises of fragmentary data in species studies (Kokhanowski, 1962). We have found that the flying squirrel is a regular species in the forests of the lower and middle mountains belt in Eastern Sayan. Animals willingly occupied nesting boxes for owls. In every case we registered breeding, collected data on phenology and other biology aspects.

Fig. 1. Flying squirrel, *Pteromys volans*, in neighbourhood of Petrozavodsk (photo: E. Zadiraka).
Owl trophic relations investigation showed that the flying squirrel is an occasional prey of this predator in the Cannes depression, in the south-western part of the South Minusinsk Depression (middle reach of the river Tashtyp), and sporadically along the eastern foothill of Kuznetsky Alatau. In Krasnoyarsk, this species was found in owl pellets in two perennial nests, although its share in an owl prey never exceeded 1%. This data is sufficient to say that the flying squirrel range covers a large part of southern Siberia – mainly its forest and mountain-forest parts.

**THE LEGAL STATUS.** Presently, in the Russian Federation the flying squirrel is listed in the Red Data Books and on protected species lists of 27 federal subjects with statuses between 4 (rare or insufficiently studied species) to 0 (possibly extinct). This species is included in the new edition of the Red Books of Vologda region (2010), Kurgan region (Polyakov & Modorov, 2012) and Pskov region (Ishtomin, 2004); in the Red Book of Moscow region its status was changed from 3 (rare) (Zubakin, 1998) to 1 (endangered species) (Emeljanova, 2008). Currently the flying squirrel is listed in the Red Data Books of the subjects in the north-western, western and south-western borders of its range, although in most of its range it is on the list of game species, being thus not only unprotected, but even vulnerable. The flying squirrel is relatively rare, though still unprotected, in some regions along the southern border of the range (Khakassia, Southern Altai) (Devyatkin et al., 2000; Prokopov, 2008). Apparently, the number of flying squirrels does not cause concern only in the central part of its range. According to Tyumen region data, the species population can be considered quite stable: it is proposed to exclude the flying squirrel from the next edition of the Red Data Book (Nizovtsev & Gashev, 2013; Gashev, pers. comm.). In the western and north-western parts of the Eurasian forest zone such significant changes in the range of the flying squirrel have occurred that a separate study will be devoted to this phenomenon.

**ACCOUNTING.** For a more objective analysis of the obtained material we have compared statistical analysis of the species accounting data and Forest Fund material of different regions to investigate the correlation between the territorial distribution of the flying squirrel and landscape dynamics and structure. For easier use of statistical programs (the SYSTAT) the investigated area was divided into squares 50 × 50 km (according to UTM co-ordinate system, more than 100 squares) then received data on the flying squirrels number was supplemented by the taiga landscapes structure information.

In general, the number of flying squirrels in Karelia, and especially to the east – in the Arkhangelsk region and Western Siberia – significantly exceeds that of Finland, but considerable spatial variability in number is obvious through all the regions: where this animals is quite abundant, or inhabits all the territory rather evenly, and there are areas where it is completely absent in vast territories even with the seemingly favourable conditions. In Fenoscandia to definitely unfavourable habitats can be referred rocky landscapes and heavily waterlogged areas, dominated by pine forests at the White Sea coastland.

FLYING SQUIRREL TELEMETRY. In the winter 2012–2013 for the first time on the territory of Russia flying squirrel telemetry studies took place in the south-west of the Arkhangelsk region (Mamontov et al., 2015). There were identified the size of the winter home range (0.0366 km$^2$), the average distance of male flying squirrels from the covert over night (49.4 ± 35.3 m, n = 78), the maximum distance during the rutting season – 1282 m. The structure of habitats on the used section, on the accessible territory (in a 100 m radius around the coverts), on the border territories (100–150 m from the coverts) and in the investigated area were studied as well. It was discovered that the flying squirrel is very selective in choosing a habitat. The used section and accessible territory were dominated by mixed stands with predominance of spruce at the age of 65 and 100 years.

USE OF SPECIAL TECHNICAL DEVICES (PHOTO-TRAPS, VOICE RECORDER). A number of reserves have used camera traps for flying squirrel monitoring. For example, the Pechora-Ilych Nature Reserve (Leonid Simakin) collected unique data on the behaviour of the flying squirrel and sable. We should note that in the plains and foothills in Pechora-Ilych Nature Reserve a significant part of the material was obtained while live trapping other animals (these studies were carried out by Sokolskiy, Kudryavtseva, Teplova (Bobretsov et al., 2004). Very curious material on the dynamics of the daily activities of the flying squirrel was collected by E. Zadiraka.

Conclusions

The factors of the uneven spatial distribution of the flying squirrel in the forest area are not fully understood. It is only obvious that this species avoids large areas of wetlands, rocky pine forests and open marshes, i.e. habitats, usually occupying significant part of the region. It is possible that causes of its range limits to the west (with a noticeable reduction in the range) are completely different compared to those in the north (the northern boundary of the range). In both cases, it has to be a complex of factors (for example, in the west – the extreme fragmentation of habitats into a mosaic landscapes, and in the north – the spread of pine forests and open marshes). Statistical analysis of the surveys shows an obvious correlation between the spatial distribution of the flying squirrels and the forest cover degree: where the forest area is less than 85%, there is a clear correlation between this indicator and the number of flying squirrels (correlation coefficient of +0.73, p <0.01). In other words, the decline of forest cover in different regions of the taiga zone inevitably leads to a reduction in the population of flying squirrels, reaching a minimum in areas where the forest coverage is 31% or lower.

However, this is only a partial explanation for such an uneven distribution of the flying squirrels. The flying squirrel is still quite difficult to study and reasons for the absence of this species in certain very favourable habitats still needs to be explained. Some reasons are: the specificity of favourable landscape, forest coverage pattern, trophic relationships with predators and genetic aspect. A number of hypotheses are supposed to be tested in the nearest future.

Acknowledgements

This work was conducted in the development process of the Russian-Finnish international project “Linking environmental change to biodiversity change: long-term and large-scale data on European boreal forest biodiversity” (2011–2015), and in framework of the state task of the Forest Research Institute of Karelian Research Centre RAS (topic number 0220-2015-00014).

В работе рассматриваются исследования территориального распространения и экологии летяги на территории лесной зоны Евразии, в период рубежа 20–21 вв. Дается описание новых методов и способов обнаружения и учета численности летяги в лесной зоне Евразии. Область обитания летяги включает территории 61 субъекта РФ, в их числе – Камчатский край и Чукотская автономная область. Численность летяги в Карелии и тем более к востоку - в Архангельской области и Западной Сибири существенно выше, чем в Финляндии, но в во всех регионах отмечена значительная пространственная вариабельность численности летяги: есть районы, где численность зверьков довольно велика, и они достаточно равномерно заселяют всю территорию, а есть места, где они полностью отсутствуют на больших площадях даже при наличии внешних благоприятных условий. Летяга остается довольно сложным для изучения видом причем причины отсутствия вида в некоторых весьма благоприятных местообитаниях еще ждут своего объяснения. Среди причин - ландшафтная специфика местообитаний, характер растительности и трофические взаимосвязи с хищниками, генетический аспект. Ряд гипотез предполагается апробировать в ближайшее время.

Ключевые слова: летяга, учет численности, ареал, лесная зона, территориальное распространение.
