Research, Practice and Collaboration in Science Education
Proceedings of the ESERA 2017 Conference

ISBN 978-1-873769-84-3

General Editors: Odilla Finlayson, Eilish McLoughlin, Sibel Erduran and Peter Childs

Co-editors:

The Proceedings of ESERA 2017 is an electronic publication for revised and extended papers presented at the ESERA 2017 conference in Dublin, Ireland during the 21-25 August, 2017. All papers in the eProceedings correspond to communications submitted and accepted for the ESERA 2017 conference. All proposals to the conference went through a blind review by two or three reviewers prior to being accepted to the conference. A total of 1246 proposals (out of which 86 were symposia) were presented at the conference and in total 243 papers are included in the eProceedings.

The authors were asked to produce updated versions of their papers and take into account the discussion that took place after the presentation and the suggestions received from other participants at the conference. On the whole, the eProceedings presents a comprehensive overview of ongoing studies in Science Education Research in Europe and beyond. This book represents the current interests and areas of emphasis in the ESERA community at the end of 2017.

The eProceedings book contains eighteen parts that represent papers presented across 18 strands at the ESERA 2017 conference. Part 18 presents papers contributed by ESERA 2016 and 2017 summer school participants that presented at the ESERA 2017 conference. The stand chairs for ESERA 2017 co-edited the corresponding part for each strand 1 to 17 and part 18 was co-edited by the host of the 2016 and 2017 ESERA Summer schools and the coordinating member of ESERA Executive Board. All formats of presentation (single oral, interactive poster, ICT demonstration/workshop and symposium) used during the conference were eligible to be submitted to the eProceedings.

The co-editors carried out a review of the updated versions of the papers that were submitted after the conference at the end of 2017. ESERA, the editors and co-editors do not necessarily endorse or share the ideas and views presented in or implied by the papers included in this book.

The appropriate APA style for referencing this eProceedings is as follows:

STRAND 1: INTRODUCTION

LEARNING SCIENCE: CONCEPTUAL UNDERSTANDING

Strand 1 focusses on the process(es) of learning science that develop understanding. The strand comprises of theories, models, and empirical results on conceptual understanding, conceptual change and development of competences; methodology for investigating students’ processes of concept formation and concept use; and strategies to promote conceptual development.

This is a central focus of research in science education as it encompasses all disciplines and educational levels. Twenty three papers are now included in the e-proceedings under this strand, highlighting many aspects of developing conceptual understanding.

But what is the basis for developing concepts or for conceptual change? Hardman argues the theoretical basis of conceptual change research and highlights the ill-defined nature of concepts, despite 50 years of research. He believes that it is time to leave behind unanswerable questions around the development of concepts and instead focus our research upon the specific contexts in which pupils develop their responses to scientific problems.

Students reasoning and understanding have been challenged in a number of different contexts using different strategies:

- through the use of modelling software (Netlogo) (Ampatzidis and Ergazaki) in the context of promoting students' understanding of the unpredictable behavior of a fully protected ecosystem
- through the use of animation software to determine understanding of dissolving sugar (Peetz and Pietzner)
- through the use of ICT and student drawings to enhance the explanation of more correct, complete and complex explanations with different contexts in the area of genetics (Garcia-Rivera et al).
- through the use of the Atwood machine and the Poggendorff apparatus. Borges, Coelho and Karam ‘introduce a problem solving instructional approach providing opportunities for students to share conceptual and procedural knowledge as well as engaging them in meaningful discussions’
- through different kinds of class interventions. Wagner et al. analyse the results of different interventions (formative assessment and frequent testing) compared to traditional teaching. They examine relationships between cognitive ability, conceptual knowledge and problem solving with different type of interventions.

The use of representations have been investigated by a number of authors as appropriate tools for effective building of mental representations Multiple representations are considered by Akman and Fechner within the context of investigating the influence of abstract and concrete external representational instruction on understanding chemical concepts in the area of acid-base chemistry. They highlight the requirement of multiple representations to show the connections between the macroscopic, submicroscopic and symbolic chemical levels. Multiple
represents in chemistry textbooks are considered by Pantazi and Tsaparlis, who emphasize the important role of teachers in encouraging the students to actually use the representations.

Various research studies emphasize the importance of engaging students in tasks that point toward the development of models, this being an activity in which their initial ideas and notions can serve to anchor and scaffold their subsequent learning. Taking an epistemological view, Kermen, analyses how well students link the experimental level and the model level. Taking into account the relevant literature in the field, she envisages the description of a chemical change as a chemical description of “reality-as-idealised” -involving chemical species which are model-objects derived from real objects by idealization- and the description of an experiment in terms of objects and events as based on the “reality-as-perceived”. Distinguishing elements of “reality-as-idealised” and elements of a model result in difficulties for students. They miss the link between the model level and the “reality-as-idealised”. The issue of establishing connections between theoretical ideas, evidence and the material world is also the focus of the paper by Kallery, Psillos and Tselves. They analyse the effects of involving students in experimental design activities in order to promote scientific ways of thinking.

Multiple modes of thinking on Chemistry can exist and the paper by Freire and Amaral aimed to ‘propose a conceptual profile of chemistry and apply it to analyse views of chemistry in episodes of classroom discourse interactions’. They consider that a conceptual profile can provide a way of bringing together Chemistry teaching and philosophical issues.

The identification of underlying mental models that students use to explain different processes in everyday contexts is the main issue for three pieces of research: the contexts studied were milk transformation to yoghurt and formation of dental caries (two papers by Muñoz-Campos, Franco-Mariscal, and Blanco-Lopez), and carbonated drinks (Cañero-Arias, Oliva-Martinez and Blanco-Lopez). These papers highlight the disjoint ideas that can be present.

Different studies have highlighted that new ideas or perspectives in curriculum may be beneficial in supporting conceptual understanding

- Stein and Galili show that introducing the concept of observer (frame of reference) can be beneficial in developing students understanding of classical mechanics. Middle school physics includes numerous observer-dependent concepts (location, trajectory, displacement, velocity, force, kinetic energy, work) and the concept of observer in the scientific discourse would change teaching physics and upgrade the curriculum. Moreover, it allows applying frame of reference dependence to the accounts of daily experiences.

- Yamashita and Miyashima use a plant factory to investigate different environments for plant growth in primary school as also a way to introduce the perspective STEM in the classes.

Organisation of difference components of knowledge can be a challenge to a learner and among the strategies suggested in this topic are the summary lectures (Goren and Galili) that intend to organize the knowledge developed in the regular disciplinary instruction. It is usually assumed that using an Expert Concept Maps as an advanced organizer improves knowledge organization and integration, and enhances deeper understanding. However, Radanovic et al.
use expert concept maps (within the context of cell division) and concluded that learning based only on ECM demonstration does not contribute to better student understanding when compared to quality teaching without concept maps.

Markic highlights the learning of scientific language and defines and develops a tool to determine the level of Pedagogical Scientific Language Knowledge (PSLK) of pre-service teachers. She considers that the tool can be used not only for identifying science teachers’ PSLK but also for stimulating self-reflection and self-assessment. Childs and Ryan also reflect on the language used in science classes. They describe the LiSP project (Language in Science Project) aimed at raising science teacher’s awareness of language issues in teaching science and develop resources to target these difficulties. They note that science classrooms increasingly contain non-native speakers who are Second Language Learners and that many everyday words undergo metamorphosis and have different meanings in science. Therefore, students with poor language skills have to try and decode their meanings and overcome the language barrier in learning science.

Pre-service teacher education, particularly with regard to global warming, is presented by Almeida and Fernandez. In a comparative study between Portuguese and Spanish pre-service teachers, they find confused ideas on both groups and propose new activities for the deconstruction of some of the usual wrong ideas.

The necessity of having textbooks that are free from misconceptions was highlighted by Dvorakova and Hula after their investigation of Czech High School students’ knowledge, understanding and attitudes to human evolution. Kock investigated how models in relation to electricity are presented in textbooks and highlights that it is important to consider how these models are used within scientific inquiry processes.

Sánchez-Gómez analyses educational constructivism in science education and concludes that constructivism is a combination of many “ideas from different fields that have a common denominator of placing the learner at the center of the educational process”.

Finally, different reflections, perspectives and views show the variety of concerns of researchers regarding students’ learning with understanding. All of them express tacitly that teaching and learning science is not a simple task but requires sufficient theoretical background in Science, Psychology, Pedagogy, Philosophy as well as consideration of learning aims, the classes’ approach, the teaching strategies, the activities to design, the language to be used, the mastering of computer tools, etc.

The papers presented here provide us with abundant ideas for effective appropriate approaches and ways to inform further teaching-learning sequences. They stimulate further research in many areas and directions.

Odilla Finlayson and Roser Pinto
THE MATTER OF LEARNING: RECONSIDERING THE
THEORETICAL BASIS OF CONCEPTUAL CHANGE
RESEARCH

Mark Hardman
UCL Institute of Education, London, UK

Since the inception of conceptual change research the field has been plagued by an inability to adequately define what concepts are or how they change. By considering the simple example of a ball being thrown in the air, this paper expounds the difficulties in defining conceptual change and links these to the theoretical roots of conceptual change within constructivist theory. By recognising advances in both philosophy and the natural sciences over the last few decades, it is argued that learning should be characterised as the co-adaptation of brain, body and context. Such a characterisation provides an improved foundation for research.

Keywords: conceptual change, complexity, materialism

INTRODUCTION

This paper sets out the need for a revision to the way that conceptual change is theorised, in order to advance both research and practice in science education. Over the last 50 years, conceptual change research has amassed a huge body of evidence around the ways that young people learn, including the difficulties that they have in many specific areas of science. It has also engaged with how teachers themselves learn, and how pupils respond to the nuances of instruction. However, over those 50 years there have been both theoretical and empirical advances outside of conceptual change research in how we understand the mind and its relation to the world. I will show how these advances have brought into question the way that conceptual change is framed as the development of mental entities, be they coherent theories or fragmented schemas of action.

Through tracing key points in the development of conceptual change theory I will highlight how it has retained a separation of mind and matter which is no longer tenable in light of advances in neuroscience, nor in the face of the philosophical debates around representation, language and mind which straddled the turn of the century. In addition to these threats from outside, debates which have emerged within conceptual change research are far from resolved, leading several authors to comment that there is still no consensus around what conceptual change involves (Clement, 2008; Vosniadou, 2008). Conceptual change researchers are not isolated from broader theoretical discussion, nor are they blind to the theoretical issues in the field. Nevertheless, the field proceeds without resolving these issues and I contend that this is preventing progress.

APPROACH

Throughout the paper, we will return to the example of an object being thrown in the air, and pupils describing its motion. This example has reoccurred through the literature and therefore provides a useful vehicle through which to explore the different characterisations of concepts within conceptual change research. It furthermore allows the paper to draw upon a systematic
review of 71 papers on conceptual change in forces and motion, which forms a foundation from which to mount the critique of concepts. The paper begins with a review of key points within the theoretical development of conceptual change research, and how these ultimately led to difficulties in defining concepts. Following this the paper examines the potential challenges from outside the field, before suggesting ways to navigate these challenges.

DEFINING CONCEPTS

Despite debate since at least the 1970s, there remains no consensus around what concepts are or what conceptual change involves (Clement, 2008; Vosniadou, 2008). I will take a typical, recent example from Graham et al. (2013), who describes a classroom situation. It involves 11, 16 and 17-year-olds (5 boys, 6 girls, diverse backgrounds).

Firstly, the pupils discuss in small groups what a force is, and then make a poster to elicit their existing understanding. These are discussed by the teacher. Next, the teacher guides discussion around an aeroplane moving at constant horizontal speed, and then accelerating. The forces are discussed, which leads to a conclusion that unbalanced forces lead to changes in motion, or shape. The teacher then gives a similar force diagram and asks the young people to vote on the resultant force. In their first vote (a further one follows discussion), they give incorrect resultant forces (e.g. 8 of them say the resultant force is up when the ball is rising). Clearly there are misconceptions despite the obvious display of understanding earlier.

ARISTOTLE’S PHYSICS

The view that the pupils express in Graham et al.’s study might be linked to Aristotle’s view of motion. Aristotle turned Plato’s contention around universal forms on its head, arguing that the essential forms of entities are to be found only in looking at their particular manifestations. Nevertheless, the essence of each entity is still characterised as a universal quality, and learning as the investigation of these essences.

Of use to our discussion is Aristotle’s preoccupation with motion as fundamental to all change (especially in The Physics), and here we come to our first example of falling objects. According to Aristotle, each object has a natural place within the (geocentric) universe: earth and water both fall downwards towards the centre of the earth/universe but earth falls through water, and occupies a natural place closer to the centre of the earth. Air rises (as is evident through bubbles in water), but fire escapes even more readily toward the heavens, so occupies a place above air. Real entities, being made of different ratios of these elements, contain an aggregate of such tendencies. Nevertheless, entities can either move according to their (aggregate) natural tendency, or be moved against them. Aristotle describes four types of cause, (as well as chance). For a stone being tossed we might describe a material cause (that the stone and person are there), a formal cause (the essential tendency of the stone to fall), an efficient cause (that the stone has come from the earth or a mountain) and the final cause (that a stone can be thrown by a person).

Aristotle’s view is pertinent to our discussion in two ways. Firstly, it became the basis for theories of impetus: that a thrown object is implanted with a certain force that continues its motion once it leaves a throwers hand. The impetus is diminished (for example by air
resistance) up to the point that the stone begins to fall again, as is its tendency. This view has been found amongst children in several studies, and some conceptual change researchers go as far as ascribing it as an Aristotelean view. This is not of primary concern here though.

ESSENTIALISM AND THE PSYCHOLOGICAL VIEW OF CONCEPTS

The second relationship between Aristotle’s characterisation and discussion of contemporary conceptual change research is the importance of forms and tendencies. Whilst it is a disservice to almost two-and-a-half millennia of human thought to say that Aristotle’s views remain unchallenged, what we can say is that the importance of forms is still implicit in many areas of science. For example Hull (1965) suggests that Aristotle’s view underpins the essentialism we see in taxonomy:

“The three essentialistic tenets of typology are (I) the ontological assertion that Forms exist, (2) the methodological assertion that the task of taxonomy as a science is to discern the essences of species, and (3) the logical assertion concerning definition.”

(Hull, 1965, p. 317)

The consideration of forms and natural kinds extends beyond taxonomy however; it informs the classical view of what concepts are.

Aristotle’s philosophy did not seek to escape the existence of universal forms, only to situate them in the particular, real entities which exist in the world. From this stems a focus upon the correct definition of a particular entity, which has arguably dominated western philosophy for millennia. Smith & Medin (1981) dubbed this the ‘classical view’ of concepts, and the fact that it is only labelled such in the early 1980’s indicates its dominance over history. This view equates concepts with categories, or what Aristotle called natural kinds:

“First, concepts are mentally represented as definitions. A definition provides characteristics that are a) necessary and b) jointly sufficient for membership of a category. Second, the classical view argues that every object is either in or not in a category, with no in-between cases.” (Murphy, 2002, p. 15)

So a dog might be specified by the characteristics that it has 4 legs, fur and barks.

As Murphy goes on to describe in his book, the study of concepts in psychology has proceeded to debate this, and there are now different views of how concepts should be defined. Very briefly, some psychologists favour a view that when we recall a type of object (e.g. dog), we recall exemplars from our past experience. Others suggest we use a ‘prototype’ concept, which distils the essential characteristics of that object. This explains why some examples of a group are more typical than others: oranges and bananas are more typical fruits than tomatoes. Other psychologists draw attention to the influence of knowledge in building concepts, and how we fit those concepts into systems of knowledge.

THE CLASSICAL VIEW AND CONSTRUCTIVISM

Murphy (2002) suggests that Inhelder & Piaget held a classical view of concepts. This can be seen in their work:
“We want to know why the organization of behaviour in classification and seriation takes the forms it does. In particular, we want to know why later forms tend to approximate more closely to logico-mathematical structures.” (Inhelder & Piaget, 1964, p. 281)

“There is certainly present to the child a whole world of thought, incapable of formulation and made up of images and motor schemas combined. Out of it issue, at least partially, ideas of force, life, weight, etc., and the relations of objects themselves are penetrated with these indefinable associations. When the child is questioned he translates his thought into words, but these words are necessarily inadequate.” (Piaget, 1929, p. 27)

In Piaget’s view, learning proceeds through stages with children first developing sensorimotor schema about the world, then having pre-operational concepts, then concrete operational concepts and finally being able to manipulate formal operations, with abstract concepts. This pinnacle means that children have acquired the correct logical specifications of a concept (e.g. falling). This is classical in the sense that ‘logic’ is specified as the correct understanding of a concept, and it has an essentialist character.

Bruner, Goodnow & Austin (1986) also focused upon investigating whether children have ‘correct’ logical specifications of concepts, and they arguably started a cottage industry in analysing the correct and incorrect concepts that children held. Bruner’s theoretical frame also includes a taxonomy of learning, centred on different forms of representation. Children move through enactive forms of representation, to iconic and then to abstract symbolic. Like Piaget’s taxonomy, the pinnacle reflects a child’s capacity to manipulate abstract concepts. The two frames for understanding learning both rely on a view of representations of reality as mental concepts which can be correctly (or incorrectly) defined. Aristotle’s essentialism is inherent in this view in that a concept is a representation of reality which reflects the essential characteristics of an object, process or physical law.

CONCEPTUAL CHANGE

Piaget and Inhelder certainly had an influence upon early thinking around concepts in science. However, research in science learning in some ways separated from mainstream psychological investigation of concepts, which focused on categories and objects. This was obviously not sufficient to support how we come to have understanding of processes and laws. In their reviews of the history of conceptual change research in science education, both DiSessa (2006) and Özdemir & Clark (2007) draw attention to how ideas from the philosophy of science filtered into views of conceptual change. This might be seen as taking the ‘systems of knowledge’ view in mainstream psychologies investigation of concepts.

Returning to our example of a ball being tossed in the air, two papers here provide a summary view of the different views of concepts that developed (as discussed by DiSessa (2006).

McCloskey (1983) discusses the naïve theories that pupils have, for example the impetus view in which a ball runs out of impetus as it rises, and then begins to fall (descended from Aristotle’s view). In this view, concepts are naïve theories which, like scientific theories, should be
challenged by the presentation of conflicting evidence. In the very same volume however, DiSessa (1983) developed his account of ‘p-prims’: fragmented understandings often stemming from experience. For example, the point at which a ball thrown vertically is stationary may invoke an understanding of ‘balance’ (diSessa, 2006, p. 274). This may in turn lead to pupils erroneously considering that there is no resultant force acting on the ball. The well-established fault line between so called ‘coherence’ and ‘fragmented’ views of concepts influences understandings of conceptual change and pedagogy.

However, there is another strong view in the literature, that which takes a sociocultural view of concepts. This derives more from Vygotsky’s view of constructivism than Piaget’s. Graham et al. (2013), from whom we took the original example, take this view: that concepts are not individual mental representations, but emerge in the interaction between teachers and pupils. They suggest that the reason pupils give the incorrect response is because they spontaneously give a response in relation to (social) circumstances. I would also suggest, reading Graham et al.’s paper, that there is a temporal influence in the responses given: the activity prior to them being asked about rising and falling objects is a discussion of an aeroplane with balanced and unbalanced forces, so in a sense they have been ‘primed’ to see a static object as having no resultant force. The sociocultural view is not new in conceptual change research though, Mercer (2007) concludes a detailed volume on it, in which several researchers consider the social nature of concepts in science education. The issue that remains however is that there are different ways of seeing concepts. Concepts are poorly defined, despite 50 years of research.

OVERCOMING DUALISM – PHILOSOPHICAL ARGUMENTS

I believe that at the heart of our inability to define concepts, lies the essential, dualist character which is given to mind within the field. This, as I have argued, comes from Aristotle by way of Piaget, Bruner and the classical view of concepts. The issue is that concepts are seen as mental representations of the world ‘as it is’. This representational view has been challenged by discourses within the latter part of the 20th century.

In analytical philosophy, Wittgenstein (1953) challenged the claim that a concept could be logically specified by characteristics. Take the example of a dog with 3 legs, no fur and who has lost its bark: it is still a dog. There cannot be necessary and sufficient criteria for an object; the meaning of a concept is actually defined in its usage.

Furthermore, in ‘continental’ post-structuralist discourses, the representational view was troubled by showing that there is not a simple relationship between a signifier (or concept) and what is signified. Drawing on Saussure’s work, Derrida (1976, 1978) showed that meaning is bound to a shifting system of representation.

Pedro J. Sánchez Gómez presented a paper in the ESERA 2017 conference on Monday, looking at how Putnam’s ‘meaning of meaning’ challenges constructivism, and there are undoubtedly many more critiques of constructivism and how concepts are characterised within the philosophical literature.

Theory of mind is another area in which there have been significant developments over the last 50 years, accompanying by technological advances which have changed our understandings of
Strand 1

brain and mind. Ryle (2009 [1949]) challenged the “the dogma of the ghost in the machine”, arguing against Descartes’ dualist view of mind, and such arguments are only strengthened by neuroscience as it develops at pace. Not only are neuroscientists defining the ways in which grey matter underpins our thoughts and actions, but they are also showing the subtleties of the material influences upon thought and response. For example, in relation to watching an object being thrown in the air, neuroscience suggests that our responses would differ whether we observe the motion from the first or third person perspective (Jackson, Meltzoff, & Decety, 2006), and our acceptance of any description of forces acting would be influenced by our relationships with others and their subtle gestures (Baaren, Janssem, L, & Dijksterhuis, 2009). Studies of this kind show a clear link between mind, matter and material context; something which is often overlooked within conceptual change research.

Furthermore, in my doctoral thesis (Hardman, 2015) I investigated the way that complexity theory undermines a separation of mind and matter. Briefly, the question posed by complexity is how mind and matter can interact given the multitude of influences which interact nonlinearly within a complex system: where does mind stop and matter begin?

In recognising the decline of dualism, the question arises as to whether we can sustain an ontological distinction between individual minds, social interaction and material context. I propose that we cannot.

THE ISSUES WITH CONCEPTS

There are philosophical issues with defining ‘concepts’ therefore. I propose that this is already well recognised within science education research. As Toumlin (1972, p.8) complained “The term concept is one that everybody uses and nobody explains – sill less defines” (in diSessa, 2006). DiSessa goes on to say that “The “conceptual” part of the conceptual change label must be treated less literally.” (DiSessa, 2006, p.265). He notes that many different terms are used, each with slightly different meanings in relation to children’s thinking. In the review of literature which underpins this paper, we encountered reference to mental representations, P-prims, naïve theories, beliefs, mental models, cognitive structure, and ontologies. Even within mainstream psychological research into concepts, we find an awareness that any label might be applied: “numerous different representational structures, with different processes operating on them, can be formulated to explain any given research finding.” (Kosslyn, p.219, in Rosch et al. (1978) pp. 217–257). The point is that ‘concepts’ are abstractions, and I suggest that they are in the eye of the beholder.

As well as being ill-defined, science education research recognises that when we are talking about conceptual change, we are not talking about cognition or thinking. Richard Brock’s paper follows mine at the conference, so I have playfully used a quote from him here, in which he and Keith Taber refer to an ‘underlying cognitive structure’:

> “a change in what a person is thinking (which is what a researcher can hope to directly infer by interpreting data elicited at any one time) from one time to another, may, or may not, reflect a substantive change in the underlying cognitive structure (which is only partially and less directly reflected in research data).” (Brock & Taber, 2016, p. 5)
Researchers have also been clear from the outset of conceptual change research that concepts refer to the abstract level, and not to embodied perceptions or sensorimotor actions. Nor is conceptual change just a process of biological maturation. This can all be traced back to Inhelder & Piaget:

“From the very beginning of symbolization, all mental activity, whether pre-operational or operational, is invariably accompanied by a sequence of mental images, i.e. by representation in the form of images. Now mental images have their own laws which are different both from the laws of perceptions and from those of operations.” (Inhelder & Piaget, 1964, p.295)

As noted earlier, contemporary research also recognises the difficulty in distinguishing individual, cognitive views of conceptual change from social views of conceptual change:

“any new empirical evidence is unlikely to lead to a simple theoretical resolution in favor of an extreme situative or cognitive explanation of conceptual change.” (Mercer, 2007, p.77)

In summary, science education research clearly admits that we have no idea what ‘concepts’ are!

**HOW SHOULD TEACHERS PROMOTE CONCEPTUAL CHANGE?**

However, we all know what we mean when we talk about concepts, so does it matter that we cannot define them precisely? – Yes it does! I will outline how this lack of definition has implications for practice, as well as research.

The different views of what concepts are, can be associated with different suggestions for how we should promote conceptual change: learning. I will here give substantial simplifications in order to illustrate this point with some example from the literature. If a teacher believes that children hold Naïve theories (e.g. McCloskey, 1983), then they may proceed by introducing counterevidence (or ‘cognitive conflict’) in order to show the limitations of that theory and promote change. If however, a teacher characterises concepts as fragmented (e.g. diSessa, 1983) then they might proceed by trying to uncover and then weave together these fragmented understandings into a coherent framework. Other options exist though, Potvin et al (2015) draw on neuroscience to propose that children actually hold multiple views at the same time, they investigate the advantages of direct instruction around the ‘correct’ scientific concept before trying to challenge ‘incorrect thinking’. As we have mentioned, there is also a sociocultural view of conceptual change; adherents to this view would focus on group work and interaction in the social construction of the correct scientific ideas. The issue therefore is that the view one has of concepts, informs how pedagogy is characterised.

**ARGUMENTS AGAINST CONSTRUCTIVISM**

There are furthermore arguments mounting against ‘constructivist approaches’ in teaching. It is a leap from constructivist theories of learning to suggestions of practice, so a failure of approaches which might be labelled under the banner of ‘constructivist’ cannot be taken as the
death knell for constructivism itself. Nevertheless, constructivism might be held accountable for at least some of the issues with such approaches.

There is a growing (but still minority) argument for a return to more ‘traditional’ forms of teaching which favour direct instruction and the acquisition of knowledge, as specified in curricula. This is being mounted against discovery learning, group work, inquiry and other forms of pupil-led pedagogies. One of the strongest critique of such approaches can be found in a paper called “Why Minimal Guidance During Instruction Does Not Work: An Analysis of the Failure of Constructivist, Discovery, Problem-Based, Experiential, and Inquiry-Based Teaching” by Kirschner, Sweller & Clark (2006). They draw on empirical studies to argue that such approaches do not have a marked impact upon attainment. Whilst I do not accept all of their arguments, they do echo a concern which has emerged from my (subjective and anecdotal) experience in hundreds of classrooms over the last 13 years as an educator and researcher. Teachers often conceive of learning as something which emerges from the activities that they ask pupils to do. However, many do not consider the detail of these activities in terms of how learning will actually occur. For example, a student might be asked to do calculations around Newton’s 2nd law, and from this it is assumed that the student gains an understanding of how objects fall. However, there is a certain ‘looseness’ around how it is assumed that engaging with this particular representation (mathematical equations) enables conceptual understanding. Concepts, to many teachers, are things that are acquired through activities, and this is treated unproblematically. Again, this does not pin the blame directly on how concepts are characterised, but my strong suspicion is that the looseness around definitions of concepts is echoed in the looseness around how they are acquired and change in classrooms.

CONCEPTS AS PROBLEMATIC

Here I wish to bring together the argument so far. The literature on conceptual change has failed to provide a specific definition of what concepts are. This owes a lot to the essentialist character of concepts, and the dualism which is inherent in seeing concepts as direct representations of natural kinds, or indeed of process or laws within science. This is problematic in the guiding of teaching practice, because how one sees these mental entities guides how you might proceed in changing them. I therefore propose that concepts are abstractions which are unnecessary within educational research. This is a speculative aspect of my thinking at the moment, but I suspect that our reliance on concepts to describe the thinking of others stems from two areas: our language, which has inherited dualist and representational character from history, and secondly our use of empathy in how we relate to each other. It is important to have a model of what other people are thinking, and theory of mind develops in young children, as it does in many other animals. It may be important and inevitable that teachers use their assumptions about what other people are thinking during the dynamics of a classroom, and go as far as making judgements about what a young person is able to do at that particular moment. However, when a researcher makes a claim about concepts (which are not the same as thinking or action) they are making a claim about a psychological state which is inaccessible to the researcher, but also inaccessible to the subject(s) of the research. In short, these concepts simply do not exist.
To reinforce my argument I will here specify the issues with postulating concepts as mental entities. As I have outlined, the ontological commitment to mental entities as distinct from matter, and as representative of essential elements of the world is a position which is greatly in decline within philosophical discourses. Investigations into mental entities is also problematic from a philosophy of science view: if we take Popper’s (1959) contention that our hypotheses must be falsifiable, then we see that it is impossible to falsify claims about the nature of mental entities. To illustrate my point with a (somewhat obtuse) example, I could claim that there are fairies in my mind (or perhaps leprechauns since we are in Dublin), and when I answer a question correctly it is because the fairies have woken up. I could even claim that this corresponds to brain activity seen in the prefrontal cortex. This cannot be falsified in any scientific sense. More pragmatically, the focus on concepts and what they are is a distraction within research, occupying time and money with little hope of being resolvable, as intellectually stimulating as the debate is. If one decides that it is necessary to postulate mental processes, those processes should be framed within a ‘hypothetic model’. To be honest though, even that is problematic, and I am struggling to see in what circumstance postulating concepts is directly useful without it being problematic.

**DELEUZE AND CONCEPTS AS MATERIAL**

The main point of this paper is to highlight the issues with specifying mental concepts. However, I want to outline (as far as I can in a 15 minute presentation) that there are alternative ways of framing learning which still uphold many of the insights from conceptual change research. Here I find the philosophy of Gilles Deleuze especially helpful (but there are other staring points for the ‘neo-materialist’ position I am going to outline). Deleuze recognised that there are repeated patterns in the world, be they dogs or the application of Newton’s laws. However each instance of such a pattern is unique; it exists in different circumstances and is constituted of different arrangements of matter. We nevertheless link these differences through a common label, or concept. Taking this view then, we might say that a concept is a shared label which describes multiple unique instances.

Deleuze’s (2004 [1968]) ‘difference and repetition’ is also helpful in seeing that concepts are emergent: they stem from repeated exposure to similar (but ultimately different) instances of phenomena, including the ways that other people label those phenomena.

**NESTED COMPLEX SYSTEMS**

Again, there is very little time to develop this properly, but learning might be seen as the adaptation of nested complex systems. Here I am using ‘complex’ in a specific way (rather than just ‘highly complicated’) to denote multiple, nonlinear interactions which mean that a system is potentially sensitive to fine detail, and emergence of new forms of interaction are possible. Davis & Sumara (2006) use nested systems to describe classroom complexity, however I have here adapted it to a neo-materialist view by taking out their reliance upon subjective understanding. There are physical, material bases for each level of analysis we might consider in a classroom, but complexity theory tells us that we cannot reduce things to these material bases (see Hardman, 2015). Adaptation might therefore take place within the brain, in electrical signals and connections; we might see changes in gesture and speech which
have a material basis in the body, as well as other physiological changes. Extending beyond the body we can look at the nature and specific of interactions with other people, but also with material artefacts. I have described elsewhere how models can be seen as material artefacts essential to science learning (Hardman, 2017). We can also model a broader level of pedagogic practice over time, or even describe how the use of Newton’s laws changes over time. Yet we do not need to lose sight of these having a material basis, even though in it impossible to reduce to this basis. We should also note that all of these systems interact, so any claims of hierarchy or being able to focus on a specific level only should be treated as modelling statements to be contested.

REFRAMING EXISTING RESEARCH

Learning, when framed in this way becomes something that can be investigated. We have seen a great deal of excellent research which deals (explicitly or implicitly) with these material realities during the ESERA 2017 conference. Neuroscience is becoming increasingly important and we have heard over the last few days about neurological and physiological correlates to learning. At my institution there is a concerted effort by researchers to consider the neuroscience related to ‘conceptual change’ (e.g. Mareschal, 2016). I feel they would benefit from recognising the difficulties of abstracting to mental entities, but their research will nevertheless be instrumental in changing how we view learning. The two papers that follow mine at the conference consider microgenetic methods. As we have already seen, Brock & Taber (2016) postulate a ‘cognitive structure’ beyond momentary thought. My respectful challenge to the next two papers then is whether their arguments still hold if they do away with the reliance upon mental entities – I suspect they do. Colleagues such as Carol Callinan (2014) have looked at gestures as an important part of conceptual change, and I am working currently with John-Paul Riordan to look at what experienced teachers actually do in classrooms, building on his excellent work already on this (Riordan, 2014) and his paper in this conference). There have also been some great papers on facial recognition at the conference which affords a great deal of potential. The last paper in the same session as this one at today’s conference considers actor network theory, and, again my suspicion is that the potential of such views of learning remain even after we escape commitment to mental entities: concepts. There has also been a lot of excellent work presented at conference around the relationships between models, representations and learning, and the artefactual view of models (amongst others) frames models as material artefacts through which reasoning takes place. This is commensurate with a view of learning as complex and material in basis.

The real potential of changing our view of concepts from that of mental entities, to labels for repeated yet unique, material situations is that learning can be investigated in a more scientific way. We can investigate how neural correlates relate to gestures and speech and models in the classroom to better understand learning science. This will always involve human interpretation and value judgements, but it need not rely on indefinable mental entities.

SUMMARY

In summary, there are considerable issues in postulating concepts as mental entities. 1) They are ill-defined despite 50 years of research. 2) They are characterised as dualist: mental
representations of essential aspects of the world. This is considerably eroded in contemporary philosophical discourses. 3) There is ambiguity as to how conceptual research should guide practice, and I believe this is a symptom of unresolved debates about what concepts are. Put together, these arguments make the case that postulating concepts as mental entities is highly problematic. Although I have not been able to fully develop it here, I hope to have given a flavour of how seeing learning as the co-adaptation of (nonreducible, material) complex systems allows us to put research into learning on much firmer foundations, through redefining concepts as labels for the repetition we see in different, unique circumstances. This recognises that concepts are labels to be contested in relation to empirical evidence, not through abstraction to an untenable mental world.

CAN RESEARCH-INFORMED NETLOGO MODELS PROMOTE THE IDEA OF CONTINGENCY IN ECOSYSTEMS' BEHAVIOUR?

Georgios Ampatzidis and Marida Ergazaki
University of Patras, Patras, Greece

This paper reports on a case study performed in the 3rd cycle of a developmental research, which aims at designing a learning environment with research-informed NetLogo models that could help non-biology major students in challenging the ‘balanced nature’ idea. Our focus is set on whether and how students’ reasoning about ecosystems’ response to human-driven disturbance or protection altered after their engagement with specially designed models of terrestrial or aquatic ecosystems studied by ecologists. Informed by constructivism and problem-posing approach, our CSCL environment highlights ecosystems’ contingent behaviour through the currently valid idea of the ‘resilient nature’.

Forty-four 1st-year educational sciences students were introduced to the assumptions of this idea in five, 2-hour sessions by exploring in triads our NetLogo models aided by worksheets, which asked for predictions/explanations before/after using the model. Each model had two versions showing two different trajectories of an ecosystem, which were linked to differences in initial conditions or human actions for its recovery. The two different trajectories shown in the two versions of each model were discussed in whole class discussions at the end of the sessions. The analysis of students’ responses to certain items of the pre/post-test showed that the ideas of a protected ecosystem’s stability and a disturbed ecosystem’s full recovery retreated in the post-test, while the idea of ecosystems’ contingent behaviour appeared for the first time in high frequencies.

Keywords: Ecological reasoning; model-based learning; resilient nature

INTRODUCTION

The idea of the ‘balance of nature’ (‘BON-idea’) is a rather popular and persistent idea, that implies a predetermined order and stability in nature, guaranteed by a God’s will or by nature itself (Cooper, 2001). It has been criticized for not being representative of the natural systems (Scheffer, 2009); however it seems to prevail in public opinion and school science (Korfiatis, Stamou, & Paraskevopoulos, 2004; Ladle & Gillson, 2008). In fact, the ‘BON-idea’ has been reported as a belief that students express quite strongly when reasoning about ecosystems and particularly about how these respond to disturbance caused – or protection ensured – by humans (Ergazaki & Ampatzidis, 2012; Zimmerman & Cuddington, 2007).

The ‘BON-idea’ may interfere with environmental awareness, since it may imply that ecosystems have an inherent ability to restore their initial state after a disturbance and thus it may undermine the significance of preserving their status quo (Westra, 2008). Moreover, the BON-idea may hinder conceptual understanding as well, since it opposes the currently valid ‘resilient nature-idea’ which favors contingency and disregards order and ‘balance’. Ecosystems are believed to function in multiple – self-organized through feedback loops – alternative states and to shift between these states in abrupt, reversible or irreversible ways (Scheffer, 2009).

Moreover, the ‘resilient nature-idea’ seems to offer an appropriate context for fostering systems
thinking skills, which are considered important for everyday life as well (Ampatzidis & Ergazaki, 2017).

Thus, our 3-cycle developmental research addresses the question of whether it is feasible to design a learning environment that could support non-biology major students (a) in challenging the idea of the ‘balanced nature’ and constructing an up-to-date understanding about ecosystems’ function, and (b) in using this understanding to advance context-free ideas such as interdependence and reciprocity, which have to do with systems thinking in general. Our learning environment is supported by ecosystem models informed by current ecological research and designed within NetLogo (Wilensky, 1999). Computer simulations have been widely used for science teaching and ecology teaching in particular (Rutten, van Joolingen, & van der Veen, 2012), to help learners visualize dynamic processes taking place at organization levels or time-scales that cannot be easily accessed (Ergazaki & Zogza, 2008). It has been argued that computer simulations may function as highly effective educational tools, by representing more concretely significant aspects of the natural world that are too abstract or complex to deal with in other ways (Smetana & Bell, 2012).

In this paper, we report on the case study we performed in the 3rd cycle of our developmental research; we are particularly concerned with identifying whether and how students’ reasoning about ecosystems’ response to human-driven disturbance or protection has been altered after being engaged with specially designed NetLogo models based on findings of ecological research. So, the research question is: ‘what kind of predictions do students make about the future of disturbed/protected ecosystems and how do they justify them before and after their engagement with the specially designed research-informed NetLogo models integrated in the 3rd version of our learning environment?"

**METHODS**

**The overview of the study**

This is a case study within a developmental research (Akker, Gravemeijer, McKenney, & Nieveen, 2006) concerning the design of a computer-supported collaborative environment, which has been informed by the problem-posing approach (Klaassen, 1995) in the broader context of social constructivism (Driver, Asoko, Leach, Scott, & Mortimer, 1994). We designed the learning environment in order to highlight the contingent behaviour of ecosystems through the assumptions of the ‘resilient nature-idea’, as well as to help students use this new understanding about nature for advancing their systems thinking in general; the latter is out of focus here. We also designed a pre/post questionnaire with open-ended items in order to collect data about the effectiveness of our learning environment accompanied by short interviews when needed. The questionnaire was delivered to students as a pre-test one week before the classes and as a post-test right after the classes. Finally, we analyzed students’ responses using the qualitative analysis software ‘NVivo’ and tested for the statistical significance of their progress using the quantitative analysis software SPSS.
**The participants**

The participants of this case study were 44 first-year students of the Department of Educational Sciences and Early Childhood Education of the University of Patras, who were attending the optional course ‘Essential Concepts of Ecology’ offered by the 2nd author. All participating students had completed the same ecology curriculum, they were familiar with computers and group-work, and they appeared to be interested in ecology in terms of raising/answering questions in the course’s regular classes. These 44 students from a total of 180 who were enrolled in the course, volunteered to participate in the study, after they had been informed of its goals and time schedule, as well as reassured that they were free to end their participation at any time.

**The learning environment**

The learning environment aims to highlight the contingent behaviour of ecosystems through the basic assumptions of the ‘resilient nature-idea’. The learning objectives (LOs) have to do with understanding these assumptions (LO1–LO4), and with using them to (a) challenge the notion of balance as an inherent feature of nature, and (b) move to the notion of contingency (LO-contingency). For an overview of the LOs, see Table 1.

</tr>
</tbody>
</table>

Students were introduced to the assumptions of the target-idea in five, 2-hour sessions within an optional ecology course. In the first four sessions, they collaborated in triads to explore a ‘NetLogo’ model (‘NM’), with the aid of a worksheet that asked them for (a) predictions about the ecosystem’s behaviour before exploring the model, and (b) explanations afterwards. The four models we developed were based on current ecological research and simulated terrestrial/aquatic ecosystems facing internally/externally triggered changes. The two different trajectories simulated by each model were discussed in whole class discussions at the end of the sessions. The interface of the models included the following: (a) a series of ‘boxes’ showing population size and the level of key abiotic factors (e.g. nutrients) whether applicable, (b) a ‘simulation window’ showing the individuals of the different populations in different shapes and colors, and (c) a ‘graph window’ showing changes regarding population size and levels of abiotic factors with time and thus providing students with a graphical representation of the trajectory of the ecosystem they were exploring. Here we focus on the ‘NM’ used in sessions 1 and 3, which are outlined below.
NM1-Forest

NM1-Forest simulates a forest with two plant populations (bushes, spruces) and three animal populations (rabbits, budworms, passerines) connected with the following food relations:

- Budworms feed on the leaves of the spruces upon which they live.
- Passerines feed on budworms that they find on the spruces.
- Rabbits feed on the leaves of the bushes.

The forest is going through a maturation process which results in changes of the size of the forest populations. Within the 1st version of the model, the ecosystem remains at the same stable state despite the changes that take place, while within the 2nd version the populations of bushes and rabbits die out and the ecosystem shifts to another stable state (Figure 1). The design of NM1-Forest was informed by the research of Gunderson, Allen, & Holling (2010) regarding a Canadian forest ecosystem under maturation. Their study concerns the abrupt increase of budworms that parasitize spruces, as spruces mature and passerines have difficulties in detecting budworms among spruces’ ever-increasing leaves. If the budworms population increases over a threshold, it can destroy large parts of the forest, leading it to another stable state. NM1-Forest focuses on LO1, LO2 and LO_contingency.

Figure 1. The two-version NM1-Forest model: version 1 at the top, version 2 at the bottom.
NM3-Lake

NM3-Lake simulates a lake with two plant populations (surface plants and lakebed plants) and two animal populations (‘fish-a’, ‘fish-b’) connected with the following food relations:

- ‘Fish-a’ feed on surface plants.
- ‘Fish-b’ feed on lakebed plants.

Extra nutrients are introduced in the lake, which results in size changes of the lake populations. Subsequently, a recovery plan is implemented, which includes removing nutrients and adding the populations that died out, along with other corrective actions. Within the 1st version of the model where the missing populations are re-introduced gradually - so that the lakebed plants have the time to develop their soil-retaining roots before ‘fish-b’ are added and start blurring water and blocking light as they search for food near the lakebed - the lake shifts back to its previous stable state. On the contrary, within the 2nd version where the missing populations are re-introduced all together and the side-effects from ‘fish-b’ food-search are present, this shift is not possible (Figure 2).

The design of NM3-Lake was informed by the study of Scheffer (2009) regarding the recovery of a eutrophic lake. According to his findings, the removal of a big number of fish from the lake limits the side-effects from their food-search near the lakebed (see blurring water and blocking light) and gives the lakebed plants a chance to grow. This growth may result in the increase of the oxygen levels in the water, stopping the release of nutrients (phosphorus) from the bottom of the lake (Scheffer, 2009). NM3-Lake focuses on LO1-4 and LO-contingency.

Figure 2. The two-version NM3-Lake / recovery plan model: version 1 at the top, version 2 at the bottom.
The pre/post-questionnaire

A pre-/post-test questionnaire with equivalent items, derived from questionnaires used in previous research cycles, was filled in by the participants, after it was explained to them that this process should not be considered as an exam. Items 1 and 4 which concern us here, required reasoning about the future of (a) an ecosystem protected by humans, and (b) an ecosystem disturbed by humans who then attempted to restore it (see Table 2).

Table 2. The pre/post-test questionnaire.

<td>Reasoning about the future of a lake where salinity / nutrients are increased by humans (this makes an animal population go extinct) / restored by humans who also re-introduce the extinct population</td>
<td>LO3-4, contingency</td>
</tr>
</tbody>
</table>

The 1st author read all of the responses as soon as the students had completed the questionnaire and carried out short interviews with those whose responses needed clarification.

The analytic procedure

Students’ responses to the pre/post-questionnaires, in the light of related notes from the interviews where applicable, were transcribed and coded within NVivo. The several ‘categories’ that emerged, were organized into a ‘coding scheme’ divided (a) in students ‘predictions’ about the future of the ecosystem in question (e.g. ‘different picture’, ‘no recovery’, ‘contingent picture’), and (b) in students’ ‘justifications’ for what they predicted (e.g. ‘possible feedback change’, ‘possible recovery process’, ‘changes in populations’ relationships’). Each response could be coded at a unique prediction category and a unique justification category. The coding was performed by both the authors with a satisfactory agreement: Cohen’s Kappa with regard to items 1 and 4 that concern us here was estimated at 0.85.

Moreover, to test students’ progress and its statistical significance, we developed a scoring grid for their responses to each item of the questionnaire (Table 3). The score of each response was the sum of two sub-scores: one for the prediction about the future of the ecosystem in question and another for the justification provided for that prediction. The scoring grid was developed so that predictions contributed more than justifications to the total score: satisfactory predictions with non-satisfactory justifications got a higher score than non-satisfactory predictions with satisfactory justifications (Table 3).

FINDINGS

Students’ pre/post-reasoning about a protected ecosystem

Regarding students’ reasoning about the future of a protected ecosystem (item 1), the prediction of ‘same picture’ justified by the ‘self-regulation of the populations if not disturbed by humans’ appeared less often in the post-test (16/44) compared to what happened in the pretest (31/44) (Figure 3). In students’ own words: “Since the area is completely protected, it is natural to have a relatively smooth course of population in time, as the food chain remains intact”.

24
Moreover, the prediction of a ‘different picture’ was less popular in the post-test (3/44) than in the pre-test (5/44), as shown in Figure 3. Students predicting a ‘different picture’ for the ecosystem justified their prediction appealing to ‘changes in populations’ sizes’. An example of such reasoning is shown in the following quote: “The food chain takes the following form: plants $\rightarrow$ herbivorous animals $\rightarrow$ carnivorous animals. The plants will begin to decline over time and gradually die out since the herbivorous animals feed on them. The herbivores will also gradually die out as there will have no food, and, moreover, they will be eaten by the carnivores. The carnivores will be reduced because there will be no food. Moreover, the decomposers (bacteria and fungi) will feed on the dead organic matter. So, the plants will die out first, whereas the animals and decomposers will follow”.

Students who predicted a ‘possibly different picture’ were fewer in the post-test (2/44) than those who gave such a prediction in the pre-test (8/44) (Figure 3). The justifications had to do with ‘possible changes in environmental factors’ (see the quote below), ‘possible changes in populations’ sizes’, and ‘possible changes in populations’ sizes and environmental factors’ (Figure 3). In students’ own words: “The ecosystem may remain the same but it may also change. Although human activity is prohibited, the park’s picture may change due to a variety of natural disturbances (rain, wind, snow, etc.)”.

Figure 3. Categories of students’ responses about a protected ecosystem (item 1).

Finally, slightly more than half of the students (23/44) predicted a ‘contingent picture’ for the ecosystem in the post-test, justifying their prediction by appealing to the ideas of ‘unpredictable factors’ or ‘possible change of feedbacks’ (see the quote below) (Figure 3). In students’ own words: “The populations living in the aquatic park are likely to remain relatively stable in size with small ups and downs. But there is a possibility that the park shifts to another stable state if some population falls below a critical point of size because of its consumption by another population; that is, if a counteracting feedback-loop breaks, whereas a reinforcing feedback-loop begins”.

A Wilcoxon signed-rank test did show statistically significant differences between pre-test and post-test scores (item 1: $Z=-4.156$, $p<0.01$).

Students’ pre/post-reasoning about a disturbed ecosystem

Regarding students’ reasoning about the future of a lake in which – due to human activity – (a) either salinity or the level of nutrients in water increased, leading to the extinction of one population, and (b) subsequently decreased followed by the reintroduction of the extinct
population (item 4), the prediction of ‘full recovery’ based on a ‘recovery process’ or ‘counteracting feedback loops’ (see the quote below) appeared significantly reduced in the post-test (6/44) compared to the pre-test (32/44) (Figure 4). In students’ own words: ‘Some nutrients end up at the bottom of the lake, while others on the surface. This brings changes in the sizes of the lake populations. The nutrients return to their initial size. And the lake populations likewise, as counteracting feedback loops function. The lake will have the same picture as at the beginning’.

Figure 4. Categories of students’ responses about a disturbed ecosystem (item 4).
The ‘no recovery’ prediction became less popular in the post-test (3/44) compared to the pre-test (10/44). The justification of a ‘tipping point reach’ appeared twice for the first time in the post-test (see the quote below), while ‘changes in populations’ relationships’ and ‘evolution’ decreased (Figure 4). In students’ own words: ‘*The counteracting feedback loop of the ecosystem has apparently been broken and so a fish population has died out. After some years the ecosystem will not be able to recover its initial state, as a tipping point has been met and the situation is irreversible.*’

The prediction of a ‘possible full recovery’ based on the ‘possibility of a recovery process’ appeared once in the pre-test and once in the post-test (Figure 4). In their own words: ‘*There is a chance that the increase of the nutrients’ level may be successfully restored to its initial state, and, so, the ecosystem as well.*’

Finally, in the post-test most of the students (33/44) predicted a ‘contingent picture’ for the disturbed ecosystem (Figure 4), supporting their claim on ‘unpredictable factors’ (see the quote below), ‘possible side effects’, ‘possible differences in recovery handlings’, ‘resilience’, ‘feedbacks’, or ‘possible tipping point reach/feedback change’. For example: ‘*The lake may recover its initial state or not. For a full recovery to be possible, it is not enough to reverse the changes that have occurred, but we also need to take into account more factors that are not obvious in the first place.*’

A Wilcoxon signed-rank test for both items did show statistically significant differences between pre-test and post-test scores (item 4: -5.409, p<0.01).

**DISCUSSION**

According to the findings, our computer-supported learning environment was rather effective in advancing students’ understanding about ecosystems’ function. In the post-test, the idea of contingency in the behaviour of an ecosystem under human-protection, which was absent in the pretest, (item 1) was provided by slightly more than half of the students (23/44). In the post-test as well, the number of students who predicted that the protected ecosystem will show the ‘same picture’ some years later, was significantly decreased (16/44) compared to the pre-test (31/44). We argue that students’ engagement with the two versions of ‘NM1-Forest’, which simulated a forest that is not externally disturbed, helped them effectively to reach the idea of the ‘unpredictable/contingent’ future of even protected ecosystems. The whole class discussion at the end of session 1 contrasted two different trajectories of ‘NM1-Forest’ and highlighted the idea of ‘contingency’. This way, students appeared to have moved from the idea of a ‘never changing nature’, which was highly frequent in the pre-test, to the idea of a ‘nature’ characterized by ‘contingency’ even in the absence of external disturbances.

Similarly, in the post-test, the idea of contingency in the behaviour of a human-disturbed ecosystem in a process of a human-led restoration (item 4) was provided by most of the participating students (33/44). In the post-test as well, the number of students who predicted that the disturbed ecosystem will ‘fully recover’ some years later if humans reversed what caused the initial shift to a different stable state, was significantly decreased (6/44) compared with the pre-test (32/44). We argue that the students’ engagement with the two versions of ‘NM3-Lake’, which simulated a lake that is disturbed by humans, helped them effectively to
reach the idea of the ‘unpredictable/contingent’ future of a disturbed ecosystem in the process of a human-led restoration. The whole class discussion at the end of session 3 contrasted two different trajectories of ‘NM3-Lake’ and highlighted (a) the fact that the picture an ecosystem may show some years after it was disturbed and subsequently attempted to be restored is ‘contingent’ on differences in the recovery plan, and (b) restoring the condition that caused an ecosystem to shift to a different stable state does not necessarily cause it to shift back to its initial stable state. This way, students appeared to have moved from the idea of an ‘always recovering nature’, which was highly frequent in the pre-test, to the idea of a ‘contingent’ nature which was the target one. So, despite the persistence and popularity of the ‘BON-idea’, it seems possible with the aid of technology to support students in building a contingency-based understanding about how nature may respond to human protection or disturbance.

EVALUATION OF STUDENTS’ UNDERSTANDING OF DISSOLVING SUGAR USING AN ANIMATION SOFTWARE

Michael Peetz and Verena Pietzner
Carl von Ossietzky University, Oldenburg, Germany

For successful teaching, teachers need to take into consideration the ideas that students bring into the classroom, which are often based on experiences from everyday life and previous chemistry education. Therefore, teachers should be aware of the existence of such (mis-)conceptions and, if necessary, be able to address them properly. In the study presented here, we wanted to find out whether animation software can be used to get an insight into the chemical concepts of the students. Animations offer the possibility to work with visualisations that include time-dependent aspects of a phenomenon, what is of high relevance for learning chemistry. In this study, students of grade 7 developed their own animation on molecular level about the dissolution of sugar in water. First results indicate that the students can work with the software easily and that their animations show not only the already known misconceptions about solubility, but also provide additional information about the students’ concepts.

Keywords: computer animation, dissolution, students’ conception

INTRODUCTION

The fact that students have misconceptions of chemical processes is well known by teachers and researchers. They have to be recognized by the teacher and then carefully addressed (Barke, Harsch, & Schmid, 2012, p. 17 ff.). While most studies on the identification of students’ conceptions work with paper and pencil tests, drawings or interviews, a different approach was taken in this study. To investigate the students’ conceptions regarding a chemical concept, the students should visualize their conceptions by creating a computer animation to a given topic. Animations of chemical processes show a time-dependency that static pictures cannot provide properly. A possible language barrier, as mentioned by Ebenezer and Erickson (1996) and Çalik and Ayas (2005), which prevents a student from accurately describing his or her concept of a chemical process, might be circumvented by this method.

In some studies, computer animations were already used as a tool to teach or to visualize a concept by a teacher or the interviewer as a part of the methodology (Ebenezer, 2001; Kelly, Barrera, & Mohamed, 2010; Kelly & Jones, 2008, Tasker & Dalton, 2006). In another study, student teachers had been asked to create their own animations regarding different chemical processes (Toplis, 2008). Schank and Kozma (2002) described how learning chemical concepts can look like when students create own animations within a knowledge building environment (Schank et al., 2002, 268 ff.).

Solubility in general and the dissolution process in particular has been chosen to be the topic of this study for various reasons. One important reason for this is that the solubility is taught in different grades according to the requirements of the German chemistry curriculum, beginning with grade five. Therefore, it will be possible to investigate the development of the concept of solubility at different grades. The study presented here took place in a 7th grade of a German gymnasium and addressed the solubility of sugar in water. Another reason for the choice of
solubility as the investigated topic is the time dependency. The dissolution process of sugar in water can be observed over time, whereas many other processes cannot. As mentioned before many studies on the topic of solubility and the dissolution process have been conducted. Therefore, another reason to choose the dissolution process is it’s good literature foundation (see paragraph “Students’ conception of solubility and dissolution”). Many conceptions are already known and the results of this study can well be put into context. Also animations have already been used to teach solubility (Kelly & Jones, 2007) and were created by students to learn and reflect their perceptions (Schank et al., 2002). With this and the possibility of a follow up study on a possibly more detailed level of understanding of older students, the solubility is a good topic to choose.

**The topic of solubility and dissolution in the curriculum**

In accordance with the requirements of the curriculum in Lower Saxony, Germany, the topic of solubility and the dissolution process is repeatedly taught in different stages during the student’s school career (Achtermann et al., 2007; Achtermann et al., 2009; Achtermann, Hildebrandt, Rebentisch, & Witte-Ebel, 2015).

The curriculum of Lower Saxony lists skills and competencies, which students should learn in the respective grades. It is structured so that the learning objectives are always listed for the grades from 5 to 10. In the upper secondary level (grades 11-13), all objectives are assigned to one of the basic concepts: substance-particle, structure-property, energy, donator-acceptor and kinetics and chemical equilibrium (Achtermann et al., 2009). In lower secondary level, the last two basic concepts are replaced by the concept of chemical reaction (Achtermann et al., 2007; Achtermann et al., 2015).

At first in the grades 5 and 6, as part of the substance-particle concept, the students learn about substances and that they have specific properties. Every substance can be described and differentiated from other substances by these properties. One of these properties is the solubility. At this stage, mostly water is considered to be the solvent. At the end of grade 7 they also should know the difference between pure substances and mixtures and be able to describe substances on a submicroscopic level using a basic particle model (Achtermann et al., 2007, pp. 51–53). In later years, also as part of the substance-particle concept, the students learn advanced particle and atomic theories, which allow them to describe the dissolution process in more detail. Within the concept of structure-property, the students learn about intermolecular attraction, structure and composition of molecules, ions and atoms. In upper secondary level, the students also learn about organic compounds and the topic of solubility and dissolution is taught once more. Here, the aspect of van der Waals forces is taken into account when the dissolution of organic substances in other organic substances is taught (Achtermann et al., 2009, p. 14).

**The dissolution process**

The term ‘solution’ from a chemical or scientific point of view has no universal definition. One definition from Mortimer and Müller (2014) is that a solution is a homogenous mixture, with the substance with a higher percentage is called the solvens (Mortimer & Müller, 2014, p. 211). A more specific definition is given by (Binnewies et al., 2016, p. 200): “In the broadest sense,
we can define a solution as a homogeneous mixture of different substances with variable composition and statistical distribution of all components, where the same composition is found at each section of the mixture.” Other definitions even mention a particle size of the solute. McMurry and Fay (2014) classified homogenous mixtures accordingly. “Solutions […] contain particles with diameters in the range 0.1-2 nm, the size of a typical ion or small molecule.” (McMurry & Fay, 2014, p. 400) According to Holleman, Wiberg, and Wiberg (2001) “solutions are homogeneous mixtures of pure substances” (Holleman et al., 2001, p. 16). Depending on the size of the solute particles a solution is described a ‘true’ solution, if the solute particles are less than 1 nm of size (Holleman et al., 2001, p. 869). All these definitions are basing a solution on the concept of a homogenous mixture but differ slightly from one another. With this as a common ground the question left is how to get to this state of a homogenous mixture beginning with a solid solute and a liquid solvent like water. For this study, other existing homogenous mixtures, which also can be called solution, are not considered, because they most likely are not known by the seventh grade students.

To get to the final state described above, the whole dissolution process has to be considered. The dissolution process is a dynamic process that can be described along a timeline. When a crystal of a certain compound is given into water or another solvent, the crystal at first is simply surrounded by water molecules. The water molecules then adhere to particles (atom, ion or molecule) at the outer edge of the crystal according to intermolecular attractions that occur. Those can be for example be hydrogen bonds between water molecules and the hydroxyl group of sugar molecules. The attraction between several solvent molecules and the particles of the solute crystal then pulls out single particles out of the crystal lattice. After leaving the crystal, a shell of water is formed around the particle that is called hydrate shell. Afterwards, the hydrated particles diffuse through the solvent (McMurry, Castellion, Ballantine, Hoeger, & Peterson, 2009, p. 258 f.).

**Students’ conception of solubility and dissolution**

Many studies have been conducted to gather information about students’ conceptions about solubility and/or the dissolution process. The age of the surveyed students differs, ranging from kindergarten, students at school as well as students at colleges or universities. Even teachers at universities have already been interviewed about their ideas in some studies. Grüß-Niehaus (2010) compiled a far more detailed list of studies about the dissolution process, structure of matter or atomic models (Grüß-Niehaus, 2010, 79 ff.).

The dissolution of sugar in water was chosen as a suitable process for examining grade 7 students’ conceptions of a chemical process using computer animations because this example is mostly chosen by German teachers to introduce this topic. In addition, the dissolution of sugar in water is a process that can be well observed over time and therefore can be represented in an animation (Kelly & Jones, 2007). The result of the process can be described as a homogeneous mixture of water and sugar (Çalik & Ayas, 2005; Prieto, Blanco, & Rodriguez, 1989). This mixture is usually described by students partly on the particle level, but partly also only on the substance level (Prieto et al., 1989). In studies where drawings have been used by the participants, drawings of both levels can be found. On a particle level, the sugar particles are shown as evenly distributed in the solvent water and on a substance level, only one phase
is drawn. Without any guidelines the students’ drawings are based on different concepts which include continuous and discontinuous concepts of solutions (Prieto et al., 1989). In a study with a given picture of a crystal surrounded by a solvent (each represented by different coloured dots) students depicted the dissolved crystal with overlapping dots (Longden, Black, Solomon, & STIR Group, 1991). Other descriptions of the dissolution process relate directly to the substance to be dissolved. It breaks up into smaller particles (Prieto et al., 1989) (the descriptions here take place at the particle and substance levels) or the substance to be dissolved ‘melts’ (Çalik & Ayas, 2005; Ebenezer & Erickson, 1996; Longden et al., 1991; Piaget & Inhelder, 1974, 72 f.). Also, a transfer of properties of the substance to be dissolved on the solvent has already been mentioned by students as a description of the solution process. For example, water as a solvent can change its taste, color or smell. Other factors involved in the dissolution process, such as temperature, agitation, or simply the material properties of solvent and solute have already been reported by students (Blanco & Prieto, 1997; Prieto et al., 1989). A more general misconception of chemical processes is found by Brook, Briggs, and Driver (1984). Macroscopic changes were transferred to submicroscopic particles, which means that for the students, particles are able to melt or change their size.

The methods used in these surveys were pencil & paper tests and interviews. However, since the dissolution process itself is a dynamic process (see above), the question arose as to whether this could not be better represented by using a dynamic method, like animations. This has led to the following research questions: Are students able to use animations to represent a chemical process, such as the dissolution process? On which aspects of the dissolution process are the students focusing their thoughts and animations on? In addition, perhaps most importantly, can more information about student concepts be obtained by using animations as tool compared with traditional paper-based testing?

**METHOD**

To answer these questions, eighteen students of grade 7 of a German Gymnasium participated in this study. The survey took place briefly before the summer holidays at their school during class hours, so the possible pressure of grades being given for this interview was minimal. Every student was asked individually to create the animation. The software used for the study is the freeware ChemSense Animator (SRI International, 2004).

The ChemSense Animator software works like a flipbook. From a toolbox (see Figure 1, red box) users can choose particles, chemical bonds, atoms or ions and drag them onto a simple white screen. There, the particles can be moved via a drag-and-drop system. The animation itself is then created by copying the current images and adding those copies to a timeline. Then, the copy can be modified. With this, a frame-by-frame sequence is created (as shown in Figure 1, in the orange box), which can be played during the creation at any time and at the end, when the whole animation is completed.

Before the students work on their animation, an introductory assignment was given to become familiar with the software. A circle had to be moved in little steps over the screen to understand the frame-by-frame function of the software. Afterwards, simple tools from the toolbox and useful keyboard shortcuts were explained.
For the actual animation, a start screen was prepared (see Figure 1). Previous tests showed that it is not very easy for grade 7 students to create their own start screen within a reasonable time. The given screen is based on the students' current level of submicroscopic understanding and based on a simple particle theory. Water and sugar particles were depicted as little triangles and hexagons, respectively. The sugar particles form a crystal that is placed in the middle. The possibility to change this start screen (if needed with the help of the interviewer) was given to each student before starting the creation of the animation. For the task, no time limit was set and the students did not receive any help except answering questions about the functions of the program.

![ChemSense Animator window with toolbox, screen and the timeline section including the control elements.](image)

Figure 1. ChemSense Animator window with toolbox, screen and the timeline section including the control elements.

After the students completed their animation and they confirmed the completion of the animation, a short interview was conducted in which the students discussed their animation with the researcher. It was an open structured interview because the content of the animation was unpredictable and too far-reaching to be able to reduce it to specific, generally valid questions. The questions mostly focused on the content the students presented in their animations. As an example, a few recurring topics are listed here: Overlapping particles, the general order of action regarding sugar and water particles during the dissolution process, the size of jumps the particles made from one frame to the next, or what was meant by changing the size and shape of the given triangles and hexagons.

Screen capture and taping of interview was done using the software Camtasia (TechSmith, 2017). The advantage of this approach was that everything that was said during the creation of the animation and the interview was recorded at the same time together with the screen. So even comments made during the creation of the animation could exactly be linked to a certain action on the screen.

Both the animations as well as the following discussion are analysed based on a category system inductively build based on the material (Mayring, 2010, p. 67 ff.). The category system includes categories regarding the dissolution process itself, the use of ChemSense Animator.
and the participants’ personal opinion of the program used. The category catalogue was reviewed and intensively discussed together with colleagues. Therefore, comprehensibility and inter-subjectivity is ensured (Kuckartz, 2016, 216 f.; Steinke, 2010, 187 f.).

RESULTS

All students were able to create animations with ChemSense Animator. Although every student was given the opportunity to change the given start screen, none of them decided to do so. It was mentioned by some students and their teacher, that in their chemistry lessons so far different coloured circles had been used to describe submicroscopic processes.

The following table gives an overview of the creation process of the animations. Most of the students created their animations within 15 minutes and a mean frame count of 14.

Table 1. Creation time and mean frame count of the created animations.

</tbody>
</table>

The final image count of the animations ranged from 5 up to 100 frames. Especially the animations with a low frame count were rather disjointed because of the intention of the students to get the particles to their final position at the cost of more traceability of the particles.

To give an example, two frames from two different animations are displayed in Figure 2. The left one depicts a picture shortly after the start of the animation, where the crystal had broken apart in all directions. The water particles on the other side did not move yet. On the right side, a final picture of an animation is shown; the completely dissolved sugar crystal is displayed. It is depicted as evenly distributed sugar particles throughout the solvent.

Figure 2. Two typical frames from created animations. One at an early stage (left) and one frame that is a good example what most of the final frames look like.
As it can be seen in Table 2, concepts that have already been reported in other studies have been found and therefore confirmed using the new method.

Table 2. Summary description of the found concepts. The number in brackets shows how many students showed this concept in their animation.

</tbody>
</table>

All students let the crystal break apart in smaller particles at least at one stage of their animation. Including the information gathered in the interviews, two conceptions can be identified. Firstly the disappearance of the particles merely on substance level. The students explained that the sugar is not visible any more but still existing on the particle level. The second conception contains an almost disappearance on both the substance and the particle level. Students in previous studies had used both conceptions, as well as the concept of overlapping particles and the change of particle size as a representation of a solute being dissolved in water. One newly found conception is that three students are not be able to differentiate between the dissolution process of sugar in water and the evaporation process of water from a sugar solution. When asked in the interview, these students confirmed that the evaporation of water is an inherent part of the dissolution process and those two processes could not be separated. This conception is probably based on a common student experiment done in German Chemistry lessons and that the students mentioned during the interview. Salt is dissolved in water and afterwards regained by heating the salt water again. This experiment should demonstrate that the salt is not gone. All other students concluded their animation with a frame that displayed a homogeneous mixture of sugar in water (like in the right frame in Figure 1). For students of the seventh grade this is what was expected to be the final state.

In one case, a student even had an idea of a hydrate shell. He moved around sugar particles surrounded by water molecules. He compared the movement of those groups with the movement of a human being in a car, with the man being the sugar and the car representing the water particles. It is not yet reported in the literature that a student of grade 7 could already have such an elaborated concept of the dissolution process.

Another aspect that is worth mentioning is that almost all students began the dissolution process by letting the crystal disintegrate into smaller particles. Only afterwards, the water particles
moved to fill in the resulting void. Therefore, the sugar acts as the sole actor at this moment, while the water just reacts but does not take any active part in the dissolution process.

**SUMMARY**

In summary, all 7th grade students were able to create animations of dissolving sugar in water using the ChemSense Animator software with a given start screen. The animations differed in length, creation time and level of details. The time the students needed for create the animations ranged from round about 4 to 30 minutes, and thus varied from student to student. The frame count varied as well between 6 and up to 100 frames with the 100 frames animation being an exception. Most of the students tended to create shorter animations with a mean frame count of 14 frames.

The final frame of the animations often showed sugar particles distributed throughout the water particles on the screen. The focus of the animation is on the breakup of the crystal into smaller pieces and finally into separate particles. As previously described, the method of creating animations confirms previous results from other studies, but it also shows other students’ concepts regarding the dissolution process. Time-dependent information, such as the order in which the dissolution process takes place, can be recorded using this dynamic method, whereas this is not possible with drawings of just the final state.

**OUTLOOK**

This study will be followed by two similar studies, which investigates students’ conception of solubility in later years of their school career; grade 10 students and first year chemistry teacher students at university will be interviewed. Both of these groups have learnt advanced models of the submicroscopic structure of matter in the preceding years. Students in the 10th grade should know about differentiated atomic theories (up to the Bohr model), that are needed to explain example ions, hydrogen bonds and electrochemical processes. At university level, the students will have had lectures about general and inorganic basic chemistry, thermodynamic basics and have learnt about the orbital model. Therefore, each group in theory has more possibilities to explain and represent the dissolution process or the substance property solubility. Whether this deeper knowledge affects the quality of an animation will be one question that can be answered by the respective surveys.

According to the advanced possibilities of presentation and explanation, the setup of the survey will be changed. The older students will only get an introduction in the program functions and features, but no start screen will be given. Additionally, the solute will be changed from sugar to sodium chloride. This change is made due to the students’ ability to construct a start screen within a reasonable time and that some aspects of the dissolution process of sodium chloride such as the correct use of ions end the correct formation of a hydrate shell may or may not be seen otherwise.

**ACKNOWLEDGEMENT**

We would like to thank Dr. Heike Pöpken for supporting this study and the Albertus-Magnus-Gymnasium for the opportunity to conduct the study in its facilities.

GENETICS REPRESENTATIONS OF HIGH SCHOOL STUDENTS WORKING IN DIFFERENT MULTI-REPRESENTATIONAL ENVIRONMENTS

Beatriz Eugenia García-Rivera, Araceli Báez-Islas, Fernando Flores-Camacho and Leticia Gallegos Cázares

Centro de Ciencias Aplicadas y Desarrollo Tecnológico, Universidad Nacional Autónoma de México, Ciudad de México, México.

This work shows the results of a project that analyses the construction of representations about genetics of high school students. In order to determine several possible levels of representation, three didactic sequences were developed, all of them with the same concepts and number of activities, but differing in the use of ICT and didactic tools. Each sequence was applied to a different group of students from the UNAM High School, who worked with the guidance of their respective teacher. A questionnaire was developed with 18 items that allow the characterization of different types of representations, and was validated in terms of reliability. The sample consisted of 186 students. To determine the differences between groups, a one-way ANOVA test was applied. The results show that the group that worked with the most technological support (sequence III) obtained the highest means, gave more complete descriptions and achieved greater precision in their graphical representations (drawings and diagrams); the groups with intermediate use and low technological support (sequences II and I, respectively) also showed good results in written explanations, but not so in the use of drawings and diagrams. These findings allow us to point out that the three strategies helped students to achieve the same conceptual objectives, however, when the use of tools that enable graphic representation is promoted, the construction and explanation of complete and complex representations is favoured.

Keywords: genetics, representations, teaching strategies

INTRODUCTION

Research in the field of science learning has moved from interpreting concepts to representations, as cognitive tools that allow subjects to organize and make explicit their ideas or models with respect to a particular phenomenology. This has important implications in the educational, psychological and epistemological fields. As far as education is concerned, it is necessary to transform teaching methods, learning objectives and didactic situations (when concepts are decentralized, require changes in their organization, execution and evaluation). This leads to generation of proposals that promote the cognitive processes, which encourage students to construct and transform their representations to obtain specific achievements of specific knowledge or skills. In this paper we present the results of the differences in the representations about genetic inheritance mechanisms that high school students generate when they work in differentiated environments with the support of ICT and didactic tools oriented to a multi-representational classroom approach.
THEORETICAL FRAMEWORK

The idea of representation, as a construction closer to the phenomenological explanation, implies that the subject generates a structure with which possible properties or qualities of what he/she is representing can be inferred. In this structure, and its possibilities of making predictions and generate explanations, lies the importance of representations, since they are manifested as useful elements to account for processes that satisfy the minimum coherence that the subjects required to interpret and function in their milieu (Flores and Valdez, 2007).

In the educational field, the construction and transformation of representations (Tytler and Prain, 2010) can be favoured by an educational process that considers, among other aspects, that the student needs to make sense and explain the phenomena and achieve a representational transformation. This transformation can occur through processes organized around a specific theme, such as didactic sequences that make it possible to analyse related phenomena in different contexts, and that are supported by different alternatives to represent the phenomena.

In this sense, one of the advantages offered by the use of digital technologies in the teaching of science can be various forms of representation that, as educational research has shown, provide an understanding of scientific knowledge (Waldrip, Prain & Sellings, 2013; Ainsworth, 2006; Schnotz and Bannert, 2003; Kozma, 2003).

The purpose of this research was to investigate how the representations made by high school students on the subject of genetics are enriched and transformed when they work in a context of multi-representational learning supported by ICT and didactic tools.

The genetics topic was selected because it is a fundamental topic in Biology, it allows an understanding of how genetic characteristics are transmitted from generation to generation, as well as allowing an analysis of the origin of variability, etc. However, the research shows than for students it is difficult to move between the different levels and process that this topic entails: cells, DNA, chromosomes, genes, nucleotides, mitosis, meiosis, fecundation, inheritance mechanisms (Diez de Tancredi, & Caballero, 2004; Lewis, Leach, and Wood-Robinson, 2000).

That is why we analyzed representations, because they are cognitive elements with which processes and conceptions are interpreted, and also, to teach and learn it, it is necessary to understand and use different external representations of structures and processes (Figure 1).

METHOD

In order to know the representations that students generate when they work on the topic of genetics, three didactic sequences were constructed with the same conceptual objectives. These sequences were organized and divided over seven sessions (2hrs each), but differed in terms of the use of ICT and didactic tools, which allowed the construction of diverse forms of external representation. Table 1 indicates what was contemplated in each one of the sequences. Three groups participated in the study, each of them approached, with the guidance of their respective teacher, one of the sequences.
The sample consisted of a total of 186 students (60 G1, 60 G2 and 66 G3), from 17 to 19 years old, sixth grade high school, area II (chemical-biological), morning shift, who studied the subject of Biology V (Public High School of the National University of Mexico).

To determine the representations of the students after having worked on the corresponding sequence, a questionnaire was validated (Cronbach’s alpha coefficient of 0.88) and completed. The questionnaire consisted of 18 items, ten of which focused on descriptions, explanations and written interpretations of the situations presented, the other eight items considered, in addition to the conceptual explanation, the students’ explanation of their representations, through drawings and diagrams they made. To consistently qualify students' answers, a rubric was constructed for each item (Table 2), based on Wilson's scale (2005) proposal determined
by levels ranging from 0 to 5 (where 5 is the highest level) which was validated and difficulty characterized using Rasch Partial Credit Model.

### Table 2. Criteria for the elaboration of Rubrics

*Source: Adapted from Wilson (2005).*

### Process

Each group, with its respective teacher, worked the corresponding sequence; G1 and G2 worked in a traditional lab (with blackboard on the front and furniture to work in pairs), both teachers used their personal computer and a projector in a single session. G3 worked in two spaces, one room (with individual desks, blackboard, projector and the teacher's personal computer) and a laboratory that has work tables for eight teams, each with a computer and free access to the Internet, and simulators. One week after the work with the sequences, the questionnaire was applied to each group, and was qualified with the rubrics, obtaining the numerical databases for analysis.

### RESULTS

The ANOVA test was applied by the use of the sequences (I, II or III), which showed significant differences between the three groups, values of F were between 18 and 56 (p <0.05) in different items; the highest means for all items corresponded to G3. Table 3 shows an example of question 4, where students drew the information they recognized in sperm.

The lowest mean of G3 and G2 was in items 1 and 12, respectively, (both involved written responses, to explain how the genetic variability between generations originated).
Table 3. Examples about how the different levels of genetic information are represented in a sperm.

Student of group 1. Level 1 of the rubric. Generates representations of the phenomenon based only on its physical features: uses only sperm representation.

Student of group 2. Level 2 of the rubric. Generates representations of the phenomenon based on both observed physical features unobserved: sexual cells and chromosomes.

Student of group 1. Level 4 of the rubric. Makes connections across two different representations: nucleotides symbols, chromosomes, DNA and genes.

The lowest mean of group G1 was in item 6 (which required the elaboration of two diagrams, and they show the differences between the genetic information in the sperm and a skin cell) (Table 4).

</tr>
</tbody>
</table>

DISCUSSION

The results showed important differences in the level reached in the student’s representations when they work in a multi-representational context, enriched with ICT and didactic tools. It was identified that the students of G3 gave the best answers in all the items, and emphasized still more in those whose justification implied some type of graphical representation; it was observed that in the items that required written descriptions, G1 and G2 reached averages closer to G3. For example, although item 18 had the highest mean in all three groups, the significant value of F that it reached accounts for the difference between them, as students in G1 and G2 did not reach the same scoring levels as achieved the G3 with the rubric, referring to the graphic representation. The example of item 13 is an instance where the three students described the problem correctly, however, only the G3 student was able to graphically represent the different terms used in his written description. These findings reinforce the importance of incorporating a multi-representational approach into the classroom, as they provide alternatives for students to achieve more correct, complete and complex explanations with different contexts.

THE ATWOOD MACHINE, THE POGGENDORFF EXPERIMENT AND THE LEVER: A POWERFUL ANALOGY

Paulo de F. Borges¹, Ricardo L. Coelho² and Ricardo Karam³

From the analogy between the Poggendorff apparatus, the lever, and the compound Atwood machine we propose a pedagogically useful strategy to transform between dynamic and static situations in order to improve students' understanding about Newton's Laws and equilibrium. This approach is particularly useful for students meeting these concepts for a second time. The cognitive level is extended but the fundamental concepts that form the relevant knowledge do not need to be modified thus provoking the deepening of already acquired knowledge and addressing the learning gaps in the subject knowledge. In addition, a deep and unexpected connection between the static and dynamic magnitudes will be uncovered.

Keywords: Poggendorff, Atwood Machine, Lever

INTRODUCTION

Students have several difficulties in learning concepts from Physics and Mathematics. These have been described by many researchers working in Math and Physics Education research. These difficulties are related to three critical aspects in the education of the student: their prior conceptions that must be modified in the course of the scientific practice, the gaps in technical knowledge acquired early in their education but that still do not represent a whole coherent and accessible knowledge, and a lack of understanding of more basic, underlying concepts. When the student is able to explain the concepts and construct a full descriptive and explanatory system based on that knowledge that is intended she has learned, that is, knowledge is available to the student deliberately, hence the learning is complete (Scherr, 2007). To overcome the long prevalence of flawed thinking and the uncritical application of familiar knowledge changing the student’s conceptual weakness, gain mastery on commons misconceptions rose by training and also fills the gap among pieces of knowledge (Scherr, 2007); we are proposing to use this analogy to rescue students that have stories like that.

Atwood machines have many interesting properties and are a pedagogical tool of great value. Physics education researchers have used the machine not only to introduce Newton's Second Law and other related concepts, but also to investigate how students understand the concepts involved (McDermott, Shaffer and Somers, 1994). Crawford (1987), Gonzalez (1998), Jafari Matehkolaee (2011) proposed, independently from each other, new strategies for solving the compound Atwood machine problem. Despite the variety of studies on Atwood machines (Atwood, 1784), there is a seminal approach to the topic, which has been lacking. This is Poggendorff’s experiment (Poggendorff, 1854). His experiment consisted of a horizontal bar supported at its centre of gravity, an Atwood machine with two masses on the left side, and a
third mass, the counterweight, on the other side. Firstly, the machine is kept at rest. A tiny thread prevents the motion of the heavier body on the machine. At this first stage, Poggendorff's apparatus is in equilibrium. When that thread is pulled, the Atwood machine begins to move and the equilibrium is lost, showing that the machine becomes lighter. Coelho, Silva, Borges (2015) presented a modern version of this experiment. As the equations of motion of the Poggendorff apparatus and the compound Atwood machine are the same when rod, ropes and pulleys are massless and frictionless we will prove that the equations for rebalancing the Poggendorff apparatus, like a lever, provide us with another way of obtaining the equations of motion of that same Atwood machine. The latter provides a powerful analogy between the static and dynamic situations.

**CONTEXT**

The activity starts with the ideal Atwood machine setup (see Figure 1). A comparison between the masses of the rope, the pulley, and the bodies hanging from the machine allows us to argue that only the masses of these bodies are relevant to the dynamics. The role of friction is also investigated, and when compared with body weights it also appears too small for its contribution to dynamics to be considered. Next, we begin the construction of a simple Atwood machine where the hanging bodies have equal masses, that is, the tension on the rope due to the support of the bodies is the same on both sides of the pulley.

![Figure 1](image1.png)

**Figure 3 - George Atwood 1784, fig. 83.**

Newton's third Law tells us that the tension applied to the rope and the traction applied to the bodies form an action-reaction pair and therefore are equal in magnitude and have opposite directions. The free body diagram of the bodies hanging on the machine shows us that in each body only the force applied by the rope and the weight are present and, as they act in opposition to each other, their sum must be zero if bodies are in equilibrium. At this point we consider and discuss the concept of equilibrium. Atwood machines are in equilibrium when bodies’ relative positions do not change. They do not start to move if their masses are equal. To become unbalanced there needs to be a mass difference between the bodies which implies a weight
difference between both sides of the pulley. Now we have to show to the student that the acceleration with which the body of larger mass falls has the same numerical value as the acceleration with which the lighter body rises. This is done by the experiment and the construction of the graphs corresponding to the observed motion. Next we discuss the consequences of this result, for example, that even with bodies of different masses the rope is tensioned with the same force on both sides of the pulley. Newton's third Law continues to tell us that tension on the rope and force on the bodies are equal, but the free-body diagram tells us that the sum of the weight with the force on the bodies must be nonzero because now bodies are no longer in equilibrium, and when released, in any position, immediately begin an accelerated motion. From this moment Newton's second Law will be discussed and the association between accelerated motion and nonzero resultant force will be studied in a systematic way. To do this, based on our initial Atwood machine with equal masses, we will make mass additions on one side by increasing the mass difference in a fixed ratio and by measuring the acceleration of the bodies with each new addition which allows us to write a proportionality relationship between the resultant of the forces and the acceleration acquired by the bodies.

**Parallel activities I:**

i - Introduction of the concept of reference system;

ii - Characterization of motion:

- relating to the reference system: progressive and retrograde;
- relating to the direction of acceleration, if it is the same as that of the motion or contrary to that direction: accelerated or retarded.

iii - Determination of an expression for the acceleration, for the traction on the bodies and for the resultant on each body. To show that with the acceleration obtained the resultant force is in agreement with the expression $F = m.a$.

In the following we shall increase the complexity of the Atwood machine or the situations in which it appears with two remarkable devices: the compound Atwood machine and the Poggendorff machine (see Figure 2). The goal is to show that Newton's laws can be used to solve complex systems and also introduce the concept of equivalent mechanical systems. The equivalence will be demonstrated by the equality of the equations of motion obtained for these systems. In addition, the analysis of Poggendorff's device shows that what we have is a scale that is inferring the weight of the Atwood's machine. The machine will be in equilibrium when the arm is perfectly horizontal. To the surprise of the students, if we put on one side of the scale an Atwood machine and the other a body of the same weight and then let the bodies in machine go into motion, the arm will not remain horizontal indicating that the machine became lighter than when the bodies were at rest (see Figure 2). A new discussion of the concept of equilibrium is needed at this point in order to include the new situation.
Parallel activities II:

i - Introduction of the concept of center of mass;

ii - Discussion on the movement of the center of mass of an Atwood machine with different masses. Even though it is in a fixed support its center of mass is not in equilibrium;

iii - Discussion on the weight difference between an Atwood machine with its moving bodies and an Atwood machine where the bodies are kept at rest despite their mass difference;

iv - Analogy between the Poggendorff machine and the Lever.

v - Comparing Poggendorff machine and the Lever’s parameters in order to show that the acceleration of bodies are numerically equal to the lever balance lengths when the same bodies get hung in it.

An example of our didactical devices can be seen at https://www.youtube.com/channel/UCpy1vABd1mU80HleQzsfPlg/videos.

EQUATIONS OF MOTION

In the nineteenth century, a simplified form of the machine, as we use it nowadays, became common. This was also the form used by Poggendorff in his experiment. This experiment consists of a horizontal bar supported at its center of gravity, an Atwood machine with two masses on the left side, and a third mass, the counterweight on the other side. Firstly, the machine is kept at rest. A tiny thread prevents the motion of the heavier body on the machine. At this first stage, Poggendorff’s apparatus is in equilibrium. When that thread is burned, the Atwood machine begins to move and the equilibrium is lost, showing that the machine becomes lighter. We will show that the equations of motion of the Poggendorff apparatus have the
equations of motion of a compound Atwood machine as a special case. The equations for rebalancing the Poggendorff apparatus provide us with another way of obtaining the equations of motion of that same Atwood machine. The equations of motion are deduced from Newton’s second law. In a second step, we obtain the solutions for an ideal apparatus (massless rod). These equations coincide with the equations of motion for the compound Atwood machine with three bodies. Therefore, if the mass of the rod \( m_b \) is equal to zero, the Poggendorff apparatus and the compound Atwood machine are mechanically equivalent.

To obtain the solutions for an ideal apparatus, we have considered the equations of motion with \( m_b = 0 \). The equations of motion representing an inertia frame are:

\[
T = \left( \frac{4m_1m_2(m_1 + m_2)}{4m_1m_2 + (m_1 + m_2)^2} \right) g
\]

\[
T_3 = \left( \frac{8m_1m_2(m_1 + m_2)}{4m_1m_2 + (m_1 + m_2)^2} \right) g
\]

\[
a_1 = \left( 1 - \frac{4m_2(m_1 + m_2)}{4m_1m_2 + (m_1 + m_2)^2} \right) g
\]

\[
a_2 = \left( 1 - \frac{4m_1(m_1 + m_2)}{4m_1m_2 + (m_1 + m_2)^2} \right) g
\]

\[
a_3 = -\left( 1 - \frac{2(m_1 + m_2)^2}{4m_1m_2 + (m_1 + m_2)^2} \right) g
\]

where \( T \) is the traction on \( m_1 \) and \( m_2 \), \( T_3 \) is the traction on body \( m_3 \), \( m_1 + m_2 = m_3 \) and \( a_1, a_2, a_3 \) the accelerations acquired by bodies \( m_1, m_2, \) and \( m_3 \) respectively. Therefore, in the ideal case these equations are independent of the rod’s inclination angle.

**AN ANALOGY BETWEEN THE STATIC AND DYNAMIC SITUATIONS**

An intuitive idea is to move the lever's fulcrum to restore equilibrium. We gradually introduce this analogy beginning with numerical example and generalizing the result afterwards. Figure 3 schematically represents the Poggendorff experiment. The masses on the Atwood machine are 0.2 kg and 0.3 kg and the other mass is 0.5 kg. Thus, if the Atwood machine is prevented from moving, it is balanced by the counterweight. If the machine is allowed to move, the equilibrium is lost. The weight of the simple Atwood machine in motion is no longer \( W = 4.9 \) N but rather \( W' = 4.704 \) N, as measured by Graneau and Graneau (2006, p.160).

To rebalance the Poggendorff apparatus, we have to move the fulcrum by distance \( \Delta s \) closer to \( m_3 \) according to \( 4.9N \cdot (L - \Delta s)m = 4.704N \cdot (L + \Delta s)m \). It follows therefore that:

\[
\frac{\Delta s}{L} = \frac{4.9N - 4.704N}{4.9N + 4.704N}.
\]

If we had the same weights on an Atwood machine, we would have

\[
\frac{a}{g} = g^{-1} \left( \frac{4.9N - 4.704N}{4.9N + 4.704N} \right).
\]
Therefore, \( \frac{\Delta s}{a} = \frac{g}{L} \). In this expression, the acceleration of \( m_3 \) measured in an inertial frame is \( a \).

It is the same acceleration measured for the pulley on the other side of the machine. As \( L \) is arbitrary, we can choose \( L = 9.8 \) m, which is only an expedient for obtaining \( a \) by means of \( \Delta s \). Using this value of \( L \), \( \Delta s = 0.2 \) m. If we now represent the Atwood machine on the Poggendorff apparatus (Figure 3) by a massless rod with the same bodies (Figure 3) and require that all bodies balance \( 4.9N \cdot (9.8 - 0.2)m = 2.94N \cdot (9.8 + 0.2 - \Delta t) + 1.96N \cdot (9.8 + 0.2 + \Delta t)m \), it follows that \( \Delta s' = 2 \) m. This result provides us with the solution for an Atwood machine with the bodies of mass 0.5 kg, on one side, and a small Atwood machine with the masses 0.2 kg and 0.3 kg, on the other side. If \( \Delta s \) corresponds to the acceleration on the main Atwood machine and \( \Delta s' \) to the acceleration on the small one, the prediction of the Atwood machine motion is: body 5 moves downwards with acceleration 0.2 ms\(^{-2}\) and the small pulley upwards with the same acceleration; in this non-inertial reference frame, body 3 moves downwards with acceleration 2 ms\(^{-2}\) and body 2 moves upwards with the same acceleration.

Regarding the inertial frame, we only have to add or subtract both accelerations, i.e. \( a_2 = -0.2 \text{ms}^{-2} - 2 \text{ms}^{-2} = -2.2 \text{ms}^{-2} \) and \( a_3 = -0.2 \text{ms}^{-2} + 2 \text{ms}^{-2} = 1.8 \text{ms}^{-2} \). That analogy holds generally, the apparent coincidence between the displacements of the fulcrum to obtain equilibrium and the accelerations of the bodies since the simplest case, namely the analogy between a lever and a Poggendorff machine provides a general solution for the numerical example presented above. We can show that this analogy is expressed by:

\[
\frac{\Delta s'}{L} = \frac{a'}{g}
\]

where \( a' \) is the acceleration of \( m_1 \) and \( m_2 \) measured in a non-inertial frame fixed on the pulley. This generalization reveals a deep and unexpected connection between the static and dynamic magnitudes (Coelho, Borges and Karam, 2016). However, in the ideal case compound Atwood machines and Poggendorff machines are equivalent. Thus we can apply this analogy to solve Compound Atwood machines.
CONCLUDING REMARKS

The Atwood machine is pedagogically very useful because it may be addressed at different levels, depending on the physical aspects to be outlined with benefits for the enlightenment of some physical concepts. In fact, as pointed out by Newburgh et al. (2004, p. 290), it seems somehow surprising that the weight of an Atwood machine is reduced by its motion. If the Poggendorff lever is rebalanced, the conditions for static equilibrium provide us with an analogy to determine the accelerations of the compound Atwood machine problem. In addition, we can use the Atwood machine and the Poggendorff’s apparatus to introduce a problem solving instructional approach providing opportunities for students to share conceptual and procedural knowledge as well as engage in meaningful discussions. They can demand clarification, justification and elaboration from one another improving conceptual learning and students' analytical skills (Heller, Keith and Anderson, 1992). Qualitative problem solving strategies developed to explain lever balance behavior highlight the role of conceptual knowledge for successful solutions for not so simple devices (Leonard, Dufresne and Mestre, 1996). The analogy should be applied in order to win the long prevalence of naive reasoning, the noncritical application of familiar knowledge, mature the misconceptions introduced during a first educational process and fill the gaps in knowledge acquired in pieces.

RELATIONSHIP BETWEEN COGNITIVE ABILITY, CONCEPTUAL KNOWLEDGE AND CONVENTIONAL PROBLEM SOLVING

Clemens Wagner, Daniel Braitsch, Andreas Lichtenberger and Andreas Vaterlaus
Solid State Physics and Education ETH Zurich, Zurich, Switzerland

Learning of Physics concepts has moved into the focus of Physics education and Physics education research. In our project with the goal to foster concept knowledge of high school students by formative assessment, we investigate the relationship between cognitive ability, learning of conceptual knowledge, and conventional problem solving. In this study we compare traditional teaching to our formative assessment approach. We find that both teaching methods favor high and low cognitive ability students to the same degree. Moreover, there is no preference with respect to cognitive ability when we compare the results of male and female students separately. However, when we look at underachievers, we see a remarkable difference between traditional teaching and formative assessment. The formative assessment approach produces almost no underachievers, whereas the traditional teaching group contains around 10%.

Keywords: cognitive ability, physics concepts, conventional problems

INTRODUCTION

In recent years, physics education research has focused on conceptual understanding. Since the development of the Force Concept Inventory (FCI) (Hestenes, Wells, & Swackhammer, 1992) and the application of the FCI in largescale studies, e.g. Hake et al. (Hake, 1998), the lack of understanding of Physics concepts has become evident. Big efforts have been undertaken to remedy the deficits by changing instructions from teacher centred to student centred, inquiry-based teaching (McDermott, Shaffer, & Vokos, 1997). One possibility to particularly foster conceptual knowledge is peer instruction suggested by Eric Mazur (Mazur, 1997). It encompasses a set of clicker questions (multiple choice concept questions), which are first solved individually, then discussed in small groups and finally solved in a classroom discussion with the teacher. We have used a similar approach in our study of fostering conceptual knowledge by formative assessment in teaching Physics at Swiss high schools (Lichtenberger, Hofer, Stern, Vaterlaus, & Wagner, 2017).

However, many high stakes assessments at Swiss high schools are still conventional, numerical exams. Therefore, teachers in Physics focus on solving conventional problems, which is often based on plug and chug. Much time is used to furnish students with enough routine to reach a sufficient score in the exams. The focus on routine has an unwanted consequence: There is a group of students with high cognitive abilities who gets bored by routine problems and then fails in the conventional exam. These students are called underachievers.

Students in our project have solved two tests after the intervention, a conceptual test and a conventional exam. The goal of this work is to evaluate the performance of students in the formative assessment approach depending on their cognitive ability. In particular we are
interested which of the teaching methods has a different effect on high and low cognitive ability students and which method produces less underachievers.

**DESCRIPTION OF INTERVENTION**

We have recruited 19 high school teachers and asked them to teach the content of basic Kinematics for 14 lessons without homework. The teachers were divided into two groups by a random process. In the first group, the so-called formative assessment group (FA-group), teachers conducted two clicker sessions with approximately eight clicker questions each, the first one after four lessons and the second one after thirteen lessons. The teaching sequence of the FA-group was interrupted after seven lessons and a diagnostic test was applied to the students. The analysis of the answers provided a detailed feedback for the students about their conceptual knowledge and the presence of misconceptions. The diagnostic test was followed by a reflective lesson, where students had time to work on their deficits regarding their concept knowledge.

To summarize, students from the FA-group had four lessons to prepare for the Kinematics Concept Test and ten lessons, including theory and exercises, to get ready for the conventional exam (see Figure 1). All teachers used the conventional exam as high stakes exam except two teachers of the FA-group. The latter two conducted the conventional test as an exam but the students knew that the result would not count for the school report mark. Since the overall time for teaching was kept constant for both groups, the FA-group had four lessons less time to work on conventional problems than the TT-group. Therefore, in order to solve the conventional exam students from the FA-group had to transfer their conceptual knowledge and apply it to the conventional problems. A second group of nine teachers formed the traditional teaching control group (TT-group). Their task was to teach the given content in the way they are used to do. Students from the TT-group had 14 lessons to get prepared for the conventional exam. However, there was no lesson designed to work on conceptual knowledge. Therefore, they had to extract the concepts from solving conventional problems.

The Kinematics Concept Test (KCT) consists of 49 multiple-choice questions, whereby each item can be assigned to one of the seven concepts defined beforehand (see (Lichtenberger, Wagner, Hofer, Stern, & Vaterlaus, 2017)). The conventional test encompasses five problems with contexts given in Table 1.

Figure 1. Design of the formative assessment project for the FA-group and the TT-group. The formative assessment group as well as the traditional teaching group had 14 lessons to teach the prescribed content. The focus of the traditional teaching group was on solving conventional problems whereas the formative assessment group included two lessons for solving concept questions in the peer-instruction approach. The teaching flow of the FA-group was interrupted after seven lessons by a diagnostic test, which was applied to the students. It provided an individual feedback of the conceptual knowledge for each student as well as of the presence of misconceptions. Teachers of the FA-group obtained a detailed feedback about the average conceptual knowledge of the class. The diagnostic test was followed by the reflective lesson, where students had time to work on their conceptual deficits. Students from the FA-group had to transfer their knowledge to solve the conventional problems whereas students from the TT-group had to extract the concepts from the traditional teaching and apply it to the Kinematics Concept Test.

METHODS

The data were collected in fall 2014 at Gymnasiums (high schools) in the German part of Switzerland.

Data acquisition

The KCT was used as pre- and post-test to measure the concept knowledge and the conceptual learning gain. Students had time for 45 min to solve the 49 multiple-choice questions on the computer (Lichtenberger, Wagner, et al., 2017). The score of the test is the number of correctly solved items. We normalized the results by the maximal achievable score so that student attainments are in the range between zero and one.

To solve the conventional exam students also had 45 min available. The maximal score was 35 points. The exam was given to the students right after the last lesson of the intervention. The teachers received the exam in general 5 days before the exam took place in order to prevent teaching to the test.

Finally, we measured the cognitive ability of students using Raven’s progressive matrix test set II. Set I was used as an exercise for the students in order to adapt to the test. Set II consists of 36 items which corresponds to the maximal sum-score of the test.

The TT-group comprised 194 students (9 teachers) of which 115 were females and the FA-group contained 168 students divided into 92 females and 76 males (10 teachers). Only students who solved the KCT as pre- and post-test, the conventional exam and the cognitive ability test were taken into account.
Data analysis

We analyzed the traditional teaching method and the formative assessment approach based on the cognitive ability of the students. Therefore, we divided the sample into high and low cognitive ability. The maximal score of Raven’s Progressive Matrix Test is 36. The average cognitive ability score of all students was 26.25, which was used as threshold to split the TT-group and the FA-group into low and high cognitive ability subgroups. Thus, the group of low cognitive ability resulted in an average of 22.86 for the TT group and 23.16 for the FA-group, and the high cognitive ability groups showed a mean score of 29.7 and 29.76 for the TT-group and the FA-group, respectively. The number of students of the subgroups is given in Table.

Table 2. Dividing the traditional teaching group and the formative assessment group into male - female and high - low cognitive ability subgroups. The number of students per subgroup is displayed.

To identify underachievers we used the two step cluster analysis of SPSS. The variables are the cognitive ability and the sum score of the conventional exam. The algorithm determined three clusters for the high cognitive ability subgroups of the TT-group and the FA-group.

HYPOTHESES

Since learning of Physics concepts requires a cognitive effort we were convinced that students from the FA-group with high cognitive ability would benefit more from the formative assessment approach than students with low cognitive ability. Therefore, we expected, as our first hypothesis, that the difference between the high and the low cognitive ability subgroups of the FA approach is bigger than the difference of the TT-group.

The second hypothesis was based on a paper by Lorenzo et al. (Lorenzo, Crouch, & Mazur, 2006). The authors found a reduced gender gap when applying peer instruction to first year university students. Thus, we hypothesized that the gender gap, usually observed in Physics education research, might be reduced by our formative assessment approach, in particular for the high cognitive ability group, due to the proximity between peer instruction and clicker sessions.

If students with high cognitive ability do not perform well is a waste of resources. This kind of students are often called underachievers (Hofer & Stern, 2016). Our third hypothesis was that underachievers will benefit from the formative assessment approach resulting in an increased performance.
RESULTS

We first present the results for the high and low cognitive ability groups for the KCT pre-test, the KCT normalized gain, and the conventional exam.

Comparison of teaching methods

First, we investigated the KCT pre-test in order to determine the initial conceptual knowledge (see Figure 2). Although there is no statistically significant difference between the TT-group and the FA-group in the overall normalized sum score, we find a significant difference in the low cognitive ability subgroups ($F(1,184) = 6.853, p = 0.010, d = 0.3827$) as shown (Figure 2).

![Figure 2. Results of the KCT pre-test of the TT- and the FA-group for the low- and the high cognitive ability subgroups.](image)

In Figure 3 we show the averaged normalized gain (Bao, 2006) of students for the TT-group and the FA-group. For the TT-group, the level rises from 0.23 to 0.31 from the low to the high cognitive ability group. A similar increase from 0.39 to 0.47 can be observed for the FA-group. The difference between the TT-group and the FA-group regarding concept knowledge is almost equal for the low and the high cognitive ability subgroups.

![Figure 3. Result of the normalized gain of the TT- and the FA-group for the low- and the high cognitive ability subgroups.](image)

Finally, if we consider the conventional exam, it turns out that the level of the low ability subgroups of the TT-group (sum score: 15.4) and FA-group (sum score: 15.1) is the same (see Figure 4). Although a slight difference between the scores of the TT-group and the FA-group can be observed for the high cognitive ability subgroups (TT-group: sum score 21.3 and FA-group: sum score 19.3) it is not statistically significant ($F(1,174) = 2.72, p = 0.101$).
Figure 4. Result of the conventional exam of the TT- and the FA-group for the low- and the high cognitive ability subgroups.

Gender gap

In order to analyze the gender gap, we just split the high and low cognitive ability groups into male and female students. The corresponding distribution is shown in Table 2.

As presented in Figure 5, it is quite obvious that the gender gap could not be reduced by the formative assessment approach. The male students of the FA-group outperform all other groups. Interestingly, the female students of the FA-group achieve the same conceptual knowledge as the male students of the TT-group. Most low performers regarding the KCT normalized gain are female students from the TT-group. Although there is a tendency that the high cognitive ability groups attain a higher level of conceptual knowledge than the corresponding low cognitive ability groups, however the differences are statistically not significant. There is one exception, the female FA-group, but the p-value of 0.024 is quite high.

Figure 5. Result of the normalized gain of the KCT from the pre-test to the post-test. The TT- and the FA-group are divided into low- and the high cognitive ability group and male and female students.

The analysis of the conventional exam doesn’t lead to a different result (see Figure 6). The performance of the two female groups is below the performance of the two male groups. The differences are statistically significant if we compare the male TT group to the female TT group (low cognitive ability group: $F(1, 101) = 18.09, p$-value $< 10^{-3}$; high cognitive ability group: $F(1, 89) = 12.65, p$-value $= 0.001$) and the male FA-group to the female FA-group (low cognitive ability group: FA-group: $F(1, 81) = 20.88, p$-value $< 10^{-3}$; high cognitive ability group: FA-group: $F(1, 83) = 7.70, p$-value $= 0.007$). Furthermore, the differences between the low cognitive ability subgroups and the high cognitive ability subgroups are also statistically significant. Here the exception is the FA-male-group.
Figure 6: Results of the sum score of the conventional exam for the high and the low cognitive ability group. The groups are further divided into male and female subgroups. The two male groups outperform the two female groups.

Underachievers

Underachievers are students with high cognitive ability but low performance. They were identified by the two-step clustering algorithm of SPSS applied to students with high cognitive ability. The algorithm recognizes three different clusters for the TT-group and the FA-group. In order to show that a cluster cannot be assigned to a single teacher we averaged the clusters among the classes. Most of the clusters occurred in all classes. The distribution of students to classes and clusters is displayed in Table 3.

Table 3. Cluster analysis. Distribution of high cognitive ability students to classes and clusters for the TT-group and the FA-group.

The three clusters recognized by the algorithm for the TT-group and the FA group are shown in Figure 7.

Figure 7. Clusters of the high cognitive ability students of the TT-group (A) and the FA-group (B). Data points represent averages over classes.
The three clusters of the TT-group can be characterized by “above average (cognitive ability) – low performance (conventional exam)” (cluster 1), “above average – high performance” (cluster 2) and “high cognitive ability – low performance” (cluster 3). The three clusters of the FA-group can be distinguished by “above average – low performance” (cluster 1), “above average - high performance” (cluster 2) and “high cognitive ability – high performance” (cluster 3). In the traditional teaching group, cluster 3 is typically the group of underachievers. This group performs much better using the formative assessment approach.

**DISCUSSION**

This paper discusses the effect of two different teaching methods on the performance of students regarding their cognitive abilities. The teaching methods are on the one hand traditional teaching and on the other hand formative assessment (Lichtenberger, Hofer, et al., 2017). The performance was measured by the Kinematic Concept Test and the conventional exam. The goal of this study is to figure out which teaching method fosters high cognitive ability students more than low cognitive ability students or vice versa.

In contrast to our first hypothesis, the analysis revealed that both teaching methods are fostering high and low cognitive ability students to the same degree. Therefore, the curves in Figure 3 and Figure 4 run almost parallel for both methods. The same is found when we even further split up the groups into male and female students (Figure 5 and Figure 6).

Considering the second hypothesis we observe that the gender gap does not get reduced but rather opens by the formative assessment approach when compared with the traditional teaching method. This statement holds for the low as well as for the high cognitive ability students. It is in clear contrast to observations of other groups e.g. (Lorenzo et al., 2006).

Finally, the third hypothesis is supported by our data. The group with very high cognitive ability but low performance of the TT-group appears to turn into a high-performance group in the FA-approach as shown in Figure 7.

To summarize, the data show that our formative assessment approach fosters low and high cognitive ability students to the same degree as the traditional teaching method independent of gender. The major difference is that there are almost no underachievers in the formative assessment group whereas there are about 10% in the traditional teaching group.

CONCRETE AND ABSTRACT EXTERNAL REPRESENTATIONS IN CHEMISTRY EDUCATION

Perihan Akman and Sabine Fechner
Paderborn University, Paderborn, Germany

Using multiple external representations is fundamental for explaining and understanding phenomena in science education. Students’ knowledge and its internal representations about chemical concepts relate to external representations. Especially in chemistry, phenomena like an atom are not available to the senses so consequently they have to be visualized by external representations. Nevertheless, students have difficulties in translating and linking between external representations while experts link and manipulate representations without problems. There are many research studies focusing on novices’ problems with linking and translating between multiple external representations. However, focusing on what the concepts “concrete” and “abstract” mean for understanding seems to be unattended. Furthermore, there is no consistent definition of the terms “abstract” and “concrete” when referred to representations in chemistry education and students attitude towards them are unknown. Therefore, the goal of this research study is to examine the influence of abstract and concrete external representational instruction on understanding chemical concepts in the area of acid-base chemistry. For this purpose, a semantic differential scale based on empirical evidence and a definition of “concrete” and “abstract” was developed in a first step to measure students’ perception of different external representations. First-year chemistry students were supposed to estimate to which extent the different representations comply with characteristics of “abstract” and “concrete”. The results of the first part will be used in an intervention study to construct different abstract and concrete representational learning environments and to measure the influence on learning chemical concepts. Preliminary results of the pilot study indicate that students perceive concrete external representations as more difficult and complex. Nevertheless, a comparison between a content knowledge test and a representation test shows that students are able to retrieve and identify information from more concrete representations even without knowing the underlying content knowledge.

Keywords: abstract, chemistry, representations

MULTIPLE EXTERNAL REPRESENTATIONS IN SCIENCE EDUCATION

There is consensus about the relevance of using multiple external representations (MERs) in teaching and learning science concepts (Ainsworth, Bibby, & Wood, 2002; Harrison & Treagust, 2000). Hence, curricular standards increasingly require the knowledge and use of MERs in science education because it seems to be an essential competence in scientific literacy, especially in problem solving (Gabel, 1999; Prain & Waldrip, 2006; Talanquer, 2011). Several research studies indicate that using MERs has an advantage over single representations and leads to deeper conceptual understanding (Ainsworth, 1999; Kozma, 2003). Chemistry is a representation-rich domain which involves the use of many external representations (ERs) for the same target system in order to understand and explain chemical concepts (Justi & Gilbert, 2000).
Recent international studies have evaluated MERs from different perspectives. A remarkable variety of research studies focus on the differences between novices’ and experts’ ability in using and translating between MERs (Chi, Feltovich, & Glaser, 1981; Kozma & Russell, 1997). These research studies report of novices’ difficulty in translating and linking between the three corners of the chemistry triplet according to Johnstone (1993) and to translate a representation into one another (Hinton & Nakhleh, 1999; Kozma & Russell, 1997; Taskin & Bernholt, 2012). Especially low prior knowledge learners have difficulties in using MERs to achieve deeper conceptual understanding and pay more attention to superficial features of the representations (Cheng & Gilbert, 2017; Corradi, Elen, Schraepen, & Clarebout, 2014; Johnstone, 1993; Taber & Watts, 2000). The differences between novices and experts indicate a high correlation between domain-specific content knowledge and the ability to use MERs (Ainsworth & VanLabeke, 2004; Corradi et al., 2014). Further research studies examine students’ and teachers’ knowledge about models and representations and assume that using representations in science also depends on knowledge about the different representations (Grosslight, Unger, & Jay, 1991; Oh & Oh, 2011). Ainsworth (2008) asserted that there are certain preconditions enhancing the acquisition of scientific concepts through MERs. Learning with MERs requires students to understand how a) to encode a representation and the presented information, b) the representations relates to the domain to retrieve relevant information, c) to select an appropriate representation, d) to construct a representation for a special purpose, e) to relate different kinds of representations for the same phenomena.

Only a few studies examine the effectiveness of different types of multiple representational learning environments to enhance science learning (Jaakkola & Veermans, 2015). Ainsworth and VanLabeke (2004) suggest categories of MERs such as abstraction, sensory channel, dimensionality etc. Furthermore, there are less investigations to examine the ability of students to extract information from the different ERs in chemistry education (Jaakkola & Veermans, 2015; Lin, Son, & Rudd, 2016). Research studies focusing on concrete and abstract representational learning environments in mathematics and physics report inconsistent results so that there is an ongoing debate whether concrete or abstract representations should be preferred in science education. Some empirical evidence verifies that learning with abstract representations leads to better outcomes in science education (Gilbert, Reiner, & Nakhleh, 2008; Goldstone & Son, 2005; Kaminski, Sloutsky, & Heckler, 2009; Lin et al., 2016). The advantage of abstract representations over concrete ones could be explained by the assumption that concrete representations consist of distracting elements and students are not able to focus on information that is relevant for conceptual understanding (Chi, 2008; Kaminski, Sloutsky, & Heckler, 2008). Lin et al. (2016) analysed the directionality of concrete and abstract representational instruction in chemistry and report that students performed the best on abstract-to-abstract-questions, then concrete-to-abstract questions, and worst on abstract-to-concrete questions. Contradictorily, Jaakkola and Veermans (2015) report that learning instructions with multiple concrete representations are more productive than abstract ones. However, the research studies refer to different domain-specific definitions of concrete and abstract like the definition according the theory of Johnstone (1993), van Oers (2001) or Schnottz (2002). The assumed classifications of MERs are derived from theories and there is no evidence for their suitability. Furthermore, there are limited findings for the benefit of
Strand 1

can be abstract representations on the submicroscopic level in chemistry. Therefore, the goal of this study is to examine the influence of abstract and concrete external representational instruction on understanding chemical concepts.

THEORETICAL FRAMEWORK

Giere (2004) defines an external representation as “S uses X to represent W for purposes P” (p. 743). According to his definition a representation can be things e.g. a theory, model, diagram, word or symbol that signifies or visualizes a real object of the world and which is used by scientists for a specific purpose. The term “multiple” means using different forms of external representations for the same concept. Using MERs is also explained as “…practice of re-representing the same concept through different forms, including verbal, graphic, and numerical modes, as well as repeated student exposures to the same concept” (Prain & Waldrip, 2006, p. 1844). Ainsworth and VanLabeke (2004) suggested categories to classify MERs (Figure 1). One of these categories is the degree of abstraction that varies between the MERs. The degree of abstraction can clearly be defined by Schnotz’ theory (2002).

According to his theory, MERs can be differentiated into depictive and descriptive external representations, which differ from each other by their reference to a target system and the sign system on which they are based. While descriptive representations consist of a symbolic sign system depictive representations include icons. Schnotz (2002) assumes icons to be more concrete because they are associated with the content they represent such as common structural similarity. Symbols, on the contrary, are described as more abstract because of their arbitrary structure, which corresponds with the designated object simply by conventions and the absence of common visual features. Some representations possess characteristics of icons as well as symbols. Schnotz (2002) assumes that a representation which includes characteristics of abstract and concrete representations belongs to the class of representations from which it possesses more characteristics.

Figure 1. Definition of concrete and abstract representation (based on Ainsworth & VanLabeke, 2004; Schnotz, 2002)
Furthermore, Schnotz (2002) suggests that MERs can differ from each other by means of their information content and usability. The information content of a representation describes the set of information which can be extracted from the representation. It depends on its structure and the procedure needed to operate on the structure. MERs are informationally equivalent if the same information can be extracted from different representations. With respect to a specific set of tasks, representations are also informationally equivalent if there is the possibility to extract the information from each of the representations necessary to solve the task (Schnotz, 2002). Even though two representations are informationally equivalent, they can differ in their usefulness. The usefulness of a representation refers to the information retrieval or computation of new information. Depending on the representation structure and the process operating on it, the information retrieval can be easy or difficult (Schnotz, 2002). Especially the information retrieval with the help of different chemical representations is unknown.

Apart from Schnotz, Gilbert (2008) also suggests a categorisation of MERs according to a system depending on the number of physical dimensions of the representation. Referring to the chemical ERs of an atom, Gilbert (2008) calls the existing structural similarity between representations and the represented object as a positive analogy while absent structural properties are called a negative analogy. Furthermore, he assumes that 1D representations such as chemical symbols are inherently abstract and consist of symbols.

In this research study, MERs of atoms in chemical compounds within the topic of acids and bases are investigated: structural representations (space filling model and skeletal formula) and symbolic forms (molecular forms and words). Based on the theoretical assumption the structural representations can be categorized as more concrete while the symbolic forms are more abstract.

**RESEARCH AIM AND QUESTION**

Based on current research evidence the two following research questions are posed:

Q.1: Which external representations at the atomic level are perceived as more abstract or concrete in the topic of acids and bases?

Q.2: What influence do different abstract and concrete representational learning environments have on learning chemical concepts?

The following part provides details on the first research question.

**DESIGN AND METHOD**

In a first step, a textbook analysis was performed to see which kind of ERs are frequently used in the area of acid and bases. The analyzed representations are also used as a basis for the construction of the representation test. The textbook analysis shows that the space-filling model, structural formula, molecular formula and words are used frequently in textbooks in the area. Based on this, a paper pencil test was developed which is divided into three parts: the parts investigate 1) the ability to extract information out of MERs, 2) the perception of different MERs and 3) the underlying content knowledge.
In the first part, the participants fill in a representation test which requires them to extract chemical knowledge out of MERs. In the representation test, the content of each item of the corresponding content knowledge test was illustrated by two chemical equations with different representations (Figure 2). The representation test is administered according to a balanced incomplete block-design with four different test booklets. The 48 items were allocated to different blocks with twelve items each. One test booklets should not include two items based on the same content knowledge item. With regard to Schnottz’ theory (2002) the two equations representing the same content knowledge with different ERs are informationally equivalent. The information retrieval from the MERs is going to be analyzed in the third part. Students have to analyze the chemical equations and match it with the right answer. This test is used to analyze whether students are able to extract information from a representation without knowing the underlying content knowledge and whether one representation works better than another does.

In the following reaction aluminium chloride reacts as...  
\[ \text{AlCl}_3 + \text{Cl}^- \rightarrow \text{AlCl}_4^- \]
- an electron-pair acceptor.
- an electron-pair donor.
- a proton acceptor.
- a proton donor.

In the following reaction aluminium chloride reacts as...

\[ \left[ \begin{array}{c}
\text{Cl}^- \\
\text{Cl}^-
\end{array} \right] + \left[ \begin{array}{c}
\text{Cl}^- \\
\text{Cl}^-
\end{array} \right] \rightarrow \left[ \begin{array}{c}
\text{Cl}^- \\
\text{Cl}^-
\end{array} \right] + \left[ \begin{array}{c}
\text{Cl}^- \\
\text{Cl}^-
\end{array} \right] \]
- an electron-pair acceptor.
- an electron-pair donor.
- a proton acceptor.
- a proton donor.

Figure 2. Item example of the representation test

The second part includes a semantic differential scale that measures students’ perception towards the use of different MERs known from the representation test. Students are asked to rate their perception of the MERs on a six-point Likert scale. The scale is based on Schnottz’ (2002) definition of abstract and concrete representations and consists of eleven dichotomous attributes derived from the theoretically assumed characteristics of the different representations.

Furthermore, a content knowledge test with 32 multiple-choice questions was designed to measure students’ knowledge on the topic of acids and bases. Validity is ensured by matching the content with the curriculum and a concept map (Ross & Munby, 1991). The participants of the pilot study were twenty prospective chemistry students from Paderborn University attending a chemistry summer school.

**PRELIMINARY RESULTS**

For reliability analysis, Cronbach’s alpha was calculated to assess the internal consistency of the content knowledge test and the representation test. The internal consistency of the content knowledge test ($\alpha = .93$) as well as the representation test ($\alpha = .88$) are good so that the tests can be used for analysis and the main study.

The preliminary results of the pilot study show a statistically significant correlation between the total scores of the content knowledge test and the representation test ($r_{PP} = .92, p < .001$). These findings confirm the assumption of an interdependence of the ability to use MERs and content knowledge.
Furthermore, the analysis of the semantic differential scale indicates that students estimate the structural similarity between the MERs and the atomic level similar to the theory (Figure 3). Nevertheless, students specify their perception with the help of the six-point Likert scale that it is more difficult to extract information from equations with more concrete representations like structural formula and the space-filling model than with words or molecular formula. This result is contrary to the expectations because more concrete representations contain more information and structural properties of an atom than words. On the other hand, this finding could be in agreement with Gilbert’s assumption (2008) that students pay more attention to superficial features of the representations and are not able to focus on the relevant ones.

**Figure 3. Results of the semantic differential scale**

A comparison between the items of the representation test and the corresponding items of the content knowledge test shows that if participants were not able to solve the content knowledge item, they were more frequently able to extract information from the more concrete representations and match the right answer than from the abstract ones without knowing the content knowledge.

**DISCUSSION AND IMPLICATIONS**

The results of the pilot study show that the tests can be used in the main study. The number of the participants, which took part in the pilot study is low, so that the results are tentative and more participants are needed for future analysis. So far, one hundred thirty-six undergraduate chemistry students from Paderborn University took part in the main study and the analysis is about to be started. Because of the balanced incomplete block-design of the representation test, item response theory will be used in addition to classical test theory for further analysis. The analysis indicates a significant correlation between the representation test and the content knowledge test so that it has to be proven whether the tests measure two different constructs.

Furthermore, a factor analysis with the semantic differential scale will be performed to extract factors that support the perception of a representation as being more abstract or concrete. In
addition, a comparison of extreme groups with regard to the semantic differential scale has to be conducted to analyse whether there are differences between students with low and high prior knowledge.

The results of the first part will be used in the second study to construct different abstract and concrete representational learning environments. Therefore, an intervention study in a comparison group design will be conducted. The intervention is accompanied by a pre-post design. Three groups learn in different experimental learning environments which differ in the types of MERs (concrete vs. abstract) that are used to learn acid-base chemistry.

IMAGES AND HYPERLINKS IN THE GREEK LOWER-SECONDARY CHEMISTRY E-BOOKS

Giannoula Pantazi¹ and Georgios Tsaparlis²

¹Science Laboratory Center (EKPhE) of Preveza, Preveza, Greece
²Department of Chemistry, University of Ioannina, Ioannina, Greece

This study undertook to analyze (record and classify) the images/illustrations and the hyperlinks included in the enriched with hyperlinks electronic textbooks for the 8th and the 9th grades of Greek lower-secondary school, under the project “Digital School”. A chemical representation, which simultaneously involves all three levels of chemistry (the macroscopic, the submicroscopic and the symbolic), helps pupils understand a phenomenon and shift from one level to another, irrespective of whether the representation is the form of an image, a video, a virtual experiment, a simulation or an interactive game. Images take up more and more space in textbooks, while, and at the same time, useful educational software is available. The present proposal considers the types of representations in lower-secondary Greek school chemistry textbooks with respect to the three levels, and the role they play in understanding by the students of the chemical phenomena and concepts. In addition, the contribution of the hyperlinks in the e-books to the understanding of the above representations is also examined. The images and hyperlinks were analyzed by two teachers, with a 98% agreement rate.

Keywords: lower secondary chemistry e-books, multiple representations, images and hyperlinks

INTRODUCTION

The visualization of chemical phenomena is necessary for the development of chemical understanding (Gkitzia, Salta, & Tzougraki, 2011). According to Johnstone (1991, 1993), chemistry functions at three levels: the macroscopic, the symbolic and the submicroscopic. However, conceptual understanding of chemistry cannot be achieved merely through images at the macroscopic level (Cabel, 1999; Tsaparlis, 2009). Chemists have devised molecular formulas, chemical equations, and chemical models to enable students to link the three levels (Hoffman & Laszlo, 1991; Mathewson, 2005), but this is a difficult task for students (Tsaparlis, 2009).

After the teacher, books constitute the main means of transfer of knowledge, being used regardless of the school structure (material/technical infrastructure). Books are used by the students not only for study at home, but also in subsequent courses and even after graduation. Illustrations and text in the books play a central role both in the teachers’ job and the pupils’ concept understanding. Images are also used to attract the pupils’ attention. In recent years, images take up more and more space in school textbooks, while educational software is also being developed. The pupil’s enriched e-book visualizes situations that cannot be described in words. It combines graphics, videos, music, sounds and text, learning content, additional information from encyclopedias, animation, etc. All the above may have color, movement, and sound, so that they can attract students’ attention more than still images.

Many chemical entities and phenomena, such as atomic and molecular structure and the interactions between atoms and/or molecules are not directly observable by naked eye.
Therefore, teachers, textbooks, interactive books in the digital school and the laboratory must encourage the student to create mental images of phenomena and concepts, so that these images make sensible the invisible world of chemistry. The external world can be represented either verbally or by virtue of one’s mind (Eysenck & Keane, 1990), and in this way the acquisition of knowledge becomes more user-friendly (Freedberg, 1989). The way we read an image depends on the mental representations that are stored in our minds (Gombrich, 1972; Chalkia & Theodoridis, 2002). The use of technology and especially of computers can contribute to better teaching and learning, while the use of models and simulations as well as of visualization techniques can help students overcome their misconceptions (Tsaparlis, 2009).

Due to the teachers’ comfortable ability to move from one chemical level to another, many teachers assume that their students can do the same (Treagust, Chittleborough, & Mamiala, 2003). However, studies have shown that the understanding of the content of the images is not possible, especially when the student does not know their "code". Hence, the teachers should devote time and effort until their students understand the "visual language", which implies that they understand not only the meanings of the images but also the vague notions that they could convey (Pinto & Ametller, 2002). In addition, the images should not only help students to understand the different chemical concepts, but also support teachers in their job (Gkitzia et al., 2011). For example, the concept of a chemical reaction when presented in a school book should include all three chemical levels. At the macroscopic level, pupils watch the phenomenon under examination; at the submicroscopic level they must understand the explanation of the phenomenon; and at the symbolic level they learn to use chemical symbols and equations as a shortcut written representation of atoms, molecules, and chemical reactions (Gkitzia et al., 2011).

To sum up, it is necessary to study the images and the content to which the hyperlinks of the enriched digital chemistry schoolbooks lead. This is necessary in order to examine whether the macroscopic, submicroscopic, and symbolic levels are all represented, and if they fulfill their role in the understanding of chemical phenomena, as well as if their relative participation is adequate and acceptable. This study includes the analysis (that is recording and classification) of the images and hyperlinks in the enriched interactive chemistry schoolbooks for the 8th and 9th grades (classes B and C, ages 12-14) of Greek lower secondary school. The aim was to investigate the extent to which students are exposed to the three chemical levels through them. The study was guided by the following research questions:

1. What are the different types of images and hyperlinks used in the enriched chemistry schoolbooks of the Greek digital school, for the 8th and 9th grade of lower-secondary school?

2. What are the relevant numbers of submicroscopic, symbolic and, especially, multiple representations in the enriched chemistry schoolbook for the 8th grade in relation to the enriched book for the 9th grade?

**METHOD OF CODING AND ANALYSIS**

Using the coding developed by Gkitzia, Salta, & Tzougraki (2011), each page of the enriched interactive books of the "digital school" was analyzed according to the type and number of
images and hyperlinks it contains. In particular, the images and hyperlinks of the interactive e-books were coded with the terms: macroscopic representations, symbolic representations, submicroscopic representations, hybrid representations, multiple representations, and mixed representations (Gkitzia et al., 2011). (See Figure 1 and Figure 2, and the examples of hyperlinks.)

**Macroscopic representations:** They use images (photos or drawings) or videos to portray phenomena from everyday life or from the laboratory, according to the human visual sense.

**Symbolic Representations:** They use chemical symbols, letters, numbers, symbols, graphs, chemical and mathematical equations, Lewis structures, etc.

**Submicroscopic representations:** They use images (photographs or drawings), videos, animations and molecular models to depict phenomena from everyday life or the laboratory, with the aim to represent the chemical structures, both still and in motion. The aim is to develop in students the ability to penetrate into the world of atoms and molecules with the eyes of their mind and to interpret the phenomena. The students can also, through them, convert a macroscopic phenomenon into a submicroscopic one.

The mental visualization of the microcosm, for example the particulate nature of matter, is the basis for the interpretation and understanding of chemical phenomena. Colored spheres and springs or sticks are the tools/structures we use in class and in the laboratory to represent tangible molecular models. It is the kind of representation that we usually use to depict the particulate structure of matter.

**Multiple representations:** They depict a chemical phenomenon simultaneously at two or all three chemical levels by combining 2 or 3 distinct one from the other(s) representations.

**Hybrid representations:** They depict a chemical phenomenon by combining the characteristics of two or three chemical levels to form a single representation.

**Mixed representations:** They depict a chemical phenomenon by combining the macroscopic or submicroscopic or symbolic level, or two of these or all three, simultaneously with an analogy (an analogical mapping / an across-the-domain analogy). In the example shown: an anthropomorphic analogy.

Images and hyperlinks were classified by two independent and experienced teachers. The rate of agreement between them was 98%.

**EXAMPLES OF IMAGES**

Figure 1 provides examples of representations from the chemistry books of the Greek lower-secondary school at various levels: macroscopic, submicroscopic, symbolic, hybrid.

Figure 2 shows an example of a multiple representation which comprises all three chemical levels.

RESULTS AND DISCUSSION

Images

The percentages of images with macroscopic representations in the interactive e-books for both the 8th and the 9th grade are much higher (62% and 47% respectively) in comparison with the symbolic, submicroscopic, multiple, hybrid and mixed representations, while the percentage of mixed representations is 0% in both e-books (see Table 1). The percentages of symbolic representations are 27% and 34% respectively, while the submicroscopic representations are only 4% and 5%, respectively. Multiple representations account for 7% and 13% respectively.

In more detail, of the 18 multiple representations of the enriched interactive book for the 8th grade, 2 are macroscopic-symbolic, 2 are macroscopic-submicroscopic, 5 are submicroscopic, and 9 are macroscopic with verbal explanations. None of the 18 representations represent the chemical phenomenon at the same time at all three chemical levels (see Table 2).

Of the 31 multiple representations of the enriched interactive book for the 9th grade, 12 are macroscopic-symbolic and 16 are submicro-symbolic. Only 2 of the 31 representations show the chemical phenomenon at the same time at all three chemical levels (see Figure 2) and 1 representation depicts the chemical phenomenon at the macroscopic and submicroscopic level, while next to the symbolic level are written the chemical equations which belong to the main text and not as a caption.

Hyperlinks

Of the 157 hyperlinks of the enriched interactive e-book for the 8th grade, only 5 refer to submicroscopic structures, while, in the case of the e-book for the 9th grade there are only 6 hyperlinks from a total number of 183 (see Tables 3 and 4). We also notice that the percentage of macroscopic hyperlinks decreases in the 9th grade relative to the 8th grade. The percentage of multiple hyperlinks almost doubles, while the percentage of the symbolic hyperlinks becomes almost six times higher. Although the multiple representations which comprise all three chemical levels can convey a very powerful message to the pupils and cause them to deal with the chemical phenomenon, linking it to the science of chemistry and to their daily life, the percentage of multiple representations is very small. In the 8th grade school e-book it is 0% (0/256 images and 0/157 hyperlinks), and just a little above 0% (3/233 images and 6/183 hyperlinks) in the 9th grade school e-book. Also, mixed representations, which combine one or more chemical levels in the same image with an analogical image do not exist, despite the fact that analogies may be more efficient than text information for the dealing with students’ alternative ideas (Tsaparlis, 1997).

CONCLUSIONS AND RECOMMENDATIONS

"The image is not an innocuous decorative element in the natural sciences school textbooks or in other educational material. On the contrary, it is a charming and complex tool that requires a lot of attention in its handling to prove effective in the everyday educational practice” (Chalika & Theodoridis, 2002). It goes without saying that chemical representations contribute to learning only if students can understand the concepts which they represent. According to Ainsworth (2006), by choosing the appropriate representation for a specific instructional intervention, we can increase the students’ understanding of a specific concept as well as their performance in relevant examinations.

We must take into account, however, that research has shown that students are unable to perceive the correct message that the various types of images intend to convey (Abraham, Williamson, & Westbrook, 1994; Ben-Zvi, Eylon, & Silberstein, 1986; De Vos & Verdonk, 1987a, 1987b, 1996; Garnett, Garnett, & Hackling, 1995; Haidar & Abraham, 1991; Hesse & Anderson, 1992; Krajcik, 1991; Keig & Rubba, 1993; Kozma & Russell, 1997; Nakhle, 1993; Novick & Nussbaum, 1981; Tsaparlis, 2009). In addition, most teachers use chemical representations to check whether students can describe verbally a chemical phenomenon and/or use chemical symbols, but they do not encourage students to use the representations to transfer e.g. from a macroscopic to a symbolic or a submicroscopic representation (Philipp, Johnson, & Yezierski, 2014). So, the mere presence of chemical representations in a textbook does not ensure that they enhance learning.

In our research, we observed a slight increase in the symbolic and in the submicroscopic representations and a larger increase in the multiple representations in the e-book for the 9th grade in comparison to that for the 8th grade. However, only three (3) multiple representations and six (6) hyperlinks refer simultaneously to the three chemical levels. For this reason, the authors of the schoolbooks should display the elements of the representations. Their choice and design should take into account the connections between the macroscopic, submicroscopic and symbolic chemical levels (multiple representations, with all three chemical levels), so that students can fully understand the three levels of chemistry. Our expectation is that the authors of the chemistry schoolbooks will pay more attention to the need and importance of submicroscopic representations, mixed representations, and especially multiple representations.

EXPERIMENTAL AND MODEL LEVELS IN CHEMISTRY TEACHING: ANALYSIS OF STUDENTS’ REASONING

Isabelle Kermen
LDAR (EA4434), UA, UCP, UPD, UPEC, URN, Université d’Artois, Lens, France

The knowledge to be taught regarding chemical changes and equilibrium states in the French chemistry syllabus (grade 12) has been categorized in terms of theory, models and reality. The experimental level is split into reality-as-perceived and reality-as-idealised which leads to two descriptions of experiments. The different models that interpret an experimental situation depending on the issues raised are presented. This categorization of knowledge constitutes a framework which is put to the test to analyse students’ understanding during teaching sessions. We seek to determine whether this framework enables to characterize the different kinds of knowledge at stake in the classroom and students’ reasoning about chemical changes. Two case studies are set out: in the first one the students had to write a chemical equation to predict a chemical change knowing the composition of a mixture whereas in the second one they had to write the chemical equation after having done an experiment. The interactions between the teacher and the students are analysed in terms of concepts attributed to the different levels of the framework. The analyses reveal the students’ difficulty to master the chemical equation, to mobilize a kinetic model, to make a proper link between the model level and the reality-as-idealised or the reality-as-perceived.

Keywords: chemistry, models in sciences, conceptual understanding

INTRODUCTION

Chemistry is a science which interprets and predicts experimental facts by means of models. Chemistry teaching uses school science models (Harrison & Treagust, 2000). Students encounter difficulties to use models and to make proper connections between models and reality (e.g. Cooper, Underwood, & Hilley, 2012; Sensevy, Tiberghien, Santini, Laubé, & Griggs, 2008; Tiberghien & Vince, 2005). This study sets out a framework which is the result of an epistemological analysis of the content to be taught about equilibrium states and incomplete chemical changes (grade 12, in France). Then, it is used to analyse the students’ reasoning and the different kinds of knowledge at stake in the classroom in a laboratory session. The results are then discussed.

EPISTEMOLOGICAL ANALYSIS OF THE CONTENT

The knowledge to be taught can be viewed as belonging to three levels, the theoretical level, the model level and the experimental level (Tiberghien, Psillos, & Koumaras, 1994). A school science model is adapted from a science model (Adúriz-Bravo, 2013) considered as a set of interrelated concepts (Johsua, 1994) and built to answer some questions about a restricted part of the real world. Applying this reasoning to the French chemistry syllabus (grade 12) about chemical changes and equilibrium states, leads to consider three school science models stemming from two theoretical domains to describe and explain chemical changes which belong to the experimental level (Kermen & Méheut, 2009, 2011). These three levels constitute three levels of knowledge.
Characterising the experimental level

At the experimental level, the description of an experiment in terms of objects and events (Sensevy et al., 2008) is based on the reality-as-perceived (Gilbert, Pietrocola, Zylbersztajn, & Franco, 2000). It involves liquids, solids (and gas) which are objects of this level. The colour may change, a solid may appear or disappear, the value on a pH meter (a technical object) may change; these are events. An example of such visible modifications is reported in Figure 1a.

A chemical change corresponds to a chemical description of the reality-as-idealised (Gilbert, Pietrocola, et al., 2000) involving chemical species which are model-objects (Gilbert, Pietrocola, et al., 2000) derived from real objects by idealization (Fernández-González, 2013). A chemical change occurs if some chemical species appear and disappear after mixing some objects. Namely the amounts of the chemical species vary when comparing the composition of the initial state and that of the final state of the system (Figure 1b).

The experimental level is thus divided into two sub-levels, the reality-as-perceived and the reality-as-idealised (see Figure 2). If the same species in different amounts are mixed, several chemical changes occur, which constitute a family of chemical changes. These changes are all modelled by one chemical reaction which is symbolised by a chemical equation (see Figure 2).
This analysis is valid when the students begin to study chemistry and are confronted to complete chemical changes. An elementary kinetic model involving colliding particles can be added to explain the modification of substances.

**Characterising the model level**

In grade 12, incomplete chemical changes are studied, and the analysis of the content leads to three general school science models stemming from two theoretical domains (thermodynamics and kinetics) to explain and describe chemical changes.

The thermodynamic model is the most general one and allows the prediction and explanation of the direction of change provided that a chemical equation is known. The chemical equation symbolises a pair of opposing reactions, the forward reaction and the reverse reaction. The functioning of this macroscopic model relies on the comparison of the reaction quotient to the equilibrium constant and is called the evolution criterion.

The kinetic models are explanatory but not predictive. The macroscopic kinetic model comprises the rate of the forward reaction and the rate of the reverse reaction which are different if the composition of the system changes, and are equal at equilibrium state.

In the submicroscopic model, the system is composed of continually moving and colliding entities. During active collisions bonds are broken, electrons are transferred, entities are modified. Thus, substances are modified at the macroscopic level.

Considering chemical changes that concern acidic and basic species a specific model, the Brønsted model, is needed to explain and predict their interactions. Since chemical species are model-objects, they cannot supply any prediction by the direct application of logic because they are idealised empirical objects (Gilbert, Pietrocola et al., 2000). But if they are incorporated in the Brønsted model it is possible to imagine an interaction between some of the species involved. This model allows the foreseeing of a chemical reaction and to write the corresponding chemical equation. Likewise, a specific model is added for redox chemical changes. The connections between these different fields of knowledge are gathered in Figure 3.

![Figure 3. Levels of knowledge regarding chemical changes.](image-url)
PURPOSE OF THE STUDY

The above analysis results in a framework (summed up in Figure 3) a previous version of which was applied to analyse students’ answers to questionnaires (Kermen & Méheut, 2011). It enabled the link to be made between the model level and the reality-as-idealised. In this study we put the framework to the test to analyse the students’ understanding and line of reasoning when they encounter an experimental situation in the classroom. The goal of this study is to examine the connections made by the students between the levels and sub-levels. Moreover, we intend to find out what information the use of this framework gives of the students’ reasoning and the different kinds of knowledge at stake in the classroom.

METHOD

In a previous study, several chemistry laboratory sessions were filmed to characterise the teacher’s practices. Therefore, the students’ reasoning and the interaction between the teacher and the students were analysed. These sessions provided a selection of episodes in which the students had to establish connections across the experimental level and between that level and the model level. Two of these episodes were kept because they showed examples of links between levels and a student’s difficulty or misunderstanding in connecting two levels. Words and sentences were categorised and attributed to the various levels to determine the level(s) at which the students (or the teacher if necessary) expressed their reasoning and to reveal the connections they made between levels and sub-levels.

Example 1

Teacher: “these mixtures are somewhat different compared to what we are used to do namely they will comprise the four species we are talking about”

The mention of the mixtures which are made with colourless liquids belongs to the reality-as-perceived. But when the teacher speaks of species, she moves to the reality-as-idealised and relies on the chemical formulae she wrote on the blackboard. In this sentence the teacher is making a link across the two sub-levels of the experimental level.

RESULTS

First case study

The task to achieve

In the first class, the teacher shows four flasks containing a colourless liquid and tells the students they will make two mixtures of four aqueous solutions (ethanoic acid, methanoic acid, sodium ethanoate and sodium methanoate solutions) at the same concentration and that each solution contains an acid or a base. The teacher writes the formulae of the acids and bases (not of the cationic species which are present in these solutions) on the blackboard (they correspond to two conjugate acid-base pairs). The teacher asks the students to reflect and to write a chemical equation to predict what could happen in the mixtures.
Expected reasoning

The students have studied conjugate acid-base pairs. They are supposed to rely on the name and formulae of species (reality-as-idealised) to resort to the Brønsted model which enables them to propose a chemical equation. At the model level a molecule of acid can donate a hydrogen ion to a molecule of base and conversely a molecule of base can accept a hydrogen ion from a molecule of acid. An acid-base reaction is the transfer of hydrogen ions between an acid and a base. The following equations are expected

\[ \text{CH}_3\text{COOH} \text{(aq)} + \text{HCOO}^- \text{(aq)} = \text{CH}_3\text{COO}^- \text{(aq)} + \text{HCOOH} \text{(aq)} \quad \text{or} \]

\[ \text{CH}_3\text{COO}^- \text{(aq)} + \text{HCOOH} \text{(aq)} = \text{CH}_3\text{COOH} \text{(aq)} + \text{HCOO}^- \text{(aq)} \]

Description and analysis of the dialog

After a while, the teacher looks at what the students have written and stops at Chloé’s place. Chloé wonders how to continue after writing:

\[ \text{CH}_3\text{CO}_2\text{H} \text{(aq)} + \text{HCO}_2^- \text{(aq)} + \text{CH}_3\text{CO}_2^- \text{(aq)} + \text{HCO}_2\text{H} \text{(aq)} = . \]

Her neighbour Lucile wrote \( \text{CH}_3\text{CO}_2\text{H} \text{(aq)} + \text{HCO}_2^- \text{(aq)} \rightarrow \text{CH}_3\text{CO}_2^- \text{(aq)} + \text{HCO}_2\text{H} \text{(aq)}. \) The teacher talks to the two girls. Both have written down an incorrect chemical equation.

Teacher (to Chloé): yes, this makes four chemical species on the left of the equal sign … and what else on the right? …

Lucile: but why are they all on the left?

Chloé: because one mixes them all?

Then, the teacher has a long dialog with Lucile to determine what she has in mind and resorts to a kinetic representation of the mixture mentioning collisions and active collisions between species. During this dialog the teacher asks: “species that are on the right [of the equation] do they play 1, 2, 3, sun? Do they wait?” Then, Lucile admits that species written on the right side of the chemical equation also continue to react and writes an equal sign (same meaning as a double arrow) instead of a single arrow. At the end of this dialog Chloé who listened without saying anything, asks: “I don’t understand if we mix all species together aren’t they all reagents?” Lucile answers “no” and the teacher tells her to think it over.

When the teacher asks Chloé what she could write on the left of the equal sign, Lucile shows that she does not agree with Chloé. The teacher and Lucile are arguing at the model level because they question the chemical equation which represents the chemical reactions. Chloé justifies her equation with a reason that belongs to the reality-as-idealised, the chemical species are mixed together so they should be written on the left part of the equation. Until now, she had only encountered mixtures initially composed of chemical species about to react and without the products to be formed. These reagents were written on the left, she just replicates what she is used to do. And she does not know how to determine the products.

The teacher adapted the kinetic scientific school model that involves colliding entities and not species. She may be not fully aware of the specific meaning of both terms. She also used
anthropomorphic terms and mentioned a children game\(^1\) (1, 2, 3 sun) to make Lucile realise that chemical entities do not stop moving and colliding which means that species are still reacting. This is an example of a teaching model (Gilbert, Boulter, & Elmer, 2000), a model built by the teacher in the context of the classroom to fulfil a specific need.

At the end of this episode Chloé still gives the same argument, belonging to the reality-as-idealised, but she starts having doubts because she expresses what she believes in an interrogative and negative wording.

**Second case study**

*The task to achieve*

In the second class the students performed two successive experiments. First, they mixed a copper sulphate (II) solution and zinc powder (in test tube 2 whereas test tube 1 contained only copper sulphate (II) solution) and then observed. Afterwards they filtered what they had obtained and added a sodium hydroxide solution drop by drop to the filtrate. They had to write down their observations and identify the chemical change in test tube 2.

*Expected reasoning*

The expected reasoning involves two steps. Two diagrams representing the successive chemical changes specify the line of reasoning the students could follow to identify the formation of zinc ions in tube 2. Figure 4 represents the balance that can be achieved for the first experiment. After filtration, the remaining solution (circled in green in Figure 4) at the end of the first experiment is used to carry out the second experiment.

![Diagram](image)

**Figure 4: First chemical change**

In the second experiment, drops of sodium hydroxide solution are added to the filtrate. A white precipitate appears and then disappears with an excess of sodium hydroxide solution (see Figure 5). These events (reality-as-perceived) should allow the students to identify the presence of zinc ions (reality-as-idealised) in the filtrate if they have previously memorized these facts.

Once zinc ions have been identified, the first chemical change is fully known. A comparison of the initial and the final states can be done to determine which species are reagents and products. It will enable to write the corresponding chemical equation. The students do not need to identify the species that appear in the stages of the second experiment, but they must realise that two chemical changes occurred before and after filtration.

---

\(^1\) A child faces a wall and say 1, 2, 3 and turns back when he/she says "sun". The other children can walk when he/she is counting but should be motionless when he/she turns back. If they do not, they have to return at the starting point. The winner is the first one to reach the wall and takes the place face to the wall.
Figure 5: Second experiment and second chemical change

Description and brief analysis of the dialog

To answer the question of the lab sheet, the teacher leads a collective dialog after the experiments are finished. This dialog is quite long, more than 11 minutes, and only a summary of it is reported. She asks them about the role of the second experiment and what species it enables to identify. No student succeeds in recognizing the formation of zinc ions using experiment 2. This reveals a missing link between reality-as-perceived and reality-as-idealised.

Then, she asks them to make an inventory of species in the initial state of the system in experiment 1 and writes these on the blackboard Cu$^{2+}$, SO$_4^{2-}$ and Zn. Contrary to what happened just before, the students establish correct links between the two sub-levels of reality. The teacher resorts to the law of conservation of chemical elements and the students propose the formation of zinc ions. At that time the chemical description of the first experiment is not fully achieved because the other product is not written down. The teacher carries on with the collective dialog to help the students find out the reagents and the products. When she questions them about the sulphate ions, they answer all together “spectator”, which is an evidence of experimental knowledge in reality-as-idealised: the students express the idea that this chemical species does not react. The teacher discards that species from the inventory which keeps only reagents and products. Finally, she writes the chemical equation on the blackboard: Cu$^{2+}$(aq)+Zn(s)→Cu(s)+Zn$^{2+}$(aq). This symbolic representation is at the model level. Note that the writing of the chemical equation was not required in the lab sheet, the teacher anticipates the resolution of the following question of the lab sheet (not mentioned in this paper). At that moment, the teacher questions the students once more and shows the chemical equation on the blackboard.

Teacher: what kind of reaction is this?
Olivier: precipitation
Teacher: Fanny?
Fanny: precipitation
Teacher: here, precipitation? precipitation relative to soda but I’m not talking of soda here.
Student: redox

Olivier’s and Fanny’s answers remind us of what happened in the second experiment. They rely on what they saw, a precipitate which belongs to the reality-as-perceived, whereas the teacher’s question is at the model level and about the first experiment. This reveals that some students did not realise that the second experiment does not correspond to the chemical change.
that was described a few minutes ago. There was no chemical description of the second experiment whilst the description of the first one was detailed.

The students lack some experimental knowledge, so the connection between reality-as-perceived and reality-as-idealised is missing to identify the presence of zinc ions. Nevertheless, they show other experimental knowledge in recognizing the absence of role of sulphate ions and the formation of copper. The law of conservation of chemical elements acts as a theoretical principle which underlies the model level and the reality-as-idealised and helps to interpret objects and events of the reality-as-perceived.

**DISCUSSION**

The Brønsted model is not working for Chloé unlike Lucile who wrote a meaningful although incomplete equation. For Chloé, the initial species mentioned by the teacher are the reagents and the left part of the chemical equation may represent the initial state of the system (Gauchon & Méheut, 2007). Distinguishing elements of reality-as-idealised and elements of a model was still difficult for her. The difficulty might have been increased because the same symbols were used to write the chemical equation and to describe the initial composition of the system (part of the reality-as-idealised), and because the teacher did not write down the symbol of the cationic species which was present in the base solution, nor that of water. Thus, Chloé did not think how she could determine what species can react with what other species namely how to use the Brønsted model. For her, the description of reality-as-idealised prevailed over the use of that model. In Lucile’s case resorting to the kinetic model helped to give meaning to what the chemical equation represents. An arrow instead of the equal sign means that species written on the right side of the equation do not interact. An equal sign means that two opposing chemical reactions model the chemical processes, acids and bases keep on reacting. At the end of the dialog between the teacher and Lucile, Chloé’s question revealed her trouble. Since she asked a question, one may think that she began to consider that all initial species were not reagents, an idea that she had not had before. Finally, the use of the kinetic model helped both students to change their mind but not at the same time.

In the second class, the students did not achieve the chemical description of the first experiment. It means that they did not move successfully from the reality-as-perceived to the reality-as-idealised because they lacked specific experimental knowledge about the researched species. This stopped the inventory of species made in the reality-as-idealised and the description of the first chemical change. The teacher’s change of strategy i.e. resorting to a theoretical principle enabled her to overcome this difficulty. The law of conservation of chemical elements is a theoretical principle of chemistry the students had in mind and were able to use. Some students failed to identify the nature of the chemical reaction because they did not realise that two successive chemical changes were involved. They remembered an object they saw, a precipitate (reality-as-perceived) without grasping that it corresponded to the second experiment. The confusion might have arisen because the teacher did not identify the second chemical change she neither describe it nor asked them to. Identifying a chemical species produced in a chemical change by means of another (or several) chemical change is quite widespread in chemistry, it contributes to defining the chemical identity of a substance (Ngai, Sevian & Talanquer, 2014). But here it seems that the students were not able to interpret
these experiments in terms of two successive chemical changes, they still needed to be guided for that. While the teacher showed the chemical equation on the blackboard, this answer about the precipitate also shows that these students did not realise they had to reason at the model level with the redox model but not to make a link between the experimental level and the model level.

In both case studies the students knew of the absence of role of spectator ions in chemical changes. This term (spectator) is a habit in chemistry teaching. In both case studies they modelled the experimental situation or used models respecting the law of conservation of chemical elements and the symbols of chemistry. These clues allow us to think that the students adopted the thought style of chemists at least partially and at an elementary level, and that they belong to the thought collective of chemists (Sensevy et al., 2008), which can be viewed as the way chemists see the world through a specific lens.

CONCLUSION

The proposed framework enhanced the importance of a kinetic model that gives meaning to the abstract concepts symbolized by the chemical equation although it is not spontaneously used by the students. Chloé’s mistake emphasised the lack of predictive power of chemical species which are model-objects and the need to include them in school science models to provide predictions. The use of the framework enabled to characterize the connections made between levels of knowledge and to interpret some mistakes as a missing link between them. The explicit use of the law of conservation of chemical elements highlights that any modelling (moving from the reality-as-idealised to the model level) proceeds by taking into account the chemical elements that compose the initial substances. All chemical descriptions (moving from the reality-as-perceived to the reality-as-idealised) also follow that principle.

Although its use was limited to two case studies, the framework seems to be relevant to characterise the students’ reasoning in the classroom. It needs to be put to the test in other teaching sequences. A future work would be to use this framework to categorise teachers’ discourses in the classroom to determine whether the teachers favour a domain of knowledge or do not, whether they promote the establishment of links between these domains or do not and to examine the impact on students’ understanding. A simplified version of the framework operating on complete chemical changes (Figure 2 and an elementary submicroscopic kinetic model) could be used to analyse students’ reasoning in lower secondary school. And finally, this framework could be presented in teacher training sessions to focus their attention on the specific difficulties the students encounter so that the teachers could devise and discuss strategies to overcome these difficulties.

STUDENTS’ EXPERIMENTAL DESIGN ACTIVITIES: DO THEY PROMOTE SCIENTIFIC THINKING?

Maria Kallery¹, Dimitris Psillos² and Vasilis Tselfes³
¹Department of Physics, Aristotle University of Thessaloniki, Greece
²Department of Education, Aristotle University of Thessaloniki, Greece
³Department of Education, University of Athens, Greece

This paper presents an analysis and modeling of students’ designs of experiments. The students’ designs were initially evaluated using a framework with the following dimensions: experimental procedure description, indication of the variables involved, defining the dependent and independent variables, initial conditions, devices and instruments, device settings and hypothesis-forming. The findings of this evaluation were then modeled using a framework which is based on the epistemology of scientific practice and is used for analyzing it. It involves three major categories of entities that are internal to scientific inquiry, namely the categories of Cosmos (C), Evidence (E) and Ideas (I). As the students’ involvement in experimental activities is considered to contribute to their scientific way of thinking, the modeling using this framework allowed us to investigate whether the students’ designs promoted desired connections between theoretical ideas, evidence and the material world which are considered essential for developing students’ scientific way of thinking. The results indicated that students faced difficulties in the representational level mostly when they were required to connect their ideas with evidence both when linking variables with their representations and when forming hypothesis. Students’ had less difficulties in the interventional level which, however, could be due to their weakness in representing the material world. These findings provide new in depth insights into students’ designs and suggest that involving them in experimental design activities does not necessarily promote scientific ways of thinking, as the latter is related both to students’ representational and interventional abilities.

Key words: experimental design, scientific thinking, inquiry

INTRODUCTION

According to science educators and researchers, the aim of science education should be the development of students’ understanding of representations of the material world in terms of concepts and models and of ways of intervening into the world by putting things to work in the laboratory according to theories and models (e.g. Bybee & Champagne, 2000). It can be argued that understanding science implies also some understanding of the practices involved in scientific inquiry, aspects of which are essential for the teaching of scientific subjects and the students’ learning. One of the best ways to experience scientific inquiry is through the design and implementation of experiments (Sieberg, 2008). Du, Furman & Mourtos (2005) express the view that inquiry-based learning forms the foundation for the design of any experiment. Karelinna & Etkina (2007) point out that students have to acquire not only conceptual and quantitative understanding of science, but also the ability to design experiments to test hypotheses, to reason from the data, construct explanatory models, and solve complex problems.
Involving students in experimental activities, apart from giving them the opportunity to experience scientific inquiry, contributes to the construction of conceptual knowledge as well as to the development of *scientific ways of thinking*.

Hacking (1995), suggested that in actual laboratory science activities, theoretical ideas, evidence and material world are entities internal to scientific inquiry and that making connections between them is characteristic of scientific practice. Based on Hacking’s framework, it has been suggested that, in educational contexts, establishing connections between theoretical ideas, evidence and material world is essential in assisting students’ *scientific thinking* (Psillos, Tselfes & Kariotoglou, 2004). Based on what is presented above and also that in science education students should develop some understanding of how scientists represent the world as well as how they intervene into the world, the aim of the present study was to investigate students’ ability to form connections between theoretical ideas, evidence and material world when involved in experimental design activities.

**RESEARCH DESIGN**

Our investigation is attempted through a re-analysis and modeling of the findings of a previous study (Hatzikraniotis, Kallery, Molohidis, Psillos, 2011) which evaluated 25 secondary students’ abilities to design an experimental procedure in order to solve the following ‘Heat and Temperature’ task: *Kate has two heat resistant mugs, A and B. Both mugs are the same, except that they are made of different materials. Kate claims that if we put the mugs on a heater, the water in mug A warms up faster than the water in mug B. How will you find out if she is right? Can you set up an experiment to check her statement? What will you need? What will you observe?* (Hatzikraniotis, Kallery, Molohidis, Psillos, 2011).

In that study, the evaluation of the students’ answers used a framework with the seven dimensions shown in Table 1 (Lefkos, Psillos & Hatzikraniotis, 2011). The evaluation classified students’ answers in three levels: ‘missing’ (level 1) – ‘partially stated’ (level 2) – ‘completely stated’ (level 3).

The findings of the above study, in terms of the seven dimensions, are modeled in the present work using a framework which is based on Hacking’s theoretical work and allows us to investigate whether in the students’ experimental designs, the desired connections between theory, evidence and the material world are promoted.

**The framework of analysis**

In this framework of analysis three categories of entities are included, namely the categories of Cosmos (C), Evidence (E) and Ideas (I). The category ‘Cosmos’ includes materials and artifacts, such as devices, measurement instruments, samples and instrument readings, which constitute the raw data. The category ‘Evidence’ includes representations of entities that have been derived either from the senses or from a systematic processing of raw data, e.g. representing them in specific ways, classifying them according to chosen criteria, comparing them with other data, etc. The category ‘Ideas’ includes specific theoretical entities, like systematic theory, models or concepts, methodological entities that gain certain meaning in a specific theoretical framework, like questions and hypotheses, and implicit views, i.e. views of
reality, causality, the relation between the subject of the knowledge and the external world, which can influence the construction of scientific knowledge. Scientific ideas and evidence represent phenomena that are part of the real world and explain or justify one another.

During the course of scientific inquiry, activities involve making connections between the entities of Cosmos, Evidence and Ideas in two-way interactions (C↔I, C↔E, E↔I) (Table 2). These connections can be distinguished as those of interventions into the material world on the basis of an idea or specific evidence (connections I→C and E→C) and those of representations of the material world (connections I→E, E→I, C→I and C→E).

The modeling process of the students’ experimental designs

Use of the above framework will allow us to detect the type of connections between Cosmos, Evidence and Ideas embedded in the student-designed experimental procedures. We will also examine the character of the analyzed activities.

The modeling proceeded as follows: First, the seven dimensions (Table 1) used in the initial study were modeled using the CEI framework (Table 2). The modeling was performed by two researchers (authors of the present paper), each working independently. The findings, i.e. the connections between the three entities C, E, I in each of the seven dimensions presented in Table 1 that were indicated by each researcher, were then compared. If differences were identified, these were discussed in group meetings until agreement was reached. These findings were then reviewed by the third author colleague science educator outside the group who had a good knowledge of the CEI model, and feedback was obtained. The final modeling of the seven dimensions was then reached. Having the modeled dimensions at hand we proceeded
with examining students’ experimental designs. The same process was followed for both the written experimental designs of the students and those coming from the individual interviews.

The findings of the modelling of the students’ experimental designs detected in the answers of all three levels for each of the dimensions are collectively presented in Table 3. The numerical results, presented in percentages for each of the scoring levels, indicate the students’ answers to the written task which were supported by the individual interviews. This holds for all the dimensions except that of hypothesis-forming, where the results of the written tasks present a small deviation from those of the interviews.

Bellow we present examples of the modeling of some of the dimension:

(a) **experimental procedure description**: how do students plan to observe and record the data? Planning, observation and recording of data.

The question (the task) given to the students concerns an evidence (E) (Kate claims that if we put the mugs on a heater, the water in mug A warms up faster than the water in mug B). Since the subjects are asked to devise an experimental set-up to carry out an experiment that will provide the desired evidence (E) about the heating rate, they should proceed from the elaboration of the ideas (I) which they will apply in Cosmos to the construction of Cosmos (C) which will provide the evidence (E). Therefore the planning of the experiment would proceed in the following way: a constant heat flow (I) (which controls the heating rate) can be succeeded by the range used (C) which causes the measurable heating rate (E). This leads to the final linking of the entities (I→C→E).
In our study, of the 24 participating students 58% were able to give responses presenting these connections, as indicated by the following representative example, and were ranked at level 3.

*I will use two containers, each of them made of a different material. I will place in them equal quantities of water of the same temperature. I will warm both on the same range and I will see which of them will reach a specific temperature faster.*

Students’ answers that were ranked at level 2 (25% of them) were incomplete, partially stating the process and missing the final connection leading to the linking of Cosmos with the expected Evidence, i.e. the connection C→E. A representative answer is the following:

*To find out we will need 2 thermometers, 2 identical cups and 2 identical ranges. We will place water in both of the cups and we will warm them to the same temperature.*

The rest of the students (17% of them) made no reference to the experimental procedure and thus did not make any of the above connections.
(d) **initial conditions**: conditions set before starting the experiment;

Setting the initial conditions for the experimental procedure is an intervention that will be made to the material world. In order for the variables to function as the experimenter desires, the students, using their scientific ideas (I), must construct or choose to use specific pieces of Cosmos with specific characteristics, linking thus the Ideas with Cosmos (I→ C).

The students (37% of them) who successfully determined the variables involved and thus made all the desired connection between Ideas and Cosmos, were ranked at level 3.

- *We are going to use 2 containers each of them made of a different material and we will place water of the same temperature in each of them. We will fill the cups with same quantities of water of the same temperature...and same heating rate.*

There were students (38% of them) who determined only some of the initial conditions (e.g. same amount of water, but not the same heating rate) and thus were not able to make all the possible connections between the two entities; these were ranked at level 2.

- *We will use 2 cups each made of a different material.*

- *We will place same quantity of water in both cups.*

The rest of the students (25% of them) made no reference to the initial conditions, making no connections between Ideas and Cosmos.

(f) **device settings**: device settings that are set before starting the experiment.

The settings of the devices are evidence (E) in the sense that they are quantitative entities read on the apparatuses. The choice of device settings is based on ideas (I) of how the variables will be handled in the intervention to the material world (I →E→ C).

A level 3 ranking was achieved by the 12% of the students who determined successfully the entire set of device settings, making all the connections between the three entities (I→E→C).

- . . . *we must warm it maintaining the same heat flux and for the same period of time.*

The 46% of the students who in their answers determined some of the device settings (e.g. same heating rate but no setting for the chronometer), making some connections between ideas, evidence and cosmos, were ranked at level 2:

- *We place the cups on the fire and we warm them for the same period of time.*

The remaining 42% of the students made no reference to the device settings in their answers, thus making no connections of the type (I →E →C).

(g) **Hypothesis-forming**

A hypothesis is a statement put forward to attempt to explain some happening. Hypotheses belong to the world of the mind and are Ideas (I). The forming of a hypothesis (I) should start from an evidence (E) and, connecting it to an idea (I), should lead to an evidence (E), making the connections between the entities  (E→I→E).

In the students’ answers to the post-instructional questionnaire, hypothesis-forming was not detected.
However analysis of the individual interviews showed that 12% of the students correctly ‘formed hypothesis’, making the desired connections between ideas and evidence in the manner presented above (E→I→E).

Below are some representative answers:

- If the walls of container B were thicker, heat transfer would be delayed.
- If the surface area is bigger it [the liquid] will warm faster.

RESULTS AND CONCLUSIONS

The modeling of the seven dimensions of the experimental design evaluation framework indicates that in the experimental design of the specific task all the possible connections between the three entities C, E, I are formed. As is shown in Table 3, these are found in connections between two different entities, three different entities, or in a quadruple connection between the three different entities and one that is involved twice. This quadruple connection is the result of the transformation of the one same-entity connection (I→I) as the latter was judged too advanced for the students’ age and background knowledge. As was mentioned earlier, possible connections between the entities C, E, I can be distinguished as those of interventions into the material world on the basis of an idea or specific evidence (connections I→C and E→C) and those of representations of the material world (connections I→E, E→I, C→I and C→E). Thus, in the students’ experimental designs of the specific task, scientific activities both in the representational level and interventions into the material world were expected.

The modeling of the students’ level 3 answers which we focus on for brevity indicated that the students faced difficulty in forming the connection between Cosmos and Ideas, in the case where these were involved in two-entity interactions.

These interactions were: i) the description of Cosmos on the basis of their own ideas where students were essentially asked to construct a scientific representation of Cosmos (C→I) through ideas (dimension b) and ii) where students were required to choose and use a piece of Cosmos with specific characteristics based on their own scientific ideas (I→C) (dimension d). However, the second type of the above connections, the (I→C), was made by a larger number of level 3 students, when this specific connection was formed involving a third entity, the evidence (I→C→E) (dimension a).

The modeling of the level 3 answers also indicates that connections of ideas with evidence (I→E) were found in a very small number of these answers (dimensions e and f). This is interesting in the sense that while almost half of the level 3 students were able to indicate how the variables would be handled in the experiment, they could not link them with their representations (i.e. with evidences) in order to produce the desired results.

Another difficulty is located in the linking of evidence with ideas (E→I) when students attributed to the variables the feature of independent or dependent or when students based on the expected evidence were asked to form hypothesis. In the first case less than half of the students were able to complete this scientific activity of connecting their ideas with evidence.
based on the latter, while in the second case none of them in their written designs were able to perform this scientific activity.

As can be seen, the most of the difficulties of the level 3 students are located in the representational level with fewer difficulties in the interventional level which, however, can be due to their weakness in representing the material world.

We consider that the present results provide for new in depth insights into students’ designs and suggest that involving students in experimental design activities does not necessarily promote scientific ways of thinking, as the latter is related both to representational and interventional abilities of the students.

ANALYSING CONCEPTIONS ON CHEMISTRY: PROPOSAL FOR A CONCEPTUAL PROFILE

Melquesedeque Freire¹ and Edenia Amaral²
¹ Federal University of Rio Grande do Norte, Natal, Brazil
² Federal Rural University of Pernambuco, Recife, Brazil

Chemistry is a simple word with many different meanings to different people. In this work, we frame different modes of thinking on Chemistry in terms of a conceptual profile taking into account a dialogic examination of different sources of data: historical and epistemological analysis of the development of chemistry, literature on students’ alternative conceptions on chemistry, and empirical data from questionnaire and discursive interactions in classroom. The proposed conceptual profile has six zones: monist, aversive, epistemic, processual, pragmatic, and attractive, which guided an analysis of discursive interactions on the nature of chemistry in undergraduate course for formation of chemistry teachers. Results pointed out that the epistemic and pragmatic zones of the proposed conceptual profile were prevalent in the students’ speeches. In addition, findings suggest that the zones of the conceptual profile provide a useful tool for structuring modes of thinking about chemistry and thus the presented profile constitutes a model to interpreting ways of speaking about chemistry enabling a characterization of the discourse on nature of chemistry issues in the educational context.

Keywords: conceptual profile, philosophy of chemistry, chemistry teachers

THEORETICAL BACKGROUND AND PURPOSE

Researches in philosophy of chemistry have investigated pluralism for conceptions on chemistry (e.g. Baird, Scerri & McIntyre, 2006, Bensaude-Vincent, 2009, Schummer, 2015). For example, some of these conceptions are: chemistry as a technoscience (Chamizo, 2013); a science of substances and processes (Stein, 2004, Earley, 2004, Bernal & Daza, 2010); a diagrammatic and dual science of classification (Lefèvre, 2012); a contextual/practical science (Müürsepp, 2016); an industrial and academic science (Lazslo, 2006); a science of material transformations (Van Brakel, 1997); a central science (Schummer, 1998), among others.

Ribeiro & Pereira (2013) pointed out pluralism of chemistry in terms of methodological, epistemological, ontological and axiological aspects. From this pluralism, chemistry may be characterized as a dual science that pursuits scientific aims and technological aplications (Sjöström, 2007, Talanquer, 2011). Kovac (2001) highlighted the importance to consider ethical issues concerning the development of technologies, since that producing and using of chemical products implies risks in several dimensions, including the social, economical, political, environmental, and ethical domains (Bensaude-Vincente & Simon, 2008). In addition, chemistry is also influenced by aesthetic values especially those of creation and innovation (Spector, 2003).

These several features about chemistry have contributed to understand the structure of chemical knowledge and they point out important implications to curriculum and instruction in chemical education (Erduran, 2001, Lombardi & Labarca, 2007, Talanquer 2011, Erduran e Mugaloglu, 2014). In regards to teacher education, studies in philosophy of chemistry also presents crucial issues about teachers’ knowledge for teaching on nature of chemistry in order to empower them
in understanding and teaching of their subject (Erduran, Adúriz-Bravo & Naaman, 2007). Other authors have highlighted that teachers should have access to additional information, practical resources and suggestions on how to promote more holistic discussions about nature of science as a significant component of their ongoing professional development, and thus avoiding a monofaceted and unproblematic view of chemistry and its teaching (Talanquer, 2011).

Chemistry is a simple word with many different meanings to different people. In this work, we took into account the conceptual profile theory to investigate different modes of thinking and ways of speaking on chemistry, considering polysemy associated to this term, both in the specific domain of science and others domains of general culture and language. Conceptual profiles theory emerged in the literature on Science Education (Mortimer, 1995) as an alternative to conceptual change models to analyse conceptual evolution in science teaching and learning. Initially inspired by Bachelard’s epistemological profile, it evolved through the incorporation of a sociocultural approach and pragmatist philosophy as a theory of teaching and learning scientific concepts (Mortimer & El-Hani, 2014).

According to the conceptual profiles theory, there is heterogeneity of verbal thinking in any culture and in any individual (Tulviste, 1991), so that individuals exhibit different modes of thinking on a single concept that can be meaningful used in different contexts. This basic assumption points out that different modes of thinking that characterize the heterogeneity of verbal thinking are interwoven with different ways of speaking, and individuals can access two or more meanings for the same word or concept in appropriate contexts. Thus, conceptual profiles are models of different modes of thinking socially constructed and attributed to a specific concept starting from a given experience, and then the heterogeneity of conceptual thinking can be modelled by conceptual profiles (Mortimer et al, 2014a).

In the research program on conceptual profiles, the theory is aligned to Vygotsky’s theory of psychological development that highlights the social dimension of the human mental process. Vygotsky (1934/1987) distinguishes between sense and meaning of a word pointing out to the heterogeneous dimension of the word. Vygotsky considered the concept and the meaning of a word as synonymous, and meaning emerges in the relationship between thought and word. The sense of a word is the aggregate of all psychological facts that results in our consciousness from entertaining the word and Vygotsky treated it as a dynamic, fluid, and complex formation, with zones varying in their stability. While sense is context dependent, meaning is much more stable and repeatable (Mortimer et al., 2014a).

From this perspective, conceptual profiles are proposed for a given concept and are constituted by several zones, each one representing a particular mode of thinking about that concept and related to a particular way of speaking. “Each mode of thinking is modelled as a zone in a conceptual profile, stabilized by ontological, epistemological, and axiological commitments underlying meaning making about a concept” (Mortimer et al, 2014a, p.15). Each individual has his or her own individual conceptual profile and the relative importance of the zones varies from person to person, when individuals in a given sociocultural context share zones or modes of thinking. Those differences in relative importance depend on the individual’s experience, which offered and offers more or less opportunities for applying each zone in its appropriate contexts (Mortimer & El-Hani, 2014).
From the conceptual profile theory, learning is conceived as two interwoven processes: 1. The construction of new modes of thinking and ways of speaking - in science education; it means to acquire or to expand scientific zones; 2. The dialogue between new and old zones enabling students to become aware of the very diversity of modes of thinking and to distinguish between their pragmatic value in distinct contexts (El-Hani et al, 2015). In this sense, teaching science implies presenting and discussing different modes of thinking in order to situate and to build meanings for scientific ideas among others.

Finally, this work presents results of an investigation that intended to propose a conceptual profile of chemistry. This paper also explores the application of this conceptual profile model to analyse discursive interactions and the meaning making processes concerning the nature of chemistry in the context of classroom. In this contribution, we are taking into account the conceptual profile theory as a model of the heterogeneity of thought and language in order to investigate different modes of thinking and ways of speaking on chemistry, considering the polysemy associated to this term, both in the specific domain of history of science and others domains of general culture and language. We argue that the variety of conceptions on chemistry, framed in the conceptual profile of chemistry model can provide a fruitful dialogue with issues on the nature of chemistry given the constitutive pluralism of chemistry, which can bring implications for chemistry teaching and learning and formation of chemistry teachers.

METHODS

This is a qualitative research, which took into account aspects of the interactional ethnographic approach (Gee & Green, 1998). The general purpose of this study was to propose a conceptual profile of chemistry and apply it to analyze views of chemistry in episodes of classroom discursive interactions.

In order to construct and characterise zones of a conceptual profile several sources of information were considered: historical and philosophical studies, literature on alternative conceptions, textbook analyses, and treatment of primary data on students’ views, gathered by both questionnaires and interviews, as well as in the discursive interactions in science classrooms (Mortimer et al, 2014). By using these sources, we may investigate three Vygotsky’s genetic domains – microgenetic, ontogenetic, and sociocultural (Mortimer et al, 2014b, Wertsch, 1985). In our research, we have proposed a conceptual profile of chemistry based on dialogic examination of data obtained from: (a) historical and epistemological analysis on development of chemistry; (b) literature on students’ conceptions related to chemistry; (c) and students’ ideas gathered by questionnaire and classes video-recordings.

The empirical investigation involved a small group of 9 undergraduate students enrolled in a course for pre-service chemistry teachers in a Brazilian public university, when they are engaged in activities carried out in a 4-day (2.5 hours for each day) course. The activities included discussions around issues in philosophy of chemistry. In order to validate the zones proposed for the conceptual profile of chemistry, we have analysed transcriptions of videos (10h), using the analytical tool developed by Mortimer and Scott (2003) in order to analyse interactions and meaning making process in science classrooms. Table 1 presents the aspects of this tool.
In this research, we have considered each aspect of this framework except the patterns of interaction. The teaching purposes are related to the goals of the teacher during the class, such as opening up the problem, exploring the students’ views, introducing and developing the content, guiding students to work with scientific ideas and apply them, maintaining the narrative. The content can be approached through description, explanation and generalization. The communicative approach provides a view of how the teacher works with the purposes and contents of teaching through different pedagogical interventions that result in different patterns of interaction. Mortimer and Scott (2003) identified two dimensions for the communicative approach – dialogic/authoritative and interactive/noninteractive – from which they proposed four classes of communicative approach: interactive/dialogic (teacher and students interact and different points of view are addressed); noninteractive/dialogic (teacher and students do not interact but teacher considers different points of view); interactive/authoritative (teacher and students interact but only one point of view is considered); noninteractive/authoritative (teacher and students do not interact and teacher considers only one point of view) (Mortimer et al, 2014b). The final aspect of the analysis (teacher’s interventions) focuses on the ways in which the teacher intervenes to develop the scientific story and to make it available to all the students in the classroom, for example: shaping ideas; selecting ideas; marking key ideas; sharing ideas; checking student understanding; reviewing (Mortimer & Scott, 2003).

In this study, this framework was useful to clarify how the ways of speaking characterized in terms of discursive aspects and related to the zones of the conceptual profile can contribute to the understanding of the meaning making process in the classroom. The conceptual profile works as a model to structure the epistemic dimension of the discursive interactions while the analytical tool makes it possible to analyse the linguistic and social dimensions for them.

RESULTS

From the data analysis we have identified epistemological, ontological and axiological commitments which stabilize modes of thinking about the concept of chemistry. We proposed a conceptual profile of chemistry covered by six zones representing different modes of thinking on chemistry: monist, aversive, epistemic, pragmatic, processual, and attractive. In Table 2, we present a brief description of each zone of the conceptual profile.
Table 2: Summary of the zones of the conceptual profile of chemistry.

<table>
<thead>
<tr>
<th>Zone</th>
<th>Description (modes of thinking)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Monist</td>
<td>Perspectives of Chemistry as essence of the reality. Chemistry is all around us and everything is Chemistry, because it will be anywhere the matter exists. Chemistry exists since the origin of Universe, outside our consciousness. Chemistry is omnipresence.</td>
</tr>
<tr>
<td>Aversive</td>
<td>Chemistry related to something malefic, lethal, contaminating agent, responsible for environmental pollution. Chemistry is associated with artificial products, in opposition to “Nature” or natural products that are supposed to be “chemical-free”.</td>
</tr>
<tr>
<td>Epistemic</td>
<td>Chemistry as a science, a systematic knowledge, a branch of scientific knowledge, a school subject. Chemistry understood as conceptual and theoretical framework. Chemistry has been seen as a difficulty subject and abstract ideas.</td>
</tr>
<tr>
<td>Pragmatic</td>
<td>Chemistry related to practical, operational and technological situations. Technoscience. Chemistry is what a chemist does. Chemistry as an industrial branch, as a career, in other words, an activity guided by specific values, rules and behaviors.</td>
</tr>
<tr>
<td>Processual</td>
<td>Chemistry is a process or event occurring with specific entities. It is transformation, chemical reaction. Here, there is an ontological tension between substances and processes.</td>
</tr>
<tr>
<td>Attractive</td>
<td>Ideas about Chemistry as a feeling, attraction, affinity, love, a strong connection between two people. “The perfect chemistry” romantically represents perfect love. Here, ideas or conceptions are related to axiological commitments more than the knowledge itself.</td>
</tr>
</tbody>
</table>

In order to validate the proposed zones and explore its utility, we have analysed discursive interaction in a course of formation for chemistry teachers. Here, we present the analysis of a teaching episode taken from the first class of a teaching sequence, in which the lecturer addressed issues on philosophy of chemistry. In the first class, students (S) and the lecturer (L) discussed a set of sentences about chemistry, elaborated taking into account chemistry textbooks. With the sentences, the lecturer had a purpose to stress different modes of thinking in the discussion. The sentences proposed were:

1. Chemistry is the study of matter and its changes;
2. Chemistry is the science that studies materials and substances: its properties, constitution and transformations;
3. Chemistry is a natural and experimental science and its methods are analysis and synthesis;
4. Chemistry is the science of molecules while Physics is the science of the atoms;
5. Chemistry is just applied physics;
6. Chemistry is a tool for other sciences;
7. Chemistry is responsible by environmental problems.

The episode 1 illustrate a moment from the first class in which these sentences were discussed. Based on Amaral & Mortimer (2007), we adopted a simplified code for transcribing the oral language in the episodes in order to indicate, for example, pauses (+), interruption (/), stress in the intonation (caps lock), comments (double parentheses).

In the episode 1, the lecturer had two main purposes: exploring the students’ views on Chemistry, and introducing and developing the subject of the class. In the discursive interactions, we can realize a negotiation among different zones of the conceptual profile, such as, monist, aversive, epistemic, pragmatic and processual.
**Episode 1:** Students expressed different ways to address *Chemistry* from the proposed sentences.

1. **L:** Let’s go (+) who is the first to speak?
2. **S4:** That first there… ((in reference to the sentence 1)) it’s from the textbook isn’t it? Because it is quite how I think … taking it experimental aspect too (+) the reaction (chemical reactions)
3. **L:** It’s also…Is it how you think? Is chemistry the science that study matter and its transformations?
4. **S4:** ((he shakes his head in agreement)) taking into account the experimental aspect as well (+) the reactions... (chemical reactions).
5. **L:** Right.
6. **S6:** This last one (+) ((he reads it aloud the sentence 7)) chemistry is responsible for environmental contamination (+) I don’t agree with that (+) because I don’t see it being the chemistry ITSELF (+) but the way how chemistry is applied.
7. **L:** Okay (+) anybody else/Come again?
8. **S2:** That other is more complete. For me, the second one ((in reference to the sentence 2’)) is more complete.
9. **L:** Why?
10. **S2:** (…) Because of the triangle… ((in reference to aspects of the chemical knowledge: properties, composition and transformations)) that is about the materials and substances (+) changes (+) properties.
11. **L:** Do you think it is more/
12. **S4:** Correct.
13. **S2:** More correct I don’t know but (+) to me…
14. **S1:** This fifth ((in reference to the sentence 5)) also is totally… ((he shakes his head in disagreement))
15. **S3:** Wrong isn’t it?
16. **L:** Do you think it is wrong?
17. **S3:** Because (+) I believe that they complement one another (+) help each other.
18. **L:** But physicists do like to say that (++) we study from subatomic particles to universe (+) all galaxies (+) physics can handle all this (+) everything is inside physics.
19. **S3:** In the same way mathematicians say that everything is mathematics.
20. **S4:** Everything is chemistry.
21. **L:** So?
22. **S3:** And chemistry as a science (+) it is not so old isn’t it? Chemistry as a science… regarding chemistry as a science I think is not so old…
23. **L:** Yeah (+) it depends what you mean by chemistry /
24. **S3:** But I mean (+) as a science.
25. **L:** Yes (+) but it is like I said (+) even as a science (+) you will have some problems…
26. **S3:** Chemistry is present ever since all things exist isn’t it? (+) if you believe that all this was created ((he point the space around him))(+) that it has had a creator (+) so chemistry was present since that moment (+) however deal with it as a science (+) like mathematics (+) that I think (+) it’s much more old isn’t it?

The episode begins with an initiation by the lecturer, encouraging students to express their opinions and points of view related to the proposed sentences. The student S4 recognizes the sentence as a piece from the textbook of chemistry and he claims for the experimental dimension of chemistry science (turn 2). The lecturer repeats the S4’s statement in order to check his understand (turn 3). S4 answers the lecturer by presenting an explanation committed to a practical perspective on chemistry once he points out the experimental dimension of chemistry (turn 4). His utterance can be interpreted in terms of ontological and epistemological commitments related to the processual zone of the conceptual profile; however, it is not clear if the term “reactions” is related to the macroscopic or sub-microscopic level. In the turn 5, the lecturer provides feedback to the student S4.
The student S6 refuses the sentence 7 considering the use of chemistry, instead chemistry itself, could promote damages, anyway he seems to express a perspective on chemistry as an entity or a transforming agent, when he suggests the way of using it (turn 6) highlighting a form of speaking typical of the aversive zone of the conceptual profile. The lecturer encourages other students to bring new contributions (turn 7) and he interacts with student S2 and S4. In the discussion (turns 8-13), they address three aspects of the chemical knowledge – properties, composition and transformations – discussed by literature in chemistry education. These ways of speaking suggest a commitment with an epistemic view of chemistry (epistemic zone).

In the turns 14-19, the discursive interactions also focused on the role played by different sciences, specifically physics and mathematics. The main point was the tendency of different sciences to define themselves as more widespread or powerful. In the turn 18, the lecturer prompts the students to think about physicalism by introducing more information on this subject. In the following, the student S3 argues upon a relativistic perspective highlighting that this mode of thinking may be also applied to other sciences (turn 19). In the turn 20, the student S4 expresses a way of speaking typical of the monist zone of the conceptual profile by defining chemistry as “everything”, including it in the roll of “powerful” sciences.

In the turns 22 and 24, the student S3 rises a point about the origins of chemistry as a scientific domain in the history, which we interpreted in terms of ontological and epistemological commitments related to the epistemic zone. He seems to recognize chemistry as science that have a historical origin in the development of other sciences. The utterance’s lecturer in turns 23 and 25 had the intention both replying the student S3 and to stress that there is a pluralism of modes of thinking on chemistry. At the end of the episode, in the turn 26, the student S3 presented simultaneously different modes of thinking on chemistry. Firstly, he suggested a theological conception, in which chemistry is related to an entity and it is present in all things (monist zone); secondly, he mentioned chemistry as a science (epistemic zone); and the processual zone seemed to emerge when he suggested processes and transformations occurring since the beginning of Universe.

We consider that the communicative approach in this episode was predominantly interactive/dialogic with a high level of interaction between the lecturer and the students, since the former listens to, and takes into account of the students’ points of view.

Following in the lessons, students predominantly presented conceptions related to epistemic and processual zones, when they discussed reductionism and autonomy of chemistry, or chemistry science among other sciences, then didactical, pedagogical and curriculum issues emerged in the classroom. From the results, we argue that the characterization of the zones of a conceptual profile, when integrated with discourse analysis, can contribute to the investigation of discursive and epistemological aspects that interact in the process of meaning making in the classroom.

### CONCLUSION

Findings showed that the proposed conceptual profile for chemistry could provide a way of bringing together chemistry teaching and philosophical issues, when philosophy of chemistry may contribute to understand students’ modes of thinking and epistemological aspects in
processes of meaning making for scientific concepts. This applied to courses for chemistry teachers can favour to address the nature of chemistry issues, improving learning in the basic education. The zones of the conceptual profile provide a useful tool for structuring modes of thinking about chemistry and thus the proposed conceptual profile constitutes a model to interpreting ways of speaking about chemistry enabling a characterization of the discursive interactions on nature of chemistry issues in the educational context.

In conclusion, we stress contributions from the proposed conceptual profile of chemistry to teacher education: providing a resource to introduce issues on philosophy of chemistry into chemistry teachers training in order to establish a first experience with issues on the nature of chemistry given the sophisticated discussions in that domain; contributing to understand some zones emerging in students’ speeches to make explicit ideas concerned to the nature of chemistry, and to analyze process of meaning making for scientific concepts.

IDENTIFICATION OF STUDENTS’ MENTAL MODELS ABOUT THE MILK TRANSFORMATION INTO YOGURT

Verónica Muñoz-Campos, Antonio-Joaquín Franco-Mariscal and Ángel Blanco-López

Universidad de Málaga, Didáctica de las Ciencias Experimentales, Málaga, España

A review of the scientific literature reveals that there is still little research on the conceptions of secondary school students about chemical reactions involving microorganisms, especially those related to the mental models that students use in their explanations. This paper describes a study concerning the different mental models related to the milk transformation into yogurt with 83 students from a Spanish secondary school of 8th and 9th grade (13-16 years) developed in the framework of a research that intends to use the elaboration of this product as a context for the teaching and learning of chemical reactions through modeling approaches. In order to identify the students’ mental models, in this paper we consider the milk transformation into yogurt as a process in which its main components are: the entities involved (milk and bacteria), the interaction between them and the result (yogurt). A simplified school model of this process would involve students considering that bacteria use the sugar in milk to transform it into lactic acid through a chemical reaction to obtain the necessary energy. Using this scheme in interaction with the students’ answers, the underlying mental models were identified. Although almost half of the students showed great difficulties explaining the process, five models have been identified. Students often consider the milk transformation into yogurt primarily as a physical process of agglutination or change of state. These models are far from a school model in which the bacteria have a fundamental role in the transformation of milk into yogurt by a chemical reaction.

Keywords: mental models, lactic fermentation, secondary education.

INTRODUCTION

Modeling can be understood as a group of tasks related to the use of scientific models. It involves not only learning the models of school science but also elaborating and reviewing them, as well as speaking and expressing opinions about them, understanding their usefulness, their approximate and changing character, and also their limitations (Jiménez-Tenorio, Aragón-Núñez, Blanco-López and Oliva-Martínez, 2016).

From this perspective, it is considered that models are the central core around which knowledge is generated, both in science and students. It constitutes one of the scientific practices included in "the Framework for K-12 Science Education" of the National Research Council (NRC, 2012).

The modeling-based science teaching consists in approaching concepts through simpler representations that help students to construct and understand the phenomena studied (Justi and Gilbert, 2002; Coll and Treagust, 2003). Teaching through models should be understood as a good practice for the acquisition of scientific knowledge in compulsory education (Aragón-Núñez, Oliva-Martínez and Navarrete, 2014).

This approach has proven effective for students to approach scientific models and theories as well as research processes, but in some cases they do so in a context of experientially
decontextualized learning, which promotes rejection in students to appreciate it far from their personal interests and needs (Izquierdo, 2004).

The different teaching proposals on modeling in the classroom, start from the students' explanation of what their mental models are about the object of study (Acher, 2014), understanding that these models are the anchor point from which they could develop more complex models. Students' mental models provide valuable information about their conceptual frameworks, so their underlying knowledge structures can help to improve the design of classroom learning activities.

Despite the fact that mental models have received great attention in the area of science education, especially those related with physical and chemical phenomena, it has not been this way in the study of chemical reactions involving microorganisms (Muñoz-Campos, Franco-Mariscal and Blanco-López, 2017). The transformation of milk into yogurt shows a phenomenon of great relevance in daily life (Simonneaux, 2000) but it has been little studied from the perspective of modeling and of the mental models of the students (Moreno and Lopez, 2013).

Chemical reactions are considered as one of the most important concepts of chemistry, as shown by a large number of research carried out from the didactics of the sciences (Andersson, 1986; Boo, 1998; Aragón-Nuñez, Oliva-Martínez and Navarrete, 2013). They are the basis of various chemistry contents that are studied throughout compulsory education in most curricula and, furthermore, they are very useful to explain phenomena of daily life, as occurs in fermentation reactions that are important in the field of nutrition (Balaguer, García and Mantero, 2006), and have been shown for instance in the preparation of yogurt (Parra, 2012). This context has been chosen since, despite its daily life, it does not appear among the most used topics in the teaching of science (Jiménez-Liso, López-Gay and Márquez, 2010).

One of the main problems in approaching the fermentation reaction is to consider its biological nature. Some studies show how students attribute all diseases to microbes, without distinguishing between contagious disease and non-contagious disease and without reference to diseases derived from an organic, functional or nutritional point of view (Brumby, Garrard and Auman, 1985). However, in other studies it is reported that some students defend the idea that bacteria can be useful for the preparation of medicines or vaccines (Maxted, 1984) and that teaching proposals about the study of microorganisms stimulates their learning, its importance in food manufacturing, agriculture and the environment (Bryne and Sharp, 2006).

The elaboration of yogurt is a complex process in which several phenomena are produced and it is usually studied by different science subjects that are taught in secondary education (chemistry and biology).

In the current curricula of compulsory secondary education in Spain (MECD, 2015) the contents of chemistry most related to yogurt and its preparation are those related to chemical reactions, included in the subject of Physics and Chemistry of grades 8 and 9, within a section whose purpose is to characterize chemical reactions as changes of some substances in others. In this subject the fermentation reactions are not mentioned.
In the biology curriculum (grades 7 and 9), a section on "The world of microorganisms and their applications. Biotechnology" in which the concept of bacteria is included, it is intended that students are able to evaluate the applications of biotechnology and microbiology in the food and pharmaceutical industry, the improvement of the environment, and finally recognize and identify the different types of microorganisms involved in fermentative processes of industrial interest. In the previous Spanish curricula (MEC, 2007), still partially valid at the time of this research, fermentation was studied in grade 8 in a block of contents related to the vital functions of living beings.

Treating the chemical reaction model in the context of fermentation is a challenge to the most common teaching approaches in which the chemical reaction models are based on simpler phenomena corresponding to the inorganic world (Aragón, Oliva and Navarrete, 2010). We consider that although it can be treated in a more complex way from a conceptual point of view, the model can explain daily life phenomena and increase the students’ interest in the elaboration of yogurt.

AIMS

The aim of this study is to identify possible models in the explanations given by the students. Specifically, this research focuses exclusively on the progression of the model of students aged 13-16 years of the process of the milk transformation into yogurt and the concept of chemical reaction involved (Muñoz-Campos, Blanco-López and Franco-Mariscal, 2015). This is an initial phase for the development of a teaching proposal focused on the modeling of chemical change in the context of the transformation of milk into yogurt.

METHODS

This study was conducted with a sample of 83 secondary school students in two different secondary schools in Malaga (Spain). The subjects were 40 grade 8 students (13-14 years) and 43 grade 9 students (15-16 years old). A total of 41% of the participants were male and 59% were female. The students belong to the last two years in which the sciences in Spain are compulsory. Although these contents could be more appropriate with more mature students, our interest was focused on students of these levels since they can represent the ideas of many of them. There is no evidence that the participating students had received specific training in the modeling approach.

This paper analyzes one of the tasks proposed in a questionnaire designed for this purpose, formulated as: "Assuming that you have very powerful glasses, make a representation of the process of milk transformation into yogurt (fermentation), knowing that the most important components in this process are sugar (lactose), lactic acid and bacteria. Explain your representation". These questionnaires were administered in the chemistry class.

In order to identify the mental models of the students, we start from a scheme that considers the milk transformation into yogurt as a process (Chi et al., 1994), in which its main components are: the entities involved (milk and bacteria), the interaction between them and the result (yogurt). A simplified school model (target model) of this process would imply that the students considered the bacteria would use the sugar contained in the milk would transform it
into lactic acid through a chemical reaction and by this way the bacteria obtains the necessary energy to perform the vital functions. The way in which this energy involving molecules such as ATP is transferred has not been taken into account in this target model due to its complexity for the students age.

Yogurt has very similar composition to milk and the most important difference is the presence of lactic acid that gives the acid taste and texture that it presents. Using this scheme in interaction with the students' answers, the underlying mental models were identified. In order to categorize the students' answers, the drawings and explanations offered by them were analyzed (Ainsworth, Prain and Tytler, 2011).

**RESULTS**

The identified models, from lowest to highest degree of proximity to the target model, are shown in Table 1. An idea of progress is used in models with two dimensions: whether the students' explanations contemplate or not the bacteria and the type of specific transformation that happens, understood as a physical change to a chemical change.

Practically half of the students in the two grades were not able to offer an explanation of the process or, it was not possible to establish it by its simplicity. However, we have found five models which are shown in Table 1. Differences appear in the distribution of models in the two grades, in particular, in models 1, 2, 3 and 5. While in models 1 and 3, the percentage in Grade 9 is greater, while in models 2 and 4, it is the opposite.

In order to find an explanation to these results, the five models are illustrated below with different drawings and examples made by the students.

Model 1. Transformation is understood as a physical process very similar to a change of state, where the milk components are joining until they are together (Figure 1).

The student explained for the milk drawing: "*In the milk it looks like this because it is liquid and the molecules are separated*", while for the yogurt his/her answer was: "*The yogurt is solid, for that reason the molecules come together*" (Figure 2).
Model 1 was the most popular model found in both grades, by 15% of 8th grade students and 32.5% of grade 9. This model seems to correspond to a primary point of view of the nature of matter and its transformations, according to which matter inside is conceived in the same way it is seen and what happens to its constituents during transformations is the same as what it is observed macroscopically (Blanco and Prieto, 2004).

Model 2. The process is shown as a macroscopic mixture of milk, sugar, lactic acid and bacteria (Figure 3). Although bacteria are considered in this model, students are not able to express it in microscopic terms, but as macroscopic drawings. This model was found in 7.5% and 2.5% of students of grades 8 and 9, respectively.

The explanation proposed by an 8th grade student on both drawing was that "milk contains less elements than yogurt, since yogurt is made up of milk and more substances" (Figure 4).
Model 3. This model involves a physical process in which bacteria appear, without interaction with the milk components. The transformation consists in the joining of milk components with the bacteria (Figure 5). This model is similar to model 1 in terms of interaction type, except that students incorporate bacteria into their drawings and/or explanations. The representation used for bacteria implies that students have already had some knowledge of them although they are unable to show what role they play in the process. This model was mostly found in grade 9 students (14%) and was only used by 5% of grade 8 students.

Figure 5. Example of model 3 "Change of state in which bacteria are included".

The students explained this drawing in the same way as model 1, however the drawings included in this model clearly shows the difference between bacteria and the rest of the molecules.

Model 4. This model involves a physical process in which the bacteria are responsible for the milk components joining (Figure 6). The students’ drawings show how the milk components and bacteria are separated; with the yogurt the bacteria are joining the milk components. This model was found in both grades in a similar percentage around 10%.

Figure 6. Example of model 4 "bacteria act as a binder".
Model 5. This model involves a process in which milk is fermented when bacteria are added, but without indicating that the fermentation is a chemical process that takes place through a chemical reaction (Figure 7). This model was only found in 8th grade students (12.5%).

![Figure 7. Example of model 5 "indicate the word fermentation".](image)

The students explained this drawing indicating that "the components are grouped forming a more complex structure completing the fermentation process" (Figure 8).

![Figure 8. Explanation of a student about the drawing made for model 5.](image)

**CONCLUSIONS**

From the study findings presented above, we can conclude that the students participating in this research present great difficulties in explaining the milk transformation into yogurt referred to the submicroscopic domain (Moreno and López, 2013). Among their answers, we have been able to identify five models to explain this process in which the students consider the milk fermentation as a physical process of agglutination or change of state.

We consider these results to be insufficient, with only 6% of the students reaching the target model (5 of the 83 participants). All students who explained model 5, the closest to the school model, were in grade 8. This can be explained because it is precisely in this course that students have received training in the contents related to fermentation in the subject of biology. However, it seems that this training does not produce a lasting learning in time, since no student of grade 9 came up with this model.

In general, all the models proposed by the students are still far from those in which bacteria plays a fundamental role in the transformation of milk into yoghurt through a chemical reaction. The most important didactic implication that emerges from these results is the need to improve the learning of the fermentation process, with special emphasis on the fact that it is a biochemical process where bacteria play a fundamental role.

From there parts our interest in designing and implementing a teaching sequence on this topic as it could contribute to improve the understanding of this process while students learn to build
models to understand the science that surrounds them. To refute the mental models of the students this teaching sequence should include activities related to the preparation of yogurt.

ACKNOWLEDGEMENT

This work is part of the “I+D Excelencia” project “Development and evaluation of scientific competences through context based and modelling teaching approaches” case studies (EDU2013-41952-P), funded by the Spanish Ministry of Economy and Finance through its 2013 research call.

IDENTIFYING AND IMPROVING STUDENTS’ MENTAL MODELS OF TOOTH DECAY

Antonio Joaquín Franco-Mariscal, Ángel Blanco-López and Enrique España-Ramos

Universidad de Málaga, Didáctica de las Ciencias Experimentales, Málaga, Spain

The aims of this study were to identify the initial mental models of tooth decay among a sample of 15-16 year-old Spanish students, and then to analyse changes in these models following the students’ participation in a teaching sequence on this topic. The study focuses on the analysis of two tasks that formed part of a pre-test / post-test design whose aim was to determine whether students could provide an adequate explanation of the problem of dental caries. Mental models were identified through an iterative process that combined an examination of the nature of the concept in question with an analysis of students’ responses. Five mental models of tooth decay were identified. Three of them were associated with a single active agent (the tooth, food or microscopic living organisms). The fourth model included sugar plus a second active agent, while the active agent in the fifth model was acids. We also identified five mechanisms, which were not exclusive to any one model. The results showed an evolution in students’ explanatory models of tooth decay following their participation in the teaching sequence. Initially, the majority of students used simple models involving a single active agent (the tooth, food or microscopic living organisms). The fourth model included sugar plus a second active agent, while the active agent in the fifth model was acids. We also identified five mechanisms, which were not exclusive to any one model. The results showed an evolution in students’ explanatory models of tooth decay following their participation in the teaching sequence. Initially, the majority of students used simple models involving a single active agent, whereas by the end of the teaching sequence the majority of them were employing the most advanced models. However, formulating the mechanism through which tooth decay develops remains a complex task for students, particularly as regards understanding that the interactions which produce the active agent and its action upon a tooth are chemical reactions.

Keywords: mental models, tooth decay, teaching learning sequence

INTRODUCTION

Achieving and ensuring good oral health is an important component of children’s physical, social, emotional and intellectual development (Washington State Department of Health, 2011). In Spain, oral and dental hygiene is only directly addressed in the primary curriculum (Ministry of Education, 2015), although some recent studies (Sheiham, 2005; Ramos, 2010; Llorda et al. 2012; Patel 2012) highlight a number of reasons (e.g. poor dental habits and high rates of tooth decay) why it should continue to be addressed among adolescents.

In light of this research, we developed a teaching sequence (TS) on dental health and hygiene aimed at 15-16 year-old students (Blanco-López, Franco-Mariscal and España-Ramos, 2016). This TS, which has been implemented since 2012, can be considered novel in the Spanish context, since it regards the question of oral and dental hygiene as a relevant context in which to develop students’ scientific competences and to improve the dental health of the country’s adolescents.

One of the ways in which we have assessed the impact of the TS consists in comparing students’ mental models of tooth decay before and after their exposure to it, the rationale being that significant changes in explanatory models are one of the most important kinds of conceptual change (Lawson et al., 2000).
Mental models have received significant attention in educational research and practice over the past 20 years or so (Coll and Treagust, 2003) as they are considered to affect the cognitive function of subjects and may provide valuable information concerning the conceptual schemes used by students and the knowledge structures underlying the action (Vosniadou, 1994); all these aspects may be of interest for improving the design of school science.

The mental model construct can be defined in several ways. In general terms, it is usually considered to relate to dynamic and generative representations that can be manipulated mentally to provide causal explanations for phenomena and make predictions concerning the physical world (Vosniadou, 1994). Clement (1989) defines this model in terms of a (mental) representation of a system based on certain characteristics thereof and which can predict or explain its structure or behaviour. This implies a set of interconnected entities in a system (possible including perceptive and spatial relationships) and is the opposite to a list of isolated facts (Clement, 2008). Although mental models are personal constructs that can be maintained over long periods of time and are relatively stable, there is a consensus regarding the fact that they are subject to social influence. In this sense, teaching can influence the evolution of the mental models used by students at any given moment.

Although mental models have attracted considerable attention among researchers and educators in the fields of physics and chemistry (Clement, 2008), this has not been the case in the field of health sciences (Cabello, España and Blanco, 2017), despite the fact that the latter, together with environmental sciences, represent relevant contexts for science teaching as they are very close to students’ interests and needs (Zeyer and Dillon, 2014). To the best of our knowledge, no studies have specifically examined students’ mental models of tooth decay. Identifying these models and understanding how they develop and evolve would provide a useful platform on which to build teaching modules that could help students to understand dental caries and to improve their dental habits and health, all of which should lead to a reduction in the prevalence of tooth decay among adolescents.

In light of these aspects, the aims of this study were to identify the initial mental models of tooth decay among a sample of 15-16 year-old Spanish students, and then to analyse changes in these models following the students’ participation in a TS on this topic.

**TEACHING SEQUENCE ABOUT TOOTH DECAY**

The TS is based around the question *why do teeth decay?* and was organised into four sections: (a) Identifying the problem, (b) Preventing the problem, (c) What should I do if prevention fails? and (d) Raising awareness about the problem (Blanco-López, Franco-Mariscal and España-Ramos, 2016). This TS involved 10 one-hour sessions held in the school science lab (Figure 1).

The main criterion for selecting knowledge, skills and attitudes was their significance and relevance as regards improving students’ understanding of the situation. Different types of knowledge (sugary foods, plaque, chemical reaction, teeth,...) (Mafra, Lima and Carvalho, 2015) corresponding to different subjects in the secondary school curriculum (biology, chemistry and social sciences) are required to make decisions in this problem. Table 1 provides a description of the sections in the TS, the knowledge involved in them and the learning tasks.
METHODS

In order to identify the mental models underlying students’ understanding of tooth decay we implemented two case studies across two academic years with a total of 28 students. The present study focuses on the analysis of two tasks that formed part of a pre-test / post-test design whose aim was to determine whether students could provide an adequate explanation of the problem of dental caries. The two tasks/questions were: 1) *What factors are involved in the development of tooth decay?* 2) *Explain the role played by each of these factors and describe in detail how the development of tooth decay takes place.*

Mental models were identified through an iterative process that combined an examination of the nature of the concept in question (Franco-Mariscal, Blanco-López and España-Ramos, 2016) with an analysis of students’ responses. The use of two approaches (theoretical and empirical) confers greater validity on the procedure followed.

Dental caries may be considered under the category of scientific concepts that Chi, Slotta and Leeuw (1994) refer to as *processes*, in this case, a phenomenon that affects teeth under certain circumstances. In order to define a process (Chi et al., 1994) it is necessary to consider three questions: What material elements (or system components) are involved? What happens between them (how do they interact)? What changes occur during the process (what kind of transformation takes place)? When it comes to identifying mental models of tooth decay, there are two key aspects that must be considered: the nature of the active agent and the mechanism by which dental caries are produced. The active agent is the entity, living organism, substance or product that acts upon teeth and produces decay. The mechanism or explanatory model (Clement, 2008) accounts for the interactions between the different entities involved. In the case that concerns us here, a target mental model would be one based on scientific ideas and which considers the role played by oral bacteria, sugar and acids. The bacteria present in dental plaque transform sugar into acid, which is the active agent that reacts chemically with the substances found in teeth to produce caries (mechanism), via a chemical reaction. Thus, Muñoz (2016) defines caries as “a multifactor disease characterised as an infectious process in which carbohydrates are fermented by oral bacteria on the surface of the tooth, which results in the production of acid and dissolution of the enamel” (p.35).
**Table 1. Relevant characteristics of the TS about tooth decay (adapted from Blanco-López, Franco-Mariscal and España-Ramos, 2016).**

121
Through their participation in the TS we expected that students would become able to incorporate both the active agents and the associated mechanisms into their understanding of tooth decay. The mechanism is undoubtedly the most complex part of the model and may include how the active agent is produced, or how this active agent acts on the tooth to produce caries.

Starting from such a framework we conducted a detailed analysis of students’ responses in order to identify their underlying mental models. To guarantee the reliability of the procedure, this analysis was initially carried out individually by the three members of the research team (the authors of this study) and subsequently jointly to elucidate the classification of those responses for which discrepancies appeared.

Finally, Fisher’s exact test was used to verify the existence of significant differences between the mental models identified in the pre-test and post-test.

RESULTS

The analysis of students’ responses from the perspective of the category of scientific concepts that Chi et al. (1994) refer to as processes, led us to identify five different mental models (A, B, C, D and E) about tooth decay with different variants, defined according to the extent to which they reflected scientific ideas regarding the active agents and mechanisms involved in dental caries (Table 2). We also identified five mechanisms, which were not exclusive to any one model (Figure 2).

The order in which the mental models are presented (Table 2) shows a progress scheme to the extent that these models are formulated with an increasing degree of precision and similarity to the desired mental model. Information concerning the active agent(s) involved, the mechanism and an example of a student’s response is provided for each model and the variants identified for them.

Models A, B and C were associated with a single active agent: the tooth, food and living organisms (including bacteria), respectively and with a single, simplistic mechanism in which just one agent directly attacks the tooth (mechanism M1). This is a simple causal model (Andersson, 1986) in which the only agent (sugar or bacteria, for example) acts mechanically against the tooth and causes a wearing effect.

The explanatory mechanism associated with models D and E involved two active agents and was more complex in that it considered both how the agent was formed (stage 1) and how it attacks the tooth (stage 2) (Figure 2).

Model D includes sugar plus a second agent (saliva or bacteria) that act simultaneously on the tooth to cause caries (mechanism M2). As such, this model is an improvement on the previous models as it considers the involvement of more than one component (sugar, saliva or bacteria) as active agent. However, it still differs markedly from the scientific model as it does not identify acids as the active agent, which is the hallmark of models E.

<tr>
<td></td>
<td>E2</td>
<td>Bacteria</td>
<td>M5</td>
<td>“Caries form when sugars come into contact with the bacteria present in the mouth, which decompose the sugars and produce acids; the tooth is attacked by these acids.”</td>
</tr>
</tbody>
</table>
Figure 2. Representation of the mechanisms identified.

Model E includes more sophisticated mechanisms that present different ideas concerning how the acids that cause caries are formed: produced by a single component (saliva, bacteria, sugar) (mechanism M3), produced by the combination of two components (mechanism M4) or by the chemical reaction of two components (mechanism M5). The target mental model would be represented in this case by E2 together with mechanism M5.

Table 3 shows the frequency with which the different mental models were identified, both prior to and after the TS.

The results show an evolution in students’ explanatory models of tooth decay following their participation in the TS. Initially, the majority of students used one of the two simplest models involving a single active agent (mainly model B), with only a few students employing the slightly more advanced model C. In the post-test analysis, however, we observed a substantial shift in the numbers of students using the different models: specifically, the large majority of students now employed either model D or model E, neither of which was observed in the pre-test analysis, with the use of the most complex model E being particularly common. However,
the number of students included in the target mental model (E2) after participation in the TS was low (4).

Fisher’s exact test was used to analyse the possible differences between pre-test and post-test because of the nature of the data and the small size of the sample. This test was performed to ascertain the influence of the TS on the development of more advanced mental models (E). This test showed significant differences ($p < 0.0001$) between groups upon comparing models A, B, C and D with model E.

CONCLUSIONS

This study illustrates a way of identifying students’ mental models of tooth decay, focusing specifically on two aspects: the active agent and the associated mechanism.

The results indicate that 1) these students (aged 15-16 years) initially employed a range of mental models, none of which was complete and in some cases fell well short of a scientific account of dental caries, and 2) the teaching sequence had a notable influence on the development of students’ mental models, which in the majority of cases were now much more complete and close to what would be desirable from an educational perspective. Fisher’s exact test confirms these findings.

However, formulating the mechanism through which tooth decay develops remains a complex task for students, particularly as regards understanding that the interactions which produce the active agent and its action upon a tooth are chemical reactions. The above supports the initial proposal regarding the need to study this problem with adolescent students.

We consider this study to be merely preliminary and that it is necessary to compare the set of mental models identified with larger samples of students with different ages and degrees of scientific training. It would also be of interest to study the possible relationships between the students’ mental models and their dental hygiene habits. Thus, for example, the existence of model A2, which proposes the absence of any intervening agent other than the tooth, would mean that there is no need for oral hygiene or an adequate diet as this is a problem inherent to the teeth. This model may arise as a result of advertising that claims to “strengthen your teeth” as students may think that teeth will not be susceptible to caries if strengthened and therefore that they can eat sweets with no adverse consequences. Model B, in turn, supposes that the active agent is food but that it can be removed by washing, therefore good oral hygiene would guarantee the absence of dental caries.
ACKNOWLEDGEMENT
This work is part of the ‘I+D Excelencia’ Project EDU2013-41952-P “Development and evaluation of scientific competences through context-based and modelling teaching approaches. Case studies” funded by the Spanish Ministry of Economy and Finance through its 2013 research call.

DO STUDENTS HAVE MENTAL MODELS ABOUT THE COMPOSITION OF A CARBONATED DRINK?

Joaquín Cañero-Arias¹, José María Oliva-Martínez² and Ángel Blanco-López³

¹Science Education, University of Málaga, Málaga, Spain
²Science Education, University of Cádiz, Cádiz, Spain

Solutions are a core concept for an understanding of chemistry, and exploring them in daily-life contexts can help to foster students’ interest in and learning of science. This is also a topic that can be approached through modeling. In the framework of a doctoral thesis on the design and assessment of a teaching unit based on the contextualized modelling of solutions, this study examines the extent to which students have mental models about the composition of carbonated drinks. This issue was explored through a task in which students had to depict in a series of drawings a volume of water to which sugar and gas were then consecutively added, such that their final drawing represented a bottled carbonated drink. They also had to justify the content of each of their drawings. Analysis of the ideas represented in the drawings of over 100 secondary education students aged 13-16 years suggested that they had yet to achieve an integrated overview of the processes involved; rather, their ideas and intuitions seemed disjointed and somewhat random. The students do not, therefore, have global models for explaining or predicting the process of producing a carbonated drink. This supports the need for a teaching unit that incorporates a modelling approach, one that can help students to develop models about the process of dissolution in relation to everyday products such as carbonated drinks.

Keywords: modelling, context, solutions

INTRODUCTION

Solutions are a core concept for an understanding of chemistry (Çalýk et al., 2005) and exploring them in daily-life contexts can help to foster students’ interest in and learning of science. The relevance of solution-related phenomena to the teaching of chemistry derives from the following (Blanco, 1995):

a) In the early stages of secondary science education it is important to clarify and differentiate the forms that substances may take: mixed, dissolved or pure.

b) Knowledge about the nature of solutions is closely related to an understanding of the molecular structure of matter, a core aspect of chemistry.

c) Solutions play a key role in experimental chemistry. Much of this work, especially in schools, involves the use of dissolved substances, and hence a correct theoretical interpretation depends on knowledge of the representative entities of the chemical species present in the solution, which are not necessarily the same as those prior to dissolution.

d) This experimental work also requires a series of calculations regarding the concentration of solutions needed for a given chemical reaction or for preparing solutions of a certain concentration, etc.

e) From a more general perspective, knowledge about solutions is necessary for understanding important natural phenomena that students will encounter in other science subjects; for
instance, biochemical processes (those occurring in living beings) take place in solutions, and then there are all those aspects related to water — its purification and desalination, and the possibility of contamination.

The study of solutions is therefore a key first stage in the school chemistry curriculum and it can help students to achieve a better understanding of their immediate surroundings.

One of the main challenges facing science educators is students’ lack of interest in the subject, a problem highlighted in a number of reports; see, for example, the ENCIENDE report (COSCE, 2011) or Science Education for Responsible Citizenship (European Commission, 2015). It is widely agreed that one of the reasons for this lack of interest is the gap between the science that is taught in schools and the everyday lives of students, who consequently struggle to see the relevance of what they are learning.

In a recent study, Sheldrake, Mujtaba, and Reiss (2017) analysed the responses of students in England to surveys conducted as part of the PISA 2006 and 2015 assessments (in both of which science was the major domain of interest). They found that conveying the wider applications of science was the only teaching approach to consistently and positively associate with students’ interest in science and its perceived utility. The authors concluded that developing students’ attitudes and science-related career aspirations by highlighting the applications and relevance of science to their everyday lives could be beneficial.

For some years now, science educators from many countries have sought ways of connecting the learning goals set out in school science curricula to students’ lives (Andrée, 2005). One of the key approaches that has been developed in this regard is known as context-based education (Pilot & Bulte, 2007), in which an everyday problem becomes the focus that guides and structures students’ learning (King, 2012). There are two ways in which contextualization may be of value: first, it can make school science more relevant to the lives of students, who consequently become more interested in the subject (España, Blanco, & Rodríguez, 2012); and second, it can help students to understand concepts they often find difficult (Gómez-Crespo, 2008; Furió & Domínguez, 2007), fostering the development of scientific competences that feature in the science curriculum (Caamaño, 2011).

Carbonated drinks, as an example of solutions, are present in students’ everyday lives and they have several features that are potentially of interest to students and which might be used to teach chemistry. Indeed, explaining many of the phenomena related to carbonated drinks implies reference to a wide range of chemical concepts, starting with how such drinks are produced (i.e. the preparation of solutions through the addition of sugar, colouring agents, carbon dioxide, etc.). An understanding of these phenomena may also encompass concepts such as concentration or the application of gas laws that depend on the relationship between pressure, temperature and volume. In our view, therefore, the topic of carbonated drinks provides a useful context for teaching the chemistry of solutions (Cañero, Blanco, & Oliva, 2015), and it offers interesting opportunities in terms of developing innovative teaching materials for use in the classroom. However, given the large number of inter-related physical and chemical notions involved, and the numerous practical implications of this, it is important to achieve a balance between context and scientific content (Kortland, 2007).
In the present study, context-based learning is combined with modelling. Reasoning in terms of models is a key activity in science education (Gilbert & Justi, 2016; Harrison & Treagust, 2000) as it brings together most of the scientific competences that are targeted by today’s science curricula. In the process of modelling, students’ initial models and conceptions serve to anchor the new models they are presented with in class (Oliva & Aragón, 2009). More specifically, and as Oliva, Aragón, and Cuesta (2015) point out in their study of modelling and chemical change, model-based reasoning requires epistemic skills and values that enable students to apply and modify their existing models and, successively, to develop different models. Thus, our aims in using modelling here were that students would learn to think about solutions, and the concepts that derive from them, in terms of models, and that they would be able to apply these models and/or (re)construct new ones.

Given the difficulties that students usually experience with this topic, we believe that a model of solutions should make use not only of the kind of propositional language associated with verbal definitions and explanations of phenomena but also of images, analogies and other iconic representations that provide both a static and dynamic view of the dissolved system and the process of dissolution itself (Raviolo et al., 2004).

Drawings, when used in this context (Gilbert & Treagust, 2009), may represent several important variables, and they can therefore be subjected to various kinds of analyses. In the case of solutions, for example, one might analyse a drawing with regard to the level of representation (macroscopic, sub-microscopic and symbolic), the nature of the mixture represented (homogeneous or heterogeneous) and ideas about movement (present or absent) associated with the different components of the mixture (Aragón, Oliva, & Navarrete, 2013).

One of the challenges in teaching students about the phenomenon of dissolution is that solutions are such a familiar presence in their everyday lives that they tend to rely on their own ‘common-sense’ conceptions, which can be difficult to modify in the classroom (Rodríguez-Mora, 2016). Therefore, from the point of view of context-based learning, it is important to identify students’ ideas and beliefs about a given context (in this case, carbonated drinks), as well as the scientific models associated with it (in this case, models of solutions).

The aim of this study was to determine whether students’ mental models about the composition of a carbonated drink are integrated or, rather, based on more disjointed notions of the phenomena involved. More specifically, we sought (1) to shed light on students’ understanding of carbonated drinks by examining their responses (in the form of drawings) to a specially designed task, and (2) to analyse whether their explanations of the phenomena involved correspond to relatively well-organized mental models or, on the contrary, reveal a disparate set of ideas lacking in coherence.

**METHOD**

In order to explore students’ explanations and mental models regarding the structure and composition of carbonated drinks we first considered that the latter have three main ingredients: water, sugar and gas. We then designed a task in which students had to depict in a series of drawings a volume of water to which sugar and gas were then consecutively added, such that
their final drawing represented a bottled carbonated drink. They also had to justify the content of each of their drawings.

This task had two distinct parts. The purpose of the first (A) was to explore the extent to which students were able to apply their knowledge or ideas about the nature of matter in order to represent a process of dissolution involving three substances in different states of aggregation. The second part (B) required students to apply these ideas to a specific context involving the same three substances, namely a carbonated drink. The task was completed by 119 secondary education students (55 from year 2, 41 from year 3 and 23 from year 4) during the final term of 2015.

All the students had received at least some teaching about solutions as part of the school science curriculum. However, when faced with the task, which required them to imagine the mixture of ingredients, many of them found it difficult to produce the drawings as they had not previously been required to work with models, and here they were being asked to generate their own. This may be an indicator of the limited extent to which modelling is used in the science classroom (Ácher, 2014).

Given that the aim of this study was to identify students’ mental models we selected those aspects of the required drawings that we regarded as most relevant to a model of solutions. These aspects were as follows: level of representation (macroscopic, sub-microscopic and symbolic) (Gilbert & Treagust, 2009), nature of the mixture represented (homogeneous or heterogeneous) and ideas about movement (present or absent) associated with the different components of the mixture. For the analysis of data we categorized the students’ drawings according to the extent to which they represented the dissolution state before (A) and after (B) bottling of the carbonated drink. Table 1 shows an example of this categorization for the responses given by three students. The categorization was carried out independently by two researchers, with any disagreements being resolved by means of consensus in a joint meeting.

### RESULTS

**Descriptive analysis of the dimensions considered**

We will begin by examining students’ responses in terms of the different dimensions we used to categorize their drawings (macroscopic, sub-microscopic and symbolic representation; homogeneous or heterogeneous nature of the mixture; movement of particles). The drawings we studied are those that included the three main components (i.e. sugar, gas and water) before

In the drawings referring to the stage before bottling (A), 69.7% of students offered a macroscopic representation of the water, drawing a wavy or horizontal line to indicate the water level in the receptacle. An even higher percentage of them (89.1%) illustrated the sub-microscopic dimension, using circles or dots to indicate the components of the mixture in the water. Only 10.1% of students, however, included a symbolic representation of one or more of the three components.

Regarding the nature of the mixture prior to bottling (A), the majority of students (61.3%) did not represent the idea of a homogeneous mixture. Instead, their drawings showed the ingredients as being distributed in layers, with the gas at the top or even overlapping the depicted water level, as if it were escaping from the mixture. In addition, these students’ drawings sometimes showed one of the components as being concentrated in a particular area, which is also contrary to the idea of a homogeneous distribution. By contrast, 35.3% of students did show the components as being homogeneously distributed, thereby transmitting the idea of dissolution.

With respect to the idea of movement of particles, only 14.3% of students depicted this in their drawings, and in all cases it referred to the gas, which was represented as being at the bottom of the receptacle and then escaping from the mixture above the water level.

This analysis suggests that a prototypical drawing of the pre-bottling stage would have the following characteristics: a macroscopic representation of the water and a sub-microscopic representation of the gas and sugar, with the components being heterogeneously distributed and without any depiction of the movement of particles. In general, therefore, the students’ representations are not consistent with the concepts on which kinetic molecular theory is based.
In the second part of the task, referring to the post-bottling stage (B), the first thing of note is the increase in the number of students who did not produce a drawing (see the category ‘No answer’ in Table 3), suggesting that students were less certain about the composition of the mixture in this case. In addition, the percentage of students who produced a macroscopic representation of the water (horizontal line in the neck of the bottle), or of the drink in general, was slightly lower (i.e. 63%) than in the pre-bottling drawings. As for the proportion of students who illustrated the sub-microscopic dimension, this decreased notably with respect to the drawings produced for the first part of the task (A), specifically from 89.1% to 68.9% of students. Instead, many of them simply used a single colour to represent the contents of the bottle. As in the first set of drawings, very few students (8.4%) represented the symbolic dimension.

With respect to the nature of the mixture, there were no major changes with respect to the first set of drawings, although there was a slight trend towards showing the drink as a homogeneous mixture.

The analysis in this case suggests two prototypical drawings of the post-bottling stage, both showing macroscopic and sub-microscopic representations of matter and the absence of movement of particles, but which differ in the extent to which they represent the ingredients as being heterogeneously or homogeneously distributed.

**Study of the relationship between dimensions of analysis**

After categorizing all the data in this way we then looked for evidence of global models of solutions among the students’ responses. Given that we were considering several variables, with different response levels, we applied multiple correspondence analysis for categorical data to students’ responses in each of the two contexts (A and B). The results obtained are shown in the form of plots in Figure 1.

**Figure 1. Plot of multiple correspondence analysis (drawings A on the left and drawings B on the right).**

Broadly speaking, the Cronbach’s alpha coefficients resulting from the two analyses may be considered as indicating the internal consistency of the ideas involved and, therefore, as a measure of the degree of coherence or integration of these ideas. In this respect, it should be noted that these values are fairly low, namely $\alpha = .35$ for part A and $\alpha = .40$ for part B. This
suggests that the responses given by the same student show a minimal degree of interconnectedness, since the different response levels for the variables considered at both points A and B are barely correlated with one another at the sample level. Thus, rather than having an integrated overview of the dissolution process, the students appear to offer somewhat random possible explanations in the form of a disjointed set of ideas or concepts.

In the two figures above, the proximity of values corresponding to different variables may be taken as an indicator of the degree of relationship between them. If we analyse the plots according to the categories shown in Table 1, then the students’ drawings at point A (Figure 1 left) show a relatively solid cluster of ideas related to homogeneity, a lack of movement, and both macroscopic and sub-microscopic representations, reflecting a certain prototype of the predominant set of responses. For the drawings at point B (Figure 1 right), two clusters can be observed, one the same as in Figure 1(left) and the other comprising ideas related to movement, heterogeneity, and sub-microscopic and symbolic representations. Note, however, the absence of a link between the sub-microscopic level and movement, and between movement and homogeneity, both of which would be central features of a kinetic molecular model.

CONCLUSIONS

The analysis suggests that students’ ideas about dissolution are disjointed and somewhat random, rather than indicative of an integrated overview of the processes involved. Furthermore, the clusters of concepts that are to some extent present do not associate the idea of movement with either the molecular level of representation or the homogeneity of the mixture, both of which are essential for an adequate understanding of the kinetic molecular model of matter. In light of these data, we conclude that our students have yet to develop global models for explaining or predicting the process of producing a carbonated drink. Modelling is, however, a crucial aspect of science education, since it constitutes one of the key elements of scientific competence. Therefore, it is important to engage students in tasks that require the development of models, this being an activity in which their initial ideas and notions can serve to anchor and scaffold their subsequent learning.

ACKNOWLEDGEMENT

INTRODUCTION OF OBSERVER DEPENDENT CONCEPTS INTO PHYSICS TEACHING OF MIDDLE SCHOOL

Ben Stein and Igal Galili
The Hebrew University of Jerusalem, Jerusalem, Israel

The concept of observer (frame of reference) is one of the most fundamental in physics. However, the physics curriculum of Israeli schools (as well as in its parallels in other countries) is based on the classic perspective of the 19th century and avoids dealing with modern epistemology of physics ascribing important role to the concept of observer. This by far holds regarding the curriculum of middle school which entirely excludes observer and observer dependent description of reality. This decision seemingly draws on the assumption that students of middle school are premature for dealing with answers valid for different observers. We intended to empirically check this assumption and investigate students' pertinent abilities. Our experimental teaching comprised 15 meetings with 9th grade students and addressed mechanical concepts from kinematics and dynamics. We examined students' success in elaborating chosen concepts in different frames of references in context of regular physics teaching. We found that 9th grade students succeeded in applying frame of reference accounts. They constructed graphs expressing dependence of displacement, distance, and velocity on time for different observers. We observed positive impact of learning observer dependence of mechanical concepts on students' understanding. The new teaching established a wider space of learning and allowed students to expand the validity area of the concepts. We argue that teaching observer dependence can be a powerful tool for achieving mature and genuine knowledge of classical mechanics and creating its adequate image by students already in middle school.

Keywords: observer-dependent concepts, physics curriculum, middle school

THEORETICAL BACKGROUND

The concept of observer is one of the most fundamental and important both in classical and modern physics. It was present in the scientific discourse varying in significance during many years. Galileo's principle of relativity directly related to the concept of observer is in the foundation of classical mechanics and remains such in modern relativistic theories. Such physics topics as equivalence principle, inertial forces, and concept definitions all involve observer dependence as an essential aspect. Basic kinematic concepts, location, velocity and acceleration are all observer dependent and science instruction cannot afford ignoring that. Yet, the adopted curricula usually avoid dealing with this aspect (Galili & Kaplan, 1997). Middle school curriculum adopted in our country totally excludes observer dependence, and it is barely mentioned in high school. The issue is considered to be as a sort of advanced content to be treated at higher education level. Practically, this implies an assumption that students of middle school are incapable of learning observer based concepts as requiring dialectical (many faceted) account. In a more general sense, the approach of single perspective was associated with the disciplinary knowledge of physical theories (Galili & Tseitlin, 2013). One may assume that presentation of concepts as observer-dependent is pedagogically more demanding. Yet, these cognitive and pedagogical claims of curricular limitations could be a subject of research based testing, given the great conceptual advantage of the inclusion of observer-
dependence into science curriculum, thus creating an adequate presentation of scientific knowledge.

**RATIONALE AND GOALS**

Our experimental study includes two main operative goals:

a) checking the ability of middle school students to learn observer-dependent concepts and handle their application;

b) constructing and testing the efficiency of observer-dependence integrated teaching.

Our rationale draws on the following arguments:

1. Positive results of this study will allow changing teaching physics and upgrading the curriculum. Currently, middle school physics includes numerous observer-dependent concepts (location, trajectory, displacement, velocity, force, kinetic energy, work). Yet, they are not taught as such.

2. Positive results of this study will allow upgrading the definition of force in school curriculum and imply legitimization of inertial forces in school physics and have impact on numerous misconceptions of force-motion relationship. Changing force definition showed a positive impact on students' knowledge with regard to weight concept (Stein & Galili, 2015; Galili et al., 2017).

3. Positive results of this study will allow teachers to draw on students' intuition based on their sense experience. Personal perspective will become legitimate in physical sense. The universal view often treats students' intuition as a misleading factor (inertial forces are identified as a misconception). Teachers ignore the account in non-inertial frame of reference, in favor of the unique perspective (Galili & Kaplan, 2002). Within the advanced approach, teachers will be able to start from students' intuition on the way to the inertial frames of reference, simplifying understanding as refinement instead of replacing (Grayson, 2004).

4. Positive results of this study will facilitate implementing constructivist pedagogy in physics teaching, known for its appealing power. Constructivist teaching requires a dialogue with students’ initial ideas rather than ignoring them. Multiple observers approach will recognize students’ initial ideas based on their intuition and "body knowledge" (Reiner & Gilbert, 2000).

**METHODOLOGY**

**Participants and Setting**

Our research has lasted three years and comprised two stages:

The first (pilot) stage, took a year and included experimental teaching students of 8th grade (N=16) from a regular urban school in Tel Aviv. The activities included:

i) Pre-test which probed students' ability to analyze some situations considered from different points of view, students' intuition in that respect and their "body knowledge" of certain
situations representative with respect to the considered concepts, students' content knowledge and their perception of the concepts that they were going to learn.

ii) 15 lessons in which the students learned the concepts of observer dependent nature in the domains of kinematics, interaction and forces, weight and gravitation.

iii) Post-test that assessed students' understanding of the subject matter and their pertinent abilities after the classes they took.

The pilot stage of the experiment included instruction to one group without control group since the main objective was to shed initial light on our goal, i.e. to probe the ability of middle school students to learn observer-dependent concepts and handle their application. The post-test results were indicative and testified that learning observer-dependent concepts by middle school students is feasible. The pilot's results justified proceeding to a more comprehensive instruction and investigation. Encouraged by them, we moved to the second stage in order to promote the reliability of our inference through expanding our test population, refine the instruction and refine our first inferences. Basing on the information from the first stage we further developed the instruction and examined its efficiency with regard to students' mastering of observer-dependence as integrated in the new conceptual framework of physics teaching.

The second stage of the study lasted two years and contained four groups (in each year we had a research and control groups) of 9th grade (N=117) of the same school. The research groups learned certain concepts as observer-dependent, whereas the students of the control groups learned the same concepts in the traditional way, avoiding dealing with their observer dependent nature. All the groups were taught by the same teacher. In the second stage, we administered two different post-tests: a) The first test was given only to the experimental teaching group in order to evaluate their knowledge and skills regarding the concept of observer, and b) the second post-test which was given to both groups in order to evaluate their knowledge and skills in comparison. The test drew solely on the subject matter from the traditional curriculum.

**Data Processing**

The data was collected via two open-ended questionnaires (post-tests) and was analyzed both qualitatively and quantitatively.

The first test included 14 questions and was given only to the research group. The test of each one of the students was examined separately for each of the subjects of knowledge learned in relation to the observer concept: Kinematic- four questions; Forces - four questions; Weight and Gravitation - six questions. The analysis of the students' verbal answers was based on several categories related to students' abilities with regard to the concept of observer, e.g. diagrammatic descriptions of forces in different frames of references, construction of appropriate equations, choosing an effective frame of reference etc. All the abilities examined are detailed in Table 1 below.

The second post-test was given to both the research and the control groups. It included 17 questions: Kinematic- seven questions; Forces - five questions; Weight and Gravitation - five questions. The questionnaire examined two levels of understanding and check students’ ability
to cope with ordinary familiar questions (from the syllabus), as well as challenging creative questions, which requires more in-depth thinking. Analysis of the data included: a) checking the correctness of the verbal answers of each student; b) grading each student for each subject (Kinematic; Forces; Weight and Gravitation) with separate reference to the two levels of questions (familiar/challenging questions); c) calculating the average score of each group (research and control group) for each subject; d) comparison between the research and control groups in each of the subjects according to the level of questions. t-test for independent samples (as appropriate in the coincided context) was applied to establish the statistical significance of the comparison between experimental and control group results.

**FINDINGS AND DATA ANALYSIS**

In the two post-tests, the first proved the capability of middle school students to handle observer-dependent concepts and the second investigated their advantages. We will introduce our major findings in accordance.

a) The findings regarding middle school students' capability to learn observer-dependent concepts and handle their application. Table 1 displays the results of the first post-test categorized in subjects and abilities.

Figures 1-5 introduce representative answers of the first post-test.

Figure 3 – a student wrote: "The observer that looks on the train from outside will notice that the train is changing its velocity, while the passenger proceeds in motion due to his velocity. This observer from outside does not infer about any force on the passenger." A supportive for diagram for the passenger appeared on the right.

The student proceeds to explain: "The observer that examines the passenger from the inside of the train will say that the passenger was standing still and suddenly started to fall forward. That implies the change of his motion. Therefore, this observer will conclude that a force was involved –the imaginary force $F_i$." A supportive for diagram for the passenger appeared on the left.

Figure 4 - With regard to the upper diagram, a student wrote: "The observer from inside can't see that the astronaut is continuously changing his direction of motion and therefore the observer will conclude that the net force on the astronauts is zero. Knowing about the gravitational force attracting the astronaut the observer will infer regarding the force in the opposite direction to the gravitation that nullifies it".

With regard to the bottom diagram, the student wrote: "In the eyes of the observer who is watching the astronaut from the outside – the astronaut is constantly changing his direction towards the Earth and therefore the net force on him is not zero".

Figure 4. Drawing a force diagram for an astronaut orbiting the Earth in reference to two observers.

Figure 5. Drawing the force diagram for a ball in circular motion in reference to two observers.

Figure 5 - With regard to the left diagram, a student wrote: "According to the observer on the rotating platform, the net force is zero, and this is reasonable because the observer see that the ball is not moving."

With regard to the right diagram, the student writes: "According to the observer that watching the rotating platform from the outside, the net force is not zero, and this is reasonable because the observer sees that the ball changes his direction as it rotates with the platform."
b) Findings regarding the efficiency of observer-dependence teaching over the traditional teaching in the control group

Given to the research and control groups, the second post-test covered only subjects from the curriculum itself and did not mention any observer. Yet, in order to carefully examine the difference between the groups we deliberately wrote two kind of questions. The first kind was regular questions familiar to the students, and the other kind was more challenging that requires more creativity and deeper thinking.

As appears in the following histograms (Graphs 1-3), the research group accumulated higher scores than the control group in the majority of the questions.
Table 2 displays the differences between the research and control groups grades segmented to two criteria: (a) ordinary familiar questions; (b) challenging creative questions.

</table>

The research group outscored the control group in all cases (by an average of 13 points in the familiar questions and by an average of 28 points in the unfamiliar questions). This difference was found significance (p<0.05 as practiced in educational studies) in all cases except for the ordinary familiar questions in the forces account. The statistical analysis of the average grade also shows that (Graph 4):

(a) The research group grades are significantly higher than those of the control group (F(1)=419.09, p=0.00).

(b) Students were significantly more successful in familiar questions than in unfamiliar ones (F(1)=35.02, p=0.00).

(c) A significant compound influence was found between the question kind (familiar/challenging) and the group type, so that the difference in average scores between the control group and the research group was significantly greater in challenging questions than in familiar ones (F(1)=16.235, p=0.00).

Beyond the numerical and statistical outcomes, the research group stood out in some prominent characteristics to be mentioned:

(a) The experimental teaching group’s writing was more accurate scientifically as the students referred in their account for the situation by mentioning the frame of reference used;

(b) The experimental teaching group used richer vocabulary and the students were more precise in using definitions;

(c) A considerable proportion of the experimental teaching group regularly introduced more than one solution to each problem. For example, one of the research group students used two explanations addressing the simultaneous falling of a heavy and light bodies. The student wrote: (1) "both bodies have the same velocity because the earth attracts the heavy body (greater mass) with greater force and therefore the acceleration is the same as the formula \( F=ma \) implies", (2) at the same time, using the operational definition of weight he wrote: "as they are
free falling - both bodies weight zero, and therefore it is reasonable that they will fall at the same time”.

Another finding worth a mention was that in questions that contained moving platform (passengers in a moving train or ship) a substantial portion of 30% to 62% of the control group solved the problem with respect to the moving platform even if it was accelerating (in odds with the traditional curriculum). This finding reapproved Galili and Kaplan (2002) claim that even good students fail in keeping with the requirement to dismiss inertial force (“internal driving force”) and use force account only within the point of view of an inertial observer.

Graph 4. Compound influence between the question kind (familiar/challenging) and the group type.

CONCLUSIONS

In this study, we received unambiguous answers of our major operative goals. The results clearly illustrated the positive impact of integrating the concept of observer in middle school science teaching. Our conclusions, thus, include the following features:

1. 9th grade students clearly showed their capability of understanding and applying observer-dependent concepts as in physical situations considered in a regular curriculum. The success of the teaching is apparently connected to the fact that the free choice of frame of reference well matched students' daily experience, intuition, and "body knowledge". No resistance or significant difficulty to the new account while considering several frames of reference was recorded. This assertion holds with both kinematic and dynamic concepts. It is further supported by the significant effect of the first post-test average score of 80 (18) in kinematics, 76 (20) regarding forces and 81(15) regarding weight, weightlessness and gravitation.

2. 9th grade students succeeded in producing graphical dependence of displacement, distance, and velocity as a function of time in different frames of references.
3. Learning kinematical concepts as observer-dependent is not only feasible in middle school but it actually enhances students’ understanding of the considered concept in, and seemingly because of, the variety of perspectives.

4. 9th grade students were clearly successful in drawing a force diagrams with respect to inertial and non-inertial frames of references (a passenger in an accelerated car, falling elevator, orbiting satellite, etc.).

5. 9th grade students can successfully handle complementary definitions of weight, theoretical and operational.

6. Students who learned the curriculum contents integrated with observer dependent concepts outscored the students that learned in the traditional way. The difference was found as statistically significant: 13 points in the familiar questions ($t_{(115)}=4.129$, $p=0.000$) and 28 points in the unfamiliar questions, ($t_{(115)}=6.115$, $p=0.000$).

7. Students that learned the curriculum contents integrated with the concept of observer wrote in more scientific and restricted manner, showed richer vocabulary, used concept definition more precisely, applied multiple strategies.

8. Teaching the concept of observer and observer dependence of physical account significantly helped the students in achieving mature and genuine conceptual knowledge of classical mechanics. In fact, without considering frame of reference (inertial and non-inertial observers), teaching classical mechanics cannot appreciate the Galileo’s principle of motion relativity — one of the most important, actually, central claim of the classical mechanics.

DEVELOPMENT AND EVALUATION OF SCIENCE CLASSES USING A PLANT FACTORY AND LEVERAGING THE STEM MODEL

Shuichi Yamashita and Masato MIYASHIMA
Chiba University, Chiba, Japan

The purpose of this research was to develop a learning program contextualized around the plant factory and making use of the STEM model, and to evaluate the science lessons. The plant factory was installed in a public junior high school because Urayasu City lacks agricultural land, such as fields for rice or other crops. As the plant factory allows the manipulation of plant growing environments, it was decided to have the students compare growth states in both light and dark environments using bean sprouts. 51 junior high school students received 100 minutes of instruction by using the observation set with the reading material, and their understanding of photosynthesis was evaluated by a pre-test and post-test. The research yielded the following three results: (1) The students recognized how plant factories work and solve issues such as food problems; (2) The students came to understand the fact that photosynthesis occurs in green parts with chloroplasts; and (3) The students became capable of correlating photosynthesis with the structure and function of each organ.

Keywords: STEM, plant factory, photosynthesis

INTRODUCTION

In recent years, countries all over the world have begun focusing on education in the fields of science and technology, and in the U.S., STEM education is emphasized as a priority in science and technology related policies. STEM education collectively refers to education in science, technology, engineering and mathematics, and in the U. S., it has become a strategy for developing personnel in the field of technology. In 2012, A Framework for K-12 Science Education was published as a model for STEM education in the U. S., and the publication discussed three aspects: Practices, Crosscutting Concepts and Disciplinary Core Ideas. Next Generation Science Standards (NGSS), published in 2013, emphasize the connection between science and engineering. The standards point out that a coupling between practice and contents gives context to learning, and that students will become capable of applying what they learn by integrating practice and contents, as a focus on practice results in too many activities and a focus on content results in memorization.

In Japan, the definition of STEM education remains vague, and Kumano (2016) points out that most of what is called STEM education frequently lacks the concepts that form the core of scientific basics and all of their foundations. Shiota et al. (2016) point out the difficulty of ranking STEM education as a specific subject for the purpose of introducing it into Japan. In particular, engineering doesn’t exist as a subject in primary and secondary education, and the concepts are not even taught. In addition, most STEM learning programs on physics are focused on manufacturing, such as robot creation, etc., and there are a limited number of learning programs on biology.
On the other hand, Japan introduced its first plant factory in 2016 using an empty public junior high school classroom in Urayasu City, Chiba Prefecture. The actual plant factory consists of the small-sized (6.0m×2.5m×2.1m) plant factory shown in on the left in Figure 1, and six mobile, van-mounted plant factories as shown on the right in Figure 1. The plant factory was installed in a public junior high school because Urayasu City lacks agricultural land, such as fields for rice or other crops, as the majority of the city is built on reclaimed land, and this location would allow the students to experience seeding, transplanting and harvesting vegetables, etc.

![Figure 1. Small-sized plant factory and mobile plant factory](image)

Currently, two students are selected from each class as Environment Officials who conduct seeding, transplanting and harvesting. Class activities have included students designing the exterior of the small-sized plant factory in art classes, and cooking the harvested lettuce in home economics classes. There have been discussions about bringing the topic up in science classes during the unit on photosynthesis and energy, but this has not been realized.

Therefore, the purpose of this research is to develop a learning program contextualized around the plant factory and making use of the STEM model, to enact this program in science classes conducted at an actual junior high school, and to verify the results.

**METHOD**

**Development of a learning program contextualized around the plant factory**

1) *The STEM model and plant factory activities*

The plant factory is capable of controlling the plants’ growing environment, such as lighting, air conditioning, nourishing solution, etc., and capable of growing plants inside the classroom regardless of season or weather conditions. Applying the activities conducted in the plant factory to the STEM model, it is possible to include each STEM element, as shown in Table 1.

2) *Placement of the program within the science class*

Fifth graders in primary school conduct observations on plant growth within the context of studying “plant germination, growth and fruition” while regulating environmental conditions, and they investigate and compare plant growth based on both factors. Sixth graders conduct control experiments on photosynthesis using leaves within the context of studying “plant nourishment routes,” and confirm using an iodine-starch reaction the existence of starch within leaves that have been exposed to sunlight.
Table 1. Activities at the plant factory as applied to the STEM model

| S: Science       | · Observation of germination and growth  
|                  | · Observation of the structure and functions of plant bodies  
|                  | · Observation of the interaction between living organisms and the environment  
| T: Technology    | · Plant growing technologies  
|                  | · Construction of plant growing environments  
|                  | · Plant harvesting technologies  
| E: Engineering   | · Plant growth control  
|                  | · Improvement of plant growing environments  
|                  | · Plant harvesting  
| M: Mathematics   | · Measurement of plant bodies (length and mass)  
|                  | · Calculation of water solution concentration  

The textbooks from the main five textbook writing companies summarize the process as, “Starch forms in leaves when they are subjected to sunlight,” but this description fails to mention the existence of chloroplasts. However, the following description was found at the end of the unit in the textbook from one company: “Photosynthesis uses sunlight to turn water and carbon dioxide into oxygen and nourishment, such as starch, inside leaves.”

First graders in junior high school deal with photosynthesis within the context of studying the “structure and functions of plant bodies” in “Plant Life and Species.” The purpose is to learn the basic structural characteristics of the leaves, stems and roots of seed plants, and to achieve understanding by relating these to photosynthesis, respiration and transpiration through plant observation. In regard to colors and chloroplasts in plants, only one of the five main textbook companies included the following description: “Chloroplasts are found in all green parts of a plant, not only the leaves.”

Kudo (2001) points out that, when studying photosynthesis in primary school science classes, etc., students focus only on experiments that confirm the occurrence of photosynthesis in leaves, but this leads to the belief that photosynthesis does not occur in the stem and other parts even though they also contain chloroplasts. Based on the results of a survey of university students, Uno (2005) also points out that students lack the basic understanding of photosynthesis that “photosynthesis occurs in all parts containing green chloroplasts,” and he points out the existence of the mistaken notion that “photosynthesis only happens in leaves.”

Due to these findings, it was decided to show students in the class on the “structure and functions of plant bodies” conducted in the first year of junior high school that photosynthesis occurs in all green parts containing chloroplasts, within the context of the plant factory, and to provoke thought by relating photosynthesis to the structures and functions of each organ.
3) Learning programs contextualized around a plant factory and that make use of the STEM model

As the plant factory allows the manipulation of plant growing environments, it was decided to have the students compare growth states in both light and dark environments using bean sprouts, which junior high school students are also familiar with. When kidney beans are germinated in dark environments, the hypocotyl grows abnormally long, the cotyledon become small and yellow, and they become the white sprouts that the students typically eat. However, when germinated in light conditions, green cotyledon form, and the plant becomes green as it performs photosynthesis. It was decided to develop a learning program that could dispel mistaken notions regarding photosynthesis and in which students could achieve understanding by correlating the functions of each organ as they observe these results.

a) Development of an observation set

For the sprouts, it was decided to use green bean sprouts germinated from Phaseolus aureus seeds (Figure 2).

First, Phaseolus aureus seeds were placed one by one into moist hydroponic sponges. Two days after planting, after the Phaseolus aureus seeds germinated, they were transplanted into van-mounted plant factories with either a light or a dark environment. The light environment was set up to be illuminated by LED lights for the ten hours from 8:00 to 18:00 . The dark environment was not illuminated by LED lights, and the plants were shielded by covering the windows of the van in black paper, etc. Firm, robust, green leaves and stems appeared in the light environment thirteen days after planting (Figure 3). Whereas, the dark environment showed more extensive growth as the stems grew to several times the length of the stems in the light environment.

![Figure 2. Phaseolus aureus seeds](image1)
![Figure 3. Thirteen days after planting](image2)

An observation set was developed so the students could observe growth states as the learning program took place over a two class periods. A, B and C in Figure 4 show the growth states four days, eight days and twelve days after planting, respectively. The red portion on the left side shows those grown in the light environment, and the black portion on the right side shows those grown in the dark environment. Using the observation set made it possible to observe growth states in both light and dark environments within a short period of time.
b) Development of written educational materials

In order for the learning program to be able to take place within two class periods, in addition to the observation set, written educational materials (Why are sprouts white? The Relationship between Greening and Photosynthesis in Plants) were developed to achieve understanding by correlating photosynthesis with the functions of the entire plant body using the observed findings.

First, students reviewed what they had previously learned about photosynthesis, and a focus was placed on the green coloring in plants. Next, "sprouts" were brought up as a non-green vegetable, and the students were asked to predict what would happen if sprouts were grown in light and dark environments in the plant factory. Using the observation set, students observed the state of "sprouts" grown in light and dark environments in the plant factory. Examinations were conducted individually and in groups. In addition, the program was structured so that students could deepen their understanding of photosynthesis while reading sections titled “Experiment and Observation Summary,” “The Green Color in Plants and Photosynthesis” and “Various Vegetables and Chloroplasts.”

Design and Participants

The science class was given to 51 first-grade students in two classes at a public junior high school in Urayasa City. The class was conducted over the course of two class periods (one period: 50 min) as a supplementary learning program within the unit on “The Structure and Functions of Plant Bodies.” First, the students were given a ten-minute long preliminary survey on the day before the class.

In the first class period, the students made groups of four to five people, and decided on a leader. The written educational materials were then passed out, and the history behind the establishment of the plant factory as well as how it works was explained. Efficiency and safety regarding plant factories as well as the fact that plant factories are expected to become a new industry were also explained.

Following this, the class proceeded in accordance with the written educational materials, and the students reviewed that photosynthesis requires carbon dioxide, water and light energy and that oxygen is formed as nutrients are synthesized through photosynthesis. In addition, the explanation touched on the fact that chloroplasts are green because they contain a green
pigment called chlorophyll. Each group was asked to think about non-green vegetables, and about whether or not non-green plants contain chloroplasts and conduct photosynthesis. Sprouts were brought up as an example of a non-green vegetable, and the students were asked to predict what would happen if sprouts were grown in a light or a dark environment in the plant factory. For this, the students used the observation set, and observed the growth state of sprouts in light and dark environments in the plant factory. Students identified that 1) plants in the light environment became green, and those without light became white, 2) the stems of the plants in the dark environment grew long, and 3) the roots of the plants in the light environment grew well. The students recorded their examinations individually.

In the second class period, students reviewed the previous class, and talked in groups about the differences in sprout growth between light and dark environments. The groups came to consensus and reported their opinion.

Following this, the lesson was summarized in accordance with the written educational materials, and a summary was made of “The Green Color in Plants and Photosynthesis” and “Various Vegetables and Chloroplasts.” Finally, a partially green taro potato was given to each group, and the students were asked to think about whether it is a stem or a root. The learning contents were organized using the “Class Summary” page, the class ended, and the students were given a follow-up survey.

Data Analysis

In Question 1, students were asked to select one of four stages “4: Very applicable,” “3: Applicable,” “2: Not very applicable” and “1: Not applicable” in regard to the following items (i) ~ (vii) both before and after the class, and the results were scored from 4 to 1.

(i) I can explain what plant factories are.
(ii) I want to take a class and conduct activities using the plant factory.
(iii) I think the plant factory can solve issues in modern agriculture.
(iv) I am interested in new technology.
(v) I am interested in science-related occupations.
(vi) I think studying science is important.
(vii) I enjoy discussing and solving problems using scientific knowledge.
Question 2 focused on the color of plant bodies, and students were asked to select in part (a) whether or not it is possible to determine that photosynthesis will occur if the green parts contain chloroplasts, and to write the reason in part (b).

The correct answer for part (a) was that photosynthesis “will occur” in “green leaves on a bell pepper plant,” “a green stem on a bell pepper plant” and “green peppers on a bell pepper plant,” and that photosynthesis “will not occur” in “white roots on a bell pepper plant” and “white flowers on a bell pepper plant.” Each question was worth two points, so the section was worth a total of ten points.

Part (b) focused on chloroplasts, and students received two points if they were able to write that photosynthesis will occur because green organs contain chloroplasts. One point was subtracted for incorrect answers. Question 2 was worth a total of twelve points, combining parts (a) and (b).

In Question 3, students were asked to explain the reasons for the colors and growth states of the leaves, stems and roots of green plants in the experiment using light and dark environments in the plant factory.

In regard to “color differences,” the correct answer for the color of leaves “that grew while exposed to light” was “green,” for stems it was also “green,” and for roots it was “white.” The correct answer for the color of leaves “that grew without exposure to light” was “yellow,” for stems it was “white,” and for roots it was “white.” Each question was worth one point, so the “color differences” section was worth a total of six points.

In regard to “growth style differences,” students received one point each if they were able to write about differences in shape in plants that grew while exposed to light and plants that grew without exposure to light, so the “growth style differences” section was worth a total of six points.

In regard to “reasons,” students received one point each if they were able to write about shapes and colors. Since there is no difference in the color of roots, students received two points if they were able to write about two or more of the three aspects relating to differences in shape: length, thickness and number. The “reasons” section was also worth a total of six points.

Therefore, Question 3 was worth a total of eighteen points as “color differences,” “growth style differences” and “reasons” were worth six points each.

RESULTS

The results of examining the preliminary and follow-up surveys using the Wilcoxon signed-rank test to determine the existence of any significant change between before and after in regard to items (i) ~(vii) in Question 1 are shown in Table 2.

In addition, the results of the preliminary and follow-up surveys regarding Questions 2 and 3 are shown in Table 3, similar to Question 1. In regard to Question 3, the results are also shown separately for leaves, stems and roots.

DISCUSSION AND CONCLUSIONS

In regard to items (i), (iii) and (vii) in Question 1, a significant difference, with a standard of 1%, was found between the results of the preliminary and follow-up surveys. From these findings, it could be said that, through the class, students came to understand how plant factories work and came to recognize that plant factories are a means to solve issues such as food problems, and that students learned that it is enjoyable to discuss and solve issues using scientific knowledge. In regard to items (ii) and (vi), no significant difference was found between the results of the preliminary and follow-up surveys. The school where the survey was implemented is a pilot school for science, and the items already had the high average score of 3.25 at the time of the preliminary survey, so the lack of a significant difference was because the two-period long class was unable to evoke new interest in classes using the plant factory or fresh importance for studying science. In regard to items (iv) and (v), no significant difference was found between the results of the preliminary and follow-up surveys. The class failed to generate interest in technology and scientific careers.

In regard to Question 2, a significant difference, with a standard of 1%, was found between the results of the preliminary and follow-up surveys, as the question focused on plant body colors, it was possible to deepen understanding of the fact that photosynthesis occurs in green parts with chloroplasts.
In regard to Question 3, a significant difference, with a standard of 1%, was found between the results of the preliminary and follow-up surveys in all questions relating to each organ type: “leaves,” “stems” and “roots.” In regard to differences in color and growth states for each organ in a green plant due to the existence/non-existence of light, students became capable of correlating photosynthesis with the structure and function of each organ.

Due to these findings, it can be said that students were able to deepen understanding of the fact that photosynthesis in plants is conducted by green chloroplasts and that photosynthesis in plants is a function of the entire plant body that is mutually related to the functions of each organ, and it could be said that it the effectiveness of the developed science class was verified.

This research was conducted as a supplementary learning program in the form of a two class period long learning program contextualized around a plant factory within the unit on the “Structure and Functions of Plant Bodies” in the first grade of junior high school. As mentioned above, it was possible to achieve good results, but it was not possible to generate interest in technology and scientific careers that emphasize STEM education within the two period long learning program. It would likely require continued interaction with STEM education to change the perception of junior high school students on these matters. In addition, many of the answers to Question 3 were only half completed as it was not possible to secure sufficient time to conduct the follow-up survey due to the fact that there is little leeway in the junior high school curriculum. There is likely room for improvement in regard to this as well.

A SUMMARY LECTURE AS A DELAY ORGANIZER OF STUDENTS’ KNOWLEDGE OF MECHANICS — A DISCIPLINE-CULTURE APPROACH

Ehud Goren and Igal Galili
The Hebrew University of Jerusalem Israel

The study proposes a new educational tool – a delay organizer to support meaningful learning of physics. In particular, we emphasized a theory-based knowledge of physics and a hierarchical structure of physical theory. The instruction was embedded into a summary lecture which reviewed the major content of mechanics exemplifying nucleus, body and periphery of the theory of classical mechanics. The goal was to promote students' cultural content knowledge in this domain of school physics. The study included construction of a summary lecture and the assessment of its experimental application in high school (11th-12th grades) and educational college (preservice teachers of science). Some results of qualitative and quantitative assessment are presented. They indicated the efficacy of such intrusion and its positive impact on students' holistic knowledge and conceptual understanding. Besides, the instruction caused an increase in student interest in the subject matter presented in conceptual variation expanding the traditional disciplinary curriculum.

Keywords: discipline-culture, delay-organizer, summarizing lecture of school mechanics

INTRODUCTION

In the process of learning science, construction of meaningful knowledge and holistic understanding of the subject matter remain in focus of various researches. Science traditionally seeks establishing structural knowledge, a theory, with a hierarchical arrangement of its components. The progress in science manifests itself in introduction of new elements of knowledge and restructuring of the previous conceptions. This process establishes disciplinary discourse. Yet, in the common disciplinary teaching teachers usually present the scientific products without their background in a scientific discourse, ignoring the consolidation of the knowledge taught. Physics education research informs about the low effectiveness of such approach. Marton argues for addressing the conceptual variation and creation of the learning space in which the concepts emerge (Marton et al., 2004). Tseitlin and Galili (2005) introduced discipline-culture (DC) conceptual structure which besides emphasizing the basic concepts of the theory (nucleus) secured an explicit space for conceptual variation – periphery. The body knowledge of this structure contains multiple applications of the fundamentals. Teaching the curriculum of the new type intends to upgrade students' knowledge from disciplinary to cultural content knowledge – CCK (Galili 2012). The construction of CCK can be reached in several pedagogical ways. Of them, the most compact one is a summary lecture at the end of a traditional disciplinary course (Levrini et al., 2014). It is directed to restructuring of the knowledge gained in the regular course, to provide the hierarchy of the concepts and reveal their rivals from other theories. In short, it should serve as a delay organizer of students’ knowledge. The study by Levrini and colleagues addressed the knowledge of optics. This study addresses the contents of mechanics as taught in high school. Mechanics is the first theory students' encounter in physics class. We will present some results of our study, among them,
the choice of contents of the summary lecture on mechanics matching the format of discipline-culture, the impact on students' conceptual knowledge and their attitude to physics.

**Background**

We have first examined the textbook commonly used in mechanics of 11th grade of our high schools (e.g. Rozen, 2013). *College Physics* (Sears & Zemansky, 1988) may serve as a parallel resource among English language textbooks in physics. Such teaching provided laws, concepts, models, experiments, applications, all in sequentially unfolding manner, from the simpler to the more complex. The great amount of knowledge elements, related in various ways emerge to the learner. The strong emphasis is normally put on problem solving which supposed to indicate students' understanding and ability to apply the knowledge in concrete situations, qualitatively and quantitatively. The textbooks often have no conceptual summaries, sometimes listing the presented laws, concepts and formulas. Such presentation of the continuously growing amount of knowledge elements without hierarchical structure may produce an impression of learning as a simple accumulation: the more we learn the more we know. The students are left with only intuitive idea regarding relative importance of the concepts, practically lacking a big picture of the subject matter. The orientation of the teaching to the matriculation examination direct the class activities to solving standard problems normally leading to instrumental understanding (Skemp, 1972). The relationships of theory and reality, theory and models, laws and principles, validity limits usually – the nature of the scientific knowledge – remain a subject of intuitive coverage. There is no hint to how the knowledge currently presented in the class consolidated in a discourse among alternatives; why the concepts we learn were preferred and some others dropped.

**Delay organizer based on the discipline-culture model**

To upgrade the traditional teaching and introduce hierarchical organization of knowledge elements in a meaningful system, it was suggested to introduce triadic model for representation of disciplinary knowledge and emphasize the major ideas from the pertinent disciplinary discourse (Tseitlin & Galili, 2005). Actually, the triadic model expanded regular axiomatic organization of disciplinary knowledge – nucleus-body (similar to the organization of Euclidian geometry) – to a structure possessing an additional type of knowledge elements – periphery. The new structure converted discipline to discipline-culture (DC) providing the learners with the big picture of the subject matter in educational context.

The DC approach reveals the hierarchical organization of the subject matter in terms of a tripartite structure. It includes nucleus (basic principles and concepts), body (the derived theoretical and affiliated empirical laws, models, solved problems, experiments, etc.) and periphery (knowledge elements in contradiction with the conceptions of the nucleus). This classification promotes students' understanding of the conceptual meaning of the items they learn. By affiliating an item of knowledge to the triadic structure, the learner appreciates the conceptual variation and constructs the meaning of the item in several aspects, hierarchical, constructional, relational, and methodological. Matching each considered element of knowledge with the introduced structure, the need to consider its affiliation (to the nucleus, to the body, or to the periphery) reveals the status of knowledge elements and establishes their
meaning. This way the teaching causes understanding of the nature of scientific knowledge – cultural content knowledge of the subject (Galili, 2012).

A question arises how to apply DC approach, what pedagogical strategy to apply in order to provide students’ construction of CCK. Facing the common disciplinary instruction, Levrini and colleagues (2014) introduced a summary lecture of the school course of optics which sought arranging the knowledge of students in terms of DC – serving as a delay organizer. Here we report about the attempt to introduce and assess the same approach to the course of school mechanics, which is the central in the course of school physics and establishes the foundation of physics knowledge, as well as the science in general, on behalf of school students.

THE EXPERIMENT

At the first stage of our study, we had to adopt the DC perspective to the mechanics curriculum as adopted in our schools. For that, we reviewed the high school textbooks and constructed a summary lecture facing the problem of identification of the nucleus, body and periphery of the theory mechanics as presented at schools. We, then, applied the experimental teaching to a representative sample of the student population (regular classes of 11th and 12th grade) and preservice teachers of science from an educational college. The knowledge of the participants was assessed.

The experiment included a sequence of activities: pre-test questionnaire, lecture of about 90 minutes (two periods of regular teaching), post-test questionnaire, class discussion of the same duration in a week after the lecture and a few clinical interviews with the individuals chosen for their verbal skills shown in the class discussion.

The questionnaire was designed in open-question format given the novelty of this teaching and lack of information about possible impact of this type of contents on the students. The questionnaire included the questions used in the previous studies where they showed their validity and effectiveness (Levrini et al., 2014) and developed teaching materials from the HIPST European developmental project of 2008-2010 (Galili, 2012, 2013). The questions addressed the following aspects:

1) The holistic perception of mechanics;
2) The perception of basic elements of scientific knowledge (concepts, theory, laws, models);
3) Conceptual understanding of some problems in mechanics;
4) Understanding of theory validity/correctness;
5) The meaning of being proved in science;
6) Alternative conceptions in mechanics (the older conceptions);
7) Students’ confidence and motivation.

Some of these dimensions were added following the classroom discussion. They were included only in the post-instructional questionnaire and the interviews. Each topic was probed by more than one question, to enhance the reliability of the results and reveal a more refined picture of
students’ knowledge constructed regarding the same conceptual issue in more than a single context. The questionnaires were administrated in a regular class environment in 40 min. periods. The experiment was performed at the end of the study year during which mechanics was taught.

**Format of the experiment**

Our sample (Table 1) included participants from four classes of upper secondary school (11th and 12th grade) and two groups of preservice science teachers (educational college).

To increase representativeness of the sample, it comprised of classes from two different types of schools, regular and dedicated to sciences. College students were from two different areas of the country. The groups were taught by different teachers. Yet, the classes were checked to be approximately equal with respect to their heterogeneous social background and learning achievements making the sample representative for student population of the educational system. The experiment covered an academic year during which, teaching, observations, class discussions, assessments and data analyses took place.

**Lecture contents**

The challenge of developing summary lecture was significant. Apparently, we had to address only the most important elements of knowledge in classical mechanics. In the DC structure, that implied the focus on Newton's laws of motion – the nucleus of classical mechanics. This content was contrasted with the alternatives of the periphery of the classical mechanics – the Aristotelian and medieval accounts of motion. The lecture addressed the First Newton's Law of motion as the central conception of classical mechanics defining the natural state of motion a subject of change under the influence of the external force applied on the body (Galili & Tseitlin, 2003). The Second Newton's Law was introduced as a quantitative refinement of the First Law, and the Third Newton's Law was introduced to facilitate the expanding of the account to several bodies in interaction. The summary, thus, emphasized the central importance of the First Newton's Law and its status in contrast to the frequent considering it to be merely a special case of the Second Law.

The Newtonian paradigm was presented. It included the concepts of point masses, the state of natural motion, the instant velocity and acceleration, the force as the cause of continuous
change motion state of uniform motion, inertial mass, the central interaction of all masses at a distance – gravitation, absolute and mutually independent time and space. Furthermore, the students found the concept of mechanical energy and its conservation in mechanics as elements of the body knowledge deduced from the nucleus – Newton’s laws of motion. Figure 1 displays the aspects which were associated in presenting the First Newton's Law.

Figure 1. Newton's First Law as a context to address central aspects of classical mechanics

As already mentioned, DC organization obliged to address the conceptual accounts of motion alternative to that of Newton – the periphery. In particular, we presented the Aristotelian claims regarding natural and violent motion, their law-like regularity expressed in modern way, in exact parallel with the Second Newton's Law. The medieval theory of motion – the theory of impetus was presented as the second alternative conception of motion. The struggle of Galileo, Descartes and Newton with the two alternative accounts of motion were mentioned establishing the enlarge space of learning of the classical account. Inertial mass was introduced as the account for the resistance to the change of motion state in contrast with the previous understanding as the “resistance to motion” (preserved as a misconception).

The limits of validity of classical mechanics were explicitly stated determining the meaning of “correct” with regard to classical mechanics. In accordance, the status of being proved was defined as a procedure of displaying coherence of the claim or solution with the tenets of the particular theory, in our case – classical mechanics. The presentation addressed the concept of models and their types distinguishing among the models in the nucleus (such as point masses, instantaneous interaction), body of knowledge (such as inclined plane, simple lever, mathematical pendulum) and periphery (such as Aristotle’s positional weight, natural and violent motion, medieval dispersed impetus).

**Data processed**

The assessment prior and post the lecture provided us with rich data which was analysed qualitatively and quantitatively. Within the *qualitative* analysis, the students’ answers were processed in several steps. Firstly, students’ answers, their explanatory patterns or strategies employed, were grouped around the categories which we considered to be important.
characteristics of students' conceptual knowledge of mechanics. This grouping allowed us in the following to characterize students' representative views on classical mechanics. This structure presenting conceptual and procedural knowledge can indicate clear advantages of the applied teaching.

Within the quantitative analysis of the data, the achievement score was ascribed to students' performance prior and after the lecture. Separation of the scores among the questions and categories of knowledge indicated the impact of the instruction in specific dimensions beyond the total improvement. The quantitative results could provide a reliable evidence of effectiveness of the applied teaching beyond episodic indication.

**FINDINGS**

**Qualitative results**

In the following, we mention several categories that were important for characterizing students' knowledge in the perspective of conceptual validity and exemplify each of them by illustrative quotations from students' answers.

- **Relationship of concepts within and out of classical mechanics**
  
  *It provided the relation among what we learned in mechanics, tied the concepts together. (T1-10)*

  *It helped me to know what is Newton’s theory comparative to that by Einstein, and what is the reason that we still use one instead of the other in each case. (S12d-4)*

  (*the codification includes the code of the sample group (Table 1) following with the the number identifying the participant in the group

- **Elucidating impact of the lecture in the eyes of students**

  *The lecture surprised me, open my eyes and changed my perception of motion (S12r-7).*

  *Knowing how Newton stated his second law and the form Euler provided to it helped me understand how things emerged, made me comfortable with the formulas. (S12r-12)*

  *It was very good to tie formulas, fit them together with theories. (T1-14)*

- **Lack of conceptual structure in regular teaching**

  *To be able to answer we need to learn lots of “stuff” more… (S12r-9)*

- **The students' need of structural perspective**

  *This structure helped me to arrange the known and order it all in my head. It was good… (S11r-3)*

  *An inclusive big picture view is very important to us. It is something that can help us to understand the course. ( S12d-12)*

  *We are able to organize the material and that helps us to understand Newton's laws. (S12r-13, S11d-4)*

- **Appreciation of periphery of obsolete theories**

  *The example of the obsolete knowledge element which was removed to periphery but returned back to nucleus was very impressive. (S11r-4)*

  *It was good to see different views on the same thing [subject] (S12r-4)*
It’s very important to know from where the wrong concept comes, on what it relied on... so we can get remedy of our wrong understanding... (T1-5)

Knowing about the “other” knowledge helped us to learn and clarify our understanding. (S11d-11, T1-7)

Due to the old ideas we learned what is more important and what is less. (T2-3)

• Appreciation of periphery in making misconception a serious issue instead of embarrassing matter

I know how to solve problem but motion still feel as motion have something like internal force to move it. I know now that it is a wrong idea but couldn’t resolve the conflict. The summary lecture clarified it to me, especially the notion of state of a body. (S12d-9).

• Appreciation of knowledge genesis

We talked before on Newton’s First Law but still, it was like floating, we never connected it to anything, now I feel the connection. (T1-8)

The understandings how things develop help me specifically feel comfortable with the law formulation. (T1-15)

I liked the history of how the notion of atom moved from nucleus to periphery and then, later, back to the nucleus. (S11r-4)

• Triggering students’ curiosity and interest

[Enjoyment] It was very interesting and overall it’s good to learn on new things. (T1-14)

I don’t really like physics but I found the lecture very interesting. (T1-1)

[Enrichment, imagination, solidarity, getting narrative] I like the historical anecdotes at side of the lecture its increase my curiosity on histories facts.(S11d-7, S12r21, T2-1)

I would like to know also about physicist’s background and their relationship with culture and knowledge evolution. (S11d-8, S11-7)

[Surprising, new perspective] The summary showed us a different perspective from that we were regular in physics class. (S12r-13)

Aristotle force definition and mass as resistance for the change of state was of a real surprise. (S12d-10)

[Getting self-confidence, removal of the tension] It helped me not to fear from physics classes... well done. (T1-3)

It changed my perception of physics... I also feel more confident with the wrong concepts that can help. (T1-15, S12r-4)

[It] emphasizes and contrasts the right theories. Thanks for that. (T1-10)

“Element relation” which was very interesting and helped me feel better with what we learned already. (T1-15)

[Guiding further learning] The lecture enabled me to criticize knowledge and develop my own view on the material we learned in the class. (S11d-7)

It guided my reviewing of previous understanding. (S11d-10)

...as it helps to examine physics knowledge in different ways and creates interest in deeper understanding of the whole picture. (S11d-12)

• Cognitive resonance of teaching and students perception. Potentially possible teaching (ZPD idea of Vygotsky, 1986)

Actually, things were familiar to me, but I did not know to answer to the direct question about them before (T1-1)
I understood it, I don’t know how to explain but I felt it (S11r-8)...
Because we already knew the scientific method, it’s not that we don’t know... but lots of the things were intuitive (S12d-9, T1-1)...

Quantitative aspect

We exemplify the results of the quantitative assessments by showing the change of students’ scores in several aspects important for evaluation of conceptual knowledge of mechanics. Table 2 presents the evaluation results of students’ answers drawing on the twenty questions of the pre and post questionnaires after they were analysed regarding the aspects of better or new understanding following the summarizing lecture on mechanics. The final scores and improvement (the increase of the score from the pre to post results) are displayed.

DISCUSSION

This study has touched on the fundamental aspect of physics education – the conceptual knowledge of the students with respect to its meaning, nature and hierarchical organization. Its ambition is to try to cause a change of students' knowledge based on a single summary lecture. Our data testifies to a certain success in the specific aspects as mentioned in Table 2.

We have observed a special interest of students and prospective teachers in addressing the fundamental items of classical mechanics known to the physics educators for their complexity and multiple misconceptions. It might be especially emphasized that such issues as the role of the First Newton's Law (changing the view that it presents a special case of the second Law), the nature of physics knowledge (changing the view that it coincides with reality), hierarchical arrangement of knowledge elements (changing the view that everything learned in the course is equally important in the conceptual structure of mechanics), concepts understanding (such as mass, momentum, state of motion, rest-motion equivalence, interaction), the issue of area of validity of classical mechanics (as replacing the view of a mere intentional correctness of classical mechanics) – all and others attracted interest as novel aspects, practically not addressed in the regular teaching and learning. In that sense, the provided lecture not only summarized but taught and caused a significant impact.

The versatile interest recorded on behalf of the numerous participants revealed the affective aspects of the cultural approach in knowledge presentation – curiosity and interest of students to subject matter, on the one hand, but also to the holistic view (big picture) of knowledge of mechanics as fundamental theory of nature, philosophical aspects of epistemology and ontology of physics. The students of different experimental groups were similar in discovering for themselves the aspects of physics they either wanted to clarify or agreed that that knowledge should be considered for its perceived importance. Another affective aspect was recorded in the rise of students' confidence, removing the tension caused by unknown origin of the mechanics laws as if imposed upon them without any choice. The discovery of the historically performed choice helped to get remedy of strong misconceptions of force-motion relationship and impetus conceptions which appeared to be central alternative theories of classical mechanics. The knowledge of Classical mechanics strengthened, as a student mentioned: “We talked before on Newton’s First Law but still, it was like floating; we never connected it to anything, now I feel the connection.” (T1-8) ...

Structuring the knowledge in hierarchical manner helped the students to understand the meaning of the theory of mechanics. This confirmed our expectation of summary lecture possessing the DC-structure of knowledge elements: nucleus-body-periphery. The presence of periphery triggered the new understanding of knowledge correctness. Instead of the obscure view that all scientific knowledge is merely tentative (e.g. Lederman, 2007), the lecture stated the area of certainty and correctness of the classical mechanics with respect to the alternative theories of the past (the Aristotelian conception of motion and the medieval theory of impetus) on the one hand, and with the modern quantum and relativistic theories valid for the reality at a very small scale (quantum theory of elementary particles) and very high speeds and masses (the relativity theories), on the other hand (“Due to the old ideas we learn what is more important and what is less.” (T2-3) ...)
The students liked dealing with periphery with regard to misconceptions (“...we need more discussion of misconceptions (T2-8...), finding an opportunity to identify familiar to them conceptions (“I know from now that my views are wrong but still couldn’t get answer how to resolve the conflict”(S12r-19)...”) which added interest in knowledge evolution.

The periphery helped the students to visualize knowledge development as exchange of elements between nucleus and periphery. They said: “I liked the example of how Atom notion move from nucleus to periphery and back”. (S12d-9)

Another interesting finding was a positive cognitive resonance taking place when the provided knowledge fit the intuitive perception of the subject matter. Some students stated then that they “actually” knew the novel material of the instruction. The phenomenon could be explained by reference to the concept of Zone of Proximate Development (ZPD) introduced by Vygotsky (1986). The phenomenon was observed by Levrini and collaborators (2104) with regard to optics knowledge. We observed it with respect to structure of mechanics. Students said “Actually things were familiar but I didn’t know how to give direct answer before”. (T1-1). If so, using the DC structural representation of knowledge obtains a serious support as an approach with high chances of fast and effective adoption by the learners.

Finally, it is of importance to emphasize the obtained evidence of the especially convenient setting established by DC structured summary for addressing the important features of the nature of science (NOS) and scientific knowledge (e.g. Erduran & Dagher, 2014; Lederman, 2007; Matthews 2012). While reviewing the knowledge of mechanics in the delay organizer, we inevitably touched on the features of knowledge considered to be central: theory-reality (observation-inference) relationship, theory-based organization, theory-law-principle-model relationship, concept consolidation and definition, certainty-tentativeness of knowledge, the status of being proved in science, etc. The very representation of mechanics in terms of nucleus-body-periphery already equips the teacher and students to deal with this issue in a concrete visualized manner.

CONCLUSION

This study has shown the promising potential of the idea of delay organizer of mechanics. The initial experimental results testified of positive and effective impact of the post-course summary lecture on the meaningful upgrading of students' knowledge in a series of aspects of central importance. Among them, the hierarchical conceptual structure of mechanics knowledge, its fundamental concepts, the features of scientific knowledge and its theory based organization. This approach essentially based on the discipline-culture triadic structure was well accepted by students' interest and curiosity. We, thus, were encouraged to proceed our research in further more comprehensive studies of the suggested improvement of school curriculum and teaching methods.

THE EFFECT OF LEARNING EXPERIENCES USING EXPERT CONCEPT MAPS ON UNDERSTANDING CELL DIVISION PROCESSES

Ines Radanović1, Žaklin Lukša2, Diana Garašić, Mirela Sertić Perić1, Branka Gavrić3, Valerija Begić4 and Daniela Novoselić5

1 Faculty of Science, Zagreb, Croatia; 2 High School Josipa Slavenskog, Čakovec, Croatia; 3 Primary School Tar-Vabriga, Poreč, Croatia; 4 Primary School Sesvetski Kraljevec, Sesvete, Croatia; 5 Alfa doo., Zagreb, Croatia

The aim of the present study was to determine the effect of previous different learning experiences in using expert concept maps (ECM) on understanding cell division processes. The study included 219 elementary school students aged 13, whose task was to create their own concept maps (CM) following the same set of guidelines and 30 key-terms. Four groups of students were distinguished, based on differences in CM application within the learning process. Based on our results, we could conclude that learning based only on ECM demonstration does not contribute to a better students’ understanding when compared to quality teaching without the CM application.

Keywords: concept construction, biological concepts understanding, previous learning experiences

INTRODUCTION

The use of concept maps (CM) for instructional purposes has grown significantly over the last three decades, as they “provide a useful and visually appealing way of illustrating students' conceptual knowledge” (Zeilik et al. 1997; Jones et al. 2012). The application of CM during learning process brings significant improvements to understanding and problem solving compared to traditional teaching methods (Hsu, 2004; Gonzalez et al., 2008; Kumar et al., 2011). Conceptual mapping was developed by Novak in 1972 as a part of scientific research dealing with student knowledge changes during natural science teaching (Novak & Musond, 1991). It has been confirmed that CM greatly facilitate student understanding and enable meaningful learning, because they serve as a template in organizing and structuring facts and overall knowledge (Novak & Cañas, 2007). Concept mapping enables students to actively process information and organize their knowledge within a CM (Noonan, 2011). As it is known that our brains organize facts and knowledge in a hierarchical structure, concept mapping likely enhances memorizing, knowledge application and meaningful learning (Bransford et al., 1990; Tsien, 2007). Rice et al. (1998) suggested that CM can also be used in assessing and evaluating different (i.e., declarative and procedural) knowledge categories. Many teachers and students are often surprised by the effects of such an easy tool and its profound impact on meaningful learning, long-term knowledge retention and application of knowledge in different contexts (Novak, 1990, Novak & Wandersee, 1991).

Different CM can lately be found in natural science textbooks, most often at the end of the teaching unit, as one of the methods of repetition and systematization of the learning materials (Novak & Cañas, 2007). They are often used as media for constructive and collaborative
learning activities, and as communication aids in lectures and other study materials (Cañas et al. 2003). Thus, CM have been used by teachers (to assess students’ understanding), by students (to collaboratively compare their knowledge and understanding), and by experts (for modeling and sharing knowledge) (Reichherzer & Leake 2006). Using expert concept maps (ECM) as advanced organizers within learning process improves knowledge organization and integration, and enhances deeper understanding (Cutrer et al. 2011).

As provided through experiential learning, training students to take control and responsibility for their learning can greatly improve their ability to learn from experience (Kolb and Kolb, 2005). Following the experiential learning premises, Novak and Cañas (2007) suggest as necessary to introduce different activities into CM, as it could demonstrate students’ learning abilities, especially those demanding more skills and understanding complex concepts, which are often needed for shaping CM. One of the possible activities, which is recognized as a valuable incentive for meaningful learning, is completing ECM, whereby students review partially completed CM and fill in missing parts (Rendas et al., 2006). Montpetit-Tourangeau et al. (2017) suggested that teachers should continuously use the concept mapping and CM completion techniques – even to the same learning topics – as it encourages meaningful learning including problem solving and acquiring practical knowledge. The same authors further suggest that learning by using CM provides more benefits than learning by using poorly shaped practical tasks – both to students who already have some basic conceptual knowledge as well as to those who meet the same concepts for the first time.

The aim of the present study was to determine the effect of previous learning experiences in using ECM on understanding cell division processes, which have been recognized as a very challenging teaching topic. We hypothesized that the application of ECM during the teaching process could help students in continuous learning using the CM, which could then further enhance shaping and organizing of CM by students. We also anticipated that the application of ECM during the learning process would increase the students’ abilities to later independently apply and develop CM as an additional learning tool that would enhance their conceptual understanding.

**METHODS**

The present study encompassed 219 elementary school students (7th graders) aged 13 taught by 4 teachers, which all follow the same curriculum and use the same biology textbooks and ECM. Subsequent to learning on cell divisions, all students were asked to create their own CM following the same set of guidelines and 30 key-terms (Table 1).

Four student groups were observed:

1) **continuously taught by using ECM and constructing CM:** students continuously taught by application of ECM and construction of CM during the learning process (E1, 14%),

2) **offered to use ECM as a support for individual learning:** students who were offered to use ECM as a support for individual learning (E2, 34%)

3) **occasional demonstrations of the ECM:** students who have occasionally experienced a demonstration of ECM during the teaching process (E3, 26%),

169
4) basic experience in CM usage: students without an experience in teaching with ECM and actively using the CM, but having a basic exercise for their usage (E4, 26%).

Based on the guidelines proposed by Novak & Cañas (2008) and following a list of criteria, the hierarchical structure, key-terms and -concepts, linking words and cross-links as well as conceptual understanding within each student CM were analyzed and scored (Table 2).

By the analyses of the students’ CM, an ECM was created, which served as a template for determining the evaluation scores (Table 2). All the terms and concepts from the individual CM were counted, classified into several categories (relevant justified, irrelevant justified, irrelevant unwarranted), and then scored according to the listed criteria (Table 2). After the term analysis, the same procedure of counting, classifying and scoring was applied to the linking words and cross-links used within the individual CM. Terms and concepts described as
‘relevant justified’ were selected before the CM analyses according to the relevant biology textbooks.

To enable a simpler verification of the concept acquisition, the key-concepts used within the students’ CM were sorted into the higher-level concepts: Inheritance, Reproduction, Mitosis and Meiosis.

Differences in mean score values (for each evaluation element described within the Table 2) between student groups (E1, E2, E3, E4) were analysed by the non-parametric Kruskal-Wallis H test followed by the Mann-Whitney U test, which was used as a certain post-hoc comparison in order to detect the specific and significant between-group differences, with Rosenthal sample effect size (r) for quantifying the mean difference between two groups. Kolmogorov-Smirnov Z test was used to analyse conceptual understanding of students based on the number of understandable concepts. The significance level in all tests was set at .05. Because of the low and unequal sample sizes, the non-parametric statistical tests were used. Given that there was only one CM evaluator, the degree of reliability was not specifically determined. All statistical analyses were performed using SPSS 22.0.

RESULTS

Taking into consideration the basic CM features important for facilitating the conceptual understanding (Novak & Cañas 2007), Kruskal-Wallis test (H = 19.45; d.f. = 3, p < .01) as well as paired between-group comparisons performed by Mann-Whitney test (Table 3) confirmed the conceptual understanding differences between the four tested student groups, and significantly weaker conceptual understanding of the students belonging to group E3, when compared to the other groups.

Terms. Students belonging to the group E1 (continuously taught by application of ECM and construction of CM during the learning process) used the most terms (M = 38.55 ± 14.625) for constructing their CM. As expected, the lowest number of terms (M = 28.35 ± 10.582) was used by students without a previous experience in using ECM and/or CM (group E4) (Figure 1).

Cross-links. The student ability of conceptual understanding of the terms used for constructing the CM was assessed by number of Cross-links (Figure 2) and Linking words (Figure 3) within the CM. Again, E1-students, which were continuously taught by application of ECM and/or
CM, gained the highest score means for the cross-links (M = 53.29 ± 39.126), whereas other groups (students with less experience in the usage of CM) obtained similar mean scores ranging from 29 to 31 points (Figure 2). As expected, the highest score for the cross-links (152) was achieved within the group E1. The lowest score (-83) was observed in the group E3 consisting of students who have occasionally experienced a demonstration of ECM. The observed low score was mostly due to the usage of poorly directed links (observed in 17 out of 57 CM, i.e., at 29.82% of students), which gained a certain amount of negative points. Furthermore, it might be that the students were exposed to the demonstration of the various (E)CM forms and/or were not actively involved in interpretation of the presented concepts and/or were not fully following the teachers’ instructions.

**Figure 2.** Mean numbers of cross-links used by the four student groups to depict connections between the key-terms and -concepts within CM

*Linking words.* The highest score (108) and the highest mean score for linking words (M = 38.80 ± 25.164) were obtained by students belonging to group E1. The lowest score (-11) and the lowest mean score (M = 18.89 ± 15.470) for the linking words were observed for the students without an experience in using CM. *Linking words* was the evaluation element yielding a greatest difference between the E1 and other student groups.

**Figure 3.** Mean number of linking words used by the four student groups to explain terms and concepts within CM

*Hierarchical levels.* For this element, students achieved unexpectedly poor results (Figure 4). The lowest number of hierarchical levels (3) was depicted by students who were offered to use ECM as a support for individual learning (E2). Within the same group, the highest observed
score (15) for this element was observed. However, in comparison to other groups, the mean score for hierarchical levels (M = 3.45 ± 4.017) in group E2 was the lowest. The highest mean score for this element (M = 5.45 ± 3.341) was observed for the students who have occasionally experienced a demonstration of ECM during the teaching process (E3).

![Graph showing average hierarchical levels built in CM by the four student groups]

**Figure 4.** Mean numbers of hierarchical levels built in CM by the four student groups

**Conceptual understanding.** Regarding the mean number of the understood concepts (M = 3.7 ± 9.6) (Figure 5), students demonstrated rather weak conceptual understanding, although it significantly differed between the groups (Kolmogorov-Smirnov test, Z = 3.049; p < .0001). Considering the higher-level concepts, students generally clustered most concepts around Inheritance (44%), whereas at least around Reproduction and Meiosis (18%). Demonstrating understanding up to three concepts more than other groups, E1 students were most successful (Figure 5). E2 students evidenced to understand in average only 1-2 key-concepts within each higher-level concept, except within Inheritance, where they showed slightly better results. These students also depicted the lowest number of linking words and cross-links, but not significantly lower compared to E3 and E4.

![Graph showing mean scores achieved by the four student groups for criteria attributed to conceptual understanding]

**Figure 5.** Mean scores achieved by the four student groups for criteria attributed to conceptual understanding

The results of the Kruskal-Wallis H test proved that the observed between-group differences in conceptual understanding are statistically significant (Table 3). These differences are likely due to the different usage and students’ experiences in the application of (E)CM during the teaching process. The paired between-group comparisons performed by Mann-Whitney test indicated that the group experiencing occasional demonstrations of the ECM (E3) significantly
differed from all other groups regarding the conceptual understanding (Table 3). There was a moderate sample size effect on this trend (Table 3). Mean number of terms used by the four student groups within the CM also yielded significant differences (accompanied by moderate sample size effect) between E1 and all other groups. The same trend (accompanied by low to moderate sample size effect) was observed for the mean numbers of linking words and cross-links used to describe and depict connections between the key-terms and concepts within CM constructed by the four student groups. Mean numbers of hierarchical levels yielded statistically significant differences between the group E1 (continuously taught by (E)CM) and E2 (using ECM for individual learning) as well as between the group E2 and groups E3 (occasionally demonstrating ECM) and E4 (without experience in CM).

With an aim to simplify the concept acquisition, the key-concepts used within the students’ CM were sorted into the higher-level concepts: Inheritance, Reproduction, Mitosis and Meiosis. Mean scores (M = 3.72 ± 9.612 on a score scale spanning from -10 to 20) achieved by the four student groups for criteria attributed to conceptual understanding of mitosis and meiosis indicated a weak understanding of the concepts. However, the conceptual understanding significantly differed between the groups (Table 3).

To assess the influence of the previous students’ experience in CM usage on the conceptual understanding of mitosis and meiosis, the following between-group comparisons were done: within each higher-level concept, a mean number of lower-level concepts understood by students was compared (Figure 6). For the purpose of this analysis, groups E3 and E4 were grouped together. It was done because when analysing the concepts of mitosis and meiosis within CM constructed by students belonging to these two groups, a remarkable similarity in the presented concepts was observed (in using terms as well as linking words and cross-links). Most students used terms and concepts that could be clustered under the higher-level Inheritance, and the least students used the concepts belonging to Reproduction (Figure 6). The far most successful in understanding the higher-level concepts were students continually taught by using CM (Figure 6).
When compared to other groups, only E1 students showed significantly higher levels of creative thinking and conceptual understanding, which was evident through the diversified CM patterns, i.e., modulated usage of the given key-terms and addition of new relevant terms (i.e., linking words and cross-links) used to explain concepts and to depict connections between the key-terms and -concepts, evidencing the level of the student conceptual understanding.

**DISCUSSION AND CONCLUSIONS**

The present study evidences that only students who were continuously taught by means of ECM and systematization of knowledge by creating their own CM have successfully adopted cell-division concepts foreseen by the curriculum. Schwendimann (2016) suggested that in constructing CM, experts often use the same linking words as beginners, but they create more complex CM-patterns. It might also be the case with students in creating CM, because those students with more intense experience in ECM and CM usually exhibit greater success in demonstrating their knowledge within CM. The same was suggested by Montpetit-Tourangeau et al. (2017), who found that CM constructing and studying leads to higher conceptual knowledge at least for advanced learners.

Our results correspond to many previous observations suggesting that implementation of student-created CM greatly enhances students’ identification of internal connections among terms and concepts, and supports the thesis that “the way in which knowledge is structured by an individual determines how it is used” (Mintzes et al. 2005 and references therein). 

Due to differences in the students’ learning skills, intelligence (Gardner, 1983) and learning style (Kolb & Kolb, 2005), both students and teachers, initially experience resistance to the presentation of ECM. For this reason, it is very important that ECM is slowly introduced within teaching process, and accompanied by a detailed teachers’ explanations. Only the students with well-guided examples can learn how to properly use and construct CM to support their own learning. Based on our results, we could conclude that learning based on ECM and/or only their demonstration, does not contribute to a better students’ understanding when compared to quality teaching without the CM application.

Students who were offered to use ECM as a support for individual learning showed minimum understanding and linking concepts, because they likely relied on the presented ECM when
creating their own CM. As well, they tried to “make a perfect copy” of the ECM, paying more attention to technical details than to their own understanding, which resulted in many mistakes.

Most students initially have many problems in developing CM and meaningful learning, likely as a result of learning 'by heart' during a longer time period. When constructing a CM, students face the need for creative thinking, which is not required for learning 'by heart'. For this reason, Novak and Cañas (2007) suggested that besides practical instructions for concept mapping, students should be informed on learning skills, styles and mechanisms that might be engaged during 'organizing' and 'mapping' the (new) knowledge. The process of 'creating' new knowledge involves not only presently known terms and concepts, but also emotions in a sense of desire to search for new knowledge (Novak & Cañas, 2007).

In learning by means of ECM, a reflection interview as a knowledge integration activity (Tripti et al. 2016), and an expert reference map as an aggregate of several expert-generated maps (Schwendimann 2016) could be included, as it might encourage students in the proper use of ECM. We should definitely further investigate how teachers’ experience in the application and interpretation of the ECM could enhance students’ understanding within the teaching and learning processes.

ACKNOWLEDGMENT

We are grateful for the access to the spss software package and practical support given by the centre for educational research and development (cerd), institute for social research in Zagreb.

CHEMISTRY TEACHERS’ PEDAGOGICAL SCIENTIFIC LANGUAGE KNOWLEDGE

Silvija Markic
Institute for Science and Technology – Chemistry Education, Ludwigsburg University of Education, Ludwigsburg, Germany

Learning of scientific language and its proper use in science classes is one of the main aims of science teaching. However, it is widely known that students have different problems both understanding and using scientific language. Furthermore, science teachers are a key factor in promoting changes in science lessons. Their actions in the classroom are influenced by their personal knowledge and beliefs. Therefore, the aim of the present case study is to develop an instrument which can portray their knowledge about teaching and learning of scientific language in chemistry classes. Starting from the definition of Pedagogical Content Knowledge (PCK) by Loughran et al. (2006) and Pedagogical Language Knowledge (PLK) by Bunch (2013) a concept of teachers’ Pedagogical Scientific Language Knowledge (PSLK) will be defined. The study explores the development of and instrument representing teachers’ PSLK for teaching and learning scientific language in science classes. The present case study is based on open interviews with 11 science/chemistry teachers with regard to their knowledge concerning scientific language but also about teaching and learning of scientific language in the chemistry classroom. The results show that it is possible to develop a tool examining science teachers’ PSLK. Furthermore, the study reveals that levels of teacher PSLK tend to be quite low and in many cases represents a naïve or intuitive view of teaching of scientific language. Science teachers generally know only a few methods for teaching scientific language. Most of them do not really pay attention to it in detail during their lessons. The results will be presented and discussed. Recommendations for pre- and in-service science teacher training will also be made.

Keywords: chemistry teachers, pedagogical scientific language knowledge, scientific language

INTRODUCTION

“Science does not speak of the world in the language of words alone, and in many cases it simply cannot do so. The natural language of science is a synergistic integration of words, diagrams, pictures, graphs, maps, equations, tables, charts, and other forms of visual mathematical expression.” (Lemke, 1998)

The quotation above is listing different characteristics of scientific language. In the first insight it is clear, that there are many differences to the everyday language of our students in science lessons in general and chemistry lessons in particular. Starting from here and from the interviews with different science and chemistry teachers, language, students’ linguistic skills in general and the focus on teaching and learning of scientific language, is seen as one of the main barriers in learning the new content in science in general and chemistry in particular.

It must be also said that looking to the different studies about science teachers´ view on science and language, in most of the cases the teachers see a dichotomy between language and science (Moore, 2007). It is to assume that this could follow the idea that hard science and the humanities are two extremes in the spectrum of scientific domains. Thus, many teachers do not see the need to teach the language in their science classes or to pay attention to this issue.
Explanations differ starting from “lack of time”, “focusing on the content” to “not the part of my job”. Furthermore, the science teachers are not very sensitive to students’ linguistic difficulties and do not feel competent or even responsible to deal with such problems during their science teaching.

Speaking about the language and taking a look to our classrooms today, differences in students’ linguistic skills must also be taken into account, especially focusing on those students with poor linguistic skills. In addition to the students’ issues of using the official language of the country they attend the school in, there are also issues considering the scientific language. The importance of the use of scientific language in science lessons is not a new component in science education; it is a necessary component of understanding the subject matter (Hodson & Hodson, 1998). The scientific language is new to the students and the students’ learning of a scientific language can be understood as a learning of a foreign language (Childs & O’Farrell, 2003). This is truth for only some of the words of scientific language e.g. chemicals and materials. However, the difference comes up when we talk about the scientific terms which describes different phenomena. Learning of a foreign language means to learn new terms for phenomena that are already known. To learn the scientific language conversely means that the phenomena and the ideas / the content should be learned in parallel to the technical term that is to be learned. To speak “chemish” (Markic and Childs, 2016) is inextricable from learning its technical terms, symbols, or syntax of structuring information.

The question must be allowed if the chemistry teachers know how to teach scientific language. Looking to the curricular for different university English/French teacher education programs noticeable and common is, that student teachers for both subjects study the characteristics of the language and also language learning theories. Though science teachers need to teach new and foreign language to their students (scientific language), however, special seminar or lecturers explicitly focusing on teaching and learning of scientific language are hard to find. At some university programs only a few sessions during a module are having this topic on their curricula.

Finally, information about science teachers’ knowledge about teaching and learning of scientific language remains largely undocumented. To take the first step in closing this gap, this pilot study attempted to develop an instrument to describe the learning and teaching of scientific language. Furthermore, the aim of this project is to collect initial insights into science teachers’ knowledge in this area.

**SCIENTIFIC LANGUAGE**

The importance of language for learning chemistry has been known for a long time and has been discussed recently in several places and well summed up in e.g. Taber (2015). However, its relevance and presence of the topic language in general and scientific language in particular in science education research and in the teaching and learning of chemistry change. Over decades, language was not seen as an issue. In teaching chemistry, the main linguistic focus was seen only as the learning of nomenclature and new technical terms, and this was seen mainly in term of memory work (Fang, 2006). In our days, researchers are much more aware that the role of language in the teaching and learning of chemistry is more diverse and
challenging, especially with the changing nature and diversity of the student population in language, culture and ability (e.g. Childs, Markic & Ryan, 2015; Markic, Broggy & Childs, 2013).

For understanding chemistry lesson and learning new scientific content knowing its language is a necessary component (Hodson & Hodson, 1998). Speaking the scientific language of chemistry belongs to the culture of chemistry as well (Aikenhead, 1997; 2005). However, this language is new - and often strange - to the students and the learning of a scientific language can be understood as a learning of a foreign language (Butzkamm, 1989). Speaking chemish is inseparable from knowing the rules of the language and its characteristics, its technical terms, symbols, or pattern of structuring information, e.g. in a write up of a laboratory report or presenting the interpretation of the experiment. Summarizing, in our days every teacher – here especially a chemistry teacher - is a language teacher as well – independently from the subject domain they are teaching. Hers or his teaching of scientific language will contribute to the development of general language abilities of the students as well.

Independently from the language and persons’ background, it takes a considerable time and effort to learn and become fluent in a new language. The fact is that the language of chemistry can be interpreted as being a new language to a student. The learning of scientific language is much more difficult for students because they not only have to learn the semantic, they have to learn and understand the meaning of the word and the phenomenon.

For our students the scientific language in chemistry lesson is new and different from their everyday language in many respects. The language of chemistry:

- Changes the meaning of words from their everyday life use towards a specific scientific concept, e.g. volume (space occupied by an object vs. loudness of music), substitute (replacement vs. extra football player), solution (homogeneous mixture composed of two or more substances vs. result of the math task)
- Uses technical and specialized vocabulary of science (e.g. names of lab equipment), rarely met in everyday life, which is like learning foreign language vocabulary,
- Introduces a special symbolic language of science, particularly chemistry, which is a language in its own right – with an alphabet (element symbols), words (chemical formulae) and sentences (chemical equations) language (e.g. element symbols, formulae, equations),
- Characteristics of the symbolic language different to spoken scientific language, e.g. H₂O spoken as two hydrogens and one oxygen,
- Applies mathematics in science (symbols, equations, operations) and its own specialist vocabulary, often poorly transferred from mathematics to science classes,
- Asks for interpretation and labelling of graphs, diagrams, flow charts etc. in a scientific context
- Operates specific logical argumentation patterns in scientific arguing and writing, e.g. in a lab-report.
PEDAGOGICAL SCIENTIFIC LANGUAGE KNOWLEDGE

The construct of Pedagogical Content Knowledge (PCK) is very familiar to science education researchers and common agreement exists about its usefulness. Content Representations (CoRes) (Loughran et al., 2006) were initially developed as a tool for examining the in-service teachers’ PCK for different topics. These CoRes could be used to represent such knowledge of the teaching profession and to stimulate its further development. A CoRe is a detailed framework for describing science content knowledge, knowledge of how students learn in particular science content areas, and different teaching strategies, based on Shulman’s (1986) categories of knowledge. A CoRe is a matrix that lays out the larger ideas for teaching a particular topic, as well as aspects of teaching each idea.

Pedagogical Scientific Language Knowledge (PSLK) is defined as teachers’ Pedagogical Language Knowledge (PLK) with the focus on scientific language of chemistry. Pedagogical language knowledge is defined as a “knowledge of language directly related to disciplinary teaching and learning and situated in the particular (and multiple) contexts in which teaching and learning take place” (Bunch, 2013, p.307).

Starting from here, Pedagogical Scientific Language Knowledge (PSLK) is defined as knowledge of scientific language related to teaching and learning chemistry, focusing on different scientific topics and contexts.

The importance of the use of scientific language in science lessons is not a new component in science education. However, information about science teachers’ knowledge about teaching and learning of scientific language remained largely undocumented. Therefore, the aim of the present case study is to develop an instrument which can portray science teachers’ Pedagogical Scientific Language Knowledge. Furthermore, the aim of this project is to collect initial insights into science/chemistry teachers’ PSLK in this area.

RESEARCH QUESTIONS

Starting from the background of PCK and the importance of the scientific language, the aim of the present study it to see which Pedagogical Scientific Language Knowledge as defined above do science teachers (here focus on chemistry teachers) have when it comes to teaching and learning of scientific knowledge.

Furthermore, the question is also if scientific language can be seen as a “content” on its own or is it a part of different contents. Therefore, the question is also, if the CoRe is a good representation form for the science teachers’ knowledge about teaching and learning of scientific language in science classes.

Starting from here, the present case study is done in the meaning of a pilot study and is about to answer two research questions:

1. How can an instrument portraying science teachers’ Pedagogical Scientific Language Knowledge be constructed?
2. Which Pedagogical Scientific Language Knowledge do science teachers possess?
METHODS AND SAMPLE

Since no theories previously existed for predicting science teachers’ knowledge with respect to the inclusion of scientific language in their lessons, qualitative data in the frame of open interviews was collected in order to answer the named research questions. First, science/chemistry teachers were asked for their age, sex, and teaching experience. Furthermore, information about their linguistic background and knowledge of foreign languages were collected. The second part of the interview started with the question “How do you teach scientific language? Please describe it.” (Question translated from German by the author). No further questions were asked, except in the case that the interviewer did not understand a statement made in the answer.

Data was collected in the city-state of Bremen, north of Germany. All of the teachers involved taught in different schools. In each previous PISA study, Bremen had consistently achieved the lowest scores possible when compared with the other German states. Bremen also has the highest rate of both households disinterested in education and unemployment. Thus, Bremen can be compared with other areas of high population density in Germany and can used as a representative sample for this case study.

Data was collected from 11 teachers (6 female and 5 male), who mainly teach chemistry and biology or chemistry and physics (teaching two subject domains is typical for German system). All of them stated that about one-third to one-half of their students have linguistic difficulties in the German language. All of them speak German as a native language (typical for Germany) and have more-or-less complete knowledge of one other language (normally English).

DATA ANALYSIS AND RESULTS

This study is based on open interviews. One of the main issues of the pilot study was to identify the kinds of information which could be possibly evaluated from the initially collected data. Because there is no theory to serve as a starting point, the analysis of the interviews was performed using Grounded Theory (Strauss & Corbin, 1990). The interviews were open coded. All the details that the science teachers named were listed. Open coding included all elements providing information about teaching methods, problems and limitations, objectives, textual approaches etc. From this source, axial coding was then carried out to achieve cyclical improvement of the data. The codes from open coding were combined together into categories. Using the context of CoRe, these categories were labeled as ideas. Areas representing six ideas about teaching and learning of scientific language were evaluated:

1. Terms and definitions are contextually tied to the subject matter of the school subject.
2. Scientific language distinguishes itself through various characteristics, which separate it from the everyday usage of similar words.
3. Scientific language is comparable to the learning of a foreign language.
4. Scientific terms used in the science are not necessarily foreign words and are often used in areas outside science to mean other things.
5. Scientific terms are ordered according to a hierarchy of weighting, which determines when and in what measure they appear in lessons.

6. Each science area possesses its own, specific scientific terms.

In the selective coding phase, each idea was connected using a scale of eight questions as developed by Loughran at al. (2006). The science teachers interviewed made a list of statements about the six ideas named in CoRe about teaching and learning of scientific language. The statements covered the aims of learning scientific language, the sense behind the learning of scientific language, legitimations of the idea, the influences of the idea in science teaching and lessons, choices of possible teaching methods for teaching of scientific language, and learning strategies available for students, including the problems and limitations present in science lessons when it comes to scientific language in general.

All the steps were carried out with permanent comparisons of the authentic data. Two researchers independently filled in the CoRe matrix. Their results were then compared and the independent coders negotiated final agreement (Swanborn, 1996).

The results show that the participants` knowledge about teaching and learning of scientific language is homogeneous. It is surprising to note that no differences exist between beginning teachers and those with more than 20 years of experience. All of the teachers in the study were aware of the importance of scientific language. However, their knowledge of the teaching methods and characteristics of scientific language, including the importance of knowing about languages, remains quite low and shows itself to be intuitive in almost all cases.

However, the science teachers` teaching methods in the present study differ from one teacher to another. All teachers have in common to write down the new (as they said “important”) word on the black board, underline it or write in a red color. General it can be said, that explicit teaching of scientific language is less important for the teachers. Most of the teachers rely on their experience or the experience of their mentors in schools saying that students were learning scientific language “along the way” during the lesson and thus, the focus can be put on content learning. Finally, they see scientific language equal to foreign language. Most of them compare learning of scientific language to learning of foreign language in school.

CONCLUSIONS AND IMPLICATIONS

The present case study indicates that it is possible to design an instrument for identifying science teachers` PSLK about teaching and learning of scientific language. To sum up, this case study reveals that the science teachers interviewed possess very little knowledge of teaching and learning scientific language. Additionally, the study delivers an instrument which serves as a starting point for further improvements within the larger group of science teachers. Thus, data will be collected from an extended sample of teachers in order to better validate the developed tool.

Some implications should, however, be addressed. The instrument which was developed can be used as a tool for further developing pre- and in-service science teachers` PSLK. Furthermore, it can be employed as a tool for meditation and reflection (Hume & Berry, 2011). This will aid science teachers and teacher trainees to move across the knowledge boundary by
identifying and exploring key pedagogical issues related to scientific language in teaching and learning with the help of university educators. In-service teachers can not only collaborate with pre-service teachers when designing such an instrument, but also when evaluating and reflecting upon an already existing one. Within the framework of in-service teacher training, it can be used as a tool for a self-reflection and self-assessment. In summary, the developed instrument can be used as tools for stimulating pre- and in-service metacognitive awareness of teachers’ professional knowledge and may aid in developing it further.

The most worrying aspect however in this study is that the participants seem to not have an extended knowledge about teaching and learning of scientific language in their science classes. For some of them it can be said that they also do not see the need to teach scientific language explicitly and see it as one of the goals of their lesson. Especially when it comes to the methods, strategies and tools for teaching scientific language the teachers’ knowledge can be described as incomplete and insufficient. However, there are different methods which can be used (e.g. Markic, Broggy & Childs, 2013). Thus, the following step after making science teachers aware of the issue of learning and teaching of scientific language should be by presenting and training the teachers in using different methods and strategies to support students’ learning of scientific language. To close up the cycle of teacher education, in-service chemistry teachers act also as mentors to our pre-service teachers during their internship. Thus, the Pedagogical Scientific Language Knowledge can be passed to in-service teachers to pre-service teachers as well.

LISP: THE LANGUAGE IN SCIENCE PROJECT

Peter E. Childs¹ and Marie Ryan²

¹Chemistry Education Research Group, Department of Chemical Sciences and EPI*STEM, University of Limerick, Limerick, Ireland,
²Our Lady’s Secondary School, Templemore, Ireland

The multiple languages of science present a problem in the teaching and learning of science, especially in junior secondary school, where most students meet formal science for the first time, and for second-language learners. (Childs, Markic and Ryan, 2015) Students meet many unfamiliar technical words in chemistry, for example, and a strange, symbolic language of chemical formulae and equations. Many everyday words undergo metamorphosis and have different meanings in science and beginners have to try and decode their meanings. The Language in Science project, LISP, at the University of Limerick attempts to address such issues in junior secondary school (JSS) by a focused set of resources and strategies. (Childs and Ryan, 2016) It is in JSS that most students meet formal science for the first time. This paper will describe the project and evaluate its effectiveness in improving students’ learning and mastery of the language of science. The project also aims to raise science teachers’ awareness of the language issues in teaching science, and these issues continue into senior secondary school and into university. Recognising the problem and implementing appropriate teaching and learning approaches, is a necessary and vital part of the science teachers’ work. This is especially so for students with poor language skills and the greater diversity and heterogeneity of school classrooms and university lecture halls in 21st century Europe, makes attending to the language barrier in teaching and learning science even more important (Childs, 2016).

Keywords: secondary science, language in science, intervention project

INTRODUCTION

This project started from an observation by one of the authors (MR) of the problems faced by girls in an inner city school with the language of science as a barrier to their learning. This observation is captured by Jonathan Osborne: ‘Science without literacy is like a ship without a sail. So just as it is impossible to construct a house without a roof, it is impossible to build understanding of science without exploring how the multiple languages of science are used to construct meaning’ (Osborne, 2002). The multiple languages of science present a problem in the teaching and learning of science, especially in junior secondary school, where most students meet formal science for the first time, and for second-language learners (Childs, Markic and Ryan, 2015). Students meet many unfamiliar technical words in chemistry, for example, and a strange, symbolic language of chemical formulae and equations. Many everyday words undergo metamorphosis and have different meanings in science and beginners have to try and decode their meanings. Little attention has been devoted to the role of language in teaching science in Irish schools and the Language in Science Project (LiSP) was launched to address this problem using an intervention strategy and prepared teaching materials. The research project involved a number of Phases. Phase 1 looked at science teachers’ views on the issue of language; phase 2 investigated the use of non-technical words in science with different meanings to their everyday use, among school students and trainee science teachers (Ryan, 2015). In this paper we report only on the results of Phase 3, the intervention project.
The Language in Science project, LiSP, at the University of Limerick attempts to address the language issues in teaching science in junior secondary school (JSS) by a focused set of resources and strategies (Childs and Ryan, 2016). It is in JSS that most students meet formal science for the first time, and they are introduced to a massive amount of new vocabulary (Figure 1).

Figure 1. An illustration of the large number of new, technical words met in junior cycle science.

This paper will describe the project and evaluate its effectiveness in improving students’ learning and mastery of the language of science. The project also aims to raise science teachers’ awareness of the language issues in teaching science; these issues continue into senior secondary school and into university. Recognising the problem and implementing appropriate teaching and learning approaches, is a necessary and vital part of the science teachers’ work. This is especially so for students with poor language skills and the greater diversity and heterogeneity of school classrooms and university lecture halls in 21st century Europe, makes attending to the language barrier in teaching and learning science even more important. (Childs, 2016)

LITERATURE REVIEW

Wellington and Osborne (2001) claimed that “Language is a major barrier (if not the major barrier) to most pupils in learning science” (p. 2). Science has its own language and learning the language acts as an impediment to many students’ acquisition of scientific knowledge and understanding. Language in science is a multi-faceted issue: it includes not only technical words, but also non-technical words used in a different context; it includes command words and logical connectives; it involves symbolic and mathematical language (Childs et al., 2015).

The work of Cassels and Johnstone (1980 and 1985), Johnstone (1988), Johnson and Selepeng (2001) has shown that the problem lies not only in the technical language of science, but also in the vocabulary and usage of normal English in a science context. Students and teacher see familiar words and phrases which they both ‘understand’, but they do not share the same meaning.
The Report of the Board of Studies for Languages (CEB, 1987) in Ireland defines the curriculum category “language” as follows: Language is:

- the chief means by which we think – all language activities, in whatever language, are exercises in thinking,
- the vehicle through which knowledge is acquired and organised,
- the chief means of interpersonal communication,
- a central factor in the growth of the learner’s personality,
- one of the chief means by which societies and cultures define and organise themselves and by which culture is transmitted within and across societies and cultures.

This reminds us of the central role of language in education of any subject and at any level. Postman and Weingartner (1971) expressed a similar view regarding the role of language in science when they argue that:

“Almost all of what we customarily call ‘knowledge’ is language, which means that the key to understanding a subject is to understand its language. A discipline is a way of knowing, and whatever is known is inseparable from the symbols (mostly words) in which the knowing is coded. What is biology (for example) other than words? If all the words that biologists use were subtracted from the language, there would be no biology. This means, of course, that every teacher is a language teacher: teachers, quite literally, have little else to teach, but a way of talking and therefore seeing the world”.

To date in Ireland, little research has been conducted into the role which language plays in the teaching and learning of science at third level, or on the transition from second level.

**METHODOLOGY**

The rationale was that it is not possible to improve Irish second-level science education without addressing the underlying problem of language in science teaching. The results of phase 1 and 2 highlighted the need for a programme to be developed to help teachers tackle the problem of the role of language in science teaching and learning and increase their awareness of the problem. The methodology of the LiSP intervention is described below.

**Decide level and topics to be covered.**

It was decided to focus the intervention on the teaching of science in the junior cycle for a number of reasons: there is a common curriculum, taken by >90% of students; teachers teach similar topics at the same time in the school year; this is when students meet formal science instruction for the first time. After studying the curriculum and when teachers teach the various topics, it was decided to focus on five Junior Science topics for the LiSP intervention programme.

- Food
- Digestion
- States of Matter
- Classification of substances; elements, compounds and mixtures.
- Atomic Structure
Develop the intervention package for the 5 topics.

After studying the science curriculum and drawing on the findings of phases 1 and 2, and surveying the literature on tackling language issues in science teaching, a variety of LiSP teaching materials were developed for each topic. The materials included word searches, crosswords, word matching exercises etc. and were made available as photocopiable paper copies and in electronic form.

Pilot implementation, evaluation & revision of the intervention.

The materials and suggested teaching approaches were first piloted with teachers in a local school and based on their feedback, the materials were revised.

Distribution of the Intervention Package and training of teachers.

Schools and teachers were recruited by asking for volunteers from schools who had responded to the questionnaire in phase 1. In total 11 teachers from 7 schools were involved in the intervention (269 students) and 5 teachers from 5 different schools (144 students) acted as a control group.

The researcher (MR) visited teachers in each school to introduce the materials and describe how they could be used in teaching the five topics. The science teachers were then asked to teach the topics over the course of a term and to give their students an end-of-chapter test for each topic. Before the intervention a standard test provided by the researcher was completed by all students from both the intervention and control groups, to check that the groups were comparable in ability and to add validity to any deductions that could arise from the results of the end of chapter tests. The standard test and end of chapter tests for the intervention group and control group were identical and were administered in the schools by the teachers. The results were provided to the researcher for analysis. The aim was for the teachers to teach the topics in the normal way except for the use of LiSP materials with the intervention groups. The tests used were of similar structure and style to those normally used.

The evaluation of the LiSP programme focused on two groups: the science teachers and their students.

Teachers: The teachers’ views were collected through a teacher portfolio (describing what they did in class), regular contact with the researcher by email and phone, and a pre- and post-teacher questionnaire, and post-intervention interviews.

Students: The end-of-topic test results of the intervention student group were compared with those of the control group (taught in the traditional way) in order to determine if the intervention programme had any effect on their ability to understand the concepts and main points of each of the five topics.
RESULTS

Results of phase 1 (Ryan, 2016)

• Based on a survey of 86 teachers, while Irish Science teachers are aware that the language of science is a barrier, their awareness appears to be almost completely limited to the technical language of science e.g. isotope, photosynthesis.

• The results of the teacher questionnaire found that 87% of teachers (75) were aware that the vocabulary and usage of normal English in a science context was a problem for students, e.g. solution.

• This survey raises concern about how aware teachers are in practice to these non-technical words or words which a have a dual meaning and as such how are they dealing with these words when met in their own teaching.

• 67% of the teachers felt that they are not adequately equipped with teaching methodologies and strategies to deal with this problem especially considering the linguistic diversity of our classrooms.

• Only 11 teachers (41%) of a sample group in a separate study highlighted non-technical words in the two extracts from a science textbook (case study n=27).

Results of phase 2 (Ryan, 2016)

Phase 2 involved a study of the understanding of non-technical words in science by school students and trainee science teachers (university students). The study used the methodology of Cassels and Johnstone (1985), but adapted to the vocabulary used in Irish science textbooks. The following general results emerged.

• The first is that very few of the words tested turned out to be satisfactory in all formats. When one compares the results from the current study and the 1985 Cassels & Johnstone study, the differences are alarming. The evident deterioration in Irish students’ understanding of the given words is shocking (-38%).

• Many of the words which Irish science teachers use are not readily accessible to all their students.

• Things are at their most dangerous when both a learner and teacher know the meaning of a word, and each assumes that the other shares the same meaning. They use the same words but do not mean the same thing.

Various factors were investigated from the data to see if they were significant.

Gender: No significant difference was found.

Age: General misunderstandings diminish with age, but a degree of misunderstanding is still apparent even with third-level trainee science teachers and the format of the question does have an effect.

Native or Non-native English Speaker: Native English-speaking pupils outperformed their non-native counterparts with 69% of native pupils giving correct answers in comparison to 31% of non-native English speaking pupils.
These results were important for the design and focus of the teaching materials used in Phase 3.

**Results of phase 3**

**Can the intervention and the control groups be compared?**

In order to determine this, cross tabulation tests were done between the results from the two cohorts on a standard test completed prior to teaching the topics, using SPSS 21 for Windows. Results of significance tests should have p-values greater than 0.05 to indicate that these two groups can be compared with each other. This was true for 13 out of 17 items, with only 4 showing a significant difference (see Table 1).

The questions in each of the end-of-topic tests for all five topics were analysed to compare the performance of the two groups.

An example for the topic Atomic structure is shown in Table 2. The final column shows the percentage difference in score between the intervention and control groups. In Tables 2 and 3 only the results for the first 4 questions are given for reasons of space.

In addition in a case study school, parallel classes were taught with and without the language intervention, to eliminate the effect of the school and teacher. Sample results are shown in Table 3, together with tests for significance.

</table>
The intervention pupils scored higher in all the questions on the ‘Atomic Structure’ test in comparison to the control group pupils. The differences were significant in 15 out of 26 questions. On no items did the control group perform better. These results are a very positive indicator of the effectiveness of the ‘LiSP’ intervention programme and were also found in the other topics.

While significant p-values favouring the intervention group were found in all of the end-of-topic tests, comparing the intervention and control groups, the largest number of significant results (those highlighted in khaki green) were found for the end-of-topic tests on ‘Atomic Structure’ and ‘Elements, Compounds and Mixtures’. The following reasons may account for the high level of significant items in these tests:

- These chapters are more cognitively demanding, than the other topics, for example, the food chapter. Even without engaging in the ‘LiSP’ programme, chapters such as food may not pose much of a problem for many students because of their familiarity with the topic.
- Other topics have words which are more familiar from everyday life, whereas these topics introduce new vocabulary.
- These chapters have a greater concentration of scientific and technical terms, which are better targeted by the ‘LiSP’ programme than normal teaching methods.
- The intervention package was produced to accommodate a wide range of learning styles e.g. visual learners, thus reaching more students than a traditional, didactic teaching approach.

The following general conclusions can be drawn from the results on all five topics:

- Students in the intervention group were significantly stronger in performance than students in the experimental group, based on the results of the end-of-topic tests and the standard test.
- Participation in the ‘LiSP’ intervention programme was shown to have a positive effect in promoting students’ correct understanding and use of language in science education.
- According to the in-class observations and the responses in the teacher interviews, the students who participated in the LiSP programme enjoyed the group work and competitive elements of the package the most.
- The student participation level in class increased as a result of using the intervention programme package and teaching ideas, indicating improved motivation.
- The teachers who participated in the intervention programme were very positive about it and felt that it was very appropriate for Junior Cycle students.
- The teachers who participated in the intervention programme stated that they will use the intervention programme package again and will incorporate the teaching ideas and materials into the teaching of other chapters.
DISCUSSION

None of the teaching ideas used in the LiSP materials was original, but the provision of a package of ideas for science teachers to use related to a specific topic meant that teachers could easily implement the language intervention strategy in their classrooms.

The following recommendations follow from the results of the LiSP project in Irish junior cycle science classes.

1. A concerted effort should be made to make all science teachers aware of the issue of language and the research that has been done in the area.
2. In-service science teachers and pre-service science teachers should receive professional development (PD) in this area both in their initial training and also long-term CPD.
3. Materials like those used in the LiSP project should be prepared for all the junior science topics and teachers trained in their use and given access to them.
4. Students should be assessed for their language ability at the start of their second-level education and remedial help provided as required. This is particularly important for second language learners.
5. Teachers should employ formative assessment of their students’ language skills in relation to science at regular intervals to identify any problems.
6. Teachers should use an agreed list of command words in tests and make students familiar with them. External examinations should also use the same set of command words, tailored to the level of the examinations.
7. Given the increasing proportion of non-native students in schools who are second language learners, science teachers should become aware of their specific needs and provide suitable materials and use appropriate teaching methods.
8. Teachers should become more aware of the language used in written materials (textbooks, handouts, tests) and reduce the language demands using illustrations etc. Textbooks should be chosen with an awareness of language issues.

We believe that the LiSP intervention has shown that student achievement in science can be improved, across the board, if science teachers use suitable materials to address the language issues and to help students become familiar with the new vocabulary encountered in science classes. Many of the problems students have with learning science are due to the language and teachers often assume language proficiency among their students (a basic prerequisite) and also ignore or do not allow for the specific problems of language in science. Science teachers are the central agents to achieving this goal; accordingly they need to be aware of the difficulties students are presented with when learning science and must be equipped with teaching strategies and methodologies to alleviate and deal with pupils’ problems in their own teaching. The LiSP intervention has shown that this is possible without a radical change in pedagogy and even a limited emphasis on language in teaching the science can pay big dividends.

STUDENTS’ IDEAS ABOUT GLOBAL WARMING: A COMPARATIVE STUDY BETWEEN PORTUGUESE AND SPANISH PRE-SERVICE TEACHERS

António Almeida¹ and Beatriz García Fernández²

¹Lisbon Higher School of Education / Interdisciplinary Centre of Educational Studies, Lisbon, Portugal
²Faculty of Educación of Ciudad Real, University of Castilla-La Mancha, Ciudad Real, Spain

This study aimed to verify the knowledge of 149 Pre-Service teachers (91 from a Portuguese institution and 58 from a Spanish one) about global warming, a subject that is approached in their courses and that they will have to teach in the future, since it is part of the Primary school curricula in both countries. For this purpose, a questionnaire was administered at the beginning of the current school year, after the subject was included in a curricular unit dealing with environmental issues in the last school year, in both institutions. The questionnaire included several open questions related to the causes and the consequences of global warming. Due to space limitations, only the results of the following three questions are presented in this paper: 1) How does the use of fossil fuel contribute to global warming? 2) How does the emission of CFCs and other equivalent gases contribute to global warming? 3) How does deforestation contribute to global warming? The answers were classified based on their correctness, from a defined standard response. The Spanish students performed a little better than the Portuguese ones in the first two questions and the reverse occurred with the third question. However, in total, less than 40% of the students were able to answer questions 1 and 3 correctly, and less than 10% question 2. Several misconceptions were revealed by the students, who confused global warming with the ozone layer depletion or revealed wrong ideas about the photosynthetic process, just to mention two of the most frequent mistakes. The results suggest that some improvements in dealing with global warming in teacher training courses are necessary, through the design of activities that include, for instance, the deconstruction of some of the ideas expressed by the students in the present and other similar studies.

Keywords: Pre-service teachers, Global warming, Misconceptions.

INTRODUCTION

Global warming has increased in recent decades due to anthropogenic activities. Among several of the main gases which are responsible for this phenomenon, carbon dioxide is perhaps the best known. Its concentration in the atmosphere has increased from 280 parts per million (ppm) before the Industrial Revolution, to 400 ppm, a value 40% higher in a period of two and a half centuries (Wang, Ge, Wang & Chen, 2014). Other gases implicated in global warming, such as methane (CH₄), chlorofluorocarbons (CFCs), hydrofluorocarbons (HFCs), perfluorocarbons (PFCs), sulphur hexafluoride, nitrous oxide, ozone at tropospheric altitudes, and water vapour, are often less mentioned but their impact is also significant. In fact, it is not only the percentage of a certain gas in the atmosphere that counts in the process of global warming, but also its effectiveness at absorbing infrared radiation, the Global Warming Potential (GWP). Compared to the carbon dioxide potential to trap heat, methane has a GWP of 21, nitrous oxide a GWP of 301 and sulphur hexafluoride a GWP of 23900, just to mention a few gases (Daniel, Stanisstreet & Boyes, 2004). But global warming causes can be even more
complex, with a chain of reactions which have the main effect of increasing the Earth’s temperature. For instance, tropospheric ozone is responsible for the inhibition of photosynthesis, which causes a decrease of absorption of carbon dioxide by plants (Daniel, Stanisstreet & Boyes, 2004).

Global warming and other environmental problems such as the ozone layer depletion are issues which are present in the curricula of several countries, from primary to higher education, naturally with an increasing degree of complexity. However, these particular phenomena have been misunderstood as to their causes and consequences and are even confounded over the years, even when students take science courses (Reynolds et al. 2010). Several studies with higher or non higher education students have found, for example, the following wrong ideas: i) carbon dioxide is responsible for global warming and also for the depletion of the ozone layer (Huxter, et al., 2015); ii) the ozone hole allows more UV radiation, which causes global warming (Michail, Stamou, & Stamou, 2007; Shepardson et al., 2009; Allen, 2010); iii) carbon dioxide is the only greenhouse gas recognized in global warming (Boyes & Stanisstreet, 1993; Fisher, 1998; Shepardson et al., 2009); iv) the trapping of infrared radiation is badly recognized as the cause of greenhouse effect (Boon, 2010).

It is important to mention that frequently these and other misconceptions are present in students of different degrees or cycles of schooling. For instance, a study promoted in Australia by Bono (2010) found that pre-service teachers and secondary students answered correctly a list of global warming statements with a very low and equivalent percentage (less than 15% in both groups). But the pre-service teachers’ results are of a particular concern, since they will have to teach this and other environmental issues to their future pupils.

The present study tried to check the ideas related to global warming in pre-service teachers from two institutions that prepare for teaching in the first six years of schooling (one in Portugal and one in Spain). In the study plans of both courses, students had approached the global warming issue in a curricular unit, during the previous school year. This kind of research is important to assess the efficacy of teacher training preparation and can help to design new approaches to help scientific accuracy. In fact, as quoted by Khalid (2003), when teachers have a poor understanding of some environmental concepts, they can be responsible for misconceptions in their pupils.

METHOD

The sample of the present study involved 91 Portuguese pre-service teachers and 58 Spanish ones, almost all females, and the average age of the groups was, respectively, 24.4 and 22.7 years old. As it was already stated, the students were from two institutions that prepare teachers for the first six years of schooling (children aged from 6 to 12). The institutions were chosen on the basis of their relevance in pre-service teaching courses in both countries and due to the fact that they are the workplaces of the research team. Therefore, the dissemination of the results is facilitated as well as the possibility of making changes in the teaching practice process of global warming.

A questionnaire was administered in both countries in October of the school year of 2016/2017. In the previous school year, the students of both countries studied this issue. In the case of the
Portuguese institution, the global warming issue is included in the syllabus of the curricular unit Earth Sciences; in the Spanish institution it is included in the syllabus of the curricular unit Natural Environment: Physics, Chemistry and their Didactics. The teaching of the global warming issue was confirmed by each of the teachers who are responsible for the curricular units mentioned above.

The questionnaire included several questions distributed by two parts concerning different causes and consequences of global warming. One part related to how pre-service teachers value and understand the impact of livestock production on global warming was already published (see Almeida, García Fernández & Sánchez Emeterio, 2016). Due to space limitations this article is focused on the results related to the following three open questions of the questionnaire:

1) How does the use of fossil fuels contribute to global warming?
2) How does the emission of CFCs and other equivalent gases contribute to global warming?
3) How does deforestation contribute to global warming?

The answers were analyzed for their content and compared with standard correct responses defined as follows:

1) The burning of fossil fuels releases carbon dioxide and other gases that trap infrared radiation which dissipates from the surface of the Earth;

2) CFCs and other similar compounds are potent molecules which retain the infrared radiation;

3) The destruction of trees reduces the amount of photosynthesis, a process that removes carbon dioxide from the atmosphere and stores it in the plants; a common process of deforestation is burning, which releases carbon dioxide.

The answers were classified according to the following criteria: Correct answer; Partially correct answer; Answer not focused on the intended relationship; Answer with correct items but with serious inaccuracies; Incorrect answers; Don’t know. To ensure consistent coding, each researcher classified the students’ answers and at the end of this process an external consultant helped to find a consensus in a few divergent classifications. Since the results from both countries were quite similar, no inferential statistics was used and only the percentage of the results is presented.

RESULTS

The results, comparing the performance of the students of both countries according to the codification used, are in Table 1.

In the first question, concerning the relationship of fossil fuels with global warming, the percentage of Spanish students who responded correctly was higher (10.3%) comparing to the percentage of the Portuguese ones (5.5%). Even so, the percentage of students with a correct or partially correct answer was, respectively, 41.8% - P and 29.3% - Sp. This means that nearly 60% and 70% of the students of both countries were incapable of establishing the relationship demanded. Also with a high incidence in both groups, 18.7% - P and 32.8% -Sp, were answers that didn´t explain the intended relationship.
Table 1. The results in percentage for the students of both countries (P- Portugal and Sp – Spain) according to the codification used: A: Correct answer; B) Partially correct answer; C) Answer not focused on the intended relationship; D) Answer with correct items but with serious inaccuracies; E) Incorrect answers; F) Don’t know.

</tbody>
</table>

In the second question, the results are even worse with only 8.6% of the Spanish students and 1.1% of the Portuguese ones giving a correct or a nearly correct answer. As in the previous question, the role of infrared radiation in the global warming process was not recognized and the students were unable to recognize the ability of CFCs and other similar gases to capture that radiation.

In the third question, the Portuguese students performed a little better. Even so, more than 60% of these students and more than 70% of the Spanish ones could not explain the impact of deforestation on global warming.

Also important to highlight is that nearly one fifth of the students of both countries don’t know how to answer the questions, except for question 3 for the Portuguese students where (9.9%) did not know the answer.

For each question we are going to present the answers given by the students of both countries in categories D (answer with correct items but with serious inaccuracies), and E (incorrect answers). This selection highlights the main misconceptions revealed by the students and allows identifying the conceptual mistakes that were more frequent. For this purpose, answers in category C (answer not focused on the intended relationship), are not relevant, since they only included correct statements which do not answer the questions. Even so, a few examples are included in the text for a better understanding of this type of answers.

In the case of question 1, the main wrong ideas are included in Table 2. Several of the incorrect answers or of those with serious inaccuracies show that a high number of students believe that the release of carbon dioxide causes the ozone depletion phenomenon and this, in turn, implies the increase of UV radiation responsible for global warming. This idea is somehow present in other answers but expressed in different ways. This is the case when students highlight the pollution emitted by fossil fuels which increases the ozone layer hole or is responsible for the increase of the temperature. As it is possible to verify, the role of infrared radiation in global warming process is completely absent in the answers of these students. Examples of answers of type C, not included in the table were: “Fuels emit gases that pollute the atmosphere”, “The constituents of fossil fuels are harmful to the atmosphere”; or “The constituents of fossil fuels are toxic”.

In the case of answers to questions 2, the results were even worse, as it was already expressed at the beginning of the present section. The main wrong ideas are included in Table 3.
Table 2. The incorrect answers for question 1) How does the use of fossil fuels contribute to global warming? revealed by pre-service teachers of both countries (P- Portugal and Sp – Spain), according to the categorization: D - Answer with correct items but with serious inaccuracies; E – Incorrect answers; F – Don’t know.

The majority of the students of both countries associated the release of CFCs and other equivalent gases with the depletion of the ozone layer. And this depletion is responsible for the increase of UV radiation, causing global warming. Therefore, they are unable to recognize their important role in capturing infrared radiation.

Other incorrect answers were somehow strange and revealed a mix of ideas that are totally wrong. This is the case of answers like: “CFCs release gases like the carbon dioxide, which is responsible for global warming”; “CFCs are very polluting gases, provoking global warming” or even “CFCs lead to a decrease in oxygen in the air”.

Examples of answers of type C were also present but to a lesser level. Examples of this type of answer were: “The CFCs destroy the ozone layer”; The CFCs are very dangerous molecules” or “CFCs can be found in the sprays”.

Finally, the performance of the students of both countries in question 3 was a little better. Even so, several mistakes could be identified and are included in Table 4.

Table 4. The incorrect answers for question 3) How does deforestation contribute to global warming revealed by pre-service teachers of both countries (P - Portugal and Sp – Spain), according to the categorization: D - Answer with correct items but with serious inaccuracies; E – Incorrect answers; F – Don’t know.

In this question, the students performed a little better. A frequent wrong answer was that “deforestation is responsible for the decrease of oxygen in the atmosphere” and the idea that “with the decrease of trees, the CO₂ is not transformed into O₂”, a misunderstanding of the photosynthesis process. However, the number of correct answers was not so high, since near one third of the students of both countries gave answers of type C. Just a few examples: “Trees have a protective function, beneficial to the planet”; “Without deforestation, there will be less rain”; As there is no vegetation, solar rays affect the soil more intensely”.

201
DISCUSSION AND CONCLUSIONS

Several authors support the importance of teaching about global warming, since it is an issue with social and personal relevance that enables the exercise of an active citizenship (Brown, 1992; Bybee, 1993; Shepardson, Niyogi, Choi & Cahrusombat, 2009). In the case of pre-service teachers, it is also important to guarantee a correct scientific learning process due to the fact that these students will be responsible for teaching young students in the near future.

The results of this study show that the understanding of the global warming process by the majority of the students of both countries is incomplete and reveals a lot of incorrect ideas and converges with other studies presented in the introduction section. It seems that several mistakes persist though time in different samples with different ages and from different cultural backgrounds. In fact, the results are quite disturbing, since the students revealed several misconceptions of the issue under discussion, and they confirm the failure of formal education in approaching the issue with good learning results. And it is important to remember that students had a formal teaching unit involving global warming only a few months before the administration of the questionnaire. Several ideas already identified in studies in other countries are also shown in the present results, such as the confusion between global warming and the depletion of the ozone layer, the incapacity to recognize other greenhouse gases beyond carbon dioxide, or the role of infrared radiation on global warming.

Therefore, it seems important to implement a few changes in the learning process of this environmental problem. In fact, consulting the syllabus of the curricular units related to environmental issues in both countries, we realized that global warming was only a tiny part of their content. Thus, one of the main reasons for the failure of the learning process can be the small amount of time dedicated to the issue and, of course, the way it is approached.

To guarantee better learning results, Rebich and Gaubier (2005) quote that the most popular instructional approach to promote conceptual change has the following steps: to identify misconceptions, to present information that causes conflict with previous knowledge, to present contradictory information; and finally to identify conceptual changes. For all these steps you need time, a precious element that is always missing, especially in higher education, but which is fundamental to guarantee the quality of the learning process.

Even so, Guzzetti et al. (1993) claim that this process is not always a guarantee of success. That is why Rebuch and Gaubier (2005) suggest a multiplicity of methods to encourage meaningful learning where the discussion of wrong conceptions can help to promote a cognitive conflict in students’ minds, and also suggest that other strategies should be used, like conceptual maps or the discussion of anomalous ideas in a cooperative and shared learning process. In conclusion, the approach to this complex issue seems to need more time and special attention should be given to the teaching methods used in its approach.

ACKNOWLEDGEMENT

This study is part of a project entitled “Research in didactics of science: implications for the improvement of teaching practices” and it is funded by the Interdisciplinary Center of Educational Studies (Centro Interdisciplinar de Estudos Educacionais - CIED) seated in Lisbon School of Education, Portugal.

CZECH HIGH SCHOOL STUDENT’S KNOWLEDGE, UNDERSTANDING AND ATTITUDE OF HUMAN EVOLUTION

Radka M. Dvorakova¹ and Martin Hula²

¹ Department of Teaching and Didactics of Biology, Faculty of Science, Charles University, Prague, Czech Republic; ² Department of Philosophy and History of Sciences, Faculty of Science, Charles University, Prague, Czech Republic

During recent years, scientific knowledge of the human evolution has been significantly modified. This study focuses upon Czech high school student’s knowledge, understanding and attitude to the human evolution and its objective is to improve the teaching of this issue. We collected data from 91 participants (final year high school students one month before exams in A-level biology) using a questionnaire in paper and pencil form. Descriptive statistics was used after coding the data. Consequently, t-tests were used to examine possible differences between groups. We didn’t recognise any gender differences in knowledge, understanding and attitude to the human evolution in our sample. Less than 5% students in our sample know hominin genera, which were described during the last 20 years, the same is true for hominin species. Strictly linear scheme of human evolution was counted as right by 93.5% students. Phylogenetic relationships among great apes were classified correctly by 35% students; the biggest source of mistakes seems to be a disproportion among knowledge of fact and understanding of the phylogram of the great apes. There aren’t any differences in knowledge, understanding and interest in human evolution between believers and non-believers among students in our sample. The only significant difference related to student’s opinion of relationship between religious and scientific points of view to the human evolution.

Keywords: knowledge of human evolution, high school students, evolution and religion

INTRODUCTION

Human evolution is an important component of high school biology - this issue lets students understand our place in nature and who we are. During recent years, scientific knowledge of the human evolution has been significantly modified in some ways. There are lots of new discoveries of fossils around the world, which extend the spectrum of known hominin species (Berger et al., 2010, 2015; Brown et al., 2004; Brunet et al., 2002; Krause et al., 2010; Leakey et al., 2012; Pickford & Senut, 2001). A modern research procedure brought a lot of new knowledge about physique of our ancestors, their cognitive abilities, social life, culture, about their environment, about relations among particular evolutionary lines and many other items (Reich et al., 2010; Sandel, 2013; WoldeGabriel et al., 2009; Wynn et al., 2013). Sure, constituent elements of scientific knowledge have different relevance in the school education. But in any case, such turbulent development in some scientific branch could be challenging for the science teaching, or more precisely - for originators of the process of pedagogical transformation. In the Czech Republic, this issue is a mandatory part of the national curriculum in the case of the subjects of biology and also history. Despite of this, the issue belongs in the Czech high school curriculum rather to the group of marginal topics, in comparison with the situation in Germany or Austria; the usual number of hours per whole high school study is
about one hour in the first year of high school study in the subject of history and about five
hours in the third (penultimate) year of high school study in the subject of biology (Dvořáková,
2015; Dvořáková & Hůla, 2016). The amount of hours devoted to this issue during high school
science teaching is not huge in the Czech Republic; nevertheless there are no evolution-creation
controversies in public and at schools like in the United States. In the United States the issue
of human evolution belongs to one of the least understood and least accepted topics of modern
science among general public, mainly out of religious reasons (Miller, Scott, & Okamoto, 2006;
Pobiner, 2016; Rutledge & Mitchell, 2002). There is a different situation in some European
countries (Graf, 2011), especially in the Czech Republic, which belongs to the most atheistic
countries in Europe (and also in the whole world) according to the Eurobarometer Pool (2010).

We had two main goals during the writing of this paper: The first main goal is to determine
the level of knowledge and understanding of human evolution in the sample of Czech high
school students; one of the secondary objectives of this paper has been to identify and explore
some common persistent misconceptions about human evolution which students get of the high
school education. The second main goal is to explore the relationship between religious
belief and attitude towards human evolution in our sample of students. We were interested
in whether (and possibly how) religious belief influences the attitude and also knowledge and
understanding of human evolution by Czech high school students.

METHODS

A questionnaire in paper and pencil form was used in this study. In total 91 participants returned
the filled-in questionnaire, 4 participants returned blank questionnaire (one just didn’t want to
fill-in the questionnaire, three other participants were in a hurry to catch the bus after the main
activity and didn’t have time to fill-in our questionnaire). The participants were final year high
school students, aged 18–19, one month before exams in A-level biology; we collected the data
during April 2015. We collected data from 70 girls and 19 boys, 2 participants did not specify
gender. 66 respondents were non-believers, 22 were believers (6 Roman Catholic and 16
without denomination) and 3 participants did not specify their belief; we are aware of the
complexity of the question about personal belief and religious attitudes and we appreciate that
there aren’t two distinct groups (believers versus non-believers) but continuous range of
attitudes in reality. Nevertheless for the purpose of this study we understand as “non-believers”
all respondents who circled in the question about religious orientation the item “without
religious belief” or filled-in the item “other possibility” with something like “atheist”, “non-
believer” and so on. And we understand as “believers” all respondents who circled some
religious denomination or the item “believer – without denomination” or filled-in the item
“other possibility” with something connected with religious belief.

Participants completed a survey with 10 items tapping their science knowledge, understanding
and attitude to human evolution. Throughout the questionnaire, respondents expressed their
agreement or disagreement with 7 presented statements on a five-point Likert scale. There were
also 3 open-ended questions about hominin species knowledge, human evolution scheme and
phylogram of the great apes. The last section of the questionnaire contained questions about
demographic data (gender, age, religion).
We analysed the data in the R software, version 3.1.3. We used descriptive statistics to characterize the respondents. We used t-tests to determine differences between believers and non-believers in their attitudes and knowledge of human evolution. The distributions of the examined variables were very similar for both groups (believers and non-believers), although not entirely normal. They also had equal variances. We adjusted the obtained p-values by Holm-Bonferroni correction for multiple comparisons.

RESULTS

As far as the question about level of knowledge and understanding of Czech high students, we find that: less than 5% students in our sample know (we mean recall the taxons from mind when answering open-ended question) hominin genera which were discovered and described in the last 20 years, namely the genera Ardipithecus, Paranthropus, Sahelanthropus, Orrorin. On the other side, the best and familiar known genera are Homo and Australopithecus, see Figure 1.

The same goes for the new species of genera Homo; the best known species are Homo sapiens, Homo neanderthalensis, Homo erectus and Homo habilis. On the other side, almost unknown Homo species, which just few students specified, are taxons like Homo floresiensis, Homo denisoviensis, Homo georgicus and so on, see Figure 2. Participants usually specify about 4-5 hominin species, the maximum was 11 hominin species.

29% students in our sample divided species Homo sapiens into another species, namely Homo sapiens sapiens, which is wrong conception, see Figure 2.

Figure 1. How many students (in percentage) know particular hominin genera
Figure 2. The best known species of the genera Homo; the species which were mentioned by less than 4 participants (i.e. less than 4.6% students in our sample) are not included.

Strictly linear scheme of human evolution was counted as right by 93.5% students, only 6.5% of students point out that human evolution was more complicated – i.e. they notice and were able to explain something like that one species didn’t continuously transform into some other, several hominin species existed in the same time in parallel and/or there were several blank lines in human evolution.

Phylogenetic relationships among great apes (genera Pongo, Gorilla, Pan and Homo) were classified correctly by 35% students. There were several types of mistakes in this question, containing all possible combinations of great apes relationship. The biggest source of mistakes was disproportion between the knowledge of facts and understanding of the phylogram of the great apes. Almost half of the participants who answered this question wrongly were able to say that chimpanzee is the closest great ape in relation to Homo sapiens, but they weren’t able to correct this fact properly in a given phylogram, see Figure 3.

There are no significant differences in knowledge, understanding and interest in human evolution between believers and non-believers among the students in our sample, see Figure 4. Non-believers among students didn’t consider this issue too controversial, the same as believers. We recognise only two significant differences between believers and non-believers among students: the non-believers in comparison to believers more often disagree that scientific ideas about human origin contradict the religious ones (t = -2.952, df = 86, p-value = 0.0284, Cohen’s d = 0.727) and also the non-believers in comparison to believers more often agree that scientific ideas about human origin supplement the religious ones (t = 4.465, df = 86, p-value < 0.001, Cohen’s d = 1.01).

We didn’t recognize any significant gender differences in knowledge, understanding and attitude to human evolution in our sample.
Figure 3. The most common mistake in the phylogram of the great apes (Students should correct mistake if they found any): disproportion among the knowledge of fact and understanding of the phylogram – the notice above the phylogram is correct, the new line in the phylogram is wrong.

Figure 4. Relationship between religious belief and knowledge of human evolution
DISCUSSION

Spectrum of hominin species and genera which are familiar to students corresponds to the spectrum familiar to Czech teachers (Dvořáková & Hůla, 2016). The best known species (Homo sapiens, Homo neanderthalensis, Homo erectus and Homo habilis) are also mentioned in the absolute majority of Czech biology and history textbooks for high school students. We estimate that the incorrect understanding of the status of species Homo sapiens and “species” Homo sapiens sapiens could be probably caused by information in majority of Czech textbooks, which represent these two taxons as two different species following each other in the evolutionary history; there is unfortunately some outdated information in biology (and also history) textbooks and this is a very common example. Only two biology textbooks and none of the history textbooks for high school students represent the proper status of the species Homo sapiens (Dvořáková & Absolonová, 2016, 2017). Students’ knowledge of the proper status of Homo sapiens corresponds with the teacher’s one; there was also more than one third of teachers in our sample who distinguish Homo sapiens and Homo sapiens sapiens as two different species (Dvořáková & Hůla, 2016). It could indicate how important is the teacher’s knowledge and proper understanding of the issue, because teachers are able to correct part of the wrong information from textbooks.

Strictly linear scheme of human evolution is a typical image from textbooks. There are also both wrong and right images of phylogenetic trees of great apes in the textbooks (Dvořáková & Absolonová, 2016, 2017); the misconception about that probably originates here. We recognize the interesting source of mistakes which students allow in the case of phylogram – the disproportion among knowledge of fact and understanding of evolutionary relations in a phylogram. This discovery correspond with other studies, which notice that Czech students are better in knowing the facts than in interpreting them, better in science knowledge than in skills in science (Blažek & Příhodová, 2016; McKinsey&Company, 2010; Palečková, 2007). Unfortunately, we did not have sufficient data from Czech teachers to compare.

We did not find nearly any difference between believers and non-believers in our sample, unlike researchers in other countries (Yasri & Mancy, 2014; Eder et al., 2011; Donnelly et al., 2009). The only difference relates to student’s opinion about the relationship between religious and scientific point of view on the human evolution. Non-believer students seem to be more liberal and broad-minded in their opinions on this issue than the believer ones. Our previous research of biology teacher’s attitudes to human evolution showed different results in this point (Dvořáková & Hůla, 2015). It could be caused by the specific position of teachers. It could be also caused by specifying non-believers and believers group because there is a huge amount of believers without any denomination in the Czech Republic. These people just feel they believe in “something” and in younger age could be more orthodox than later.

We did not recognize any gender differences but this may be caused by the highly unequal number of boys and girls in our sample. According to some authors the differences between male and female students in a similar kind of research may exist (Losh & Nzekwe, 2011b, 2011a). On the other side, some other authors in a similar kind of research didn’t take the gender as a parameter into account, because they didn’t find it important (Sorgo et al., 2014).
CONCLUSIONS

The findings of this study can be used to generate several suggestions which could help to improve the teaching of human evolution at the high school level in the Czech Republic. We assume that the starting point could be high-quality textbooks without misconceptions and also well-educated teachers, which are key-players in the process of pedagogical transformation. Our results are going to be a starting point for developing teaching strategies concerning this issue. We would like to support all teacher efforts to cultivate science skills more than science knowledge in their classrooms. The point of teaching students about human evolution is having them understand who we are and where is the place of humans in nature. Cultivating student’s disposition to think critically is a vital part of science education. There is a good chance to do it properly in the Czech Republic nowadays, because there aren’t any serious constrains from the religious groups like in some other countries.

MODELS OF ELECTRICITY IN PHYSICS TEXTBOOKS: ENABLING OR CONSTRAINING INQUIRY BASED INSTRUCTION?

Zeger-Jan Kock
Fontys University of Applied Sciences, Tilburg, the Netherlands

Models of electricity were investigated in a series of commonly used secondary school physics textbooks. Earlier studies indicated that students need a basic theoretical model in an inquiry context in which conceptual understanding is important. The way such a model is presented and used should afford conceptual and experimental inquiry activities and should respect insights from NOS. Based on a selection of articles on models in science, models in physics education, and models in textbooks, a list of 16 criteria was compiled to evaluate the extent to which textbook models are in line with NOS. Eight criteria applied to descriptive text, and eight criteria applied to student tasks. The criteria were qualitative in nature and needed to be interpreted and evaluated qualitatively. These criteria were then used to evaluate the models of electricity in a set of grade 7 to 12 physics textbooks in the Netherlands.

Keywords: models of electricity in physics, inquiry-oriented learning, textbook study

THEORETICAL MODELS TO SUPPORT INQUIRY ACTIVITIES

A goal of innovative approaches in the secondary school science subjects has been to actively involve students in scientific processes, for example by creating a culture of inquiry in the classroom (Cobb & Yackel, 1998). Inquiry engages students with scientific phenomena, emphasizes student active thinking and responsibility for learning, and uses parts of an investigation cycle (Minner, Levy, & Century, 2010). Inquiry is in line with aspects of the Nature of Science (NOS) considered important for secondary school students (Abd-El-Khalick, Waters, & Le, 2008): (a) ideas are tested by experiments, (b) models form the basis for hypotheses and predictions, (c) theories and models are used to analyze and interpret data, (d) scientific exploration is diverse, (e) science requires creativity, and (f) scientific knowledge develops over time. In physics, theoretical understanding of concepts and models is an aspect of the nature of the subject (Park & Jang, 2005). Students cannot reinvent theoretical ideas entirely by inductive experimental activities, and therefore need a basic model as a theoretical starting point for inquiry (Kock, Taconis, Bolhuis, & Gravemeijer, 2015). The main source of scientific models in the classroom, for the students and the teacher, is the textbook. Several studies have addressed NOS in textbooks (Abd-El-Khalick et al., 2008; Park & Lavonen, 2013), but there has been little attention for the extent to which the theories and models in textbooks are consistent with NOS and thus afford or constrain inquiry activities.

We first describe how criteria were developed to evaluate models in physics textbooks. Then we describe a test of these criteria on grade 7-12 physics textbooks, guided by the research question: To what extent does the way in which models of electricity are presented, explored, and used in a series of secondary school physics textbooks in the Netherlands enable or constrain inquiry-based instruction on the basis of criteria derived from literature?
CRITERIA TO EVALUATE TEXTBOOK MODELS

The criteria were developed based on the review article by Seok Oh and Jin Oh (2011) and the May 2007 special issue on scientific models in the journal Science & Education, complemented by additional articles until no major new insights were found. The articles were summarized, keeping in mind the application to textbooks at secondary school level. The resulting description follows the structure of the article by Seok Oh and Jin Oh (2011): meaning and purposes of models, relation of models with experiments, and multiplicity and development of models. We also discuss the uses of models in the physics classroom and earlier studies of models in textbooks. In the description, we refer to the criteria described later.

Meaning and purposes of scientific models.

In science, models can be defined as abstracted and idealized representations of some aspect of the world (describing an aspect of the world: criterion 1), created for a particular purpose (Develaki, 2007). The representational character of models implies that they resemble the selected part of reality (distinguish model and phenomenon: criterion 2) (Jonassen, 2008).

Models are used to describe and explain phenomena, as well as to make predictions. To that end models may contain theoretical and unobservable objects that explain mechanisms underlying the phenomena (explaining theoretical concepts and their relations: criterion 6) (Clement, 2008). Explanations can take place by showing mathematical relations between variables (calculations: criterion 13), or through causal reasoning (Justi & Gilbert, 2003). For students, causal reasoning may be more appealing and understandable than formal mathematical laws. In society, model predictions are used as tools in decision making processes or to manipulate technological systems (Van der Valk, Van Driel, & De Vos, 2007) (purposes of models: criterion 7; using models to make decisions or manipulate systems: criterion 15).

Models and experiments

The creation of a model takes place through abstraction and idealization, because reality is too complex to correspond exactly to theory (abstraction and idealization: criterion 2) (Halloun, 2007). Consequently, model predictions always have a limited precision, so that an experimental test of a model will only lead to an approximate match or ‘fit’ (addressing model precision and fit: criterion 11). Models are used to design experiments and interpret results, but experimental results may also be used to adapt and improve models and theories, for example if model predictions do not correspond to observations (testing model-based predictions: criterion 10) (Koponen, 2007).

Multiplicity and development of models

Scientific models can be physical objects, pictures and diagrams, text, mathematical equations, or computer simulations, and in this way provide the necessary language and symbols to think and communicate about aspects of reality (Seok Oh & Jin Oh, 2011). Different models can represent the same target phenomenon (different models of the same target: criterion 8; using multiple models: criterion 14). Human agency and creativity are important in determining the purpose and construction of models, the idealizations and use of analogies (use of analogies:
Models in physics education

Various model-based scientific inquiry processes can be used in education (Halloun, 2007): constructing a model, using a model to solve empirical or theoretical problems, model testing, and adapting a model based on theory or experiment (model building or evaluation: criterion 12). Models offer opportunities for causal reasoning (tasks using conceptual reasoning: criterion 9) and can be used to promote student understanding, for example by visualizing otherwise invisible mechanisms (Justi, Gilbert, & Ferreira, 2009).

Simulations using computer models can support various aspects of inquiry (Rutten, Van Joolingen, & Van der Veen, 2012) (using runnable simulations: criterion 16). For example, students can construct dynamic models, using graphical, programming or mathematical tools. However, integrating modelling activities into the lessons and the curriculum is still a point of attention and the role of the teacher is demanding (Louca & Zacharia, 2012).

Research on models in textbooks

The way models are treated in science textbooks is seldom in line with inquiry-based instruction. Textbooks often present models as static and final versions of scientific knowledge, ignoring development and limitations. Different models of the same phenomena are not distinguished, the reasons for introducing new models remain implicit, and the connection of visual models to the theory tends to be ignored. Students experiments are mainly used to verify textbook knowledge and not to develop models (Erduran, 2001). Some textbooks models are compiled from historical models in a historically incorrect way (Justi & Gilbert, 2003).

Textbook research in physics education focused more on the content of models in relation to student conceptual understanding, than on NOS-related issues. For example, Stocklmayer and Treagust (1994) investigated the representation of electric current in secondary school textbooks between 1891 and 1991. Early textbooks used fluid models. Most introductory texts from the mid 1960’s used a moving charged particle model starting from basic atomic structure and electrostatics (movement of electrons in a circuit). Recently, the field concept has been promoted as a basis to understand electric circuits (Stocklmayer, 2010). Often, analogies from other field of physics, such as water circuits and gravitation, have been seen as helpful for understanding. These are problematic when students do not understand the physics underlying the analogies. Transport or crowd analogies have been introduced and analogies in which electrons have an almost human character and carry energy in an electric circuit (Hart, 2008).

Sangam, Jesiek and Thompson (2011) found conceptual weaknesses in the presentation of DC electricity in an undergraduate textbook. Gunstone, McKittrick and Mulhall (2005) analyzed three senior high school textbooks, and interviewed the authors with regard to the concepts of electricity and the meaning of models and analogies. They noted that the authors had no clear
understanding of what a model is, and sometimes did not distinguish models and analogies. In this paper the emphasis will be less on the conceptual content of the textbooks, and more on the connection with NOS. In our perspective, the models in the textbooks should have the potential to contribute to a culture of inquiry in the classroom.

**Evaluating textbook models with the help of criteria**

Models in physics textbooks are used to describe and explain content and appear in student tasks and activities. The main aspects of models described in the literature overview were reformulated as criteria to evaluate physics textbooks from an NOS point of view (Table 1).

</tbody>
</table>
Scoring textbooks with the criteria in Table 1 will help to create a perspective on the presentation and use of models of electricity in relation to inquiry-based instruction. However, the criteria are qualitative in nature and need to be interpreted and evaluated qualitatively.

**METHOD TO APPLY THE CRITERIA TO TEXTBOOKS**

Models of electricity in recent editions of commonly used Dutch physics textbooks for grade 7 to 12, all from the same publisher, were evaluated using the criteria. The textbooks were selected based on the following considerations: (1) the textbooks covered the physics curriculum of grade 7 to 12, so that the development of models on a single topic (electricity) could be studied; (2) the textbooks were published by a single publisher using a consistent pedagogic approach, so that there was coherence in content between the grade levels; (3) recent editions of the textbooks were available; (4) the textbooks were widely used in Dutch schools.

Table 2 shows the abbreviated names of the selected textbooks: the name of the book series followed by the grade, and if necessary the edition. Chapters dealing with electricity were studied in full; chapters partly dealing with electricity were studied in part. Some models on other topics (matter, mechanics) were included in the evaluation, to obtain a fair account of how the textbooks paid attention to models. This applies to the Newton10 chapter Skills, from which the sections on dynamic modeling were included (its physics content was mostly taken from mechanics). Similarly, sections in the chapter on the structure of matter did not refer to current electricity, but partly to charged particles and to models, and so they were included.

The author applied the criteria non-uniquely to sections of text and student (sub)tasks, and made qualitative summaries. A second rater scored part of the material. Differences were discussed after which some criteria and rater instructions were reformulated and examples were added. The process was repeated and comparison of the remaining differences indicated that these did not disturb the overall qualitative evaluation arising from the scores. The criteria scores were qualitatively interpreted based on descriptive summaries of the text and task content. The approach required qualitative interpretation, because texts and tasks could meet a criterion to a greater or lesser extent and the criteria carried different weights depending on the context in which they were scored. For example, criterion 13 could be scored for model based calculations in an inquiry task, but also in the case of a traditional textbook calculation problem.
RESULTS

Descriptive paragraphs

Table 3 shows how often descriptive paragraphs met the criteria from Table 1. The table cells indicate the absolute scores, and the scores as a percentage of the total number of paragraphs. Not applicable (n.a.) was scored for paragraphs unrelated to any of the criteria or to electricity. For example: an explanation of unit prefixes (such as kilo-, milli-) was scored as n.a., because it was not related to electricity. In the evaluation n.a. scores were treated as neutral. Chapter 6 from Newton10 and 7/8 from Newton11 were not included in the table, because they contained too little relevant content to justify a score.

Note.
\(^a\)The chapter was studied in full
\(^b\)Only the parts related to electricity in the chapter were studied.

In the Impact7/8, Impact9, Newton10 and Newton12 3\(^{rd}\) Ed. chapters criteria 1 and 6 were scored the most. In Impact7/8 the concepts electric energy, current, and voltage were introduced in connection with phenomena and contexts, which received most attention. In Impact9 the focus was more on the physics concepts and their quantitative relations. The model of electricity was extended with a section on static electricity, but no connection to electric circuits was made. The Newton10 chapter on electricity overlapped with Impact9, with further extension of the theory and applications. Among others, the Newton10 chapter included the concepts of conventional current, electron drift velocity, variable resistors, Kirchhoff’s laws, and semiconductor components. Quantitative relations received more emphasis with increasing grade level: the Impact7/8 chapter contained no formulas, Impact9 contained 9 and Newton10 contained 20. Thus, the model of electricity was extended and became more sophisticated, while the core features of the model were repeated in the textbooks.
The texts explained the concepts by means of a model of flowing electrons and the occasional use of water and traffic analogies. The model was offered as a factual account and limitations of the model were not discussed. Criterion 2 (limitations of models) was scored only four times in the three chapters, for example in the case of a limitation of the water analogy (water flow does not need a closed circuit). Concepts introduced in the grade 7-10 books were applied in Newton11: current, voltage and electrons were used to describe electromagnetic phenomena.

The Newton12 3rd Ed. chapters dealt with electric and magnetic fields, the electron, and wave-particle duality. Electric fields were introduced in electrostatic situations.

In the Impact7/8, Impact9, and Newton10 chapters criterion 8 was mainly scored because of the introduction and use of pictures and circuit diagrams, and criterion 3 because of the water and traffic analogies occasionally used. The texts did not address the historical development of the scientific models, nor the development of school science models across grade levels.

Parts of the chapter on matter in Newton11 3rd Ed. described the historical development of models (criterion 4). The text gave an account of the development of models of matter in a historical succession, such as the kinetic gas theory, atoms, the Rutherford and Bohr models of the atom, the atomic nucleus, and elementary particles. The text defined models as increasingly sophisticated representations of invisible reality and addressed model limitations as well as simplifications. Making models was described as a human activity with the purpose to explain phenomena. According to the text a more sophisticated model did not make the older model useless, but the refinement of the new model enabled it to explain more phenomena. The parts of the Newton12 3rd Ed. chapters also paid some attention to historical developments.

In summary, the analysis showed that the textbooks in the study explained phenomena in current electricity submicroscopically by means of a model of flowing electrons and macroscopically by means of quantitative relations between concepts (such as Ohm’s law). The explanations were presented as a complete account of facts about nature, with little attention to NOS aspects such as model development or limitations. The models were extended in subsequent years. The consequences of the extensions (electrostatics, electric fields) for current electricity were hardly addressed. The historical development of models of matter was described in the grade 11/12 texts, with some attention to model limitations and idealizations.

**Student tasks**

Table 4 shows how often (parts of) student tasks met the criteria. Not applicable (n.a.) was scored when (part of) a task could not be related to a criterion or to electricity. For example: a factual recall task did not apply to any of the criteria. Impact7/8 and Impact9 show high scores on n.a., because many part questions concerned factual recall, and situations not related to electricity. Criterion 14 was scored in Impact7/8, Impact9 and Newton10 when tasks involved graphical representations of circuits (interpreting and drawing sketches and circuit diagrams).

The majority of the tasks in Impact7/8, Impact9, and Newton10 addressed conceptual understanding and mathematical relations (calculations) in models of electricity, but did not specifically address the model nature of these concepts and relations. Hence, the tasks did not differ from standard textbook conceptual or calculation questions. Two tasks in Impact7/8, one in Impact9, and three in Newton10 asked students to use model-related reasoning to support
decision making (e.g. selecting an electric appliance based on a model of energy use/costs; determining if cars can feasibly be powered by solar energy). The task complexity increased with increasing grade level.

Newton11 3rd Ed. Also contained standard textbook conceptual questions and calculation tasks. However, some tasks addressed aspects of modeling: students were asked to use computer models (on gas laws), to develop a model of an unknown object in line with Rutherford’s experiment, to compare and evaluate historical models, to explain current, voltage and resistance in terms of the free electron model, and to compare given data to model calculations.

The tasks in Newton12 3rd Ed. included conceptual questions and calculations in various contexts, at the level of the national exam. One question asked students to consider the idea of an electric field in a current carrying wire, creating a connection between the model discussed in the chapter and the theory of current electricity studied earlier.

All books contained student experiments: 15 in Impact7/8, 25 in Impact9, and 22 in Newton10, some downloadable as worksheets from the book’s website. Ten experiments in Impact7/8, 20 in Impact9, and 16 in Newton10 were related to the textbook models and theories of electricity. For example, in Impact9 an experiment aimed at extending the model of electric circuits by a stepwise investigation of the rules for current and voltage in parallel/series circuits. In the remaining experiments the aim was to produce a particular electric circuit or artifact (e.g. a simple electric motor), to show phenomena, to investigate a fact (e.g. the efficiency of a light bulb), or a relation between variables (e.g. the power of a solar cell depending on the load).

The amount of student guidance varied. Most experiments were guided by stepwise instructions with detailed descriptions of student actions, followed by one or more (conceptual) questions. The experiments and questions referred to macroscopic concepts such as electric current, voltage and resistance. They made no reference to the electron flow model of electric current. With increasing grade level the instructions became less detailed, but the Newton10 worksheets
still contained specific guidelines and fill in the blanks spaces for results. Newton11, Newton11 3rd Ed. and Newton12 3rd Ed. contained optional open-ended investigations. In Newton11 3rd Ed. and Newton12 3rd Ed. the investigations were described with general guidelines rather than detailed instructions. Some investigations asked for internet-based research, others for the use of a computer simulation, experiments and/or design.

In Impact7/8 and Impact9 the experimental aims remained implicit (e.g. “In this experiment you will investigate the current and resistance in a series circuit”), so that the emphasis was on the students’ hands-on activities. In Newton10 the aims were explicit and research questions were given for the four optional activities at the end of the chapter. In Newton11 all experiments were guided by research questions. In Impact7/8 and Impact9 one of the experiments followed an inquiry cycle, in which students were asked to experimentally test their prediction with some choice as to the approach. In some experiments predictions or expectations were asked (5 in Impact 9), at times after the description of the experimental steps (“did the results correspond to your expectations?”).

In all textbooks some modeling activities were present, in which students extended, modified or evaluated theoretical ideas (criterion 12). Mostly these were part of recipe type experiments. For example, Impact 9 contained an inquiry task using a simulation; in Newton10 the experimental tasks included finding quantitative relations between variables by means of a mathematical relation or a graph; in Newton11 one of the tasks involved investigating the limitations of a given mathematical relation; two tasks in Newton11 3rd Ed. asked students to compare and evaluate historical models (criterion 12); in Newton12 3rd Ed. a conceptual task included applying the model of an electric field to an electric circuit.

Chapter 6 of Newton10 contained two sections on inquiry and modeling skills respectively, mainly addressing technical aspects (e.g. data processing). The text in the modeling section explained simple dynamic models in physics and their creation using computer software. The related exercises were all taken from mechanics. Only one task was inquiry oriented: students were asked to create a dynamic model, compare the model results to experimental results and evaluate the model prediction.

In summary, the analysis showed that few student tasks were aimed at NOS aspects of models and modeling. However, many tasks paid attention to student conceptual understanding of the theory. Most experiments showed a theoretical intent, which often only became apparent from questions at the end of the instructions. In most experiments detailed stepwise instructions were used, and seldom an inquiry cycle. A few tasks asked for model related activities, such as supporting decisions or, evaluating models. The books for grade 11 and 12 contained end of chapter optional inquiry tasks. Dynamic models (unrelated to electricity) and models of matter (indirectly related to electricity) were explicitly addressed as models.

The models of electricity used in the books were a submicroscopic model of moving electrons, and macroscopic relations between current, voltage, resistance and energy. The macroscopic models used various representations (e.g. text, graphs, formulas). The microscopic model was occasionally used in explanations, but the tasks emphasized the macroscopic model.
DISCUSSION AND CONCLUSIONS

The results showed that models were treated differently in the textbooks, depending on the grade level. The books for grades 7 to 10 paid little attention to processes of knowledge development and the model nature of the physics knowledge. The theory was presented as a factual description, in which the historical development of our knowledge of electricity, or the development as it takes place for students in the course of the school years, did not come to the fore. The books for the higher grades explicitly addressed models, in ways more consistent with inquiry-based instruction. Examples are the chapter on dynamic modeling for grade 10 and the chapter on matter for grade 11. Models were presented as fallible descriptions of reality in a more or less historical sequence, with some attention to model limitations and idealizations.

In student tasks most emphasis was on the macroscopic concepts, although the relation to submicroscopic models was occasionally addressed. Experiments came with recipe-type instructions; they seldom asked students to go through (parts of) an inquiry cycle. The theoretical aims of experiments became apparent only by the conceptual questions at the end of the task, and not by asking students to express and substantiate expectations. Only the optional tasks in the grade 11/12 3rd Ed. chapters were clearly inquiry oriented.

We conclude that the way the theory was presented and elaborated in the lower-grade books and in parts of the higher-grade books was difficult to reconcile with an inquiry approach, because little was left for students to find out. Student activities that would fit such an approach, such as using models to explain phenomena, relating submicroscopic models to macroscopic concepts and relations, and using models to inform decisions, appeared only to a limited extent.

The exploration, evaluation and revision of models was not fully supported by the textbooks, although this would be helpful for students to understand phenomena and bring them in contact with scientific ways of thinking (Louca & Zacharia, 2012). The models of electricity were treated in a conventional way (Erduran, 2001): models were presented as final versions of human knowledge, and experiments were seldom used to develop, evaluate and revise models. The importance of models was recognized in the textbooks for grades 10 to 12, but not in the textbooks for the earlier years. Moreover, a consistent connection between models, modeling activities and inquiry was absent. Of course textbook authors face complicated choices when they have to decide what content to include for different grade levels. However, presenting models as facts and postponing models as purposeful representations of an aspect of the world (Seok Oh & Jin Oh, 2011) might misrepresent the nature of science for younger students. This may have a lasting negative impact on their view of science (Lyons, 2006).

An approach in line with NOS might use inquiry tasks, and not just explanations, to help students understand the relations between different models, such as the submicroscopic and macroscopic models of electricity. In higher grades more attention might be given to the electric fields concept and its role in electric circuits, as promoted by Galili and Goihbarg (2005) and Stocklmayer (2010). Model limitations deserve attention, because limitations are inherent in the model concept, and might point to new models with higher explanatory power.

The textbooks paid considerable attention to conceptual understanding, both in the descriptive text and the student tasks, which could provide a starting point for a more inquiry-based approach in future editions. Textbook authors could introduce the model nature of the theory...
at an earlier stage than in grade 11/12 in combination with more theoretically and experimentally oriented inquiry activities to bring the textbooks more in line with NOS.

The study indicates the possibilities offered by the textbook, but we did not investigate how these possibilities are used in practice. Another limitation of the study is that only textbooks from a single publisher were included. Additional research is needed to apply the criteria we developed to a wider range of textbooks.

It is important for textbook authors and teachers to be aware that models are used whenever electricity is taught and that models have a relation with scientific inquiry processes. Textbook authors could consider introducing the concept of a model as an abstracted and idealized representation of some aspect of the world at an earlier stage than in grade 10/11. In this way students may come to realize that they are constructing increasingly more sophisticated models of reality. Inquiry-based conceptual, experimental or simulation-oriented student activities could be directed towards modeling, for instance by asking students to compare model predictions, or to compare model predictions to experimental data. In some cases this requires only relatively small modifications of the tasks, such as introducing research questions and asking students to predict experimental outcomes before starting hands-on activities.

Instruction in line with NOS receives widespread attention as a means to make physics lessons more meaningful to students. It is important to critically examine the way textbooks, in descriptive content and student tasks, enable this type of instruction. We expect that the criteria compiled in this study are helpful for physics teachers selecting textbooks with an inquiry orientation, as well as for textbook authors.

**REFERENCES**

In this paper, I present an analysis of the ontology of educational constructivism in science education based on the externalist ideas introduced by Hilary Putnam in his epoch-making paper *The Meaning of ‘Meaning’*. I propose a mental experiment, adapted from Putnam’s famous Twin-Earth examples, to show that learning about natural kinds cannot be deemed to be the result of a process of subjective construction. Since natural kinds are a central part of the experimental sciences, I conclude that constructivism, in its usual presentations, is not a valid model for the teaching/learning of these disciplines. The obvious way to dodge this conclusion implies challenging the presuppositions of Putnam's analysis, and in particular to abandon the idea that there exist natural kinds. Thus, educational constructivism entails a conventionalism about natural kinds. Finally, I show that the converse is also true in this case: assenting to the existence of natural kinds involves a rejection to any form of educational constructivism.

**Keywords**: Hilary Putnam, semantic externalism, educational constructivism, science education.

**INTRODUCTION**

Although under the heading ‘constructivism’ there is not a unique theoretical approach (Matthews 2000a, b; Rowlands & Carson, 2001), all the constructivist educational proposals share a family resemblance, namely the “view of human knowledge as a process of personal cognitive construction, or invention, undertaken by the individual who is trying, for whatever purpose, to make sense of her social or natural environment” (Taylor 1993, p. 268). It is thus possible to use the term *constructivism*, in singular, to allude to a family of educational proposals based on the vision of learning as an active process where the previous cognitive contents of the learner play a crucial role (Bodner 1986; Bodner, Klobuchar & Geelan 2001; Taylor 1993; Taber 2006, 2009).

At the core of the different educational constructivisms there is thus a theory of knowledge acquisition. Learning, from a constructivist point of view, is not an apprehension of some ready-made pieces of knowledge, but an individual process of elaboration of information. I do not think that much argument is required to show that the consequences of this seemingly sensible stance are far reaching. Besides its obvious, if often overlooked, ethical and political implications, constructivism cannot be separated from some crucial epistemological and ontological questions (Matthews 1993, 2002).

In a series of previous papers I have focused on some philosophical issues that stem from the application of constructivism in several specific educational areas. On the one hand, I have shown that didactic constructivism is at odds with some basic assumptions in chemistry (Sánchez Gómez 2013, 2016; Sánchez Gómez and Morcillo 2014). In particular, I have argued that constructivism implies a semantic internalism for the chemical names, such as ‘water’ or
‘CH$_3$CH$_2$OH’. Semantic internalism is the thesis that the meaning of a word is determined by the psychological state of the person who utters it. From an internalist point of view, the meaning of a chemical formula is what the individual who writes it wants to express by using it. Thus, in this internalist perspective, the meaning of, for example, ‘water’, can be established by asking the person who utters this word to describe what water is for her or him. Thus, educational constructivism seems to be incompatible with the much cherished chemical tenet that the idea that the meaning of a chemical formula is fixed externally to the individual who uses it. This externalist position rests on the assumption that it is the microstructure of the substance it refers to what determines the meaning of a chemical name. In other articles I have analyzed the methodological commitments that constructivism poses to educational research (Sánchez Gómez 2014, 2016; Sánchez Gómez and Morcillo 2014). My conclusion is that only qualitative methodologies comply with the stringent epistemological constrictions of constructivism.

In all these papers I have explicitly drawn on the analysis of Hilary Putnam of the problem of the reference of natural kind terms, as presented in his epoch-making paper The Meaning of ‘Meaning’ (Putnam 1975).\(^1\)

In that work, Putnam took an explicit externalist stance that is well enciphered in his famous statement “Meaning just ain't in the head” (Putnam, 1975, p. 227). In this article I extend my previous ideas to any educational exchange in science education. I will delve into the ontological implications of educational constructivism, and in particular I will focus on the notion of nature implicit in this line of thought. In an appendix at the end of this article I have included a brief review of the ideas developed in The Meaning of ‘Meaning’. Readers not acquainted with the ideas of Hilary Putnam are kindly referred to this appendix.

In order to make my argument, in the next section I present an educational adaptation of the famous Putnam’s Twin-Earth mental experiment. In the third section, I analyze this experiment, to conclude that the usual versions of educational constructivism are not compatible with a realist vision of natural kinds. I further argue that the only way of sparing constructivism in science education implies accepting that natural kind terms do not refer to an actual underlying structure of nature, but to a conventional classification that responds only to the interests and abilities of the classifier. Finally, I present a preliminary revision of the ethical consequences of taking this anti-realist stance in science education.

**METHOD**

A mental experiment in science education

Let us imagine a possible world where there is a student, Pedro, who has the idea that the gas that is emitted by a piece of iron when it is treated with an acid is helium. It happens perhaps that when the reaction was explained in class Pedro only learnt that the element that the gas is made of is the main component of the Sun, and he already knew that Helios is the...
personification of our star in Greek mythology (Pedro, though not particularly fond of chemistry, has a sound classical culture). Besides, it was said in class that the gas can be employed to fill balloons, and he also knew from an alternative source that helium is sometimes used for that purpose. Thus, when he sees the gas bubbles generated in a test tube as a piece of iron is being treated with hydrochloric acid, he has good reasons to believe that that gas is helium.

In the possible world where Pedro lives there is an exoplanet, Twin Earth, almost identical to the Earth. In particular there lives a twin-student that is an exact duplicate of Pedro, to the extent that Pedro’s and Twin-Pedro’s biographies are indistinguishable, so are therefore their internal states at any time. The only difference between Earth and Twin-Earth is that in the latter the gas that is emitted by any active metal when it is treated with an acid is called helium.

And so then, the internal states of Pedro and Twin-Pedro as they think, or say, “Helium is emitted when a piece of iron is treated with an acid” are identical but their beliefs are different. When Pedro sincerely says “That gas is helium” he is in fact stating a false belief. On the other hand, when Twin-Pedro utters the same sentence, he is in fact expressing the true belief that in the Earthian dialect of English could be enciphered in the proposition “This gas is hydrogen”\(^3\).

As I elaborate in the appendix at the end of this paper, from a Putnamian point of view, one, and only one, of the following options must hold:

1) The internal states of Pedro and Twin-Pedro do not determine the meaning of ‘helium’, nor the mental content associated to this term.

2) The meaning of ‘helium’ -or, again, the mental contents of Pedro and Twin-Pedro as they think “This is helium”- does not determine the extension of this kind term.

Since ‘helium’ is a natural kind term, there is a sound argument against 2 (see Appendix) and therefore, from an externalist point view, I must be accepted.

In a synthetic way, a Putnamian interpretation of the experiment would be like follows. Both Pedro and Twin-Pedro are internally the same, but they refer to different forms of matter. It is the actual nature of helium, regardless of what Pedro of Twin-Pedro may be thinking about it, what enters into the meaning of the term ‘helium’ in their respective idiolects. But since this nature is not fully known to them, they should in the end rely on experts to decide what exactly they are thinking about as they say ‘This is helium’. The meaning of ‘helium’ for Pedro and Twin-Pedro depends on the extension of the word, and this is fixed by some well-defined physical properties of the gases they refer to in their respective linguistic environments. It is the community of chemists, and that of twin-chemists, who are to establish what are the relevant properties to be taken into account, and therefore, what helium actually is in Earth and

\(^3\)According to the theory of rigid designation that I review in the Appendix, it would make no sense to say that the name ‘Helium’ refers to different forms of matter if Earth and in Twin-Earth. Instead, it should be argued that what we have here is a case of polysemy, that the utterance ‘helium’ has different meanings in Earth and in Twin-Earth, as though in fact we had two different words. And since Pedro and Twin-Pedro are, by construction, internally identical, the meaning of ‘helium’ for them cannot be determined by their respective psychological states. If Pedro were transported to Twin-Earth, he would not be aware of being using a different word from the one employed by Twin-Pedro.
in Twin-Earth. It is easy to see that this argument is equally valid for the mental contents associated to a natural kind term. And thus, the mental contents that Pedro and Twin-Pedro have about helium are determined outside their respective corporal limits.

**DISCUSSION**

Let us take an educational look on our mental experiment. Since Pedro’s and Twin-Pedro’s mental contents about helium are not determined in their respective inner spheres, they cannot be an individual construction, in any reasonable sense of the word ‘construction’. In fact, not even a collective or social construction is acceptable, since it is nature what in the end fixes the meaning of ‘helium’. Obviously, this conclusion can be readily generalized: no idea about a natural kind can be regarded as a construction. But natural kinds are at the core of the discourse of the experimental sciences, to the extent that the usage of natural kind terms can be employed as a demarcation criterion for these sciences (see, for a rather revealing example of this position, the introduction to the entry ‘Natural Kinds’ in the Stanford Encyclopedia of Philosophy -Bird and Tobin 2016-). In conclusion, constructivism is not a valid theoretical approach to the teaching/learning of the experimental sciences within the conditions implicit in our mental experiment. Thus, in order to study the limits of educational constructivism, these conditions must be analyzed.

It is very easy to see that there are three presuppositions implicit in Twin-Earth experiments. The first one is the validity of the Twin-Earth hypothesis itself, that is, the assumption that it is possible to have psychological duplicates in two alternative non-identical worlds. The second is assuming that psychological states are narrow. And finally, a realist vision of natural kinds. In this paper, in order to delve into the ontological implications of constructivism, I will focus on the third one.

Putnam’s analysis is crucially based on the idea that natural kind terms are rigid designators (see Appendix). A rigid designator is a word that has the same reference in any possible world. Therefore, to refute Putnam's argument one should either reject that kind terms are rigid or, of course, deny the existence of natural kinds. Regarding the former, some objections against the rigidity of kind terms have indeed been raised (see, for an excellent up to date review, the section 4.2 of the entry “Rigid Designators” of The Stanford Encyclopedia of Philosophy -LaPorte 2016-). Anyway, without entering in the extremely complex subtleties of modal logics, it cannot be said that a consensus against rigid designation has been reached so far. In fact, there is not even a specific proposal in this respect can be pointed out as particularly accepted. Thus, the obvious way to criticize a Putnamian interpretation of Twin-Earth experiments passes through objecting to the idea of natural kinds, or at least to the possibility of an epistemic access to them. In our specific example, a possible way to give a sensible explanation of the experiment of Pedro and Twin-Pedro within a constructivist vision of learning would imply rejecting that helium is natural kind.

Curiously enough, the conception that there are not natural kinds is usually called conventionalism or conventionalism -I shall use here the latter term, in order to avoid a confusion with didactic constructivism-. A distinction can be drawn between a weak and a strong conventionalism. Weak conventionalism does not denies that nature can be made up of kinds,
but it assumes that our cognitive abilities are not tuned to uncover them. Weak conventionalism is thus a form of skepticism. Strong conventionalism, on its side, takes a metaphysical stance by rejecting that there is an immanent order in reality. Thus, in sum, a constructivist interpretation of mental experiments like ours entails a number of strong logical, epistemological or even metaphysical tenets.

Let us think, for example of an educator who is sympathetic to the pupilcentric vision of the teaching/learning process that is inherent to constructivism (Gash 1993, Fourez 1998). I do not think it is too outlandish an assumption (at least it is not at all within the Spanish community of educational researchers). My point is that this position is not just an ethical view. For, in fact, our educator, by subscribing to the ethical tenets of constructivism, is also endorsing a conventionalism about natural kinds, even if she or he is not aware of it. Admitting that the student is the center of the teaching/learning exchange entails that the only rationale behind any classification employed in the classroom are her or his interests and expectations.

Thus, our constructivist educator must be ready to accept that there is not such a thing as a natural classification. It is up to them to decide whether they subscribes to this view as a part of a skeptical stance, or maybe as an outcome of something metaphysically stronger. But, of course, the converse is also true: a person who does not want to give up natural kinds cannot be a constructivist. Such is, in fact, my personal option.

CONCLUSION

Educational constructivism stems from a basic intuition that underlies all the contemporary educational research: the evidence that students have rather personal conceptions about school topics, and that these conceptions show a stubborn resistance to change. On the other hand, the idea of learning as construction is extremely problematic from a philosophical point of view. Can we account for the evidence of the irreducible variety of the students' ideas without getting into a theoretical deadlock?

I argue that any educational theory that goes beyond a specification of techniques for facilitating the learning of a given issue must be understood as a part within a larger ideological cluster. There is not such a thing as a philosophically aseptic educational theory. My point is that any educational proposal must take into account all this philosophical entourage if it aspires to coherence (and thus to usefulness). In the case of educational constructivism, the usual definitions that focus only on its psychological or epistemic side (see, for example, Taylor, 1993, p. 268; Staver, 1998, pp. 504-505) are incomplete. In my view, constructivism must be seen as a bunch of ideas from different fields with the common denominator of placing the learner at the center of the educational process. This position might be well enciphered in a statement of Protagorean ascent⁴:

*The pupil is the measure of all (the educational) things.*

Take a stance on it and act accordingly.

---

⁴ At *Theaetetus* Plato quotes Protagoras’ dictum “*Man is the measure of all things*” (Theaetetus, 160d). In the dialogue, Socrates interprets this statement as a form of epistemic relativism.
ACKNOWLEDGEMENT

This work has been supported by the Spanish Ministerio de Educación, Cultura y Deporte, through the research project FFI2014-57064-P. The author is member of the research group Methods of Causal Inference and Scientific Representation (MCISR), based at the Complutense University of Madrid.

APPENDIX: HILARY PUTNAM ON THE MEANING OF NATURAL KIND TERMS

In order to make my argument, it may be interesting to briefly present the most relevant features of Hilary Putnam's theory of natural kinds as presented in his paper *The Meaning of 'Meaning'* (1975).

Putnam acknowledges three parts in the semantics of a word: on the one hand, its reference, that is, the objects named by the word; on the other hand, its meaning, that is, the epistemic component of the world, what we want to convey when we employ it; and finally the psychological state of the person who utters or listens to a word. Putnam’s primary interest in *The Meaning of ‘Meaning’* is to criticize a time-honored semantic view that is usually known as *descriptivism*. According to this view, if we want to know the meaning of a word we must ask the speaker to describe what she or he intends to mean by uttering it. For example, if somebody employs the Japanese word ‘Ushi’ (牛), we should ask her or him to describe what an Ushi is. The speaker would probably answer by giving a series of definite descriptions such as “They are animals”, “They have horns”, “They produce milk”, and so on. The underlying assumption is that these descriptions will eventually permit the hearer to realize that Ushi are in fact what English speakers call cows. This seemingly common sense view was philosophically elaborated during the first decades of the 20th century, chiefly by Gottlob Frege and Bertrand Russell.

In a more technical way, descriptivism can be characterized as the conjunction of two independent theses (Putnam 1975, pp. 216-222):

1) *The psychological state (in the narrow sense) of the speaker determines, or fixes, the meaning of a word.*

---

5 Putnam’s ‘meaning’ is equivalent to Frege’s ‘Sinn’ or to Carnap’s ‘secondary meaning’.
The meaning of a word determines its reference. Since determination is a transitive relation\(^6\), the semantic position criticized by Putnam implies that the reference of a word is fixed by the psychological state of the speaker. For obvious reasons, the internal determination of meaning and reference is usually known as *semantic internalism*, while the rejection of this view is called *semantic externalism*. Putnam, in sum, takes an explicitly externalist stance.

Putnam’s analysis is restricted to a particular type of words, natural kind terms. A natural kind is the result of a non-arbitrary sorting of the things of the world. Typical examples of natural kinds are the chemical substances or the biological species\(^7\). Some authors, chiefly Saul Kripke (Kripke 1972), have argued that natural kind terms are rigid designators, that is, that they have the same reference in any possible world. Putnam uses this conclusion to show that the meaning of a kind term necessarily determines its reference. Thus, in order to refute semantic internalism Putnam focuses on the determination of the meaning by the psychological state.

The strategy of Putnam consists in putting forward a mental experiment that makes evident that the internal state of an individual cannot fix the meaning of their words. The specific experiment designed by Putnam consists in considering a possible world where there is an exact duplicate of the Earth, Twin-Earth, identical to our planet in any respect but in some systematic changes in the natural environment. Putnam, for example, propounds that in Twin-Earth the liquid that fills the seas, that falls from the sky in form of rain, and so on to exhaust all the descriptions that we can give of water, is not H\(_2\)O but XYZ\(^8\). In Twin-Earth, according to the conditions of the experiment, there is an exact duplicate of any person who lives in the Earth. Any earthling, by definition, share its biography with their twin-earthling counterpart so that they both are in exactly the same internal state at any time. Thus, when I say ‘Water is wet’, my psychological state is exactly the same as that of my twin-earthian mirror image. But the reference of ‘water’ in English and in Twin-English is evidently different.

As I said above, Putnam’s analysis is crucially based on the idea that natural kind terms have the same reference in any possible world, that is, that they are *rigid designators*. For Putnam, for example, the sentence “In Twin-Earth water is XYZ” would make no sense. Instead, we should say that there is not water in Twin-Earth. In other words, for Putnam it is not that the

---

\(^6\) Given two properties A and B, A is said to determine B if and only if it is the case that if two individuals coincide with respect to A, then they *necessarily* coincide with respect to B. For example, the answers to a multiple-choice test determine the mark awarded to it, since two identical tests must have the same mark. Besides, two different marks cannot correspond to identical tests, although the same mark can be awarded to different tests. In our case, if any two persons are in the same psychological state as they utter a word, the meaning of their respective utterances must be the same. On the other hand, two terms with different meanings must correspond to different psychological states.

\(^7\) There is some debate about the ontological status of chemical substances and biological species. In both cases there are some limiting cases, such as berthollide compounds or microbiological species that are difficult to sort into a well defined kind. Anyway, and always keeping in mind this problems, we can rather safely assume in this paper that the usual chemical substances and species are non-problematic natural kinds.

\(^8\) As it was noticed from the first moment, Putnam’s most known example is somehow misguided because, since water is the main component of the human body, this substance cannot be replaced without radically altering the physical constitution of a person, and thus twin-earthlings cannot be assumed to be exact duplicates of earthlings. Anyway, the argument is identical if less radical changes are adopted. Putnam himself presented alternative experiments in which in Twin-Earth elms are substituted by beeches, or aluminium by molybdenum.
word ‘water’ has different references in Earth and in Twin-Earth but instead that we have two different meanings, as though we had two different words with a common phonology. And since Pedro and Twin-Pedro are, by construction, internally identical, the meaning of ‘water’ for them cannot be determined by their respective psychological states. If Pedro were transported to Twin-Earth, he would not be aware that the meaning of his utterance ‘water’ is different word from Twin-Pedro’s.

The implications of the analysis of Putnam are immediate. First and obvious, the meaning of a natural kind term is determined by instances outside the skin of the speaker. In the words of Putnam himself, “meaning just ain’t in the head” (Putnam, 1975, p. 227). In a synthetic way, Putnam holds that it is the nature of a kind, that is, the properties that define which individual belongs to it, what actually enters into the meaning of a kind term. But since we are seldom aware of this nature, we must rely on the community of the experts in a specific field to fix the meaning of a kind term. For example, we must defer to the community of chemists to fix the meaning of ‘water’. Obviously, this scientific meaning does determine the reference of the word. Accepting, even implicitly, the opinion of the experts about natural kind terms is for Putnam an essential part of a normal linguistic competence. Thus, in practical terms, the determination of the meaning is always experienced by the individual as a socio-cultural feature. This is arguably the most relevant feature of Putnam’s externalism, and is usually dubbed as the thesis of the division of linguistic labor (Putnam 1975, p. 245 ss.). Second, although Putnam’s interests are primarily semantic, his conclusions can be readily extrapolated to the philosophy of mind, and in particular to the problem of the locus of mental contents. It is very easy to see that holding that the psychological state does not determine the meaning of a word is equivalent to stating that the mental content related to that word cannot be a subjective production either. Semantic externalism entails that our mental contents are also external (McGinn 1977).

The ideas of Hilary Putnam have given rise to a rich debate that stretches over the latest four decades (for an anthology of the main contributions to this debate up to 1996, see Pessin and Goldberg 1996). Against the externalist position there is a number of relevant philosophers, chiefly Noam Chomsky (1995), Jerry Fodor (1987, 1991), David Chalmers (1996, 2002) and Brian Loar (1988, 2003). These authors, from different positions, have defended that our mental contents are fixed internally. Nevertheless, a definitive argument against externalism has not been put forward so far. On the other hand, apart from Putnam, the most relevant author that have defended externalism is Tyler Burge (1979, 1986). Burge’s ideas intend to be more general than those of Putnam, and in particular Burge claims that externalism must be extended to any kind term, natural or not. Although I will primarily adhere to Putnam’s analysis, in this work I have adapted an example included in Burge’s Individualism and the Mental (Burge 1979) to create the mental experiment that I present in this paper. Anyway, it must be stressed that my argument here is essentially Putnamian.

---

9 I have drawn on Burge’s famous arthritis mental experiment. Burge’s compares Oscar, an individual who does not know that arthritis is a condition of the joints, and thus erroneously comes to believe that they has arthritis on his thigh, with Twin-Oscar, identical in any respect to Oscar, but one: in Twin-Oscar’s linguistic community ‘arthritis’ is employed in a wider sense, so that a pain in the thigh is also a symptom of this twin-arthritis.

STRAND 2: INTRODUCTION

LEARNING SCIENCE: COGNITIVE, AFFECTIVE, AND SOCIAL ASPECTS

The papers in the Strand 2 section of the eProceedings demonstrate the breadth of research within the strand, focusing on epistemological and ontological features of learning science, cognitive aspects of learning including representational work, and their links to emotions and attitudes, and the impact of different contextual and social features of the learning environment.

In this 2017 conference the paper set can be grouped into a number of themes of current interest. One theme is that of informal or out-of-school learning environments. Julia Suckut takes the contemporary interest in Germany in out of school laboratories and, making the point that these vary greatly in their approach while drawing on a common justification of authenticity of the learning setting, develops a schema for unpacking this notion of ‘authenticity’ that could be used in further research on the relevance of these environments for learning and motivation. Michael Budke and Marco Beeken investigate the effectiveness of the mobile ‘Greenlab-OS’ compared to university based labs on learner interest in chemistry. They showed a complex pattern of response but more positive results for the mobile lab. Dorothee Brovelli and Markus Wilhelm showed that a woodlice workshop associated with a science centre visit led to enhanced learning with no compromise in motivation, and further that a prior school based preparation lesson enhanced inquiry skills outcomes, thus demonstrating ways of optimising the outcomes of these visits. Margaret Blanchard and colleagues describe the effects on underrepresented students in the US, of programs of visits to STEM Career clubs. They used expectancy value theory to show strong motivation but no clear gain in content knowledge. In a similar vein, Susanne Walan and Birgitta McEwen in a study of students’ participation in a Swedish Science-Technology competition found students could not identify formal conceptual learning gains but were very positive about the competition as enhancing the social environment of the classroom through project based learning.

A number of the papers explore factors affecting learning and attitudes. Andrew Howes and colleagues at Manchester take the Bernsteinian notion of control as a critical pedagogical dimension to develop an instrument exploring teachers’ pedagogical choices. They then used a participatory photography design to explore students in disadvantaged contexts’ perspectives on science to show a mismatch between their interests and school science. They used a ‘funds of knowledge’ tradition to explore the potential development of a model of pedagogical choice. Samuel Wheeler and Margaret Blanchard from North Carolina examine choice in context of physics problems to show enhanced engagement and learning, differentiated on gender lines. Irene Drymiotou and colleagues from Cyprus examine the use of career-based scenarios and show these enhance situational interest, with three conditions associated with positive results. Lisa Schmitz and Sabine Fechner examine the potential of students’ questions based on everyday or theoretical contexts to form the basis of further investigative inquiry, and the conditions under which this could lead to productive work. Dennis Kirstein and colleagues explore the effect of grouping strategies on performance in inquiry learning, as a differentiated
guidance strategy. They found no direct effect from grouping but that feedback support led to enhanced outcomes. Cornelia Stiller and colleagues compared students engaged with practical work and analysis with those engaged with the analysis and reasoning only. They found the ‘hands on’ condition conferred advantages for both cognition, and motivation (using intrinsic motivation theory). Eloisa Oliveira and Brazilian colleagues explored the advantages of videos featuring presenter gestures compared with non-gesture conditions to find no difference between groups. They did however find constant spontaneous gesturing between subjects discussing physics events, leading to a conundrum as to the affordance of gesture to support learning. Finally, Bruce White from Adelaide undertook a survey of secondary students to ascertain their perceptions of what was important for effective studying. He found interest and effort to be the key features, consistent across subjects, and that there was an association between deep approaches to learning, and successful study skills. Eitemüller and Walpuski investigated motives for taking / dropping chemistry at upper secondary level in Germany and tried to determine predictors for academic success in chemistry.

Birgitta McEwen provides a theoretical account of epigenetics as a possible explanation for experimental findings concerning the effect of physical education on learning across subjects. She argues for an increase in physical activity in the curriculum.

Two papers explore the entailments of students’ epistemologies for learning quantum physics. Giovanni Ravaioli and Olivia Levrini interviewed students who did not accept quantum interpretations. They identified epistemic refusal as the basis for refusal for some students but also ontological and cognitive dimensions such as difficulties with spacetime visualisation. In a related paper, Malgieri and colleagues use markers in interviews to examine the processes of appropriation in students’ learning of quantum mechanics. They identify the effects of students’ idiosyncratic voices on their take-up of epistemological positions, and personal identity construction.

Shingo Unchinokura examines students’ use of particle models to represent dissolution, under different prompting conditions. The differences showed up in representing unfamiliar contexts. Students’ low awareness of models and modeling points to the need to make modelling work a more constant aspect of teaching and learning. Thomas Plotz and Fanny Hollenthoner undertook a repeat study of students’ representations of ‘radiation’. They found that compared to earlier studies students did not associate radioactivity with the Fukushima disaster, and that there was an increased association with cell phones and computer monitors, associated with increased exposure to media.

Finally, two papers explore the link between academic performance and emotion. Antonia Acedo and colleagues used a questionnaire to explore correlations between secondary students’ positive and negative emotions and their physics and chemistry grades. They found a highly significant link. Jose Marcos-Merino and colleagues explored the association between learning outcomes and emotions over the longer term, and different settings. They found an association that was sensitive to context, and differentiated on gender.

Russell Tytler and Graça S. Carvalho
In science education, out-of-school learning environments are viewed as especially authentic compared to school. Their authenticity is depicted as a feature that has a great positive influence on learning. Therefore student labs could provide better learning results than in-school teaching (Euler, Schüttler & Hausamann, 2015). Expectations regarding the effects of authenticity on learning results are high: It boosts motivation (Chinn & Malhotra, 2002), supports the ability of the students to act on their knowledge, fosters self-regulated learning and allows the students to develop more realistic views on the nature of science (Schwartz, Lederman, Crawford, 2004). In Germany student laboratories as a special type of out-of-school learning environments are very popular. But they differ greatly from each other. One consequence of this is that the research done in the area of student labs and its results is very difficult to compare. I present an operationalization of authenticity that provides a scheme to categorize student laboratories as well as discuss research results on student laboratories in relation to each other. It also directs the focus on some yet unanswered questions regarding the importance of authenticity.

Keywords: authenticity, student laboratories, out-of-school learning environments

OUT-OF-SCHOOL LEARNING ENVIRONMENTS AND STUDENT LABORATORIES

Out-of-school learning environments

Out-of-school learning environments encompass different places such as museums, science centers or the zoo. They can be labeled as “informal” learning environments in contrast to the “formal” learning environment at school. The informality is characterized by voluntary attendance, a non-didactic curriculum as well as nongraded activities (Rennie, 2007, p. 127). By integrating such learning environments in the teaching at school, parts of that informality are revoked. More so, if the visit is regarded as a learning resource, less so, if it is predominantly regarded as a social event for the class (Rennie, 2007, p. 141). In this article, the focus lies on the visit of out-of-school learning environments as part of school lessons. Therefore they are, despite their out-of-school context, regarded as environments than exhibit characteristics of formal as well as of informal learning. Generally, teachers visit out-of-school learning environments with their classes to enable the students to gain experiences that are not available at school, add perspectives not possible at school, or as a special event without clear connection to lessons.

Student laboratories

In Germany, a special type of out-of-school learning environment has become very popular since the late nineties: the so-called laboratories for pupils or student laboratories
(‘Schülerlabore’). They originate in the STEM subjects, but in recent years the offerings for other subjects like history, philosophy, languages or social science have increased (Haupt, 2015). Since the 2000s the number of student laboratories in itself is increasing, as is the number of published research regarding student laboratories. In 2015 over 300 laboratories were counted in Germany (Haupt, 2015). Research topics are mostly the effect of visits of student laboratories on the students’ motivation and interest (Scharfenberg & Bogner, 2014). The laboratories are mostly implemented at universities, research centers or industrial facilities (Dähnhardt, Haupt & Pawek, 2009). Mostly they offer the students the possibility to conduct experiments in professionally equipped laboratories and or the use of and interaction with real scientific objects or materials (Haupt & Hempelmann, 2015). It is often emphasized that student laboratories offer a more authentic learning than school and are therefore advantageous (Euler, Schüttler & Hausamann, 2015). I will further focus on this type of out-of-school learning environment.

THE CHALLENGE OF CATEGORIZATION

The initiators of student laboratories claim that these laboratories provide learning opportunities that school cannot offer. To be able to describe that uniqueness and maybe even transfer insights from research results gathered in this field on school lessons, some means of generalization is needed. The coined term “student laboratory” encourages the illusion of a well-defined environment of learning. The generalizability of the research results is despite that difficult as the researched student laboratories vary greatly in the executed kinds of learning arrangements and underlying concepts. Starting with the amount of time the students spend at the laboratory and not to end with the if or if not or how much self-regulated learning is possible. This is to an even greater extent true for out-of-school learning environments in general (Scharfenberg & Bogner, 2014; Itzek-Greulich et al., 2015). The idea is that if it is possible to describe student laboratories in a way which allows for a comparison regarding learning, that this way of description can be broadened to encompass all types of out-of-school environments of learning.

So far two main attempts at categorizing student laboratories have been developed. Both aim at very different distinguishing aspects, and they have certain shortcomings. The first was to categorize the student laboratories by funding (Dähnhardt, Haupt & Prenzel, 2009). While that is fruitful when describing the motives and aims of the student laboratories, it is not applicable in the context of generalizing research results on learning. A recent actualization of this one is a categorization by objective (Haupt & Hempelmann, 2015), which remains not useful concerning research results on learning. A second attempt is a description of subsets of student laboratories by using the learning activities of the students (Euler, 2009; Engeln, 2004). Here the special characteristics of student laboratories as learning environments different from school are not taken into account. Therefore it would be fruitful if a system of categorization could be found which focusses on learning related aspects and displays these differences.
THE CONCEPT OF AUTHENTICITY

The advantage of out of school learning environments and especially of student laboratories is claimed to be their authenticity (Braund & Reiss, 2006; Euler, 2009). That common reference to authenticity in the context of student laboratories supported the idea to use that concept to describe and categorize student laboratories. Authenticity is also a key aspect in current learning theories: In the context of situated learning, learning is regarded as a social activity, dependent on the persons from and with one is learning as well as the environment it takes place in (Brown, Collins & Duguid, 1989). Student laboratories provide a different learning environment than school, closer to the application of the content, and therefore enhance learning. A similar argumentation can be derived from the concept of anchored instruction (Bransford, Sherwood, Hasselbring, Kinzer & Williams, 1990). Taking a look at motivation and interest, authenticity can foster the development of those as well. The model of Deci and Ryan includes, that the learning of a person is supported when being embedded in a relevant context (Ryan & Deci, 2000). The person-object-theory of interest states that authenticity influences the development of interest (Krapp, 1999). Also, authenticity supports the development of adequate beliefs in NOS (Schwartz, Lederman & Crawford, 2004). To summarize, authenticity is a feature claimed to be sported by many student laboratories in contrast to school, while also being relevant for learning processes and the development of interest.

Authenticity contexts are transformed – authenticity as a perceived aspect

Authenticity is a concept used in everyday language with a meaning of “being original”. It is that meaning in which it is mostly used regarding student laboratories, but it lacks a clear definition (Bencze & Hodson, 1999). Authentic contexts are generally understood as “contexts where the knowledge [students] are learning can be realistically applied” (Herrington, Oliver & Reeves, 2003, p. 59). In contrast, a not authentic environment would be, where a realistic application does not take place. But then again, what means “realistic”? When preparing a topic for teaching at school it is often reduced, to make it digestible for the students (didactic reduction). By doing so its authenticity is transformed if not lost. Following constructivist views on learning, this school content is interpreted by the students, attributing to it their very own values and judging by that its authenticity. That means looking at learning environments three different authenticities are coming together: the original, authentic context of the content; the transformed content to adapt it to the learner (and other restrictions apparent at school); and the perceived content with the attributions to it by the students (Figure 1).

Operationalization of authenticity in four dimensions

The question is now, how can this transformation be operationalized? Lee and Butler (2003) speak of a “transformation of content knowledge, scientific thinking skills, and resources” (p. 927). Similar aspects are used by Chinn and Malhotra (2002) to define the differences between authentic inquiry and the one done in school: “Authentic scientific inquiry is a complex activity, employing expensive equipment, elaborate procedures and theories” (p. 177). Summarizing that and the above cited literature on learning, interest, and motivation, four dimensions can be distinguished in which the transformation of the authentic context happens:
1. The dimension of the thematic context, which encompassed the objects, theories, and content knowledge.
2. The dimension of the reason for dealing with a content.
3. The dimension of the used materials and the applied methods as well as their complexity.
4. The dimension of the physical and personal environment, including the dedicated time and the immersion into the original community.

Figure 1. Three authenticities at play

DIFFERENT AUTHENTICITIES – THE ORIGINAL AND THE TRANSFORMED: AN EXAMPLE

The transformation of a context along the four dimensions is depending on the learning environment it is adapted to, its and the learners' boundary conditions and the learning goals pursued. The following example on the physics of flying illustrates the idea of transformation.

The Original

In physics, the science behind a flying plane is to be discussed. So the “original” is the flying airplane itself. One can describe it in the above mentioned four dimensions: the context where it is used e.g. the transportation of goods or persons, relevant theories are aerodynamics, fluid dynamics and so on. The reason (why bother with the science) could be the technical challenges which have to be solved, e.g. build a plane which transports more goods faster while consuming less fuel. The materials with which the engineer concerned with that project will work are technical plans, requirements from the company or government regulations, the materials of which the plane could be built, like steel, carbon etc. The methods the engineer uses are his or her specific knowledge, tools of engineering, special software etc. The environment in which
that all takes place is the company, the office of the engineer and his or her colleagues, maybe suppliers, and subcontractors. Now, this context is transformed into different learning contexts (Figure 2).

![Diagram showing transformation](image)

**Figure 2. Example of transformation**

**The Transformed – A: At school**

I offer the description of a not very context driven introduction of the topic, a bit exaggerated for the benefit of highlighting the concept of the four dimensions. Here the context is the lesson. The physics why a plane flies is a topic in the school book, the only reference to actual planes is a picture of a plane next to the text. The reason the teacher offers the students is that its part of the curriculum and will be included in the end-of-year exam. The materials are the school book, maybe some experimental set-ups especially designed for school, dating back to the sixties. The used methods are methods known from former lessons, mainly the teacher talking, writing on the board and conducting one experiment up front, where two students assist. The environment is the school itself, the classroom, fellow students and the teacher.

**The Transformed – B: At a museum**

Imagine a museum on the history of flying with an actual plane as an exhibit. The context is provided by the plane itself, the panels explaining about the plane, its origin and its purpose. The reason why bother with the science behind flying is also introduced via the panels, as the shown plane holds the record in revenue load. The materials are the plane itself, maybe a flyer
about it, the visitors cannot interact with the exhibit, but solely read and look. The environment is the museum with its exhibits, fellow visitors, maybe a guide.

**The Transformed – C: At a student laboratory**

As another type of out-of-school learning environment, now imagine a course day at a student laboratory situated at the company in the “original”. It is expected that the students conduct several experiments on the science behind flying. The context is provided by the teaching materials. In contrast to the materials used at school, the student laboratory provides context-based materials, informing at length about the technological challenges that need to be addressed. The experiments are specially designed set-ups, re-modeling the tools of the engineer in the “original”. The environment is the laboratory, the company, and its surroundings, the introducees maybe students, scientists, or the engineer him- or herself.

**The Perceived**

As stated above, authenticity in itself is something prescribed to something by someone. As known from constructivism, every learner constructs his or her environment and interprets it based on his or her previous experiences and beliefs. Therefore the authenticity of the original maybe by definition authentic but could not be perceived as authentic by the learner. For example, if the engineer is not wearing a lab coat and behaves in a way not attributed by the learner as authentic.

**APPLICATION ON RESEARCH STUDIES ON STUDENT LABORATORIES**

Applied to actual student laboratories, challenges of the usage of this concept of authenticity and its transformation become apparent. To test the operationalization I categorized three student laboratories mentioned PhD-theses or research papers (see Table 1). In none of them perceived authenticity is addressed and it is also difficult to find a concrete “original”. The closest description of an original can be found by Sumfleth and Henke (2011). Their project addressed gifted students at the end of their time at school. The complexity of the original context is less reduced while the other two student laboratories address younger students. In Materials and methods, the first two of the laboratories do not seem to differ from school. Regarding the communicated reason different values can be found. The first one very close to the one depicted in my imaginative school setting, the last one very close to the “authentic” one, and the second one situated in between. The environment is not school, but in the first to laboratories appears rather disconnected to the authentic context, whereas the third one seems to be rather close to the scientific laboratory.

DISCUSSION & OUTLOOK

The here depicted system of categorization allows to describe student laboratories and to compare those. Albeit it requires a certain depth in the available information on the laboratory. A more detailed description of different levels of transformations in the four dimension would enhance its informative value. Looking at the three analyzed student laboratories the question arises, if the uniqueness of laboratories may not root in their authenticity but in something else. Two of the looked at laboratories seem to be closer to school than to the authentic context. A finer operationalization of authenticity is needed to be able to answer that question. Also, the question arises, how much “authenticity” is needed to be advantageous. And finally, how – once a more authentic learning environment is realized – to ensure that it is perceived as authentic by the students, and how in it all that relates to learning, and the development of motivation or interest of the students.

ACKNOWLEDGEMENT

Part of the work was conducted within the project “Zukunftsstrategie Lehrer*innenbildung (ZuS)” (Future strategy for teacher education). This project is part of the “Qualitätsoffensive Lehrerbildung”, a joint initiative of the Federal Government of Germany and the Länder which aims to improve the quality of teacher training. The programm is funded by the Federal Ministry of Education and Research.

"ES GEHT UM DIE WURST!" - THE GREENLAB_OS

Michael Budke and Marco Beeken
University of Osnabrück, Osnabrück, Germany

Labs’ for school students at universities enjoy great popularity and offer valuable opportunities to enrich the everyday school life of students. But not for every class it is possible to participate at these locations - often a long journey, temporal expenditures and costs for transport can be reasons to not make use of such a learning opportunity. The GreenLab_OS project thus presents a mobile extracurricular learning location which relates to relevant issues of ecological sustainability. Especially, disadvantages of stationary student labs shall be compared to this mobile version with a questionnaire study. The value of mobile student labs as an appealing alternative for students in correlation with higher motivational effects in regular chemistry lessons shall be determined. Results from a pilot study (n=270) indicated no significant difference between both learning locations concerning self-concept, subject- and object interest, whereas the study yielded significant changes in students’ motivational attitudes towards chemistry classes. In this context, initial findings suggest the effect to be significantly higher in students participating in the mobile student lab than in those visiting the stationary variant at the university.

SOCIETAL RELEVANCE – WHY SAUSSAGES?

In October 2015, the International Agency for Research on Cancer (IARC) issued a press release suggesting proceeded meat to have carcinogenic effects. According to the IARC, proceeded meat includes all dry-salted, fumed or in any way cured or taste enhanced meat products, thus also referring to sausage products (IARC, 2015). With this press release newspapers titled that “Processed meats rank alongside smoking as cancer causes” (The Guardian, 2015) and “The World Cancer Research Fund International (WCRF) advises that people can reduce their bowel cancer risk by eating no more than 500g (cooked weight) per week of red meat, such as beef, pork and lamb” (The Telegraph, 2015).

The Guardian
Processed meats rank alongside smoking as cancer causes – WHO

Figure 1. Newspaper article Monday 26 October 2015, The Guardian

Not at least due to such reports, the annual demand for sausage products has constantly decreased in the last years. Nowadays the general amount of sausage products consumed has dropped by eight percent in comparison to 2008 and the demand for meat almost by nine percent (Gesellschaft für Konsumforschung e.V. [GfK], 2015). The trend towards a meat reduced consumption lifestyle is moreover supported by nutrition industry and according offers. Sales of such “green” food products have nearly doubled within the last four years (Pech-Lopatata, 2015). Figures released by the Consumer Index of the GfK demonstrate this increase to be more than just a current trend: a new market sector has developed with meat...
equivalent products forming one sub category of meat replacement products (GfK, 2015). This
category refers to products looking like meat or sausages and bearing corresponding names
like “vegetarian Schnitzel”, or “vegetarian sausages” (Pech-Lopatta, 2015).

While in 2016 the general consumption of meat continued to decrease, January 2017
constituted a turning point though, showing again an increase in comparison to the previous
years (GKF, 2016; GKF, 2017). At the end of the last year the numbers of sold vegetarian meat
substitutes have likewise significantly decreased – a change which might be explained by the
low quality of meat substitute products and the fact that often consumers liked to try these
products once in order to follow the trend but did not stick to this product type permanently
(Spiegel online, 2017). It remains to be seen how the trend will develop but the society is
increasingly aware of a responsible meat consumption.

With continuing social debates on subjects like climate change and scarcity of resources, the
topic of agriculture-nutrition-health increasingly comes to fore. Consumption of sustainable
food items can make an important contribution to food since sustainable food aggregates
several ecological, economic, social, and health-related demands (Riegel & Hofmann, 2011).
Prima facie vegetarian meat substitutes appear to represent an alternative choice to meat
consumption. A representative survey in 2014 conducted by the Federal Environment Agency
of Germany on environmental awareness in youth demonstrated that merely 21% of
adolescents in Germany define a good life by enjoying nature and preserving an intact
environment. However, most are familiar with ecological impacts due to an extent meat
consumption and an increased environmental awareness can be noted in this regard. Notably,
in their opinion environment-related topics are not sufficiently addressed in schools and more
offers are requested (Umweltbundesamt [UBA], 2014). Because of these findings it seems to
be an important topic to increase the awareness among pupils concerning a sustainable
environmental consciousness. During the traditional chemistry lessons there are also less
opportunities for teaching evaluation skills – it is still about teaching professional knowledge
in chemistry. Especially chemistry and physic classes are rather unpopular among pupils
because the lessons are

- focused on purely systematic technical learning
- poorly orientated on the goals of a general education for all
- neglecting the social dimensions of general education
- show no consideration for the interests of the majority of the pupils who are not
interested in a later career in chemistry or physics (Feierabend & Eilks, 2011).

As a consequence of the development and findings it was decided to design a motivating an
innovative setting in which societal relevant topics are focused on and pupils need to reflect
and discuss these.

Despite the many benefits of student labs like excellent attendance, high motivational effects
for boys and girls alike and long-lasting effects which have been shown by an empirical study
of the IPN Kiel, there are also negative effects for stationary labs for pupils at university, school
students research centres or facilities at science companies. To visit such facilities, the pupils
often have to travel a long way and bear the costs on their own. Especially the lab itself and the
materials used may lead to a small payment by the visitors. For every school excursion an
additional accompanying teacher is needed whether there is a supervision at the learning location or not. Further permissions by the principal and an information notice for the parents are essential. This organisational effort leads to the fact, that it’s not practically for every teacher to visit an extracurricular learning location.

Sometimes universities provide boxes containing experimental sets, but these also need to be picked up at the university and need to be returned quickly after usage so that they can be newly prepared for the next group. Thus a mobile lab can in comparison to other opportunities lead to a profitable simplification for teachers.

In the field of mobile offers, there are already a few from a small bike with a trailer up to a big truck containing a complex laboratory. The Humbold Bayer Mobil, achievement of the cooperation of the Humbold-University of Berlin and the Bayer Science & Education Foundation, is offering a mobile lab for pupil’s grade 5-8 for Berlin and Brandenburg representing a good opportunity to experience science with experiments. Its main focus is to increase the interest in science and show some career prospects (Humbold university, 2016). The RWTH Aachen had a similar project called the RWTH Science Truck. With topics like the operating principle of GPS or the production of alcohol, the truck was in usage around the year 2002. Since then the topics have changed and now it’s rather a commercial truck to promote the courses at the university of Aachen (RWTH, 2017). The IPN Kiel is running the mobile “Forschungsexpress” (= research express) for pupils of primary schools in Schleswig-Holstein which offers an opportunity for explorative research (IPN, 2017). Also the GreenLab_OS shall be such an opportunity for pupils from grade 7-9 with a focus on a self-guided experimental amount and elements of science communication.

THE GREENLAB_OS AND GENERAL THEORY

The innovative approach of the mobile student lab shall be an extracurricular learning location for high school students with a mix of event entertainment and education, as well as it shall offer an open space for scientific experimentation. Up to now, the topic of the GreenLab_OS is a comparison between vegetarian and meat sausages and their ingredients. Additionally, a lab-day about the problems of micro plastics and the role of chemistry in forensic science of real criminal cases will be developed soon. These lab days are assisted by several university students and can take place at university or at school. The content of the GreenLab_OS – theoretical as well as experimental – is the same at both locations. As former studies have shown, a cross-linking with chemistry classes is essential for the success of such extracurricular activities (Rehm & Parchmann, 2015). Every participation at the GreenLab_OS is well prepared in school by the teachers who are assisted with material from the university. The duration of one lab-day is like a normal day in school for around 5 hours. Its structure is inspired by Chik and the concept of exploratory and evolving teaching procedures by Schmidkunz and Lindemann (Demuth, Gräse, Parchmann & Ralle, 2008; Schmidkunz & Lindemann, 2003). Because of the problem-based orientation the pupils are offered to generate new elements of knowledge throughout cognitive activity (Pfangert-Becker, 2010).
The structure of the lab-day is designed as follows: At first a short film is presented in which students meet to have a barbeque. For this, meat and veggie products have been bought leading to an argument about it. Then the participants of the lab day are asked to discuss their own experiences and opinions. In an ensuing blind tasting, two different sausage products – one traditional animal sausage product and a vegetarian alternative – is presented to the school students. Since both cannot univocally be sensorically assigned, the necessity for several experiments in order to classify the presented products arises. For this purpose, students conduct respective experiments on chemical separation and hereby detect, inter alia, plant pigments and nitrite.

To analyse the water content, the products are dried in a microwave. Afterwards the fat is extracted with acetone. The nitrate amount can be measured with an aquarium test. The plant dye can be detected by acid and alkaline solutions because the dye reacts like a pH-indicator and the amount of energy is measured by a low cost calorimeter. The workshop lasting several hours is concluded with a discussion on several vegetarian and conventional products based on explicit assessments (Eggert & Bögeholz, 2006).

It is the aim of this project to conduct the workshop as a stationary offer at universities as well as a mobile alternative in schools. Both variants shall moreover be evaluated in terms of possible differences concerning areas like subject interest, motivation, and learning success. As relevant studies in the field of psychology demonstrated, learning success is not only associated with previous knowledge. It can also be related to the level of attentiveness and the interest of the learner as well as the learning context or the place of leaning (Roth, 2004). The subjects learned are hereby for example linked to the original source of information in the process of learning. Spatial and temporal memories develop likewise (Schacter, 1996). In 1981 Gordon H. Bower could prove it to be easier to retrieve previously learned information if the location of learning corresponds to the place of retrieval. Apart from the place of learning, emotions prevailing during the time of learning can likewise facilitate the learning process – should they be congruent during the time of learning and retrieval of information, knowledge reproduction has proven to turn out better. Transferring this model to the context of school and
the GreenLab_OS, it can be assumed that students participating in the mobile workshop conducted in the regular context of school can more easily retrieve information learned during this process, than information learned in other contexts (= stationary student labs at universities). These might be accompanied with divergent emotions. This could likewise imply an increase in motivation concerning regular chemistry classes if the learner experiences the GreenLab_OS in school contexts, since the information learned in the workshop can then more easily be related to regular lessons. If significant differences between learning environments of school and universities can be detected this could also have an influence on the effectiveness of mobile vs. stationary student labs.

Based on that, we want to know if the participation in the mobile GreenLab_OS leads to a higher increase of interest for regular chemistry classes than the participation in the stationary GreenLab_OS. Moreover, it shall be analysed if there is an improvement in the learner’s interest in the subject, professional interest or self-concept with reference to the place of learning.

**METHOD**

To analyse the effects of the mobile and stationary variants of the GreenLab_OS, a Questionnaire for three different occasions in a pre-, post- and follow-up-test design was chosen. The student questionnaire includes items being used in previous studies to measure effectiveness of scientific subject- and object interest, self-concept and several items relating the GreenLab_OS were added (Huwer, 2015; Marsh & Yeung, 1986; Rheinberg, 2001; Shavelson, Hubner & Stanton, 1976). Students’ responses were surveyed by means of a 6-point-likert scale (1 = “totally disagree” to 6 = “totally agree”). 270 Students from eight different classes from grade 7-9 participated in the pilot study whereas 116 cases could be used because they participated at all three times of testing (m= 69, f= 47; age ≈ 13,28). 47 students visited the university and 69 were visited at school.

**FIRST RESULTS AND DISCUSSION**

A reliability analysis showed a high internal consistence for the 15 items for the scales subject- and object interest as well as self-concept with a reliability coefficient between 0.695 and 0.877. For each time of data collection, no significant influence of either the stationary or the mobile student lab intervention on subject- and object interest of the participants could be detected. The data of the pre-test indicates that the students - visited at school - already show higher values in all three factors before the intervention. A two-way ANOVA indicates that the students of the school group also show a significantly higher interest in the subject \( F(1, 114)=9.498, p=.003 \), professional interest \( F(1.901, 216.701)=15.013, p=.001 \) and self-concept \( F(1, 114)=6.335, p=.013 \) at all three times of testing but there is no interaction between the groups. While the means for the two factors - interest in the subject and professional interest - do not show any change over time for all students there was a significant increase in self-concept for girls in general eight weeks after the intervention \( F(1.797, 80.855)=5.065, p=.011, \eta^2=.06 \). For this effect no difference between the mobile and the stationary GreenLab_OS could be observed. Maybe the theme of healthy
food and sustainability is a more girl-related topic and the fact that the girls are especially asked to perform experiments on their own in which they perform well has led to this small increase.

Figure 3: Means of the three factors in the pre test, separated by location

Additionally, the students were asked to give their opinion on different statements about the GreenLab_OS. The first one was if the participation in the GreenLab_OS has led to a higher interest in chemistry lessons. Results show that the mobile GreenLab_OS has a significantly higher influence on the interest in chemistry lessons than the stationary GreenLab_OS $F(1, 109)=19.991, p<.001$, Hedges $g=0.79$. But for both groups there is a significant decrease from post-test to follow-up-test $F(1, 109)=21.024, p<.001$. Notably, both groups agree to the statement in the post-test eight weeks later. However, only the school-group still sees an influence on their interest in chemistry classes like its shown in Figure 4.

Figure 4: Interest in chemistry lessons rated by the pupils
Although this single item shows that the students subjectively see an influence on their interest on chemistry classes, this effect could not be observed in the factor interest in the subject. It remains to be seen if this effect can be shown with a greater sample in the main study. Another statement was if there should be more extracurricular activities for the location they participated at. The rating of the students shows that there is a greater wish for such activities among students visited at school ($M=5.12$) than at university ($M=4.76$). But the difference between both groups is not significant. Finally, the students were also asked if they preferred to participate at the GreenLab_OS in the location they have not participated at.

**Figure 5**: Wish for a change of location for the lab day

**Table 1**: Means for the item “change of location” and Mann-Whitney-U-test

<table>
<thead>
<tr>
<th></th>
<th>university</th>
<th>school</th>
<th>Mann-Whitney-U</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change of location</td>
<td>2.73</td>
<td>3.26</td>
<td>$z=1.74$, $p=0.082$</td>
</tr>
</tbody>
</table>

There is a slight tendency to participate at university but the difference between the values is quite small and there is no significant difference between both groups. While the university-group seems to have a higher wish to perform the lab-day again at university the school-group does not prefer one of the two locations at all. It is interesting to see that the school students in general seem to have a higher wish for more activities at school but slightly prefer the university as a learning location.

**CONCLUSION AND OUTLOOK**

Interesting results could be found regarding the student’s assessment of how motivating the student lab was perceived for their regular chemistry lessons. Results indicate a decrease of the previously heightened motivation level for chemistry lessons for both stationary and mobile labs after the intervention took place to eight weeks later. But the middle-term motivation for chemistry stays at a higher level for students who participated in the mobile lab as well as the values show that those students still agree to the statement that the participation at the GreenLab_OS has led to a higher motivation for their regular chemistry classes while the group which participated at university mentions that they would disagree to this statement eight weeks after the intervention. The divergent rating of the small wish for more activities at school and the slightly higher preference for the learning location university should be made subject of further research. During the upcoming main study, the initial findings will be focused on more intensely and an emotion test shall additionally compare the two learning locations with each other and the regular chemistry lessons. For this reason, a third group shall be added in which
school students perform the content of the lab-day at school during regular school lessons over several weeks. It might be interesting to see if effects differ concerning the one-day intervention compared to the middle-term intervention in school. Some students will moreover in the context of a qualitative interview study be asked which location will be preferred before and after the intervention. It will be interesting to see which expectations the students have for each learning location and how far these expectations are met. It might also be interesting to see if there are relevant differences between classes from schools located close to the university in comparison to groups of students who travel a long way.

Many science centres offer opportunities for laboratory experiences to school classes with the aim of fostering motivation as well as learning achievement. The present study examines the effectiveness of the lab workshop “Woodlice Behavioural Study” at the Swiss Science Centre Technorama, and also addresses the impact of a preparation lesson about scientific methods. It investigates the effects of the lab workshop on motivation (interest/enjoyment, perceived choice/autonomy and perceived competence) and learning achievement (topic-specific content knowledge and scientific inquiry skills) for four different treatment conditions that include a workshop or an in-school preparation lesson or a combination thereof into the science centre visit. The results imply that the workshop session does not decrease any of the motivational measures but increases perceived competence. Taking into account the pupils’ prior achievement and gender, multilevel analyses revealed several differences between the treatment conditions. The two workshop groups score significantly higher on the content knowledge test about rough woodlice than the groups without a workshop, while the preparation lesson did not promote content learning. Both the preparation lesson on scientific methods at school and the lab workshop at the science centre proved to be efficient in enhancing scientific inquiry skills. However, pupils who participated in a combination of a preparation in school and actual inquiry workshop experiments performed best on the inquiry skills test.

Keywords: science centre lab workshop, motivation, achievement

INTRODUCTION

In recent years, many science centres have established school and outreach programmes including learning labs and scientific workshops. Schmidt, Di Fuccia and Ralle (2014) identified improving learners' motivation and attitudes as well as providing opportunities for more practical lab work as major reasons for teachers to visit a student laboratory. In addition, science centre outreach labs provide the potential for fostering scientific inquiry skills, as investigated by Itzek-Greulich, Flunger, Vollmer, Nagengast, Rehm and Trautwein (2015). According to the National Research Council (1996), scientific inquiry skills include “asking questions, planning and conducting investigations, using appropriate tools and techniques to gather data, thinking critically and logically about relationships between evidence and explanations, constructing and analysing alternative explanations, and communicating scientific arguments” (National Research Council, 1996, 105). Moreover, Garner and Eilks (2015) report that content knowledge gains are considered more important by pupils than by their teachers when visiting non-formal laboratory environments.

In order to reach these goals, different designs of a science centre field trip are feasible. Itzek et al. (2015, 2016) report differential effects of the teaching arrangement on motivational and cognitive achievements by comparing the effects of lab work in a classroom setting to a science centre setting. Among other choices, the science centre exhibition can be visited on its own or in combination with a lab workshop. Besides, teachers can choose to prepare for the practical
lab work during a lesson in their classroom, linking formal and non-formal learning (Eshach, 2007). The present study sets out to investigate the effect of integrating a lab workshop into a science centre visit as well as the effects of a preparation lesson about scientific methods by pursuing the following research questions:

- Does learning achievement increase from participation in the workshop?
- Does participation in the workshop impede overall motivation?
- Does it increase perceived competence at the expense of interest/enjoyment and perceived choice/autonomy?
- Is there an additional benefit of an in-school preparation on scientific methods?
- How do the covariates prior achievement and gender affect these findings?

To this end, motivation and learning achievement are compared for four different treatments (PEW, EW, PE or E) including the following elements: preparation in class (P) – visit of the Technorama exhibition (E) – workshop on scientific methods in biology (W). Pupils’ prior achievement and gender are also taken into account.

**METHOD**

**Experimental design**

The intervention took place at the Swiss Science Center Technorama, which is the largest science centre in Switzerland, with over 500 exhibits or experimental stations on display and more than 250’000 visitors every year, including about 3’500 school classes with over 60’000 schoolchildren. The Swiss Science Center Technorama offers an experimental field that allows visitors to explore scientific phenomena in an informal, hands-on, self-directed way (Ludwig-Petsch, 2014). All participating classes explored the interactive exhibition (unguided experiments) at the Swiss Science Center Technorama on their own.

In addition, the Technorama provides experimental and laboratory facilities with more than 30 workshops for biology, chemistry and physics for scientific work. Half of the classes in this study participated in a workshop lesson on the topic “Woodlice Behavioural Study” (Figure 1). This learning environment was developed with the aim of fostering scientific inquiry skills like collecting data, supporting conclusions with evidence and taking into account typical difficulties when studying living organisms, while also learning about the classification of arthropods as well as the characteristics and behaviour of land isopods (Cox-Petersen & Olson, 2001).

At first, the pupils were given information on scientific observations, experiments and comparisons as elements of the scientific method. Then, they were introduced to the scientific process from posing a research question to making a hypothesis, testing predictions and finally drawing conclusions on the basis of the information gathered in the experiment. After observing, comparing and classifying the animals, the pupils carried out this process in the lab: They investigated the question of whether woodlice prefer dark or light conditions for a habitat by using a choice chamber, i. e. a petri dish divided into two segments, with a dark and a light side or a damp and a dry side (Nuffieldfoundation.org, 2015). They also discussed how to
control experimental conditions, e. g. by always using the same number of woodlice or by counting the woodlice on one side every 30 seconds for 5 minutes. All workshop lessons were taught in the same way by the Technorama’s workshop instructors using a tightly worded script. The duration of the workshop lesson was 45 minutes.

![Figure 1. Workshop “Woodlice behavioural study”.](image)

Half of the workshop classes and also half of the classes that visited the exhibition (unguided experiments) without a workshop were taught a lesson on scientific methods by their teacher before coming to Technorama. The lesson centred on the question of how researchers work. After reading an interview with a scientist describing her work, pupils identified relevant elements of the research process and used them to fill in a work sheet on scientific methods. Subsequently, they played a card game in groups. On the cards, case examples of pupils investigating a research questing were described. Following several criteria for good research practice, they had to decide which approach was the best. Examples included e.g. questions on determining the preferred food of wasps or the boiling point dependence on altitude. The duration of the preparation lesson was 45 minutes. It was taught a week before coming to the science centre.

**Procedure and sample**

The participating pupils attended year 5 or 6 in Swiss primary schools. Of the N=348 pupils 51.4% were females and 48.6% males. The average age was 11.42 years (SD = .74).

Half of the classes participated in the inquiry-based workshop. Half of all the classes were taught the lesson on scientific methods by their teacher before coming to Technorama. The 21 participating classes were assigned randomly to one of four groups with 5 (6) classes each:

- n=102 pupils took part in the preparation lesson, spent a day at the Technorama’s exhibition with a workshop lesson included (PEW-group: preparation-exhibition-workshop).
- n=76 pupils spent a day at the exhibition with a workshop lesson included (EW-group: exhibition-workshop).
- n=89 pupils took part in the preparation lesson and spent a day at the exhibition (PE-group: preparation-exhibition).
- n=81 pupils in the control group spent a day at the exhibition (E-group: exhibition).
A pre-, post- and follow-up-design was employed (Figure 2): The pupils were assessed on topic-specific content knowledge and on scientific inquiry skills right before the intervention (one week before the Technorama visit, before the preparation lesson), at the end of the science centre day and six weeks later, and on motivation at the end of the science centre day and six weeks later.

**Measures and statistical analyses**

Pupils’ intrinsic motivation was assessed on a five point Likert scale by means of the “Kurzskala intrinsische Motivation, KIM” provided by Wilde, Bätz, Kovaleva and Urhahne (2009), which is a translated, modified version of Deci and Ryan’s (2010) Intrinsic Motivation Inventory (IMI). Only three of the four subscales were used: interest/enjoyment, perceived choice/autonomy and perceived competence. The subscale pressure/tension was omitted due to time restrictions, its lower internal consistency and the fact that pressure was expected to be low in the setting of this study. A sample item is, “I am satisfied with my performance in Technorama”.

Learning achievement was conceptualized as a two-dimensional construct including **topic-specific content knowledge** on the workshop content “rough woodlice” as well as **scientific inquiry skills**. The test on topic-specific content knowledge consists of five dichotomously coded multiple choice questions, like “Woodlice are a) crustaceans b) insects c) spiders d) worms e) millipedes.”

Scientific inquiry skills were assessed by tasks on critically evaluating and planning biological experiments similar to the ones performed in the workshop. The test was constructed on the basis of an assessment task developed by the „Konsortium HarmoS Naturwissenschaften+“.

259
(2010). As part of the validation process of the “HarmoS” competency model in the context of a large-scale education policy reform project in Switzerland (Labudde, 2008), paper-pencil and performance tasks were developed. For this study, the “HarmoS” example task on inquiry skills involving woodlice was modified to a paper-pencil task involving earthworms, in order to depict a situation slightly different from the one encountered in the workshop (example item see Figure 3). The test included close-ended questions (sample items: “Which conditions are compared in the experiment described above?”, “How could you improve the experiment?”) as well as open-ended tasks (sample item: “Design and draw an experiment to investigate the earthworms’ response to another stimulus.”) that were graded using a rubric by two raters with a satisfactory interrater reliability (Cohen’s κ=0.73).

The adapted motivation test was characterized by factor analyses and multi group modelling using AMOS 24. The motivation data was analysed using ANOVA. To recognize the data hierarchy, multilevel regression analyses were conducted for the learning achievement data (first level: pupils; second level: classes) using the SPSS MIXED procedure.

![Figure 3. Example of an experimental situation given in the scientific inquiry test.](image)

**RESULTS**

Factor analyses confirm the three-factor structure of the KIM data and show a high internal consistency of all the motivation and achievement scales (.69< α<.78). The three motivation scales are correlated (r > .40) with each other, as well as the two achievement scales (r = .26), whereas only weak correlations were found between motivation and achievement scales (r < .17). Multi group modelling comparing group dependent factor patterns shows some evidence that the meaning of the latent constructs shifts across treatment groups.

Multivariate ANOVA for the motivation scales revealed no differences between the treatment groups with the exception of the post-test scores on perceived competence (F(3,344)=2.90, p<.05, η²=.025). Results of post-hoc comparisons indicated that the two groups with a workshop had a significantly higher mean perceived competence score than those without the workshop (p = 0.004).

Two multilevel regression models for the post-test scores of the two achievement scales were compared. In model 1, the treatment conditions (represented by dummy PE, EW and PEW) were entered as predictors at the class level, with the exhibition only group (E) as the reference
group. Prior achievement and gender were entered as additional predictor variables at the individual level in model 2. A likelihood ratio test comparing model 1 with model 2 confirms that the observed difference in model fit is significant (topic specific content knowledge: \( \Delta D = 62.36***, \Delta df = 5 \); scientific inquiry skills: \( \Delta D = 127.51***, \Delta df = 5 \)).

Figure 4 shows the results of the multilevel analysis on topic specific content knowledge and scientific inquiry skills for model 2. Depicted are the \( z \)-standardized mean scores in achievement, adjusted by prior achievement and gender by treatment group, based on the fixed effects (regression coefficients): fixed effects for topic specific content knowledge: \( \hat{\beta}(\text{Intercept}) = -.68***, \hat{\beta}(\text{Dummy: EW}) = 1.39***, \hat{\beta}(\text{Dummy: PE}) = -.01 \) and \( \hat{\beta}(\text{Dummy: PEW}) = 1.42*** \) and fixed effects for scientific inquiry skills: \( \hat{\beta}(\text{Intercept}) = -.47**, \hat{\beta}(\text{Dummy: EW}) = .39*, \hat{\beta}(\text{Dummy: PE}) = .26 \) and \( \hat{\beta}(\text{Dummy: PEW}) = .69*** \) (reference group: E). Results show that the two groups with a workshop performed better on the topic-specific content knowledge post-test (EW, PEW vs. PE, E). However, the preparation lesson did not significantly affect content learning (EW vs. PEW).

Scientific inquiry skills improved for both the group with the preparation lesson (PE) and the group with the workshop (EW), while the highest performance was achieved by the classes that took part in a preparation and a workshop session (PEW). The intraclass correlations (ICC) range from .04 to .30.

Note. \( z \)-standardized mean scores in achievement, adjusted by prior achievement and gender.

Figure 4. Results of the multilevel analysis on topic specific content knowledge and scientific inquiry skills by treatment group preparation-exhibition-workshop (PEW), preparation-exhibition group (PE), exhibition-workshop (EW) and control group exhibition only (E).

No gender effect was found on motivation or content knowledge, but girls outperformed boys on the scientific inquiry test. While prior knowledge does have a large effect on the content knowledge score, this is mainly true for the groups without workshop. Prior knowledge on scientific inquiry had a large effect on the post test score, regardless of the treatment group.
DISCUSSION AND CONCLUSIONS

The results from the multivariate ANOVA on the motivation scales imply that integrating a workshop session in a visit to a science centre does not necessarily decrease motivation. Pupils who participated in the workshop consider themselves more competent in their science centre activities. Moreover, even though the guided lab style of the workshop reduced the participating pupils’ freedom of choice as compared to exploring the exhibition (unguided experiments), no difference in perceived choice/autonomy was found. A possible reason might be that the pupils valued the (rather limited) choices provided in the workshop’s scientific inquiry learning process more, because these were relevant to the pupils’ goals and interests and also met their need for competence, thereby supporting their perceived autonomy (Katz & Assor, 2007). On the other hand, the science centre exhibition provides a rather complex decision-making environment, in which children might randomly select activities without considering their options, reducing their perceived autonomy (Katz & Assor, 2007).

Due to the substantial impact of the class structure indicated by the intraclass correlation ICC in the achievement measures, multilevel models were estimated. Results show that the two workshop groups (EW and PEW) score significantly higher on the content knowledge test than those without a workshop (PE and E). The preparation on scientific methods did not promote content learning as there are no differences for the groups EW and PEW. While prior knowledge does have a large effect on the content knowledge score, this is mainly true for the groups without workshop, who had to rely on what they already knew about the content from other sources.

When prior knowledge and gender are taken into account on the individual level, the differences between the scientific inquiry skills for the treatment groups become evident. Both the preparation lesson on scientific methods at school (group PE) and the practical lab work in the workshop (group WT) proved to be efficient in enhancing scientific inquiry skills. However, pupils who participated in a combination of the preparation lesson and the actual inquiry experiments (PEW) performed best on the inquiry skills test. Prior knowledge on scientific inquiry had a large effect on the post test score for all groups. This finding can be attributed to the fact that an understanding of the scientific inquiry process needs more time to build up compared to learning facts about certain contents.

In conclusion, integrating a scientific workshop, especially when prepared at school, into a science centre visit can promote learning progress on content and inquiry skills without sacrificing the motivational benefits of the field trip.

This explanatory mixed methods study investigates the experiences of approximately 280 rural, underrepresented middle school student members of STEM Career Clubs over 3 semesters (19 meetings), part of a larger NSF-funded project. Research questions investigated students’ perceptions of the STEM Career Club and interest in STEM subjects and future careers, and whether these changed through club involvement; students’ content knowledge following STEM Career Club meetings; and what motivational factors seemed to be most influential for the students. Data sources included surveys about STEM interests and career intentions (STEM-CIS), STEM club perceptions, and content questions. A subset of 101 students were interviewed. Students found the club an important, positive experience and the staff caring and knowledgeable, although there was no growth in their STEM-CIS scores. Students who attended meetings regularly (>10 meetings) demonstrated higher initial STEM-CIS scores and better content knowledge than students who attended sporadically. Students’ subjective task value (e.g., enjoyment, utility, cost, interest), identity, and key socializers were the motivational factors most expressed as influencing students’ learning and STEM intentions. Valuing learning for what it could mean to one’s future seemed associated with impact achievement.

Keywords: STEM clubs, under-represented students, motivation

INTRODUCTION

World citizens today, perhaps more than any other time in history, need STEM literacy in order to make personal and collective decisions on issues such as climate change, STEM cell research, renewable energy, cloning, and genetically modified organisms (Krishnamurthi, Ballard, & Noam, 2014). As technologies advance, jobs requiring STEM knowledge and skills are increasing, and the Economics and Statistics Administration of the United States (US) Department of Commerce projects that STEM occupation will increase 17% from 2008-2018 (Langdon, McKittrick, Beede, Khan, & Doms, 2011). Additionally, since the beginning of the 21st century, growth in STEM jobs has grown three times faster than non-STEM related jobs. Langdon et al. assert, “STEM jobs are the jobs of the future. They are essential for developing our technological innovation and global competitiveness” (p. 6). As more jobs require employees to be proficient in STEM subject areas, there is concern that students’ educational experiences will not prepare them to be able to fulfill the positions necessary in the workplace (Krishnamurthi et al., 2014).

LITERATURE REVIEW

Middle school is an important stage of development during which students begin weighing the costs and benefits of careers and start roughly drafting their future career pathways (Hill,
Corbett, & St. Rose, 2010; Kier, Blanchard, Osborne, & Albert, 2014; Maltese & Tai, 2010). Yet, many students, particularly underrepresented minorities and females, may be unable to see themselves in STEM careers because they perceive STEM is not relevant to their lives (Russell & Atwater, 2005). Bedward, Blanchard, and McDonald (2016) studied rural, eighth grade students in three settings. Those students who had out of school, intensive experiences with STEM had significantly higher math scores, STEM interest, school interest, and more clarified college goals than did similar students in the control (non-intervention school) or those in a classroom intervention. Students attributed to their experiences in the intensive STEM program as important influences, and the researchers documented the importance of personal identity, social supports, and out of school experiences for these students in order to develop future goals in STEM.

One popular method to increase STEM career interest that has gained traction within the last decade, is the successful development of STEM Clubs, including robotics clubs and Science Olympiad (Robelen, 2011; Vijil & Combs, 2015). Informal science settings usually need to have a strong engagement portion because attendance is not compulsory and the programs are run by facilitators who may or may not have specialized teaching credentials (Barker, Nugent, & Grandgenett, 2014). Hussar, Schwartz, Boiselle, and Noam (2008) argue that in order for out of school time (OST) STEM Clubs to be successful, they must be student centered, use cooperative learning, and conduct authentic, hands-on-activities. Additionally, many OST STEM Clubs are trying to align more closely with learning standards, not only to increase the interest in STEM content and careers, but to help transfer concepts back to the traditional classroom, as well (Carnevale, Smith, & Melton, 2011). In their assessment of an after-school program, Anderson-Butcher, Newsome, and Ferrari (2003) stated, “simply put, if youth do not attend, they will not experience the positive benefits these programs are known to provide” (p. 40). They recommended long-term, consistent student participation.

MacEwan (2013) pointed out that those who run the clubs do not necessarily need a STEM background to lead activities. Through proper professional development, educators can become more familiar and comfortable with new concepts. Desimone (2011) outlined five main features of effective professional development. Effective PD should: have a content focus; engage teachers in active learning; be coherent with other professional development, knowledge and beliefs, and policies; have duration and spread over a semester of at least 20 hours; and, be organized with collective participation from groups of teachers from the same grade, subject, or school in order to build an interactive learning community. The professional development ‘sweet-spot’ for engaging students, according to MacEwan (2013), is the proper balance between teaching STEM content and modeling best teacher pedagogical practices.

Pierce, Auger, and Vandell (2013) found that the disparity between students of high and low socioeconomic status (SES) decreased when elementary students in low-SES families participated consistently in after school programs. Sahin (2013) found that students who are regularly attending STEM after school clubs matriculate more often into post-secondary STEM majors as compared to the national average. Dabney and colleagues (2012) found that when college students with STEM majors were surveyed, many said that they had first become interested in a STEM career through OST science clubs and competitions. Kong, Dabney, &
Tai (2013) assert there is a need to understand more about what features of STEM programs benefit students. This study investigates the experiences of middle school students who participated in a STEM Career Club over an 18-month period.

THEORETICAL FRAMEWORK

This study is informed by the expectancy-value (E-V) theory of achievement motivation (Eccles, 1994). Decades of quantitative research data analyzed by Eccles indicate that people’s expectancies, ability beliefs, and values directly affect choices, performance, effort, and achievement. Other influences are socializers (e.g., parents, teachers) and one’s interpretations of previous life experiences (see Figure 1). Students’ qualitative interview data was coded using constructs from the E-V theory to help explain findings from understand more about their experiences in the STEM Career Clubs. (Each of these codes are displayed with an exemplar in the Methods section.)

**Figure 1. Expectancy Value Theory (based on Eccles, 1994).**

RESEARCH QUESTIONS

This study investigates the experiences of middle school students who have been participating in a STEM Career Club over an 18-month period, from 1-19 meetings. The research questions addressed in this study include:

1) What are students’ perceptions of the STEM Career Club and interest in STEM subjects and future careers, and do these change through club involvement?

2) How much relevant content knowledge do students demonstrate following STEM Career Club meetings?

3) What motivational factors seem to be most influential for STEM Career Club students?
METHODS

Context and Participants

Middle school students (Yr. 1: *n* = 215; Yr. 2: *n* = 243) attended after-school STEM Career Clubs at four schools, conducted by teachers who took part in 48 hours of professional development and met in pre-club meetings for approximately 18 hours. The Clubs were located at 4 rural, low-achieving, high poverty schools in 4 school districts in the southeastern US, as part of an NSF-funded project (Blanchard et al., 2014). All students at the schools were invited to participate in after-school club meetings; 6, 2-hour STEM career-focused clubs each semester, with hands-on activities (e.g., designing/launching rockets, Floors© game design, Vernier© probeware for weather). The demographic data for students in each of the STEM Career Clubs is similar to that of each school. The largest percentage of middle school students participating in the 4 clubs were African American (*M* = 53.9%), followed by Caucasian (*M* = 24.4%), Latino/Hispanic (*M* = 7.8%), American Indian (*M* = 4.4%) and Asian/Pacific Islander (*M* = 1.7%). An average of 80% of the students received free-and-reduced-price lunch (F&RP) lunch, and only 24.75% of the students, on average, passed their end-of-grade math test, and 57.7% passed their standardized 8th grade science test, at the start of the project.

Data Sources and Analyses

The STEM Career Club survey (Blanchard & Gutierrez, 2015) items (22) were informed by Epstein’s (2001) framework for six types of involvement in school, family, and community partnerships, as well as their perceptions of the value of the Club. The STEM Career Interest Survey (STEM-CIS) (Kier, Blanchard, Osborne, & Albert, 2014) was developed based on Social Cognitive Career Theory (Lent et al., 1994; 2000) and measures student self-efficacy, outcome expectations, personal inputs, and contextual supports. The interview questions were guided by the expectancy-value theory (Eccles, 1994) and previous findings (Bedward et al., 2016). The interview audio files were transcribed verbatim, then coded by two authors using a priori categories of the E-V framework. This paper focuses on the initial and final STEM Career Interest Survey (STEM-CIS) data (*n* = 172), results of the STEM Career Club survey (*n* = 172), content questions (total: 1398 items), and 112 interviews.

RESULTS

Students’ STEM Club perceptions and STEM subject interest

Descriptive analysis of students’ post-STEM Career Club survey data (1-5 Likert scale) showed students felt that: STEM Career Club is important (*M* = 4.29) and will make a positive difference in the community (*M* = 4.27). Students’ overall experience in the Club have been positive (*M* = 4.30) and the STEM Club staff has the best interests of the students in mind (*M* = 4.21). Students are learning things in the club that they have not learned in school (*M* = 3.45), and they are somewhat able to talk with others regarding the STEM Club program (*M* = 3.53).

STEM-CIS-Paired t-tests indicated a slight but significant decrease in the Total Overall STEM-CIS score means for students (*N* = 172) from pre- (*M* = 4.08, *SD* = 0.46) to post-measures (*M* = 3.96, *SD* = 0.59). Each of the STEM content areas and overall STEM score means for Spring
2016 were positive, at or above 3.9 (Agree) on a 5-point scale. Student interest in *Science, Math*, and overall *STEM* subjects differed significantly on the STEM-CIS based on student attendance. Using one-way ANOVAs of post-intervention STEM-CIS scores, students who attended ≥10 club meetings (out of a possible 19 meetings) reported higher scores on the *Science* ($F(1, 342) = 5.83, p < .05, \eta^2_{adj} = 0.01$) and *Math* ($F(1, 333) = 3.73, p < .05, \eta^2_{adj} = 0.01$) subscales, and overall *STEM* scale ($F(1, 342) = 5.26, p < .05, \eta^2_{adj} = 0.01$), than those who attended <10 meetings.

![Figure 2. STEM-CIS Spring 2016 means for STEM categories and STEM subjects overall.](image)

**Students’ conceptual learning following club meeting attendance**

After students had completed the activity, sheets were handed out that had 4-7 content items and students were asked to talk the items over with their peers or work alone, as they preferred. Their item responses were scored for accuracy by student and by school (see Figure 3). The majority of students at each of the four school sites answered >50% of questions correctly.

![Figure 3. Post-activity content question means for meetings 1-12 by school.](image)

*Note: All quizzes had 5 items, except for 1 & 3 (7Q) and 6 (4Q)
Influential motivational factors for STEM Career Club

Student interviews were conducted at the end of the year in order to triangulate the quantitative data and to help explain the results. Students’ subjective task value (i.e., enjoyment, utility, cost, interest), identity, and key socializers were motivational factors most often expressed by students as influencing their learning and STEM intentions, as shown in Table 1.

</tr>
</tbody>
</table>

Subjective Task Value items were often discussed in student interviews. Students felt as if the STEM Career Club would provide benefits to them currently, while in middle school (Utility Value) and would provide skills and content knowledge that may help them in the future (e.g., high school, college, careers) (Attainment Value). Students often discussed how much they enjoyed the activities in the Club because they were different (e.g., hands-on, inquiry-based) and considered them to be more fun than what was traditionally done during the regular school day (Enjoyment). An 8th grade Caucasian male remarked, “It [club] feels different…It doesn’t feel like you’re sitting in this room just listening to teachers drone on. It’s like you’re getting up, you’re doing stuff with your friends.”

Additionally, elements of student Identity were discussed during interviews. Students developed a sense of belonging with other students who they felt had similar goals and ambitions. One 8th grade multiracial male stated, “I enjoy that you are around an environment that isn’t if you don’t play sports you’re ridiculed for. I like that you can show off more of your intellect than what you would normally be able to without being seen as a nerd, which I am
anyway, but I don't care.” Most often, students discussed Key Socializers during the interviews. A 7th grade African American female said, “Well, I like that we can socialize with our peers and we can communicate with them and talk to them about what we learned and we can ask them for help.” Socialization with peers was a high priority for students in the STEM Career Club.

**DISCUSSION & IMPLICATIONS**

**Students’ perceptions of the STEM Career Club**

A novel aspect of the STEM club was soliciting students’ feedback on aspects of the club. The items had been generated by consulting Epstein’s (2001) work, and modifying items to this after-school STEM intervention. Students’ perceptions of their STEM Career Club experiences were reported as positive, finding their Club experiences important, the staff caring and dedicated, and believing that they learned new skills. It was gratifying that the students’ perceptions of the teachers were positive, as the teachers were operating as coaches and in a support role, rather than the more traditional, lecture and paper and pencil style generally observed at the school. Students’ responses highlighted areas for further improvement: the need to increase students’ conversations with their parents about STEM careers at home and talking with others about the STEM career club. Both of these are recommended by Epstein (2001), and both were novel activities that would likely not have been present prior to their promotion in the STEM club.

**Students’ interest in STEM subjects and future careers**

Students’ STEM-CIS scores began high (4.08), and there was a modest but significant decrease in their scores at the end of year 2. One possible explanation is that students lacked a strong initial knowledge about STEM subjects and careers, and may have given themselves higher scores for interest on some of the questions, which then declined slightly after learning more about engineering or related careers, for instance. Initial results suggest that some students became more interested or maintained their interest in STEM subjects and career potential, and others became less interested or stayed less interested. And, that those students who had more interest - either who began or developed it - were more likely to come to more club meetings. Alternately, it could be that those who were not able to come as often were less able to be positively influenced by the clubs (Sahin, 2013).

**Student content knowledge**

As a result of time constraints for pre/post testing and the fact that few students would have been familiar with the content focused on during the STEM club meetings, post-club quizzes were the only way to gather some understanding of what students had learned. Despite the fact that students were not required to complete the quizzes, nor were they counted for students’ grades, students overwhelmingly completed them. Overall, post Club, students demonstrated that they knew over half of the questions that were posed. Those students who attended clubs more regularly could be a result of higher STEM interest and student engagement. It could also be that those who already knew more science, math, and other information were also more likely to come to the clubs. However, the material taught during the club meetings was often
novel. Therefore, another explanation is that some of the students were more focused and tried to learn more, and other students, who learned less, were less interested, able, or distracted from learning in the social environment of the clubs (Anderson-Butcher, Newsome, and Ferrari, 2003).

Motivational factors

Data collected during student interviews indicated that all students gained from their STEM Club experiences, overwhelmingly identifying with the Club and enjoying the group work, socializing, and hands-on activities. One thing to note is that students who interviewed were purposefully solicited from regular club attendees to those students who had stopped coming to the clubs, or who only came sporadically. Students talked about their motivation to attend club because of the current and future value of what they were learning, and how that might impact their futures. Similar to what was found by Bedward et al. (2016) and Johnson & Blanchard (2015), valuing learning for what it could mean to one’s future seemed to impact achievement.

Limitations

However, not all of the students were interviewed, and therefore interpretations of our findings could be explained differently if other data had been collected, a limitation of our study. It is not yet clear if the STEM Club experiences increased the value of STEM to these students, as recommended by Russell and Atwater (2005), as we interviewed them at the end of the school year.

RECOMMENDATIONS AND CONCLUSIONS

We recommend trying to tease out the values of STEM to these students by collecting interview data pre and post each year. Our findings address calls in the literature by highlighting students’ motivations for attending the STEM clubs and help us to understand more about these understudied students (Kong, Dabney, & Tai, 2013).

ACKNOWLEDGEMENTS

We are grateful for funding from the National Science Foundation #DRL 1433747 and for all of the work and generous support of the teachers, leaders, students, and parents involved in this project.

STUDENT REFLECTIONS ON PARTICIPATION IN A SCIENCE AND TECHNOLOGY SCHOOL COMPETITION

Susanne Walan¹ and Birgitta Mc Ewen²

¹Department of Environmental and Life Sciences, Karlstad University, Karlstad, Sweden
²Department of Health Sciences, Karlstad University, Karlstad, Sweden

Different kinds of efforts have been made in many countries to stimulate students’ interest in science and technology, for example through school competitions. Few studies, however, have investigated the effect of school competitions in science and technology. This study centres on how students participating in the science and technology school competition The Technology Eight experienced the outcomes of taking part in the competition. Semi-structured interviews were conducted with seventeen 15-year-old students. Transcripts of the interviews were analysed based on content and resulted in four categories: Social effects, Attitude to competitions, Stimulated interest in science and technology and Gained knowledge. The students enjoyed participating in the competition and found that it had a positive effect on the social situation in the classroom. Competitions were also appreciated and seen to encourage students to work harder. However, the competition did not have much effect in changing interest in science and technology. Finally, the students found it difficult to express how the competition had contributed to gaining more content knowledge in the subjects, but they emphasised the practical aspects of learning.

Keywords: Science and technology school competition, outcome

INTRODUCTION

Many reports have discussed the problem with young people’s low interest in science education (e.g. Fitzgerald, Dawson & Hackling, 2013; Hofstein, Eilks & Bybee, 2011; Holbrook 2003; Osborne & Dillon, 2008). Students’ choices to continue with STEM (Science, Technology, Engineering, Mathematics) subjects depend on several factors such as interest, family, cultural influences, and the quality of teaching (Tytler, 2014). Research has also discussed effects of efforts aiming at stimulating student interest in STEM (e.g. Potvin & Hasni, 2014). Efforts mentioned include, for example, summer schools, STEM clubs, science museums, competitions, science fairs and after-school activities (e.g. Christensen, Knezek & Tyler-Wood, 2015; Howarth 2014; Knowles 2014; Moreno, Tharp, Vogt & Newell, 2016; Morgan, Zhan & Leonard, 2013, Xie & Reider, 2014).

Competitions in science and technology have been around for a long time. Organisations such as the Royal Society in Britain and the American Museum of Natural History in the US arrange different competitions for students. Even big companies such as Siemens, Intel and Google are involved in arranging competitions.

Studies from Australia, Canada, Japan and the US, as well as from European countries, have shown a statistically significant correlation between participation in competitions and students’ future pursuit of graduate studies in science and technology (Fisanick 2010; Sahin 2013; Woolnough et al., 1997). Thus, results from studies of such competitions have indicated that competition is successful in stimulating interest in science and technology.
Verhoeff (1997) has discussed aspects of competitions in school, for instance if competition in school should be encouraged or eliminated, claiming that this depends on the type of competition. If competitions solely focus on the competitors, they need to be abolished. On the other hand, if the focus is on a problem to be solved and a competition encourages teamwork, this is seen as positive. Voerhoff (1997) also discussed how educators argue that competitions can motivate students. Fisanick (2010) has found that teachers strongly agreed that science fair competitions promote students’ interest in science. Along with promoting interest, teachers believed that the competitions provide opportunities for students to learn about research, to communicate skills, and to provide opportunities for students to interact with each other (Fisanick, 2010). Another report about the effect of student participation in science fair competitions (Abernathy & Vineyard, 2001) also showed how this supported students in their decisions on science careers. An earlier study by Grote (1996) claimed that positive effects of competitions include improved student communication skills, as well as stimulated science learning. Furthermore, researchers (Huang, Chiu & Hong, 2016; Sahin, Gulacar & Stuessy, 2015) have argued that participation in STEM competitions has positive effects on students’ problem-solving and critical thinking skills.

From a Swedish perspective, a national delegation (The Technology Delegation [Teknikdelegationen]) was tasked by the government to investigate what efforts had been made to change the trend of low student interest in learning science and technology in 2008 (Teknikdelegationen, 2010). When the delegation presented its survey, competitions in various forms were numerous and a whole chapter was devoted to them. However, the delegation pointed out that research on the competition phenomenon was lacking. With only a few existing studies on aspects of competitions in science and technology, knowledge of participants’ experiences is needed. In an earlier study, we investigated how teachers and principals reflected on their participation in a school class competition (Walan & Mc Ewen, 2018). Here, we particularly focus on how student competitors reflect on their participation in a science and technology school competition. The Technology Eight is particularly well suited to investigate: the competition covers both science and technology, it has a long tradition in Sweden, and schools in the whole country participate. Therefore, the aim of this study is to study aspects of The Technology Eight competition as reflected in students’ responses in relation to the research question: What outcomes do students experience from participating in the science and technology school competition The Technology Eight?

METHOD

The research context

In 1993 teachers from a university in Sweden organised a competition including questions in science and technology for school classes in grade eight (Teknikåttan, 2015). The competition was named The Technology Eight. The aim of the competition was to stimulate students’ interest in learning science and technology. By 2000, the competition had become national and universities throughout Sweden arranged it. The questions had developed and were constructed in order to stimulate problem solving and creative thinking, as well as to be related to students’ everyday life. Furthermore, the technology questions gained a more prominent role in the
competition, as evidenced in the emphasis on a class challenge that formed a major part of the competition. Many students have participated in the competition, which is still running; in 2015, for example, 30,000 students participated.

Participants

We invited students in grade nine, who had participated in The Technology Eight competition during the previous year to participate in the study. The students represented three classes which had all reached the regional finals in 2015 and were from two different schools located in two district towns in the southwestern part of Sweden. Both schools have an established tradition of participating in The Technology Eight. Seventeen students, nine girls and eight boys, voluntary took part in the study, and they were all above the age of 15. The students were interviewed in groups of three, except for one group which consisted of only two students. The girls are coded as G1-9 and the boys B1-8 in this study.

Data collection and analysis

Semi-structured interviews were conducted with the students at their schools in quiet rooms separated from ordinary activities. The interviews were audio recorded and transcribed verbatim. Each interview lasted 15 to 20 minutes. Altogether six interviews were carried out. The interviews were conducted by both authors of this study. The guideline for the interviews is found in Appendix 1.

The transcribed interviews were analysed based on the research questions using content analysis as described by Cohen, Manion and Morrison (2011). The authors of this article analysed and made categorisations from the transcripts independently. Results were identified after a consensus discussion.

RESULTS

Analysis of the interviews resulted in four categories: Social effects, Attitude to competitions, Stimulated interest in science and technology and Gained knowledge. The content of each category is described in more detail below.

Social effects

The first and major finding is that the competition seemed to have had most impact on the social dimension among the students. Several students pointed to the improved atmosphere and mood while they worked with the competition, and that this rubbed off on their schoolwork as a whole:

There is a lot of cooperation, so the feeling is that we could work better after we had done The Technology Eight. [G6]

… the class was united. We were very close to one another … [G2]

Yes, you worked together more … it was like an assembled troop. [B3]

However, some students indicated that it was sometimes stressful, as some classmates were not willing to participate in the competition tasks:
Strand 2

No, but you have to arrange it so all [students] work with the class task, otherwise it will be stressful. [B3]

Despite the last quotation, the overall impression was of increased solidarity between the students in the class. This was also seen when the students talked about their relationship to other classes:

I think they [other classes] were a bit jealous. [B6]

**Attitude to competitions**

The second finding relates to students’ attitude to competitions. All students expressing an opinion about this issue thought that it was positive that an activity in science and technology was designed as a competition:

… more [students who] will appreciate school if you arrange competitions … there are many [students] who like competing so they will exert themselves more … [B6]

We wouldn’t have worked so hard then [if it had not been a competition]. [B3]

I don’t think I’d have been so psyched up … if it hadn’t been [a competition]. [G6]

Some students commented on the way the competition was arranged and said that they appreciated this set-up. They found it stimulating to work in this manner:

At first I didn’t think this [the competition] was interesting, so, I didn’t want to join as it wasn’t my thing. But when we were there, I really enjoyed it. [G4]

Yes, it was fun, you had to design the whole piece yourself. It wasn’t only making a wheel … you had to make the design … for the whole piece. [G3]

**Stimulated interest in science and technology**

The third finding is related to the category stimulated interest in science and technology. We did not notice any remarkable changes in the student group as a result of the competition. For instance, when the question about the students’ choice of future studies was raised, it was clear that participation in the competition had had little influence.

I am not quite sure … anyway, the Technology Eight had no influence. [G4]

Students rather pointed to the great influence of parents and close relatives on their interest in science and technology. They also referred to teachers they appreciated, seminars at school and participating in summer holiday courses. Practical work during school lessons was also highlighted:

… with help from my mum, she is a veterinary surgeon, so it will go on in the family. [B6]

It is about childhood and adolescence and what your parents teach you. [B1]

So, I think the technology teacher is very funny and pleasant. I don’t know why. So, if you start to like a teacher it is obvious that you start to like the subject. [B2]

To have the permission to test things … to try to build things or mix stuff … [G4]
Gained knowledge

Finally, the fourth finding is related to gained knowledge. Some students argued that they had gained knowledge through participating in the competition, but they could not specify what they had learnt. The responses to the question “what did you learn during the competition?” were rather of the following type:

Not so much, but a little. \(^6\)

The questions we missed I remember [the answers of]. \(^2\)

When the students compared taking part in the competition to traditional school lessons, their answers were more distinct, and emphasised that participation in the competition had given other experiences. One such experience was handling practical tasks:

It was very different compared to ordinary teaching. We had the opportunity to do more. When we built the wheel, we had to think in more practical terms. \(^7\)

Another aspect was that joining the competition was more enjoyable:

…we learnt perhaps in a more fun way … \(^7\)

However, one group of students stressed that they might have learnt more during an ordinary lesson. The reason for this was that early in the competition process, some students were picked out for a panel, while the rest of the class members did not have such defined tasks:

…there was much waiting time for some of us who were not so as involved as the others. So, this was a bit boring. \(^8\)

Most student groups discussed that working with the tasks in the competition had involved not only science subjects and technology, but also other subjects, especially mathematics:

Some questions rang across many areas … \(^1\)

A lot of calculation in some questions during the competition. It was fun mathematics … It was tricky. \(^7\)

DISCUSSION

The aim of this study was to investigate how students reflected on participation in a science and technology school competition. The main purpose of the competition was to stimulate student interest in learning science and technology, with a focus on tasks developing problem-solving and creative thinking skills.

The major finding is the positive social effect that participating in the competition had on the students. Fisanick (2010) discusses how participation in science fair competitions promoted student interactions. Voerhoff (1997) argues that competitions emphasising teamwork are good competitions. In our study it was obvious that the students found that their participation in The Technology Eight had a positive effect on the social climate in class since there were several comments about how they felt united as a team. This was the overall picture, even though it was reported that not all students were equally engaged in the tasks. One of the skills of importance for the future is cooperation (e.g. Jerald, 2009). Hence, the effect on the social climate in the classes as a result of participation in the competition was favourable.
The second finding is related to students’ attitudes to competitions. During the interviews the students were totally unanimous in their opinion about school competitions. It was something they really appreciated. They mentioned that they were stimulated by the fact that *The Technology Eight* was a competition and they wanted to have more competitions in school. Some of the students argued that competitions usually only existed in sports, much to their regret, since they thought competing was fun. We have not found any earlier findings in the literature about students’ attitudes to competitions in science and technology. However, this experienced positive outcome may be related to the kind of competition *The Technology Eight* is, namely, a competition in which cooperation is emphasised, rather than individual achievement as Voerhoff (1997) has explained.

The third finding is related to stimulated interest in science and technology. As mentioned, earlier studies have shown that students’ participation in science and technology competitions has had some kind of impact on their future choice to pursue graduate studies in science and technology (Abernathy & Vineyard, 2001; Fisanick 2010; Sahin 2013; Woolnough et al., 1997). Our study does not specifically support this effect since the students had already made their decisions, which seemed to be based more on the influence of parents and skilled teachers. Earlier research has shown that parents, teachers, friends and personal interests are factors that impact on students’ choice of future careers in STEM (Rodrigues, Jindal-Snape & Snape, 2011; Hall, Dickerson, Batts, Kaufmann & Bosse, 2011). However, Cerinsek, Hribar, Glodez and Dolinsek (2013) also found that out-of-school experiences such as participation in school competitions influenced students’ choice of studies in STEM. Even though the students in our study did not seem to be much influenced by the competition in their choices of future studies, they all expressed how much they enjoyed participating in *The Technology Eight*. It should be noted that the students were 15 years old and Lindahl (2003) has argued that if we want to stimulate students’ interest in science this needs to be done at an early age; many students have already made up their minds by the age of 11. This has also been claimed by Tai et al. (2006) and Turner and Ireson (2010).

Finally, the fourth finding is related to gained knowledge. Some of the students argued that they had learnt things during the competition, but it was hard for them to be specific about what they had actually learnt. Still, they made comments on how they had worked harder than usual simply because it was a competition. Others mentioned that they had the opportunity to work with practical solutions of problems to a greater extent than during traditional lessons. We did not investigate student learning in science and technology; we concentrated on how they experienced the competition. In future studies it might be of interest to investigate aspects of learning in relation to participation in the competition and to compare this with results from, for example, Grote (1996), who argued that learning in science was stimulated by participation in competitions.

It is necessary to consider that it could be difficult for students to reflect on what they actually have learnt. Maybe their ideas of knowledge are only connected to content knowledge, or aspects of knowledge that are traditionally measured in school tests. It might be hard for them to realise that they have gained knowledge in problem-solving, how to be creative and how to cooperate. The study is limited with only seventeen students presenting their reflections on
participation in a science and technology school competition. Hence, more studies about effects of participation in these kinds of competitions are needed.

CONCLUSIONS

This study reports on students’ reflections on participating in a science and technology school competition, The Technology Eight. The main outcome was the positive social effects such as increased cooperation among the students. Another finding was that the students had a positive attitude to competitions, and they requested more competitions in school, besides sports, since this triggered them to work harder during the lessons. Even though the students did not report a stimulated interest, or that they had gained knowledge in science and technology, we argue that the positive outcomes of participation in this kind of competitions are beneficial to students’ future skills.

REFERENCES

Appendix I.

Questions to students who have participated in The Technology Eight.

1. How did you find out about the competition?
   a. Did you hear about the competition a long time in advance or were you informed shortly before participating?
   b. Did you find out about the competition from friends, teachers, the principal or another person?
   c. How did you feel about the participation? Did it seem interesting, fun, difficult, or as generating a lot of work? Please describe your expectations.
   d. Do you know if your school participated in the competition in previous years?
   e. Do you know the reasons for participating?
   f. Do you remember the feeling you had when the competition started? Did you feel the same way during all parts of the competition?

2. With some distance to the competition
   a. Now you have participated. What was the best thing about the competition?
   b. Were there any disadvantages to participating?
      i. If yes, which?
      ii. Any suggestions for improvement?
   c. How would you describe the competition to younger students in grade seven who have not yet participated?

3. Knowledge of school subjects
   a. Have your knowledge of science and technology increased during the competition?
      i. If yes, what kind of knowledge?
      ii. If yes, in which school subjects?
   b. Do you think your knowledge has increased more through participating in the competition than if you only had traditional teaching in the classroom? Feel free to speculate.
   c. Can you see any differences between learning during the competition and learning in the classroom?
      i. Did you have more time to work in a specific area while you participated in the competition?
      ii. Did you get to do more practical work?
      iii. Did you find it easy to understand how things are connected so you could see the whole picture?
   d. Have your knowledge in other school subjects increased because of your participation in the competition?
      i. If yes, in which way?
   e. How do you think about learning when different subjects are involved at the same time?
      i. Does the same thing happen in traditional teaching?

4. Interest in science and technology
   a. Has your interest in science and technology changed as a result of participating in the competition?
   b. Would your interest have been the same if you only had traditional teaching? Feel free to speculate.

5. Choice of future education
   a. You are soon going to apply to upper-secondary school programmes. Is your choice of programme affected by your participation in the competition?
   b. Have changed your mind? If yes, why?

6. Affective responses
   a. Did you feel that the whole class was working on a common project?
      i. Did you often talk about the competition in the class?
      ii. Were you also involved after school and/or during breaks?
b. Was the social climate in the class affected by competition participation?
c. Was the social climate at the school affected more generally?
d. How did the school administration react while you were competing? And to the results you achieved in the competition?

7. Workload
   a. Was there a lot of work involved in participating?
      i. Too much?
      ii. Did you feel stressed during the competition?
      iii. Did you need to work after school?
   b. Were all students active?
      i. Did you share responsibility or were some working harder than others?

8. The competitive element
   The Technology Eight is a competition. How important is the competitive element?
   i. Would it have been as interesting or fun to participate if it had not been a competition?
   ii. Does the fact that it is a competition mean that it is too stressful?
PEDAGOGICAL CHOICE IN SCIENCE EDUCATION:
EXPLORING RANGE, LIMITS AND CONSEQUENCES

Andrew Howes, Zahra Alijah, Samar Albalawi and Rob Buck
University of Manchester

This paper works from two ends of the educational process in science education. On the one hand, it explores the pedagogical choices that science teachers have in contexts of disadvantage, and on the other hand it explores the range of responses that young people in such a context have to science. Through these two ends, a discussion is started into the scope and limits of science teacher agency. Educationalists concerned with schooling in contexts of disadvantage have explored many pedagogical options in order to address the inequities within which education is situated and to which it often contributes, and yet we still know relatively little about the connections and disconnections between the pedagogical actions of science teachers, and the positions developed by young people in relation to science. Theoretically, we begin this exploration of pedagogical options in science education by drawing on a simplified general model of pedagogical variation and choice due to Bernstein, and then look towards the range of positions and perspectives that young people hold and occupy, informed by theoretical perspectives including the ‘funds of knowledge’ tradition. This exploration is developed empirically, addressing the issue of the perspectives of teachers and young people. Firstly, a small-scale survey (n=44) of UK teachers’ perspectives of their practice is used to map some of the variation in teachers’ perceptions of their classroom practices, with indications of the range of differences, and of areas of perceived strong and weak control. Secondly, young people’s understandings of the meaning and relevance of science and science education in their lives are explored as a means of raising critical questions about the consequences of this pedagogical variation. We make use of participatory photography to facilitate dialogue with young people without overtly leading them through imposing particular forms of words. This results in some very rich and engaging data. Discussion of the findings of these two approaches lead to a formulation of the constraints on and choices open to science teachers, to the range of positions that young people develop and take up, and so point towards an outline of a model of pedagogical variation, choice and consequence in science education.

Keywords: pedagogy, choice, mapping

INTRODUCTION

This paper takes up and adapts an approach to mapping pedagogical variation in science education, as a first step towards a more developed critical discourse of choice, constraint and consequence in the field. An essential feature of this paper is the attempt to explore the issue from both ends, as it were; looking at teachers’ descriptions of their practice, and at young people’s understandings of science. The space between these ends is complex and largely unknowable, but bringing together data from the ends sets the context, and we hope the motivation, for further work in this space. We anticipate surprises in terms of the differences between what is implicitly intended and what is apparently understood through the process of science education. We want to disrupt the assumptions which underlie much thinking about pedagogy and curriculum in science. Our own working assumption is that these assumptions are most disadvantageous to those young people who are most marginalised in the education
Many pedagogical options have been considered in order to address the inequities within which science education is situated and to which it often contributes. These often involve addressing the barriers and boundaries experienced by particular groups of pupils. From a landmark report in an Australian context, ‘the curriculum needs to seriously cater to all students and be set within contexts that will be meaningful to all students’ (Tytler, 2007 p.64). Aikenhead (1996) adopts a language of ‘border crossings’ into the subculture of science. Osborne (2014) is among many in problematising the link from science education to the ‘real world’. The ‘funds of knowledge’ perspective (Moll et al, 1992; Barton and Tan, 2009) takes a critical, anthropological gaze towards families and communities that are frequently regarded in school discourse as deficient in some way, if they are noticed at all. In looking at what teachers and students do in classrooms and what students experience in the community, the “funds of knowledge” raises the possibility of achieving greater cultural congruence. According to Basu and Calabrese Barton (2007), a closer bond can be achieved between students’ classroom experiences and their personal lives when funds of knowledge are recognized and maximised.

We set much store by the research of these authors and the intentions behind it, but our understanding is that as groundwork for a systematic pedagogical approach to influencing young people’s thinking and positioning in relation to science, it remains at an early stage. Not only is there very little knowledge of how young people’s appreciation of and positioning with respect to science can be influenced, there is also little knowledge yet of the particular contexts in which teachers might expect to have an effect through a particular pedagogical approach. An emphasis on any given approach, based on claims for its validity, is limited in value if the specificity of the approach to particular conditions is ignored.

This paper comprises a conceptual exploration of pedagogical options in science education, based on a simplified general model of pedagogical variation and choice due to Bernstein, and a two-part empirical study looking towards the possibility of modelling likely consequences in particular contexts.

THEORETICAL PERSPECTIVES

The proposed programme of research within which this paper sits looks towards the possibility of a mapping of the consequences of particular pedagogical choices for the interpretations, understandings and positions that young people come to hold in relation to science. There are clearly many influences on young people, and so any such mapping is likely to be tentative at best – we do not yet know enough about the particular influence that teachers have, or how or when, which presents a methodological challenge to finding out, because we don’t know what we are looking for. Our position though is that however tentative, the idea of such a mapping is valuable, because of the way it forefronts the agency of teachers, too often written out of educational discourse. We say nothing here about how that agency should be conceptualized – whether as individual or collective agency in particular departments, for example. The important feature is that teacher agency should be recognized within the research framework.

For despite the context of assessment-driven standardization in science education in many
countries, there remains a huge potential diversity in science pedagogy, and therefore a wide potential space occupied by teacher agency. One theorist taking a forensic approach to exploring this diversity was Basil Bernstein, concerned with the social consequences of particular pedagogical forms. In a paper exploring the types of pedagogy that are best suited in contexts of disadvantage, Hugo and Wedekind (2013) present ‘eight questions a Bernsteinian could pose when thinking about curriculum and pedagogy in a school setting’ (p.146):

1. Would you strengthen (+) or weaken (–) the relationship between everyday experiences and understandings on the one hand and subject knowledge on the other within your lesson?
2. Would you strengthen (+) or weaken (–) the relationship between the subject being taught and other school subjects within your lesson?
3. Would you strengthen (+) or weaken (–) the line between various subsections of a school subject within your lesson?
4. Would you allow your learners some control (–) over the selection of what to do in the lesson or would you keep control (+) over selection?
5. Would you allow your learners some control (–) over the sequence of steps the lesson follows or would you keep control (+) over the sequence?
6. Would you allow your learners some control (–) over the pacing of the lesson or would you keep control (+) over the pacing?
7. Would you allow your learners some control (–) over evaluating what needs to be understood or would you keep control (+) over evaluation?
8. Would you allow a more open relationship (–) with your students or insist on a clear demarcation (+) of roles?”

These questions are framed in relation to the Bernsteinian concept of control, rooted in the notions of classification and framing that are at the centre of his understanding of pedagogy (Bernstein, 2000). This is a theoretical framework which forefronts the way the teacher, through his or her pedagogical choices, is able to influence key relations in the teaching of a subject. We interpret these questions as offering the basis of an overarching framework of pedagogical variation in science. As suggested by Hugo and Wedekind (2013), the questions present 256 discrete pedagogical variants, even where the range of each of the eight discrete variables is only the bipolar ‘more’ or ‘less’. This sets the scope for a broad study of science pedagogy, in which particular pedagogic forms such as enquiry-based learning, industrial case studies, modes of assessment, and modes of communication in classrooms are situated within a coherent framework of pedagogical choice.

In this paper, we report on teachers’ self-descriptions of their pedagogy through survey responses which relate to the first seven of the eight dimensions of variation. This marks an early stage in an exploration of science pedagogy in which teacher agency is highlighted through the idea of pedagogical choice.

In exploring the significance of these choices by teachers, we then go on to explore young people’s thinking in science in relation to the first three dimensions, and what we will later call control over sources of knowledge.

**METHODOLOGY**

Two methods were used as ways into the empirical investigation of pedagogical variation. The
aim here was not representativeness, but a grounding of the theoretical framework in relation to the views and understandings of teachers and young people.

Rather than analyzing teacher practice with respect to all eight separate dimensions of pedagogic variation, we consolidated them into three dimensions, as shown in Table 1. This simplifies the approach whilst retaining the Bernsteinian focus on control.

**Table 1. Consolidation into three dimensions of pedagogic variation**

| Teacher control over sources of knowledge | Would you strengthen (+) or weaken (−) the relationship between everyday experiences and understandings on the one hand and subject knowledge on the other within your lesson? |
| Teacher control over learning processes | Would you allow your learners some control (−) over the selection of what to do in the lesson or would you keep control (+) over selection? |
| Teacher control over evaluation | Would you allow your learners some control (−) over evaluating what needs to be understood or would you keep control (+) over evaluation? |

We judged it unlikely that these rather abstract choices would be sufficiently meaningful to science teachers in terms of reporting their classroom practices, and so we adapted a scale from a mathematics survey of teacher reported practices which utilised a series of more direct statements of practice. The 2017 survey was adapted from an existing, standardised instrument used to explore teacher perspectives on their mathematics pedagogies, with high reliability and face validity (Pampaka et al, 2012). The teachers in the sample were working in a range of schools across the north west region of England. In the results reported in this paper, survey responses were used to identify differences in terms of the features of education in science over which teachers reported control. The results can also be used to identify characteristically different pedagogical approaches among teachers. Our intention is to follow up these differences with focus groups and interviews to explore teachers’ rationales for their practice.

The specific focus of the qualitative research element was to explore students’ perspectives on the connection between science and the real world, through a funds of knowledge lens. Currently, we have very little understanding of the differences and similarities in the way that young people think about science in relation to life. In this study, we focused on pupils in one particular context in which their ethnicity and experience position them as potentially...
marginalised within the education system. There are many such contexts; by focusing on one, we make no claim to representativeness, but we would expect findings of similar distinctiveness in other contexts.

These students were all working in one school, a girls school with a high proportion of young people from ethnic minority backgrounds. Case studies of individual students were constructed through semi-structured interviews using participatory photography methods, whereby students were asked to photograph their experience of science in some way, and create captions for each photograph (Miles and Howes, 2014). Students were then asked to discuss these photographs during an interview with the researcher. The initiative in this process was with the young person rather than the researcher, leading to clearer and more particular examples and memories of topics and events, and to a greater level of reflection, compared to traditional methods (Harper, 2002). The researcher in this case, one of the authors, was a young woman from a Muslim background and for whom English was a second language. These interviews were conducted and audio-taped, transcribed and coded in order to create a range of instances of the relationship between the everyday and science subject knowledge, as perceived by young people. For some young people, English language represented something of a barrier to unambiguous communication, but it was noticeable that the process was robust enough to allow them to make some sense of their thinking with the interviewer.

Science teachers whose pupils took part in the qualitative study took part in the survey, providing opportunities to speculate on the types of links that may exist between teacher pedagogies and young people’s responses to science. The effects of teaching are not all immediate or short term, and so the possibility of these links is more suggestive than evidential.

**FINDINGS**

We report the findings of this study in two parts, the first part relating to teacher reports of their practice as interpreted from survey results, and the second part relating to young people’s understandings of science.

**Teacher practices – self reports**

The responses were analysed in relation to the three consolidated dimensions of pedagogic variation listed above. The responses associated with each dimension are shown below the mean of each response (Tables 2, 3 and 4).

The analysis of this data will later be extended in relation to demographics of the teachers concerned, and to associations with contextual features. But here, the focus is on the reported levels of control that teachers report, over these different features of educational significance, at the level of descriptive statistics.
Table 2. Teacher control over knowledge sources (4 is high teacher control, 1 low teacher control)

The main finding of note is of a difference in the mean level of control reported by teachers, of different aspects of their pedagogical practice. These reports suggest weaker teacher control of sources of knowledge than of learning processes or evaluation processes. One interpretation of this difference is that these teachers value relatively highly the knowledge that young people already have and see the importance of working with this in the classroom; their prior knowledge, their understanding of contexts for learning, each other as resources for learning, and the significance of connections between scientific ideas. More confident interpretation of this point awaits further follow up work with teachers, and in particular discussions of their pedagogical approaches, perhaps combined with observations of teaching.

These results also suggest that teachers typically restrict more heavily the control that young people have when it comes to classroom processes, such as control over selection of material, sequence, pacing or evaluation. For now, we simply note this result, but we shall return to it when we have considered young people’s responses to science education in more detail.

**Young people’s understandings of science and the real world.**

As suggested above, the data from interviews and focus groups with young people relating to the photographs they had taken was rich and complex. In order to present some of this data, we first look at it in terms of themes, and then later explore further in terms of individual young people. Most young people were keen to talk about their photographs, and to engage in dialogue on their conceptions of the real world in relation to science. So these interviews became opportunities for listening carefully to the way that young people understand the words and ideas that we largely take for granted in thinking about science education.

The approach effectively puts to the test some assumptions about the way the curriculum is experienced by young people, and about the sense that they will make of it. For example, a common assumption is that young people will develop a clear idea of what science is, and how science is related to and a feature of our experience and of the universe.

Beginning from Osborne’s (2014) modelling of science as a relationship between ideas and the real world (a relationship informed, tested and developed through enquiry) we noted the ‘real
world’ as represented and referenced in textbooks and science materials. We decided to make
the real world a feature of the discourse in which we invited young people to participate. What
would they make of the idea of the real world, and its relation to science? In particular, how
would they articulate these connections in reference to features of their own experience? We
asked young people to take a series of photographs in response to some prompting questions,
and then come back and talk about what they had done. In this way, we were able to probe into
their ways of talking about particular features of their experience as it related to science. How
did they talk? What did they talk about? The prompt questions referred to the relationship
between science and the real world, including, for example: ‘Take a picture of science in the
real world / science and the real world / the real world without science in it’.

In order to represent young people’s ways of talking, we identify some common themes, but
we also note how different their ideas were from one another. Common figures were there in
the discourse, but there were also substantially distinctive idiomatic articulations to which we
draw attention. We believe these are indicative of an important feature of young people’s
subjective positions in relation to science; how different they are, one from another.

Common themes:

Overall, we noticed how articulate the young people were in their understandings of science as
it was meaningful to them, and in terms of the relationship between science and the real world
as they saw it. In some cases this world was a religious world as well as a scientific one, and
young people worked to articulate a complex understanding of this relationship:

**Science as explanation for features of the world**

For me I think science like explained the world to me, for
example religion and science completely different things but
even though like, I think some people religious they don’t
believe in science but I think go hand in hand... If you are a
religious person you’re gonna see the world in a scientific way
and the logic behind everything in science (Amina, 14)

Some interest, but no big picture

These young people have a very unconnected sense of the branches of science, such as geology;
and yet they appear fascinated by some aspects of science that are hardly referenced in school.
Zahra is one such:
Nature

Several young people had an understanding that science was ‘with’ or ‘in’ nature. In its strongest form, the world before humans was seen as the real world, with science being in that world, in plants, in their life, the life of nature.

For some young people, the real world is separate from the world of science.

Science as separate from the real world

Fagiah presents a view of science as the foundation or source of technology.
Whereas for others, science is the opposite of technology, because technology does occupy a place in the real world.

**Science as the opposite of technology?**

This said, disconnection between the science and the real world. Because this is something human made in the real world, not in science.

It is helpful in this brief overview to present something of the complexity of views held by each individual pupil. Zoya for example spoke articulately about an inspiration for her to do science:

**This was Zoya’s picture of something that inspires her to do science:**

Because I like plants, and this is telling me if I liked the plants, science tells I can search about the plants. This is something at home, like my mom really likes the plants. It is a real plant, she always takes care of them, so when I saw her makes me think why and how those plant born [and get] older. make me really want to search about that.

She starts to elaborate her sense of the relationship between science and the real world.

**Zoya’s picture showing a connection between science the real world**

As she speaks, Zoya elaborates her ideas about science and the real world, seeing how there are lots of features of the real world which connect to science, and that this may be true in her house too.

This is a flower like in the real world. But they are not a real flower they are fake flower. they also made by human, decoration for by the flower human inspired by the real flower.

If it wasn’t plant in the real world, so they wouldn’t know about the plant or the flower all that mean. So they make it fake so it will stay for longer. For decoration like that at home.
Strand 2

Amina by contrast has a sense of the disconnection between science and the real world – perhaps the labeling of the world is science, but that act of labeling is an act of disconnection:

For Amina, food labels show science disconnected from the real world.

The disconnection is evident to her in relation to science lessons, where properties of metals are discussed, but the metals themselves are absent.

**DISCUSSION AND CONCLUSION**

This paper set out with a bold ambition, exploring the two ends of the science education process and looking towards the possibility of a more informed pedagogical model of science education. In terms of Bernstein’s dimensions, the findings from the investigation of young people’s ideas suggests a weak relation between science lessons and the everyday world, a weak relation between the sub-sections of science, and a weak distinction between science and technology.

There is much more to say on this; the conference paper rests as a stage in the construction and development of these ideas, which we continue to work on through analysis of the data.
ACKNOWLEDGEMENT

This work would not be possible without the assistance of teachers and pupils in our partner schools, to whom we express sincere thanks.

HOW DOES A CHOICE IN CONTEXT OF PHYSICS PROBLEMS INFLUENCE STUDENT PERFORMANCE AND ATTITUDE

Samuel Wheeler and Margaret Blanchard
North Carolina State University, Raleigh, USA

This research investigates the role that student choice and gender stereotypes have on student interests, beliefs, conceptual understanding, and motivation toward learning physics in a high school unit on Newton’s Laws. This mixed methods study examined how giving students a choice in the context of physics problems influenced their attitudes, interest, and performance. Seventy-four student participants in high school physics classes, from five US states, took part in this study. WebAssign homework problems were designed to investigate whether the context of a physics question, based on gender preferences, would influence students’ choices. Three question contexts were used: traditional physics; biological/health; and sports. Students were given a pre/post Force Concept Inventory to evaluate physics conceptual knowledge, and a pre/post CLASS survey to measure changes in attitudes. Female participants demonstrated greater gains in conceptual understanding compared to males. Female students also had improvements in sense making and applying conceptual understanding and were more engaged with the assignment than male students. Male students also showed a variety of gains and interest and attitude toward physics, but in different CLASS categories than female students. The findings suggest that given a choice of context, all students are more engaged and interested in the physics and show growth in understanding the concepts. Keywords: physics, choice, gender

INTRODUCTION: THE GENDER GAP IN PHYSICS

For younger students, there is no gender gap in interest in STEM subjects; yet, by the beginning of the senior year of high school, females will have lost most of their interest in STEM subjects as compared to male students (Baram-Tsabari & Yarden, 2011). Female students tend to steer clear of taking physics courses in high school, a gateway course to STEM degrees, which makes them less likely to go into a technical major in college that requires a physics background (Blickenstaff, 2005). Approximately 19% of undergraduate physics degrees were awarded to women in 2015 (American Physical Society, 2015). Women receive 23% of masters’ degrees, and 19% of PhD’s in physics (Mulvey, 2014).

Some progress has been made to address gender bias, such as including pictures of female scientists in textbooks and educating teachers about the challenges that female students face strategies that have demonstrated positive effects on female students’ interest in physics (McCullough, 2004). McCullough recommends using specific language in examples that involve contexts that are familiar and relevant and to all students, such as cars, food, and school activities. Other researchers suggest tapping into the interests of female students by integrating medical and biological fields into the traditional physics curriculum as a way to get more female students interested in physics (Gibson, Cook, & Newing, 2006). In general, male students tend to be interested in physics for the sake of physics, while female students tend to report being interested in physics for the sake of what physics can do to help humankind and other social associations (BØE & Henriksen, 2013). Research into understanding specific
science topics that girls find the most interesting list topics associated with biology as the most engaging and relatable to students (Mitrevski & Treagust, 2011). In a survey given to 103 girls aged 14-17 in Australia, Mitrevski and Treagust found the top four most interesting science topics they introduced to females were genetics, fighting diseases, workings of the heart, and respiration, while the least interesting topics were all traditional physics topics: magnetic fields, light waves, and circuits. Mitrevski and Treagust suggest that one of the remedies for lack of female interest in physics is to create curricula that relate physics issues to health applications and other topics related to the human body.

The interdisciplinary approach to teaching physics by incorporating life science into the curriculum is on the rise, mainly as a response to the greater demand for students to more fully understand the relevance of physics in relation to biology and chemistry (Crouch & Heller, 2014). Crouch and Heller designed a course for the growing number of life science majors who needed physics. They taught at two universities with diverse student populations over a two-semester sequence. Student attitudes about physics were measured with the Colorado Learning About Science Survey (CLASS) and found to either remain stable or improve over the course, as compared with the attitudes of students in the same course but taught without the biological context which showed a decline in positive attitudes about physics (Crouch & Heller, 2014).

The question of whether offering a choice to students results in positive outcomes in student performance, interest, and motivation is a question that is recognized as having many variables and that fine-tuning of the scenario is required to create a meaningful learning experience (Katz & Assor, 2006). Bereby-Meyer et al. found when the learning environment is simple and students’ choices are limited, students make choices that lead to better results and gains in learning outcomes (Bereby-Meyer, Assor, & Katz, 2004). Choice was found to be a motivating factor when the choice satisfied the students’ psychological needs (competence, relatedness, and autonomy), as described in self-determination theory, were accounted for in the learning environment (Katz & Assor, 2006). Katz and Assor suggest that for choice to be beneficial to the learner, factors such as the context in which the choice is provided must be considered, and for choice to be motivating, students’ needs, background, and abilities should also be factored in.

THEORETICAL FRAMEWORK

The theoretical framework used for this study applies a social-cognitive foundation to connect the influences of student choice, motivation, achievement emotions, satisfaction, and academic achievement together, see Figure 1 (Artino Jr, 2010).

According to Artino’s model, students who become more interested in learning will find more value in the task and feel more confident in their ability to complete the task. The learning environment and personal factors contribute to the academic outcomes, satisfaction, and instructional choices. The model predicts that students’ satisfaction and choices are linked to their motivational beliefs and socio-cultural influences through a feedback loop.
Figure 1. Social-cognitive model of academic motivation and emotion (adapted from Artino, 2010).

RESEARCH QUESTIONS

1. When given assignment choices designed around gender stereotypes, which types of physics problems do male and female students select?

2. Are there differences in the achievement of males and females, and is this related to the types of physics questions they select?

3. What are students’ attitudes toward, beliefs about, and interest in physics? What accounts for any changes that occur over the unit?

METHODS

This research design is a concurrent triangulation mixed-methods investigation (Cresswell, 2003) that explores the role of gender stereotypes and gender biases on student interest in physics. Several different instruments were used to investigate the variables. One instrument was developed using WebAssign to determine which of three different contexts that students prefer when presented with a problem on a particular physics concept (Wheeler, 2017). The Force Concept Inventory (FCI) (Hestenes, Wells, & Swackhamer, 1992) and the Colorado Learning Attitudes towards Science Survey (CLASS) (Adams et al., 2006) were also used to measure changes in student physics conceptual understanding and attitudes towards physics respectively. Seventy-four students from five US states, 35.2% female and 63.5% male, from eight different AP/Honors Physics teachers’ classrooms participated in this study. Teachers were asked to assign the problem sets to their students as part of the normal classroom homework process or for exam preparation.

The FCI and CLASS were given as pre and post measures to the WebAssign intervention. Students accessed homework online through WebAssign (https://webassign.net) and students were presented with the choice of three different contexts for each problem, all of which were related to a two-week unit on Newton’s Laws and forces. The problem set was made up of fifteen written questions and six video format questions. Each problem consisted of the same fundamental physics question but from the perspective of three different format contexts: traditional physics examples; biology/medical; and sports. Students were asked to write a brief explanation, at the end of each question, discussing why they picked the context they chose. Student written responses were categorized and codes were developed corresponding to the
categories of their explanations. Coding of all responses were conducted blind to any student demographic information.

RESULTS

Female students primarily chose the biology context of the WA instrument, whereas male students chose the traditional context. Females selected a question mainly because they were interested in the context (34% of the time) or because they thought it looked easy (33% of the time). Males mainly selected a question because they were interested in the context (45% of the time) or because they thought it looked easy (25%) of the time. Many students (21 males and 11 females) surprisingly chose to complete more than one context per question even though they were asked to complete only one. Females tended to choose traditional/sports combinations (30% of the time) or they did all three contexts (27% of the time). Males tended to choose biology/sports combinations (28% of the time) or all three contexts (27% of the time).

Females scored significantly better (85% correct) on their first choice than did males (69% correct) regardless of context ($p \leq 0.05$) and females used significantly fewer submissions (2.11) on their first choice than males (3.22) ($p \leq 0.001$).

Achievement was defined as performance on the FCI and by the scores on the WebAssign problems. The results of the pre to post FCI show that 68% of female students significantly improved their score, compared with 38% of male students. Males who had growth on the FCI scores spent significantly more time on the WebAssign problems than did males who did not show FCI growth ($p = 0.0459$). There were no significant difference in the amount of time spent on WebAssign by females who showed growth compared with females without growth ($p = 0.053$). Females who chose to complete multiple contexts on the WebAssign problems scored significantly better (85% correct) on their first choice than did males (69% correct) regardless of context. Females who showed FCI growth chose as many traditional contexts as biology, and significantly more biology contexts than sports ($p = 0.013$). Males who showed FCI growth chose significantly more biology contexts than sports ($p = 0.033$), and significantly more biology contexts than males without growth ($p = 0.0402$). Males who had no FCI growth chose significantly more traditional contexts than biology ($p = 0.002$), and significantly more traditional contexts than sports ($p = 0.0001$). No statistically significant differences were found between male and female (average) scores on 20 of the 21 WebAssign questions; only three questions showed males with statistically significant higher averages ($p < 0.05$).

Student attitudes were measured from pre to post intervention by the CLASS-Physics instrument. Females were more likely to think about which physics concepts to apply to a problem after the intervention, from pre to post CLASS. Females were more likely to trust their calculations if they obtained an unexpected result as compared with male students, as measured by the post CLASS. Females felt less agreeable that the same reasoning skills they used solving physics problems could be helpful in everyday life, and they were less likely to believe that anyone is capable of understanding physics if they worked on it from pre to post CLASS.

The motivations for student choice were measured qualitatively through their written responses in WebAssign. The author and a second researcher coded the entries independently and
compared the results resulting in an inter-rater reliability found using Cohen’s kappa of 0.875. Differences between the results were resolved and the responses were coded according to: interest; familiarity with the problem; random choice-no preference; and easy-straightforward. Males were more likely to choose a question because they were interested in it. Females almost equally selected interest or that they perceived the question to be easy or straightforward for their rationale in context choice.

Table 1 shows the significant results of attitude and interests gains made by male and female students, from the pre to post CLASS instrument.

**DISCUSSION**

The findings suggest that, given a choice of contexts, students gain in their conceptual understanding of physics and they will be more engaged and interested in the physics. Female students made significant gains in conceptual understanding (FCI) and showed improvements in sense making and applying their conceptual understanding as measured by the CLASS. Females also seemed to be more engaged with the assignment as compared with the male students. The intervention was more successful at improving females’ conceptual understanding than that of males, especially those females who chose biology contexts. No significant difference ($p = 0.417$) in the average time spent on the entire project was found between females (300.7 minutes) and males (292 minutes). However, females tended to persist through the project and spread the time they spent on it to between fourteen and fifty days, while the majority (62%) of the male participants tended to complete the project within three
days or take longer than fifty days. By the end of the study, the data shows that females were thinking more of how to apply physics concepts to problems and how to relate physics to their own everyday experiences, but they decreased in their confidence to solve problems. The data also shows that males gained confidence in their ability to solve problems and grew in trust of the relationship between physics formula and concepts. Male students either completed the project early or put it off until the end, while females seemed to persist through the project time with a more consistent effort. Time on WebAssign was not found to have a positive correlation on FCI growth for females, but strong correlations between WebAssign scores and post FCI scores were found for both genders. The choice of whether to do multiple contexts or to do just one context made no difference in FCI growth.

Females showed drops in attitudes towards the thinking used in solving physics problems being applicable to everyday life and that they felt as if everyone could understand physics if they worked on it. This is in contrast with the significant gains that female students made on conceptual understanding as measured by the FCI. The items on the intervention weren’t designed to deliver contexts that would be familiar to students in their everyday life; rather, they were designed to deliver the content through contexts that appealed to students based on gender stereotypes. This could explain why females were less likely to think that physics is helpful in their daily life. Many of the examples used in the intervention questions were chosen for their appeal to students, not practicality in everyday life. The decrease in the belief that everyone is capable of understanding physics if they work at it could be a result of the experience that the students had on the video formatted questions and with WebAssign in general. All students had lower scores on the video questions than the written questions, and some difficulty was reported by a couple of schools with the video technology. A teacher reported frustration with WebAssign not counting the students’ answers correct on the word problems, but on closer examination the teacher’s students were used to rounding their answers and as a result their answers were out of the range of the tolerance set for the problem and WebAssign was counting the submissions wrong. The teacher and students of this school were instructed not to round on the remaining questions, but to follow standard significant digits rules. Yet, it is possible that this experience contributed to students’ perceptions of their ability to understand physics, given these setbacks but no evidence was collected on these perceptions. A study in Switzerland which surveyed male and female high school students found that females tend to have a negative view of the relationship between their gender and physics (Markarova, 2015). These findings echo what others have found and what was discussed earlier in this paper. The fact that this study saw few positive changes in female attitudes and beliefs about physics is not surprising upon further reflection. After all, many studies point to factors such as the students’ teacher, the classroom environment, female role-models, and students’ home life as major determining factors on a female’s attitudes toward a science or math subject (Meece, Glienke, & Burg, 2006).

Males had significantly higher scores than females on two questions that pertain to the problem-solving category on the CLASS. Males reported that they could usually figure out how to solve a physics problem and they were more likely to believe that mathematical formulas express a meaningful relationship among the variables. These changes could be due males being able to choose the context that they were more comfortable with, in this case the
traditional context was the primary choice for males but also due to the positive reinforcement they were receiving on their work. WebAssign gave immediate feedback on any submitted problem and it also allowed them to submit responses for each question five times before being locked out.

The use of video analysis questions in this study was not fully conclusive. Video problems were the most popular problems in the assignment since each video problem had more multiple contexts completed than written problems and students reported enjoying the video problems more than the written ones. However, students did not do as well on the video problems as on the written ones. This is in part due to limitations with the technology where two schools reported that students could not watch the embedded videos because of school policies which blocked YouTube© from being accessed. Further work is needed to better determine how to best incorporate video analysis into student choice and learning physics in the context of this study.

CONCLUSION AND IMPLICATIONS

The intervention was more successful at improving females’ conceptual understanding than that of males, especially those females who chose biology contexts. Females who chose combinations of multiple types of contexts also appear to have increased scores on the WebAssign problems, likely due to the extra practice the problems gave with the concepts. The gains made by female students seem to be a result of the opportunity to choose and the interest in the choices. However, females showed loss of confidence in some problem solving and interest aspects as measured by the CLASS. Males tended to choose traditional contexts and did not explore other contexts as the females did, but males needed fewer attempts to answer these questions. Males, overall, did not demonstrate significant growth on the FCI, but males who showed growth tended to choose more biology contexts while males who showed no growth or negative growth chose more traditional contexts. Males showed gains in their attitudes towards problem solving, but given that they chose questions from the traditional physics context which were what they were accustomed to, the instantaneous feedback that WebAssign gives was most likely responsible for this result.

Female students have shown more interest and engagement in physics when physics is presented through contexts they enjoy such as with medical applications or biological contexts (McCullough, 2004), (Crouch & Heller, 2014), but this study applied those findings to high school physics students and examined the effect interest alignment has on student conceptual understanding by incorporating student choice into the process. Students in this study were provided with choices in the type of context they wished to answer, and these choices were limited and designed to focus the student’s attention to the concepts in question based on findings from Bereby-Meyer, Assor, and Katz’s study. But different from Bereby-Meyer’s et.al. study, this study limited student choices within the assignment.

Findings from this study show that student choices in a context that interests them has a positive impact on their achievement. Student choice within an assignment is a unique approach that this study used but it is an approach that is being adapted for other applications within education. Adaptive learning, using computers as teaching devices that adapt to the learner is
being used at the university level to help students overcome knowledge gaps in chemistry, math, and biology (Liu, 2017). Adaptive learning algorithms are being used in Massive Online Open Courses (MOOCs) to increase student motivation to achieve on situational awareness training (Uskov, Howlett, & Jain, 2017).

The findings suggest that changes could be made in the types of examples given and problems presented to students in high school physics classrooms to better reach female students. The combination of contexts that appealed to female interests, student choice, and multiple chances to try a problem factors that could be implemented into future curricula designed to make a traditionally stereotypical male subject more appealing and interesting to female students. Further analysis is also needed to examine the role of teacher examples and the relationship between student extracurricular interests and performance in the context of this study. By exploring the impact of students’ choices and interests in learning physics, we can make steps in the right direction to make physics more appealing to girls so that one day, physics will not be considered just a man’s field, but everyone’s field.

USING SCENARIOS TO ENHANCE STUDENTS’ INTEREST IN SCIENCE AND PROMOTE CAREER AWARENESS

Irene Drymiotou, Nikos Papadouris and Costas Constantinou
University of Cyprus, Nicosia, Cyprus

Students’ declining interest in embarking on STEM careers has been widely discussed within the science education community since 1970. Although there have been many efforts to promote students’ interest in science and lead young people in the STEM pipeline, the lack of scientists and scientifically literate citizens remains a worldwide concern. The present study seeks to shed some light onto the intricacies associated with the design of teaching/learning environments geared towards enhancing students’ interest and improving their awareness about possible science-related careers. The study draws on three particular theoretical areas (the Social Cognitive Career Theory (SCCT) model, students’ interest and Problem-based Learning) and focuses on an empirical classroom-based study that aims to investigate the impact of career-based scenarios on (a) students’ situational interest and (b) awareness of science-related careers. Data collection included students’ questionnaires, field notes and interviews with participating teachers and students as to identify views on career-based scenarios. The findings of this study illustrate that the use of career-based scenarios as an introduction in science lessons can act as a mechanism to trigger and sustain students’ situational interest under some conditions. Moreover, the findings confirm that the majority of the students do not seem to be aware of the wide range of possible science-related careers. Also, despite having an overall view about the professions presented in the curriculum materials, their aspirations may be extremely resistant to change. The findings of this study may inform the theoretical framework on using career-based scenarios to enhance students’ appreciation of science and science-related career choices with the potential to influence educational practice in science education.

Keywords: situational interest, SCCT, science career awareness

INTRODUCTION

The demonstrably low interest of students worldwide in undertaking Science, Technology, Engineering, and Mathematics (STEM) studies has been widely discussed in the science education community and policy papers (Archer, DeWitt & Dillon, 2014; Archer, DeWitt, Osborne, Dillon, Willis & Wong, 2010; OECD, 2007). In an attempt to explore attitudes towards STEM enrolment, recent research has shifted from solely focusing on cognitive variables to also including affective variables of science learning drawing on models developed within the field of motivational psychology (Henriksen, Dillon & Ryder, 2015). Empirical evidence indicates a number of interrelated factors influencing students’ science career aspirations. The factors pertain to students’ identity (individual and psychological components) and family background as well as contextual and social influences (Wang, 2013). Emphasis was placed on enhancing students’ interest in school science suggesting that student-centred teaching strategies (Minner, Levy & Century, 2010) and context-based approaches (Bennett, Lubben & Hogarth, 2006) result in fostering positive attitudes towards science and science-related careers. Interest in science and science learning has been considered as a key factor for increasing the likelihood of selecting science-related careers (Potvin & Hasni, 2014).
confirming the urgent call to stimulate students’ interest in science. Further, research has shown that young people’s lack of awareness of science careers tends to undermine students’ interest in pursuing science careers (Taskinen, Schutte & Prenzel, 2013).

Although a number of theoretical approaches have been used to understand students’ academic and career decision-making process, the focus of this study is placed on SCCT based on the premise that interest is seen as a predictor of career goals and choice and can be developed in a learning environment that may be manipulated by environmental stimuli (Brown & Lent, 1996; Potvin & Hasni, 2014). This study also draws on Hidi and Renninger (2006) theory that suggests two forms of interest: individual and situational interest (SI). Individual interest refers to an enduring and stable orientation toward a particular topic or domain whereas situational interest is defined as a short-term form of motivation elicited by aspects in a specific situation that stimulate focused attention. The emphasis here is on situational interest given that regular experiences of situational interest in science learning can be the starting point for individual interest in science (Palmer, Dixon & Archer, 2016). However, thus far, only few empirical studies investigated the impact of teaching strategies on students’ situational interest in a subject and specifically in science contexts in relation to career aspirations. Hence, this study explores the influence of certain career-based scenarios on students’ situational interest and science career awareness as teaching innovations integrated in science teaching units. Based on the assumption that students’ motivation to pursue science careers is highly related to their interest, this study aims to answer the following research questions:

1. To what extent can the integration of career-based scenarios in science class trigger and sustain students’ situational interest?

2. To what extent can the integration of career-based scenarios in science class raise students’ awareness about science-related careers?

METHODOLOGY

This study included four case studies in a different science context in two secondary schools in Cyprus (one public and one private) as a means to address variability. The study evolved in three phases. Initially the learning environment was designed. This included the development of the career-based scenarios; the development of the evaluation tools and the planning of the teaching intervention with the teacher. The second phase involved the scenario implementation in class (classroom intervention) and data collection focusing on measuring students’ situational interest. Finally, data was collected upon the teaching intervention from both, students and teachers, to explore the extent to which the implementation of such scenarios in science teaching may enhance students’ situational interest and provide career awareness.

It is argued that students’ interest in school science declines with school years, mainly during the transition from primary to secondary education (Potvin & Hasni, 2014). Therefore, this study involved approximately 40 eighth graders\(^1\) and the classroom interventions have been extended over an eight-month period (three to ten 40-50-minute lessons) and were structured...

\(^1\) Convenience sample was used hence it cannot be considered representative of the general population. Also, claims should be treated with caution due to the limited sample size.
as follows: scenario presentation as an introduction to the teaching unit, scenario link to the teaching unit and a reflection/consolidation phase that wraps up the teaching unit and revisits its connection to the scenario.

The scenarios were developed as part of MultiCO, a European research project under Horizon 2020. The project aspires to stimulate students’ interest in science and as a discipline in the curriculum, and enhance their awareness about possible science-related careers. Scenarios are socio-scientific related ‘stories’ linked to the science curriculum and relevant, interesting science-related careers which can serve to contextualize inquiry-based activities. The terms ‘relevant’ and ‘interesting’ derive from empirical findings investigating the sources of situational interest in PBL environments referred to as scenario features. The development process of the career-based scenarios includes three stages: (1) Research; (2) Career focus based on scenario specifications and features and (3) Teaching focus based on scenario design principles and main features. The table below (Table 1) summarises the scenario integration and implementation in each case.

*This activity was not performed due to time constraints.

For this classroom-based research, both quantitative and qualitative data were collected. The primary data collection methods include (a) two different questionnaires administered during and after the classroom interventions and (b) interviews with students and teachers on the added value in terms of triggering interest and raising awareness about science-related careers brought about by the integration of scenarios in science teaching. In addition, field notes from observations during classroom interventions and planning meetings with teachers also served a useful role in both facilitating the triangulation of the primary data and supplementing their interpretation.

In particular, in response to the first research question, preliminary analysis of quantitative data was based on the central tendency (median, mode) of the following: interest/enjoyment and
interest/usefulness. These two factors form the main affective components linked to triggered situational interest combined with positive feelings toward the activity (Hidi & Renninger, 2006). The variability in this study in terms of the teacher, the teaching material, the teaching unit and the science subject were treated with caution hence further analysis was restricted to cases 1 and 2 after having identified great differences. In particular, in terms of triggered situational interest, a Wilcoxon Signed-Ranks Test was conducted to examine for possible differences with respect to students’ focused attention and usefulness of the knowledge gained in real life between the cases 1 and 2. Regarding maintained situational interest, Spearman’s rho was used with various items as to evaluate possible correlations between the three components of interest: emotional, value-related as well as cognitive aspects of interest (wishing to learn more).

Considering the second research question, in regards to the extent to which the integration of career-based scenarios in science lessons raise students’ awareness about science careers, quantitative data emerged from the second questionnaire administered at the end of the intervention as well as field notes and interviews with the students. Qualitative data with respect to the career-related skills were used to make some assertions about students’ knowledge on skills required in the professions embedded in the career-based scenarios. This data was classified under the main four categories and sub-categories of KSAVE Model (Binkley, Erstad, Herman, Raizen, Ripley, Miller-ricci & Rumble, 2012), as this was adjusted by Salonen, Hartikainen-ahia, Hense and Scheersoi (2017) in the context of MultiCO project, and concerns the following categories: Tools for working; Ways of working; Ways of thinking and Living in the world.

RESULTS

This section presents the findings from the four case studies. The findings regarding students’ triggered situational interest emerged from the analysis of students’ responses to a questionnaire consisting of five-point Likert scale items, administered after the introduction of the scenario. As shown in Table 2, in all the cases, the students reported that scenario introduction kept their attention especially in cases 2 and 4. Overall, the rating of enjoyment and usefulness aspects was also high following a similar pattern within the cases, though in cases 2 and 4 the context of the scenarios seemed to be more relatable to students and more interesting. As mentioned earlier, further analysis was conducted and a statistically significant positive correlation was identified between the aspect of enjoyment and value in all the cases (rho=.921, rho=.721, rho=.444 and rho=.600, p<.05, respectively).

These findings were consistent with qualitative data from the field notes and interviews with the students indicating positive feelings such as enjoyment and excitement (e.g. “Seriously? Turn the squash court into a club? Really cool!”). However, negative feelings were identified in cases where the scenario did not unfold as expected. For example, a teacher commented that a lot of students lost interest after encountering technical issues while interviewing the scientist. Regarding the value-related aspects, the majority of the interviewees emphasized on the importance of knowledge gained about various science-related careers (e.g. “It is important to learn about all the different jobs that someone who is going into science could branch out to”); science studies at secondary school level and topics considered as interesting and useful in real
life (e.g. airplanes’ construction). Further insights from qualitative data indicated lack of a smooth transition between the conventional teaching sequence and the implementation of career-based scenarios that might depend on the degree to which the scenario was successfully integrated into the teaching unit and also the need to connect the scenario with students’ prior knowledge.

The findings that follow concern maintained situational interest emphasizing emotional, value-related and cognitive aspects. The data were collected at the end of the interventions using a questionnaire comprising four-point Likert scale items. As can be seen in Table 3, the feeling of curiosity (“Piqued my curiosity”) was lower in cases 3 and 4 compared to cases 1 and 2. An illustrative quote from a student in case 3 is the following: “I liked the first lesson the most because it was the beginning and we were more curious to find out about the topic”. Even though this was not a common comment it is worth mentioning as it may indicate how novelty could induce interest.

</tbody>
</table>

The statement “It was fun”, tended toward a positive extreme in all the cases. Qualitative data consistent with this finding were common in all the cases. Students explained that they enjoyed the group work (e.g. “We all worked as a team to produce the best we could and was very fun and exciting!”); the contact with the scientists (e.g. “I think I really enjoyed that we actually had him in [scientist] and we were able to ask him questions (…)”) and hands-on activities (e.g. (…) we were not just sitting on the chair and listening (…) there wasn’t much text; it was a practical task for us so we liked it”), though time constraints sometimes developed negative feelings such as disappointment, stress, frustration and boredom (e.g. “It was all fun but I was a bit stressed as we had a time limit to create the poster”).

The statement “It was interesting” was endorsed by the students to the highest degree in all the cases. Further analysis indicated a positive correlation between students’ perceptions of the topic’s interestingness and personal relevance in cases 2 and 4 (rho=.455; rho=.348, p<.05,
respectively) and between topic’s interestingness and knowledge gained in cases 1, 2 and 3 (rho =.519; rho=.764; rho=.564, p<.05, respectively) where students performed the ‘be the expert’ activity. Common data from the interviews indicated that students perceived the scenario topic as interesting if it was related to their interests and aspirations (e.g. “This is very relatable to kids of our age [the club]”; “If we learn something in class that I like and I can relate to what I’m gonna do when I grow up, it’s definitely much more interesting and it keeps my attention more.”) and because of the acquisition of useful information about real-life issues, information that facilitated better understanding of science concepts using real-life applications and contacting scientists (e.g. “Basically I liked the fact that we related Newton’s 3rd law to how airplanes move forward. We learnt more about airplanes and we understood better Newton’s 3rd law”; “(...) when we see actually someone put it into practice I think it becomes a lot more real, more actual science in the world so I think it is really important to learn real-life scenarios as we go through theoretical ones”).

The cognitive aspect of interest in the questionnaire was represented by the item “It makes me want to learn more”. It is useful to note that only in case 2, which included the scientists’ visit at school, did the central tendency attain a positive value. Further analysis indicated a positive correlation between the cognitive aspect and the interesting topic in all the cases (rho=.822; rho =.805; rho=.391; rho=.475, p<.05, respectively) and personal relevance in cases 2, 3 and 4 (rho =.575; rho=.481; rho=.497, p<.05, respectively). Students argued that they wouldn’t wish to learn more if the topic was not relevant to their aspirations and interests (e.g. “I like the topic but I do not want to learn more because I don’t want that kind of job in the future”) or because there was no need to learn more (e.g. “I now know how cycling routes are made, there is no need to learn more”). Further insights from qualitative data indicated that students were not very familiar with PBL as a teaching/learning approach. Moreover, in some cases it was impossible to arrange face to face communication with scientists, e.g. due to incompatibility between the time at which the scientist could be available and the school’s timetable.

In regards to career awareness, based on the findings shown in Table 4, the knowledge gained about job and opportunities tended toward the positive extreme especially in cases 1 and 2 when discussion was developed between the students and the teacher after the presentation of the careers and also as a recap in the last lesson. Findings from the qualitative data showed that most of the careers presented were unknown to the students (e.g. “I knew that there must have been someone that works with sound but I didn’t know that they are working in such depth and they would stare at a specific job title”); it was interesting to learn about different branches of engineering (e.g. “It’s really interesting to go into all branches of building and sound”) and that contact with scientists was useful to understand the connection between theory and practice in a working field (e.g. “I learnt that a lot of things that acoustic engineers put into buildings are intentional, for example the X theatre had these specific columns which would scatter sound and I thought that it was for decoration”).

With respect to the knowledge gained about skills related to the careers presented, the median and mode values in all cases corresponded to a high degree of agreement. As shown in Table 5 which summarises the skills classified under the main four categories of working-life skills, *Tools for working* skills were considered necessary in all the careers presented in the scenarios with an emphasis placed on sector-specific skills. Students highlighted the importance of manual and technical skills as well as scientific and research skills and also sector-specific knowledge that relate to school subjects.

Note: The number shown in the sub-categories refers to the times mentioned and the most frequent skills are shown in bold.

Regarding the statement “This career might be an option for me” the most frequently occurring value was 1 or 2 that tends toward disagreement. Only a minority of the students chose these careers as future options. Findings from the interview data indicated that these careers were not aligned with their personal interests (e.g. “It’s an interesting job but I wouldn’t imagine myself as a transportation engineer”). Nevertheless, the students valued the opportunity given to gain career-related information and highlighted the importance of being aware about possible career opportunities (e.g. “It opens up our minds to many more careers than we actually knew (...) Like we knew engineers exist but we didn’t know there are different engineers, so for example acoustic and mechanical engineers”). Also, it is worth mentioning that the information acquired may influence some students’ career aspirations (e.g. “Preferably I would like to do anything with sport. But if I didn’t go towards those steps, I would think about engineering or
something like that to make stuff, I enjoyed engineering and sound engineering so it could be an option when I grow up”.

DISCUSSION AND CONCLUSIONS

The findings presented in this paper have provided insights into the extent to which the career-based scenarios integrated in science classrooms triggered/sustained students’ situational interest and also raised their awareness about science-related careers.

According to the findings derived from all the cases, focusing on the affective/emotional, value-related and cognitive components of interest, it can be argued that the use of career-based scenarios as an introduction in science lesson acted as an underlying mechanism to trigger students’ situational interest. In particular, it facilitated the elicitation of students’ positive feelings (excitement, enjoyment), sustained their attention and helped them appreciate the usefulness of such teaching innovations that introduce real-life socio-scientific issues. The value of presenting real-life issues aligns with a previous study by Rotgans and Schmidt (2012) suggesting that the presentation of real-life and mainly unusual problems in class prompts the students to confront with the unknown and makes them feel interested. Moreover, students’ engagement was facilitated when the scenario was presented in a context relevant to students’ life mediated by an interactive presentation (e.g. comic-strips/role-play) that may further captivate attention and demonstrate students’ positive feelings. This assumption is aligned with the work of Hidi and Renninger (2006) proposing that situational interest can be triggered by environmental stimuli such as character identification or personal relevance. Similarly, the expectancy-value theory by Wigfield and Eccles (2000) advocates that students might be further motivated to engage in a learning task to the extent they find the task personally important, emphasizing on utility value that relates to an individual’s future goals. It was also significant that the introduction of career-based scenarios helped students value their usefulness in real life in cases where the connection to the science teaching unit was clear and strong by constant revisit. This finding is consistent with previous studies suggesting that concrete/no abstract well-organised texts have a positive effect on students’ situational interest (Tapola, Veermans & Niemivirta, 2013) and that career-oriented activities should be integrated in ‘normal’ lessons and not run as standalones (Archer et al., 2014). In addition to this, the overall positive correlation between affective and value-related components of interest during the introduction of the scenarios seems to indicate that value can predict students’ enjoyment of science and reversely, that enjoyment can predict the value of learning science. This claim corroborates Ainley’s findings (2007) focusing on interest as an emotion not distinct from the emotion of enjoyment.

Overall, the extent to which it could be possible to sustain students’ situational interest during scenario implementation depended greatly on three factors: (a) the opportunities afforded to students for active learning focusing on the scenario-related instructional activities, (b) the usefulness and interestingness of the scenario topic, and (c) the smooth transition between the conventional teaching and scenario implementation.

The PBL approach aimed to provide an active-learning classroom environment described as an environment that provides opportunities for students to participate in class and understand the
application of science concepts in science-related career contexts. These learning opportunities promoted students’ involvement and engagement and were perceived as meaningful and personally involving, building on Renninger and Hidi’s (2011) claim that such instructional activities succeed in sustaining students’ situational interest. The active-learning environment was characterized by novel active-learning features of the specific teaching context that promoted engagement and demonstrated students’ positive feelings of enjoyment and excitement. Such features were mainly the collaborative activities ‘be the expert’ to take on the role of a scientist and the science-career oriented projects (poster design, club design and hands on activity).

During the scenario implementation, it was also noted that once the feeling of being curious about an unknown phenomenon faded away, the students tended to become less engaged and active. This is aligned with Rotgans and Schmidt (2011) studies demonstrating that once the knowledge gap initially developed by the realisation of ignorance about a topic is filled, situational interest wanes and fails to be sustained. This argument also explains the small proportion of students wishing to learn more (epistemic curiosity) reflecting the cognitive component of interest (Krapp & Prenzel, 2011). On the contrary, evidence from this study suggests that in the cases where the students experienced a new stimulator the situational interest seemed to have been aroused. Such stimulators included hands-on activities that promoted greater understanding of real-life applications in a science-related career context, videos related to the scenario, discussions to elaborate on the findings, drawing conclusions and challenging students’ learning and mostly, direct contact with scientists. This is in good agreement with Rotgans and Schmidt (2012) who support the repeated arousal of situational interest with new instructional events as a means to increase levels of situational interest.

The results of this study also revealed that the interestingness and usefulness/value of the scenario topic as attributed by the students might affect not only the triggering phase but also the transition to the second phase of interest development. Topics that facilitate understanding of real-life applications enriched with practical/hands on activities and physical contact with scientists were perceived by the students as interesting and useful. Moreover, the interestingness of the scenario topic was found to be correlated with the wish to learn more (cognitive aspect) that was as well correlated with personal relevance in two cases. One claim that could be made is that the development of value-related and cognitive components of interest during the scenario implementation seems to depend on the extent to which the topic is perceived as interesting and personally relevant. Likewise, Krapp and Prenzel (2011) pointed out that “the subjective value attached to the knowledge about an object is important for interest”. Measures about students’ prior specific topic-knowledge and learning outcomes after the scenario-related tasks would be also useful to give an insight about the relation between interest and learning (Ainley, Hidi & Berndorff, 2002). A previous study by Ainley and Ainley (2001) similarly found that where science education is perceived as personally important to students and develops the feeling of being self-efficacious, a stronger interest in science will result. Hence, self-efficacy may be also taken into consideration in future research as it is linked to interest and career aspirations (Potvin & Hasni, 2014).
Nonetheless, an interesting topic might not be the optimum strategy to engage students in learning (Jenkins & Nelson, 2005). The way it is taught often determines its interestingness (Swarat, Ortony, & Revelle, 2012). A useful suggestion for future implementations is to include topics presented in a multidisciplinary context reflecting authentic science where the interaction between different branches of science is continuously becoming stronger and more critical.

Although there was an overall positive attitude towards the scenarios, it was indicated that lack of good planning that developed negative feelings and hindered students’ engagement, might have prevented situational interest to be triggered or sustained. Some examples are practical issues (e.g. impossible to arrange meetings with scientists and time-consuming beforehand arrangements) and the lack of compatibility with the learning objectives and teacher’s experience in a PBL environment. According to expectancy-value theory (Wigfield & Eccles, 2000), these negative aspects reflect the cost value that an individual has to manage as to accomplish a task and be further motivated to initiate a learning behaviour.

Concerning the extent to which the career-based scenarios raised students’ awareness about science-related careers, an overall finding is that the students’ majority was not aware of the science-related careers presented. This finding supports a previous study by Maltese and Tai (2011) with respect to students’ lack of awareness of career options. However, it is indicated that students formed an overall view about science-related careers as well as skills required mainly in the branches of engineering and were able to recall this information even after quite enough time from the intervention. It can be assumed that wrap-up discussion about the careers presented might have facilitated the students recalling this information. Thus it could be useful to provide opportunities for consolidation and reflection in such programmes (Archer et al., 2014).

It is worth noting that the contact with the experts engaged and motivated the students to make links between science concepts taught in the teaching unit related to their mission and investigate even more the corresponding science field. This finding confirms the assumption stated in Salonen et al. (2017) suggesting that students can obtain wide-ranging information about science careers when interacting with real work life problems and scientists. It also supports findings of earlier studies that promote partnership between schools and industries (Schütte, & Köller, 2015). It can be stated that such collaborations can be promoted as an aid to school-curriculum activities with career orientation providing first-hand experiences in science.

Considering the categorisation of working-life skills based on students’ perceptions, Tools for working and mainly sector-specific skills and knowledge are the most prevalent skills in the science-related careers presented. This finding agrees to a great extent with the study of Salonen et al. (2017). Sector-specific knowledge focused on physics and mathematics as school subjects showing students’ perception of school subjects as being significant for working life. This is consistent with previous studies indicating that students’ future career choices may be influenced by the school science subjects (Lavonen, Gedrovics, Byman, Meisalo, Juuti & Uitto, 2008).
Even though career-based scenarios had a positive effect on broadening students’ awareness about science-related careers, students’ responses regarding choosing such careers as possible future options were mostly negative with minor exceptions. The main reason for rejecting these options was the lack of relevance with students’ personal interests and career aspirations, highlighted also in previous studies (Taskinen et al., 2013). Indicatively, students’ aspirations may indeed be extremely resistant to change even after intervention programmes attitude and also may be formed within the family context confirming ASPIRES’ project findings (Archer et al., 2014).

It is worth mentioning that a limitation of this study resides on the lack of students’ awareness of the careers presented prior to the interventions. Such data could be used to assess the extent to which the implementation of career-based scenarios raised students’ awareness of those careers. In addition to this, the evaluation of students’ interest about the specific scenario topic before and after the interventions could also suggest a different approach to science teaching and indicate possible correlations between interest and knowledge acquisition. A final and interesting issue about this study concerns the lack of repeated measurements of situational interest at different points in time after the introduction of the scenario. This could give an insight into the intensity of situational interest.

Reflecting on the findings of this study, PBL can be seen as a learning environment that could offer the contextual affordances and according to SCCT model affect the learning experiences and develop interest. The use of career-based scenarios as an introduction to science lessons can serve as a mechanism to trigger and sustain students’ situational interest under the conditions mentioned above. At the same time the data fail to indicate substantial improvements in terms of students’ career awareness and aspirations. This also suggests that designing instruction to impact on students’ science career awareness and aspirations is not an easy task. The findings reported in this study can shed some light onto the intricacies that may hamper the attempt to impact on students and suggest specific design principles that may facilitate the use of career-oriented instructional material to enhance students’ appreciation of science and science-related career choices. Further research in exploring the interrelations between SCCT constructs while intervening in the classroom environment could contribute to meaningful implementation of such career-oriented instructional material.

IDENTIFICATION OF STUDENTS’ QUESTIONS IN CONTEXT-BASED LEARNING APPROACHES

Lisa Schmitz and Sabine Fechner
Paderborn University, Germany

Students’ questions are an integral part of science education because the ability of posing questions and formulating hypotheses plays a crucial role for scientific literacy. Furthermore, several research studies show that students’ questions are a potential resource for classroom interaction and enhance learning. Consequently, they are an important aspect for both teaching and learning in science education. However, evidence shows that students have difficulties in posing their questions. Across age groups, students ask rather unsophisticated and - in comparison to teachers – infrequent questions. With regard to the worldwide trend to innovate school curricula into the direction of context-based learning approaches, this result represents a problem for further improvement of chemistry education. The German approach, for example, contains student-generated questions as an important part for further investigations in chemistry lessons. As a result, teachers are encouraged to promote students’ questions and to implement them efficiently in their lessons. Hence, the presented research study focuses on the generation of students’ questions using real life contexts. Moreover, the study is supposed to identify and classify the generated questions asked by students and to investigate their suitability for context-based chemistry lessons.

Keywords: chemistry education, student questions, context-based

BACKGROUND AND RATIONALE

Over the last decade, several research studies have highlighted the fact that students’ questions have major relevance in science education (e.g. Almeida, 2012; Chin & Osborne, 2008; Chin, Brown, & Bruce, 2002; Chin & Kayalvizhi, 2005; Cuccio-Schirripa & Steiner, 2000; Dori & Herscovitz, 1999; Watts, Alsop, Gould & Walsh, 1997; Wong, 1985). It is known from the literature that they have the potential to direct students’ learning, help them to evaluate their understanding and increase students’ motivation and interest in a topic. Apart from this, the ability to pose questions and formulate hypotheses is considered an important component of scientific literacy (Chin & Osborne, 2008; Millar & Osborne, 1998). As Chin and Osborne (2008) have stated, “The formulation of a good question is a creative act, and at the heart of what doing science is all about” (p. 1). Therefore, students’ questions are assumed to be a potential resource for classroom interaction and thus for teaching and learning in science education (e.g. Almeida, 2012; Chin & Osborne, 2008; Chin, Brown, & Bruce, 2002).

Accordingly, students’ questions provide the possibility for enhancing discussion, fostering argumentation as well as to provoke students’ critical thinking in science (Chin, Brown, & Bruce; 2002; Cuccio-Schirripa & Steiner, 2000; Shepardson & Pizzini, 1991). In addition to these findings, the regional chemistry curriculum of Northrhine-Westphalia in Germany requires students to be able to formulate scientific questions and set up hypotheses for further investigations in chemistry lessons (MSW NRW, 2011). However, different research studies also show that students have difficulties in posing their questions and thus their potential is generally not exhausted (Almeida, 2012; Chin & Osborne, 2008; Graesser & Person, 1994;
Dillon, 1988). As reported, this phenomenon can be explained by the fact that students ask few and unsophisticated questions (Graesser & Person, 1994; Dillon, 1988). In contrast, teachers mostly ask a high number of questions and dominate the verbal interaction in class (Almeida, 2012; Graesser & Person, 1994). Moreover, it can be seen that students’ questions “…are not always welcomed by teachers” (Chin & Kayalvizhi, 2002, S. 271). Consequently, teachers infrequently encourage students to pose their questions and/or do not implement them efficiently in classrooms (Vos, Taconis, Jochems, & Pilot, 2011). However, they should be the base for stimulating further inquiry and student-led investigations (Demuth, Grisel, Parchmann, & Ralle, 2008; Chin & Kayalvizhi, 2002).

Another reason for the inefficient use of students’ questions may be the difficulty to handle an unknown question spontaneously, or the ineffectiveness to transfer the question into a reasonable lesson plan. Concluding, teachers face the challenge to implement students’ questions successfully in chemistry classrooms. Unfortunately, it remains unclear how real-life contexts affect the question quality as well as how students deal with their own questions in terms of further investigations in chemistry lessons (Chin & Kayalvizhi, 2002). Hence, this research study aims to identify and analyze the kind of questions students ask when confronted with different real-life contexts and to investigate their suitability for context-based chemistry lessons.

**THEORETICAL FRAMEWORK**

According to Almeida and Neri de Souza (2010) as well as Graesser and McMahen (1993) the generation of a question follows three stages (Figure 1). The first stage is referred to as disequilibrium detection. Here, students have to identify their individual knowledge gaps by detecting a conflict in their knowledge and understanding. Apart from this, they need awareness of the discrepancy to go into the second stage, called verbal coding, or more precisely the articulation of the consisting conflict. Essential aspects such as a demand to expand the knowledge and/or interest in the nature of the topics is necessary for the generation of a question (Chin & Osborne, 2008; Graesser & Olde, 2003). Furthermore, students’ questions may stem from curiosity about the world, events and interactions with real-world problems. The filling of knowledge gaps can only be achieved by expressing a question in a certain social environment, which is called social editing. However, in this third stage, the articulation of a conflict by concrete words can be an obstacle. Over all stages, the generation of a question takes a considerable long time. Therefore, there is an existing competition for teaching time between students’ self-generation and teachers’ time management (Niegemann & Stadler, 2011).

Previous research studies have illustrated students’ difficulties in posing their questions. They only ask few questions and the quality is referred to as “low-level” (Chin & Osborne, 2008). It is known from the literature that both prior knowledge as well as individual experiences can be factors for the quality of a question (Almeida, 2012). Based on Coutinho and Almeida (2014) the quality of a question can be defined as low-level (closed questions) or high-level (open questions) measured by the information content of the respective answer and the scope to answer the question. Low-level questions have one correct answer or an answer from a narrow range, while high-level questions have a wide range of responses (Almeida, 2010).
Several research studies suggested different category systems to classify students’ questions (e.g. Chin & Osborne, 2008). According to Renkl and Helmke (1992), categorization problems are caused by the development of different category systems. This situation makes it difficult to achieve a uniform definition, in particular relating to high-level questions. However, in context-based learning approaches, students’ questions are used to plan further investigations and to promote the scientific method to acquire knowledge (Demuth et al. 2008). Hence, this study is focusing on the classification of students’ questions according to Chin and Kayalvizhi (2002) and their categorization of investigable and non-investigable questions. In this regard, an investigation can be defined as a way of problem solving with multiple possible ways to come to a solution and no straight-forward answer (Duggan & Gott, 1995). In addition, Lock (1990) defines an investigation as experiments which require the participation of the students and provide evidence. Although the role of students’ questions and their potential for science education is well documented “…, there is little research on the kinds of problems and questions that pupils pose when they are asked to generate their own investigations” (Chin & Kayalvizhi, 2002, p. 272 ). Therefore, this study focuses on the development of an effective implementation of students’ questions in conjunction with their own investigations in chemistry lessons. In a first step, questions are identified that are suitable for this project.

**RESEARCH QUESTIONS**

Based on the presented recent research results and the research aim, the following questions arise:

Q1: Which kind of (chemically investigable) questions do students ask when they are confronted with real-life contexts?

Q2: In what way are these students’ questions suitable for further investigations in the chemistry classroom?

In order to answer the research questions the study is divided into two parts. The following descriptions elaborate on the research design and methods as well as the preliminary results of the first research question.
RESEARCH DESIGN AND METHODS

In order to answer the first research question an interview study is conducted. The interview is divided into three sections based on the stages for generating a question (Figures 1 and 2).

Figure 2. Design of the interview study

The first section primarily serves the context selection as well as the self-generation of questions. For this purpose, the students are confronted with contexts presented as illustrations in the area of ester formation and synthesis of macromolecules (van Vorst, 2013). Based on their individual interest the students are asked to choose a context and are supposed to write down their self-generated questions after some time for brainstorming. While taking time for brainstorming, students are supposed to detect a conflict in their knowledge based on their individual questions. The subsequent generation of questions in the form of individual notations serves the stage of verbal coding where students articulate their knowledge gaps in the form of a question. In the second section, a guided interview was developed for each context, to activate students’ prior knowledge and enable the generation of additional questions. Moreover, the guided interview phase serves the aim to support the detection and awareness of a conflict in students’ knowledge and understanding. This is necessary if the brainstorming phase was not fruitful enough. The last section is conducted as an open interview, to include an interactive question generation phase. Consequently, the self-generated questions from the preceding two sections are discussed to specify and modify unspecific questions. Furthermore, this phase follows the social editing, by expressing and discussing their detection with the interviewer. Students’ preconditions such as prior knowledge are not tested with questionnaires but will be qualitatively analyzed through the guided interview phase. The main interview study will be performed with students from tenth-grade classes of secondary schools until the principle of saturation is reached.
PRELIMINARY RESULTS

At this moment, the pilot study has been finished and a sample of five primary school teacher students (subject: science and sociology) were interviewed. The students have attended a course in elementary chemistry so that their prior knowledge can be regarded as comparable to tenth-grade students of secondary schools who are investigated in the main study. The focus of the pilot study was to examine whether the interview structure is suitable for generating questions or the interview needs to be optimised, especially the guided interview phase. For the data collection, audio records were used and completely transcribed. To analyze the collected data, qualitative content analysis based on Mayring (2014) has been applied. Therefore, the transcripts as well as the written questions of the students were taken into account and questions identified. Through this procedure, a total number of 142 questions could be determined. Initial results also identify the type of the generated questions in the respective contexts.

Based on the literature, three superordinate categories to assign the generated questions to could be determined. The first category specifies whether the questions are considered *investigable* or *non-investigable*. For this purpose, the classification scheme according to Chin & Kayalvizhi (2002) was used. Questions are considered *investigable* if they have a chemical reference and the option to plan and conduct an experiment to answer the question. An example for such a question could be “Are swimsuits made of neoprene?”. This question might be answered by material analysis and a comparison to other substances with the help of different experiments. For example, the substances could be examined with regard to their fusibleness, flammability or solubility in other chemicals. As the example shows, there is a wide range of responses to answer the question. Consequently, the quality of the question is referred to as high-level (open question). On the other hand, *non-investigable* questions include basic information questions, so that the quality is referred to as low-level (closed question). This type of questions do not allow experiments for their response and/or have no chemical reference, e.g. “Where is the wax in the honeycomb?”. Figure 3 contains the number of questions, coded as *investigable* or *non-investigable* ($N_{\text{total}} = 142$). Accordingly, 52.1 % of the questions are *non-investigable*, whereas 47.9 % of the questions are *investigable*. However, this result is similar to the literature.

![Figure 3. Investigable and non-investigable questions](image-url)
A further classification of the generated questions was made according to the form and stage of generation based on Almeida and Neri de Souza (2010) as well as the characteristics of the real-life contexts (van Vorst, 2013). The form and stage of question generation is divided into three categories, which result from the interview phases. Hence, questions could be generated in an active, passive or collective form. Actively self-generated questions arise from the first and second interview phase. Here, the students were explicitly invited to generate questions themselves. In contrast, passively self-generated questions arise without a request, but they evolved during the conversation. Collectively generated questions date back to the discussion with the interviewer and include the specification of unspecific questions. They are collectively modified if there is the possibility to bring the questions in an investigable form. The results show that most of the non-investigable questions (n = 74) stem from the actively self-generation phase with 82% (Figure 4). Moreover, only in this phase investigable questions were less frequently formed than non-investigable questions.

**Figure 4. Investigable and non-investigable questions according to form and stage of generation**

The selected contexts of the pilot study can be distinguished into two characteristics, called everyday and unique (van Vorst, 2013). It was examined whether there is a difference between the questions in terms of the characteristics and their suitability for the question generation (Figure 5). The results show that the percentage of investigable questions (n = 68) in everyday contexts (54%) are only slightly above the percentage of non-investigable questions (46%). In unique contexts, non-investigable questions (55%) are only slightly above the percentage of investigable questions (45%). However, students selected unique contexts more frequently.

**DISCUSSION AND CONCLUSIONS**

The presented results show that the interview structure provides usable data and can be part of the main study. Thus, students ask questions which can be investigated in chemistry lessons. Therefore, the data supply the base for the second part of project. In addition, the following tendencies are apparent.
Figure 5. Investigable and non-investigable questions according to characteristics of real life contexts

It is assumed that students need to be supported for question generation. Even if the phase of *active self-generation* provides many questions, it is important to reiterate that a large part of these questions cannot be categorized as *investigable*. Therefore, the results are in line with the literature. It appears that students have difficulties to specify their questions and to formulate an existing conflict in their knowledge. This is also evident in the interview phases involving an interaction with the interviewer. Although there were less questions generated, the questions are rather *investigable*.

Furthermore, the characteristics of the contexts should be considered. However, there is no association between the characteristics and the generated questions so far. Only tendencies can be considered. It seems that *unique* contexts stimulate students’ curiosity and interest, but they provide *less investigable* questions. Otero and Gallástegui (2016) found similar evidence when they examined the role of knowledge in asking questions when students were confronted with objects about which they knew little. Therefore, less prior knowledge could be the reason for low-level questions. A closer look at the generated questions within *unique* contexts confirmed this assumption. In this case, *non-investigable* questions correspond to basic information questions, while *non-investigable* questions stemming from *everyday* contexts are considered too complex, e.g. “How are chemical fibers build up?”. Another reason to exclude questions is the missing chemical reference, e.g. “How long can a rose live without water?”. With the help of the guided interview phase, data is analyzed on students’ prior knowledge, so that more valid statements can be made in the main study.

In the main study tenth-grade students from secondary schools will be investigated. The interview study will be conducted with as many students as necessary until the principle of saturation is reached. A context has to be selected from the interview study which is suitable for generating questions and usable for the second study. The second study will involve a field study in chemistry lessons where students have to generate their own questions and teachers need to cope with the ambiguity of handling the question-generation of their students in class. Student and teacher attitudes will be observed in a design-based research setting.

DEALING WITH LEARNERS’ DIVERSITY IN PERFORMANCE DURING EXPERIMENTAL INQUIRY-LEARNING IN CHEMISTRY

Dennis Kirstein, Sebastian Habig and Maik Walpuski
University of Duisburg-Essen, Faculty of Chemistry (Chemistry Education)

Recognizing differences between students’ cognitive abilities and their effect on learning is a core issue for science education and educational research. For this reason, research has to look for appropriate approaches for dealing with learners’ diversity at school. Suitable learning environments like inquiry-learning tasks offer both, the opportunity to discuss competence-orientated learning and aspects of individual learning. Especially with regard to aspects of cooperative learning during inquiry-learning a small-groups’ composition can be used as the basis for a specific support. Within the context of this study differential effects of the existing guidance strategies ‘feedback’, ‘structuring aid’ and ‘communication support’ have been analysed with regard to different small-group compositions concerning prior knowledge and cognitive abilities. On this basis, performance and process data were analysed by using quantitative and qualitative methods. The results show no specific effect for the use of the existing guidance strategies with regard to small-groups composition. Small-groups supported by ‘feedback’ have higher learning outcomes independent of their abilities and the composition of abilities within the group. However, the process data show that specific problems occur depending on the groups’ abilities. Hence, suitable guidance strategies have to be orientated towards group-specific abilities and difficulties.

Keywords: ability-grouping, inquiry-learning, adaptive support

AIM OF THE STUDY

Scientific Literacy as a part of general education is an important learning outcome for every student in our modern society. There is international agreement that chemistry education as part of science education has to focus on educational aims, which are necessary to develop a general understanding of important scientific ideas and concepts as well as typical scientific practices and knowledge about science itself (AAAS, 1990; NRC, 2013; KMK, 2004). In this context inquiry tasks such as conducting experiments have to be seen as an important part of competence-based chemistry learning. On this basis, PISA 2015 examined 15-year-old students’ levels of scientific literacy (OECD, 2016). The results show a broad range of students’ competences in science (OECD, 2016). It can be assumed that students not only reach different stages of scientific competence but also have different cognitive abilities. In consequence, the individual abilities of students within classes have to be integrated into lesson planning to a higher degree. The study presented in this paper refers to this initial situation and investigates the effects of different guidance strategies combined with inquiry learning tasks and how they are related to individual prerequisites of students.

CHEMISTRY LEARNING IN CONTEXT OF DIVERSITY

Teaching and learning in context of secondary school education have become increasingly complex activities. General educational aims like the development of scientific literacy as well
as different individual prerequisites and abilities are the reasons for this. At the same time, this field is in the area of conflict between uniform standards in science education on the one hand and very diverse individual prerequisites and demands of students on the other hand.

Equality and Difference as Part of Chemistry Learning

There is international agreement that the development of competences in scientific literacy is one of the most important educational aims for science education (AAAS, 1990; NRC, 2013; KMK, 2004) as a prerequisite for becoming a part of the modern society.

Therefore a general understanding of important scientific ideas and concepts as well as typical scientific practices and knowledge about science itself is necessary to develop (AAAS, 1990; NRC, 2013; KMK, 2004). In this context inquiry tasks such as conducting experiments have to be seen as an important part of competence-based chemistry learning. On this basis, PISA 2015 examined 15-year-olds’ levels of scientific literacy (OECD, 2016). The results show a broad range of students’ competences in science (OECD, 2016). It can be assumed that students not only reach different stages of scientific competence but also refer to different cognitive abilities during chemistry learning. In consequence, the individual abilities of students within classes have to be integrated into lesson planning to a higher degree. On the one hand there are curricular standards for the development of scientific literacy but on the other hand there are students with different prerequisites. Within this field of equality and difference chemistry education has to focus on these educational aims and individuality of students at the same time. Therefore suitable learning environments are necessary. Such learning environments bring curricular ideas such as important scientific concepts in accordance with relevant aspects of scientific inquiry as a process. This requires tasks which allow an open process of learning with different ways of thinking (Altrichter, Trautmann, Wischer, Sommerauer, & Doppler, 2009)

All in all, scientific literacy is a general educational aim for every student in science education. In this context chemistry education has not only to focus on learning facts and concepts but also on gaining knowledge about science and its typical practices. This requires a more competence-oriented view on learning processes and includes experimental practices especially in chemistry education.

Learner’ Diversity and Experimental Inquiry-Learning

Experimental inquiry learning tasks (e. g. Walpuski, Wahser, & Sumfleth, 2008; Habig, 2017) provide the opportunity to consider both competence-oriented learning goals and students’ individual prerequisites at the same time. On the one hand, such learning environments bring curricular ideas such as important scientific concepts in accordance with relevant aspects of scientific inquiry as a process. On the other hand, students work autonomously in small-groups, hence they process the task depending on their individual abilities and the small-groups’ composition. Both, students’ individual abilities and the composition of learning groups can influence learning (Lou et al., 2000). In consequence, strategies for optimal support are necessary (Lunetta, et al., 2007) including ways of graded support. Regarding the use of hands-on inquiry learning tasks previous research has identified several guidance strategies like ‘feedback’ and ‘structuring aid’ (Walpuski et al., 2008) and also ‘communication support’ (Knobloch, Sumfleth, & Walpuski, 2012). While ‘structuring aid’ intends to support small-
groups by focusing on relevant aspects of scientific inquiry as a process, the use of ‘feedback’ aims at supporting the inquiry-process as well as the learning process by discussing it at the end of each lesson. In contrast, ‘communication support’ introduces a separate phase to the working process where the small-groups are asked to explain the task within the group at the beginning and to discuss their results at the end of their working process.

To sum up, hand-on inquiry learning tasks offer many opportunities for chemistry learning in heterogeneous classes. Both, knowledge of different small-group compositions and knowledge of possible guidance strategies already exist. However, there have been no investigations on group specific effects on learning considering the composition of small-groups so far. Therefore, the aim of this study is to clarify whether there is a specific impact of these guidance strategies depending on the small-groups’ composition.

In this study, both prior knowledge and cognitive abilities are used as differentiating characteristics of small-groups during inquiry learning tasks. From prior research (e. g. Furtak, 2006) we know that students’ learning processes are not only influenced by their individual prerequisites but also by the extend of guidance while working on inquiry learning tasks. A promising guidance strategy for homogenous small-groups with low prior knowledge can be ‘structuring aids’. These aids help students to pass through the problem-solving process without being cognitively overloaded (Sweller, 1988). For homogenous groups with an average level of prior knowledge, however, a beneficial guidance strategy should consider the possibility to give feedback, hence the group can overcome difficulties which in advance cannot be solved due to knowledge gaps. It is assumed that learners in heterogeneous groups can be supported best by enhancing group communication. This is because knowledge differences are compensated and integrated in the groups’ learning process.

**DESIGN OF THE STUDY**

This study was conducted as a reanalysis of existing data by using a combined design of quantitative and qualitative methods. For this purpose, data from previous studies (e. g. Walpuski et al., 2008) on working with inquiry learning tasks on the topic ‘acid and bases’ in the first year of chemistry education were used. Therefore quantitative data from knowledge tests were used as well as video data of the process of the small-groups’ work. Those tests show good and sufficient statistics. All in all, data from 85 small-groups (with 4 students each) have been used as the basis for this study. Within this sample the small-groups have been categorized based on scores in a prior knowledge test and a cognitive abilities test as relevant predictors for learning (e. g. Weinert, 2001). Small-groups can be composed by students with similar prior knowledge and cognitive abilities (homogenous small-groups) or by students with various prior knowledge and cognitive abilities (heterogeneous small-groups). Additionally, the average level of prior knowledge and cognitive abilities within a small-group is determined by the categories low, average and high. Both, variance (homogenous and heterogeneous) and level (low, average, high) in prior knowledge and cognitive abilities have been determined by comparing a small-groups’ composition with the test scores on the individual data set. In consequence the effect on learning achievement concerning chemistry knowledge has been analysed within different types of small-group compositions: homogenous small-groups with low prior knowledge (small-group type I), homogenous small-groups with average prior
knowledge and high cognitive abilities (small-group type II) and heterogeneous small-groups (small-group type III). Therefore the residual pre- and post-test difference was used to compare the effect of the guidance strategies.

In addition to the results from the quantitative analysis process data were analysed to get more information about the found effects. Therefore, grounded theory (Glaser & Strauss, 2009) was used to generate theories out of the process data. These can be used as explanatory approaches for the found effects as well as for concluding consequences for an optimal support of small-groups during inquiry-learning tasks. For each small-group composition the process data haven been analysed using a comparative open coding. Relevant aspects about performance of the small-groups have been collected and were used to generalise explanatory approaches for the found effects from the quantitative analysis of the performance data.

RESULTS

Within each small group the average test score in the prior knowledge test was used to identify the small groups’ level of prior knowledge (M). The difference between the highest and the lowest performing student was used to identify homogenous and heterogeneous small groups (R). Different small-group compositions have been characterised by comparing average test score and range of the students test score within a small-group with the whole samples mean variation (upper and lower quartiles) and variance (interquartile range).

The process of small group characterisation shows that homogenous small groups can be differentiated from heterogeneous small groups as well as different levels in prior knowledge (Figure 1). All in all, the effect of different guidance strategies in homogenous small-groups with low prior knowledge (small-group type I), homogenous small-groups with average prior knowledge and high cognitive abilities (small-group type II) and heterogeneous small-groups have been analysed.

The analysis of the quantitative data was conducted based on the already mentioned small-group compositions. A linear model of regression (residuals) for the learning achievement in chemistry knowledge was used to describe the effects of different guidance strategies within different small-group compositions. In this model the learning achievement can be analysed more precisely because the performance in the pre-test is related to the learning outcomes. As shown in Figure 2 no differential effects of the existing guidance strategies between the different types of group compositions could be found.
Figure 1. Results of the small-group characterization

Figure 2. Group specific effects of different guidance strategies for chemistry learning

However, analyses of variance show a significant effect of different guidance strategies for both heterogeneous groups \((F(3, 42) = 3.654; p = .002; \eta^2 = .311)\) and homogenous groups with average prior knowledge and high cognitive abilities \((F(3, 42) = 5.072; p = .005; \eta^2 = .281)\). For homogenous small-groups with low prior knowledge a similar but marginal significant trend can be found \((F(3, 11) = 3.654; p = .063; \eta^2 = .578)\). Within each small-group the highest learning gains can be seen for the use of feedback, whereas supporting by structuring aids lead to the lowest effect independent of the small-groups’ composition \((F(1, 76) = 37.398; p < .001; \eta^2 = .333)\).

Against our initial expectation feedback emerged to be the most efficient guidance strategy for all groups. Therefore, a following analysis focused on the video-taped learning processes. The
qualitative data reveal that the small-groups which received feedback irrespective of their composition perform better concerning the use of content knowledge and the way they perform the process of inquiry. As the process data show feedback can help small-groups to structure and reflect the process of working on the task so that those small-groups more often articulate ideas, use suitable experiments and draw adequate conclusions. In addition, already known concepts are used more frequently to work on the task as well as new content knowledge is integrated in the learning process. As a possible reason for this the process data show that feedback is used more often and more successfully than structuring aid.

CONSEQUENCES FOR FURTHER STUDIES

The results show a similar trend for the effects of the guidance strategies within different small-group compositions. Looking at stages of the working process aspects like ‘structuring the process’ and ‘using chemical knowledge’ can explain the high learning gains of successful small-groups. This is related to the structure of feedback including opportunities for students to confirm single steps of the inquiry process. Moreover, this is further supported by a general discussion at the end of each lesson.

In consequence, it can be assumed that other guidance strategies are necessary to support small-groups more effectively. Considering this, limitations are related to the data set which only includes data of students from a higher knowledge range because the data has only been collected at one school type. In addition, prior knowledge and cognitive abilities were not considered when composing the small-groups, initially. In consequence there is a small number of students in homogenous groups with low prior knowledge. This can explain the similar trends from the quantitative as well as from the qualitative analysis because the sample already consists of students with similar abilities. Also, there is only a small contrast between different small-groups which can be explained by the nearly homogenous data set from only one school type. To sum up, this study focusses on supporting different small-groups by using existing guidance strategies without looking for aspects the small-groups need to learn successfully.

According to the results of this study our following research project will focus on aspects of different small-group compositions and their effect on learning processes during hands-on inquiry learning tasks. Therefore, following our results specific difficulties during hands-on inquiry learning will be analysed and used as the basis for optimal guidance strategies. The limitation of the first study will be overcome by collecting data from all existing school types in North Rhine Westphalia (Germany), hence a broad range of performance can be used as the basis for further analyses. Different inquiry learning tasks with varying topics will be used in a way that difficulties can be described irrespective of the topic. The analysis will be conducted as qualitative content analysis (Mayring, 2000) by developing a system of categories as relevant difficulties during hands-on inquiry learning tasks. The results regarding the connection between a small-groups’ composition and specific difficulties will be used to develop appropriate guidance strategies to support small-groups more efficiently.

Scientific experimentation at school is often associated with a motivating and interest-promoting effect. At the same time, the experimental setup can be complicated. Thus, learners may perceive the experimentation process as confusing and unproductive for their learning. In addition, the practical steps of experimentation require a considerable amount of time and material resources. If the main goal of biology lessons is scientific reasoning, one way to circumvent these problems might be to perform the reasoning part of scientific experimentation without conducting the practical steps of the experiment itself (practical work). The aim of this study was to examine whether students who have actually carried out all steps of an experiment differ in terms of motivation and knowledge acquisition when compared to students who executed the reasoning part of the experiment but skipped the practical work. The sample consisted of 163 10th- and 11th-grade students from four secondary schools. The participants in the practical group (n = 84) conducted a dose-response experiment that included all steps of the experimentation process (planning, practical work, data analysis, interpretation). The non-practical group (n = 79) received the same teaching unit but did not carry out the practical steps of the experiment. A knowledge test on the topic of ecology was used for the pre- and posttests. A translated version of the Intrinsic Motivation Inventory was administered during the posttest as well. All scales showed satisfactory reliability (Cronbach’s Alpha: .65 - .91). ANOVAs were conducted to test whether there were differences in motivation and knowledge gain between the two groups. The results concerning the motivational scales showed significant differences in favour of the practical group for the subscales perceived competence, interest/enjoyment, and effort. The increase in knowledge, measured by open questions, was higher for the practical group. Our findings show that both students’ motivation and knowledge growth seem to benefit from the practical work they do while conducting experiments. The extent to which these advantages can outperform the necessary costs of time and material resources must be evaluated by the teacher for each experiment.

Keywords: experiment, motivation, scientific reasoning

INTRODUCTION

At school, scientific inquiry is primarily concerned with conducting and understanding the scientific way of working and thinking (NRC [U.S.], 2000; Colburn, 2000; Flick & Lederman, 2006). One method of scientific inquiry is experimentation (Lederman, 2006; Mayer, 2007). According to the educational standards of Germany (KMK, 2005) as well as the general perception of teachers (Lehrer, 2001; Wirth, Thillmann, & Künsting, 2008), experimentation is regarded as an essential method for acquiring and consolidating knowledge in science lessons. It is believed to facilitate students’ understanding of the processes of scientific inquiry and the scientific way of thinking (Mayer & Ziemek, 2006; Wirth et al., 2008). Teachers also view these key elements as important goals of classroom experimentation (Hodson, 1990; Johnstone & Al-Shuali, 2001). In addition, they are supporters of classroom experimentation.
because of its motivating and interest-promoting effect (Hodson, 1990; Johnstone & Al-Shuali, 2001).

Despite its high praises, some studies have shown that the practical part of conducting classroom experiments can be distracting and unproductive - or even confusing - for students and the objectives pursued in these experiments were mostly not achieved (Abrahams, 2011). One plausible reason could be that students perceive the process of experimentation as being very complex (Harlen, 1999; Hodson, 1990). Consequently, feelings of demotivation may arise while conducting the experiment (Harlen, 1999; Hodson, 1990).

At school, learning processes depend on motivational conditions (Ryan & Deci, 2002b). According to self-determination theory, one requirement for motivated action is that three basic psychological needs (the need for social relatedness, competence, and autonomy) are met (Deci & Ryan, 2002). In the school context, the satisfaction of these needs might yield pupils who are more likely to engage with the learning content and enhanced learning performance (Niemiec & Ryan, 2009). With an appropriate degree of support, creating learning environments that allow students to experiment autonomously in the sense of discovery learning may be a suitable way to deal with some of the problems associated with experimentation (Kirschner, Sweller, & Clark, 2006; Mayer & Ziemek, 2006; Wirth et al., 2008). By carrying out experiments in this manner, students are given the opportunity to study scientific questions autonomously, which ultimately fosters their feeling of competence. Inquiry-based learning that includes both hands-on and minds-on approaches might promote motivation (Potvin & Hasni, 2014). Although experimentation with a focus on minds-on activities (e.g., scientific reasoning) and hands-on activities (e.g., experimentation) is considered to be extremely important, it is rarely used in German classrooms (Schiepe-Tiska et al., 2016); this is possibly due to the significant amount of time and material resources that such learning environments require.

When it comes to experimentation, current approaches of teaching and learning research place less importance on its practical steps and focus more on other aspects such as generating hypothesis, planning experiments and analysing data (Höttecke & Rieß, 2015). This raises the questions, if the practical steps in experimentation and thus the associated increase in time and material costs are always necessary and to what extent do students have to perform the practical steps of an experiment so that they still support successful learning processes in scientific reasoning.

THEORETICAL BACKGROUND

Scientific inquiry and experimentation

In natural science lessons, experimentation is seen as a way to facilitate the understanding of the process of scientific inquiry and provide learners with an understanding of scientific thought and work (Wirth et al., 2008). The process of scientific inquiry can be described as a problem-solving process (Abd-El-Khalick et al., 2004; Gott & Roberts, 2008; Klahr, 2000; Mayer, 2007). Klahr’s (2000) Scientific Discovery as Dual Search model (SDDS) involves searching in two problem spaces: a hypothesis space and a experiment space. The aim of the search in the hypothesis space is to generate a universal, precise, and testable hypothesis on the
basis of previous knowledge, existing data, or observations. The search in the experiment space involves ‘testing the hypothesis’. This entails the development of an experiment which tests the hypothesis, makes (an) assumption(s) about the outcome of the experiment, outlines the practical steps to conduct the experiment, and compares any previous assumptions with the actual results. The result of the search in the experiment space is a representation of evidence which has to be analysed in the next step. For the evaluation of the evidence, the data must be analysed and interpreted and the hypothesis needs to be confirmed, rejected, or reversed.

The steps in the SDDS model are related to the steps and phases of experimentation (Figure 1). Hodson (1996) differentiates between four phases in experimentation. In the first phase, the design and planning phase, the research question and the hypotheses are formulated and the experimental procedures are devised. In the second phase, the performance phase, the experiment is conducted and the data is collected. The subsequent reflection phase includes the analysis of the data, the interpretation thereof, and a conclusion. The recording and reporting phase is the final phase and serves to summarise the results for personal use as well as making it possible to share them with others. While engaging in experimentation, students need to generate questions and hypotheses, design and run experiments, and collect and evaluate data (Abd-El-Khalick et al., 2004; Mayer, 2007). Since conducting the practical steps of experimentation (performance phase) in school requires considerable time and material resources, it is no surprise that teachers often refrain from offering their students opportunities to experiment (Schiepe-Tiska et al., 2016).

334
Self-determination theory

Besides the reasoning behind and the practical steps of experimentation, further aspects have to be considered when designing learning environments that include experiments. One such aspect is learner motivations, which has a significant effect on learning processes at school (Ryan & Deci, 2002b). According to self-determination theory (SDT), one requirement for motivated action is that three basic psychological needs (specifically, the needs for social relatedness, competence, and autonomy) are met (Deci, Ryan, & Williams, 1996; Deci, Vallerand, Pelletier, & Ryan, 1991; Niemiec & Ryan, 2009; Ryan & Deci, 2017). In the school context, the satisfaction of these basic psychological needs foster student engagement during learning activities and their learning performance (Niemiec & Ryan, 2009).

In SDT, different forms of motivation can be distinguished (Deci, Ryan, & Williams, 1996; Deci, Vallerand, Pelletier, & Ryan, 1991; Ryan & Deci, 2000a, 2000b, 2017). Regarding the learning-process, intrinsic motivation means learning takes place for the sake of enjoyment. An intrinsically motivated student learns because of the subject itself. Extrinsic motivation learning is based on generating positive rewards or outcomes or avoiding negative ones. The regulatory styles can be arranged on a continuum that ranges from the purely controlled form of regulation, the external regulation, over introjected, identified and integrated regulation to the purely autonomous form of regulation, the internal regulation (Ryan & Deci, 2000a, b, 2017).

RESEARCH QUESTION

In educational contexts, experiments are mainly used to introduce students to scientific reasoning. However, not only are they costly and time-consuming, but they can also be confusing, and the complexity of the setup might increase cognitive load. One possible way to avoid these disadvantages and still foster the development of scientific reasoning is to go through the experimental process (planning, data analysis and interpretation, etc.) without conducting the actual practical steps of the experiment. The key research question that arises from this perspective can be formulated as follows: Are the additional resources required by practical experimentation (mainly time and materials) essential for acquiring high degrees of motivation and knowledge acquisition? If two experiments were identical in terms of the scientific reasoning that underlies them, but one of them were to be without the practical steps (‘no practical’), would there be an additional benefit of the ‘practical’ approach when compared to ‘non-practical’ approach regarding motivation and knowledge acquisition? In short, is the benefit of practical experimentation worth the additional required resources that are needed to conduct it?

METHOD

In order to answer the question whether the extra effort of practical experimentation is worthwhile for students in terms of motivation and knowledge gain, this study was conducted as a quasi-experimental pretest-posttest comparison group design (Figure 2). The study was embedded in a four-lesson (non-practical group) or a six-lesson (practical group) teaching unit dealing with the relationship between organisms and their environment.
Sample and study design

The sample consists of 163 10th and 11th grade students from eight classes at four secondary schools in Germany. In their current biology courses, the students completed a teaching unit on ecology that was taught by a teacher trainee. The eight classes were randomly assigned to two treatment conditions. Students in the practical-treatment (practical group) carried out an experiment with all steps of the experimentation process including the practical steps of the experiment. The practical group consisted of 84 students. The students in the non-practical treatment (n = 79) received the same teaching unit, but they did not carry out the practical steps of the experiment (performance phase). The students in both groups were nearly the same age (practical group: $M = 16.86, SD = 0.84$, non-practical-group: $M = 16.81, SD = 0.81$). However, there were a lot more girls than boys in the practical group (practical group: 75.3% female, non-practical-group: 47.9% female). A knowledge test on the topic of ecology was administered both before and after the intervention. In the pre-test the students’ motivational regulation and in the posttest the motivation during the lesson was assessed.

Teaching unit

The teaching unit consisted of six lessons for the practical group and four lessons for the non-practical group. The teaching unit included an experiment on the effect of salt concentrations on the germination of seeds. In both groups, the teaching unit started with an introduction to ecological concepts such as biotic and abiotic environmental components, physiological and ecological spectrum, ecological optimum, preference range, and tolerance range. After the
introduction, the research question and the hypotheses were developed by the students and the teacher trainee during a class discussion. Afterwards, the students and the teacher trainee planned the experiment together and the results of the planning process were documented. The objective of this approach was to involve students in the discussion about the basic ideas and principles that constitute the experimental process (forming hypotheses, planning). Moreover, when a manual is worked out together, it helps to guarantee that all conditions, methods and variables are considered. After the planning phase, the students in the practical group performed the practical steps of the experiment, whereas the non-practical group did not. The latter group received a table of raw data from the experiments conducted by the practical group, which they used in the next phase for the data analysis. The subsequent steps in the experimentation process were carried out in both groups in the same manner.

In summary, the students in the non-practical group had to conduct all phases in experimentation according to Hodson’s (1996) four phases of experimentation except for the performance phase (Figure 2). Regarding the time needed to complete the phase, the teaching unit comprised six lessons for the practical and only four lessons in the non-practical group.

Measurement
In the pretest, an adapted and translated version of the Academic Self-Regulation Questionnaire (SRQ-A) with the four subscales external (Cronbach’s α = .65), introjected (Cronbach’s α = .66), identified (Cronbach’s α = .79), and intrinsic regulation (Cronbach’s α = .93) was used (Müller et al., 2007). A five-point rating scale ranging from ‘strongly disagree’ to ‘strongly agree’ was administered to answer the items. Using the subscales of the SRQ-A, the Relative Autonomy Index (RAI) was calculated. The RAI serves as a measure of students’ perceived degree of autonomy. The more positive this value is, the more autonomous the student is regulated, whereas the more negative it is, the more controlled the student is.

In the posttest, the participants’ intrinsic motivation was assessed using a translated version of the Intrinsic Motivation Inventory (IMI, McAuley, Duncan, & Tammen, 1989; Ryan, 1982). We applied the subscales perceived competence (Cronbach’s α = .78), perceived choice (Cronbach’s α = .75), interest/enjoyment (Cronbach’s α = .91), and effort (Cronbach’s α = .82). According to SDT, perceived choice and perceived competence can be viewed as positive predictors of intrinsic motivation. The interest/enjoyment subscale is considered to be the self-report measure of intrinsic motivation. Effort is an outcome variable that can give hints as to how far motivation has resulted in engagement.

In addition, a knowledge test on the topic of ecology with eight open-ended questions (maximum score: 16 points, Cronbach’s αposttests = .72) and seven multiple choice questions (maximum score: 28 points, Cronbach’s αposttest = .79) were administered in the pre- and post-test. All scales showed satisfactory reliability (Cronbach’s Alpha: .65 - .91). The students’ answers were scored using points. On the open questions, missing or wrong answers were awarded 0 points, partly correct answers 1 point, and completely correct answers 2 points. On the multiple-choice questions, each correctly answered option (i.e., ticked if the answer alternative is true and unticked if not true) received one point. Thus, a maximum of four points could be achieved for each question.
Strand 2

Statistical Analysis

To test whether there were differences between the two groups in the motivational domain, univariate ANOVAs were conducted. The knowledge tests were analysed with mixed-ANOVA.

RESULTS

Preconditions

As one factor influencing the outcome in motivation during the lessons, the general form of learning motivation is relevant. The ANOVA showed that both groups differed significantly with a moderate effect size in the Relative Autonomy Index ($F(1; 141) = 5.61, p < .05$, partial $\eta^2 = .038$). The RAI was somewhat higher for the non-practical group ($M = 2.93, SD = 3.92$) than for the practical group ($M = 1.32, SD = 4.22$). The effect size suggests low practical significance.

Effects on motivation and knowledge

The results of the univariate ANOVA concerning the scales of the IMI (Table 1) showed significant differences in favour of the practical group in the subscales perceived competence, interest/enjoyment and effort. The effect sizes indicate low practical significance for perceived competence ($\eta^2 = .024$) and interest/enjoyment ($\eta^2 = .038$) and medium practical significance for effort ($\eta^2 = .074$). The subscale perceived choice revealed no significant differences between the practical and the non-practical group.

In the cognitive domain (Table 2), the scores on the multiple-choice test suggest that the participants in both groups had acquired a significant amount of knowledge. The interaction effect group x time was not significant. Regarding the open-ended questions, there was also evidence for a significant degree of knowledge acquisition for both groups and the interaction
effect was significant as well. The increase in knowledge, which was measured using open-ended questions, was higher in the practical group than in the non-practical group. The effect size emphasizes large practical significance regarding knowledge gain and low practical significance for the interaction effect.

**DISCUSSION**

The results suggest that there are relevant differences between the students in the practical group and students in the non-practical group. With regard to motivation, the practical group seems to have benefited from the practical steps of the experiment in the classroom; they had higher levels of perceived competence, interest/enjoyment representing the self-reported intrinsic motivation, and willingness to put effort into their work. Presumably, the students in the practical group had more opportunities to perceive themselves as competent while performing the practical steps of the experiment. According to SDT, the fulfilment of the basic need for competence results in more intrinsic motivation (Deci, Ryan, & Williams, 1996; Niemiec & Ryan, 2009; Ryan & Deci, 2000a, 2017), and this increase in intrinsic motivation might, in turn, lead to more effort (Ryan & Deci, 2000b). In this study, the students in the practical group reported that they had put more effort into their work than in the non-practical group. These findings support the general assumption held by teachers that conducting the practical work of an experiment does indeed promote motivation (Hodson, 1990; Johnstone & Al-Shuali, 2001). The results showed no significant differences regarding perceived choice. As the treatments did not differ with respect to the number of choices given, the findings were as expected.

The students benefited from conducting the practical steps of the experiment in the cognitive domain as well. The practical group learned better than the non-practical group on the tasks in which the students not only had to reproduce their knowledge but also apply it. The data suggest that the greater resource demands (i.e., effort of time and material) required by the practical steps of the experiment seems to be beneficial, especially in terms of motivation and cognitive development. However, the motivational and cognitive benefits in most of the reported differences were only minor. By contrast, the time and material effort of hands-on activities in
school is often high. In this study, the teacher had to invest roughly a third more teaching time to conduct the practical steps of the experiment.

Teachers quote a lack of material at school and an enormous amount of time as disadvantages of experiments in school lessons (Klaustke, 1997). In conclusion, teachers need to consider whether the extra amount of time and materials that are necessary to conduct the practical steps of an experiment is worth the relatively small motivational and cognitive benefits that they yield. In this study, we did not investigate whether it would be more useful for motivation and knowledge acquisition to use the two extra more teaching time to delve deeper into the learning content. This might be the true for some experiments (e.g., if practical experimentation does not require practical skills or if there are no challenges to support practical skills during the practical experimentation because they are not necessary for the students to conduct the practical steps of the experiment). In these experiments, it might be more appropriate to trace the process of scientific inquiry and the scientific way of thinking without doing the practical experimentation. These assumptions should be investigated in further studies.

The present study does have some limitations that need to be addressed. Firstly, the study should be replicated on a larger scale in order to improve its generalisability. Secondly, the students in both groups differed slightly with regard to their general motivation to learn biology. Thirdly, as there were quite a few more girls than boys in the practical group, the sample was somewhat skewed in terms of gender. It would be interesting to see whether the study would show similar results if the gender imbalance were balanced out or even reversed. In addition, the experiment on seed germination lacked complexity and did not place high demands on the students' practical skills. It would be interesting to conduct the study with a more sophisticated experiment that requires the learners to apply more complex practical methods. Due to these limitations, our findings should be interpreted with caution.

CONCLUSION

The current study provides some insights into whether hands-on activities might be important for learning. The extra amount of time and material resources required to carry out the practical steps of the experiment seems to benefit learners in terms of motivation and cognition. The extent to which these advantages can outperform the necessary costs of time and material resources must be evaluated by the teacher for each individual experiment. The trade-off between somewhat lower motivational and cognitive benefits on the one hand and time and material resources on the other could not be resolved by this study.

Gestures are essential elements for the understanding of thought or discourse. When considering the relationship between a teacher and student, there must be a deeper understanding of their own role. Thus, in this work, we investigate the influence of gestures in the learning of physics concepts, such as conservation of momentum and elastic and inelastic collisions. We conducted an experiment with 38 undergraduate students in a sciences undergraduate course. We investigated the following scenarios: 1) watching a video that leverages gestures, 2) watching a video that does not leverage gestures, and 3) reading a transcript of the video. We conducted a pre and post-test and the results indicate that there was no statistically significant difference in the level of understanding of physics topics when controlling for the aforementioned scenarios.

Keywords: gestures, learning, physics

INTRODUCTION

Gestures are present in the creation of human language meaning and they are essential in interpersonal communication (Chue, Lee, & Tan, 2015; Scherr, 2004). Depending on the way they are performed, they can indicate an idea or information, representing objects and events in the actual and fictive worlds (McNeill, 1992; Scherr, 2004). Also, speakers often use gestures to reveal what is relevant in the context (McNeill, 1992).

To understand the meaning of gestures, we need to have in mind that speech, thought, and gestures are parts of a single process executed by a speaker (Scherr, 2008). According to McNeill (1992), gestures are not just explained in purely kinesic terms, for instance, arms waving in the air. Gestures are symbols that reveal a full range of meanings.

The use of gestures also can be considered a simulation allowing both actions and perceptual states to be experienced by those who speak. Empirical evidence in neuroscience research reveals that simulations can activate motor cortex areas responsible for the creation of movement. It means that, when talking about the crash between two billiard balls, the speaker forms a mental simulation of the scene that includes both the action and its perceptual components (Hostetter & Alibali, 2008, 2010).

There are several investigations that link learning with gesture. A research conducted by the Chicago University points out that the gestures are a facilitator of thought. They reduce the speaker's cognitive resource demands and frees cognitive ability to perform other tasks, such as memorization (Goldin-Meadow, Nusbaum, Kelly, & Cook, 2001).
A work conducted by McNeill (2005) has classified gestures according to its features: iconic gestures relate to the content of speech and support illustrating what is being said; beat gestures emphasize the speech; metaphoric gestures represent abstract expressions, and deictic gestures involve pointing to existing or virtual objects. Iconic gestures are of particular interest to us, as they serve as a kind of mind reading tool. In other words, iconic gestures have the power to reveal aspects of the speaker’s mental process and “points of view toward events when these are not articulated in speech” (McNeill, 1992, p.109).

According to Chue et al. (2015), lecture practices are the most common pedagogical format and it is widely used in education for transmitting a huge volume of information. This pedagogical format demands that teachers use their bodies and voice to express themselves. Hence, Chue et al. (2015, p.2) claim that we need to recognize iconic gestures as “part of the vast repertoire of meaning-making resources for teaching”.

Research questions

The purpose of this research is to investigate the role of gestures in physics learning. Our two fundamental questions are:

RQ1) Is there a difference in the level of understanding of physics concepts when students (i) watch an explanation that contains gestures, (ii) watch an explanation that does not contain gestures, and (iii) read a transcript of the explanation?

RQ2) Do students who learn with gestures tend to explain the learned concept using more gestures compared to those who learn without gestures or by reading?

METHOD

Participants

In this research, we collected data from 38 students attending the first year of the Sciences Course in an University in São Paulo, Brazil.

Research development

We created three videos in which a teacher explains some Physics concepts. The first video addresses the issue of conservation of momentum, the second video deals with inelastic collisions, and the third video addresses elastic collisions. In each of these videos, which have an average duration of 3 minutes, the teacher explains the concept and gives examples related to the theme. For inelastic collisions, for instance, the teacher exemplifies collision by punching one hand against the other, as if one hand was a car and the other was a truck. The teacher uses, in most part of the time, iconic gestures to represent the speech.

In the original videos, the teacher was filmed from the waist up and the gestural activities were shown. We then created new versions of these videos by simply cropping his body and zooming in his face. Now we had the same content of the original videos, but without any gestural activity. Moreover, the original videos were transcribed, allowing us to have a text-only version of the explanation. The image below shows a frame of each type of video and how the text was presented.
An experimental design with three groups, pre-test and post-test was undertaken. The students were randomly assigned into three groups, which we call With Gestures Group (G_{gesture}), Without Gestures Group (G_{no-gesture}) and Text Group (G_{text}). Each group had pairs of students and each duo had one student called Instructor and the other one called Listener. The Instructor of each pair watched the videos of one category or read the text and, after that, explained the content to the other student, the Listener. All this part of the activity was recorded. At the end, the With Gestures Group had 16 students, the Without Gestures Group had 12 students, and the Text Group had 10 students. The difference in the number of participants per group is due to experimental mortality.

In order to investigate the role of gestures in learning, we assessed students using two exams. One was applied right before the activity (pre-test) and the other was applied right after the activity (post-test). All students took the two exams. These exams consisted of 13 multiple-choice questions extracted from textbooks widely used in Brazil, and the questions addressed only the topic explained in the videos. The tests had different questions. A sample question used in the pre-test is shown below (Figure 2).

A particle moves with uniform speed $v$ over a straight line and collides unidimensionally with another identical particle, initially at rest. Considering the elastic shock and neglecting friction, we can affirm that after the shock:

a. Both particles move in the same direction with speeds equal to $\frac{v}{2}$;

b. Both particles move in opposite directions with speeds $-v$ and $+v$;

c. The incident particle reverses the direction of its motion, while the other remains at rest;

d. The incident particle is at rest and the other moves with speed $v$;

e. Both particles move in opposite directions with speed $-v \pm 2v$.

Figure 2. A question used in pre-test (translated to English)
For each instructor, we calculated a *delta score*. This score corresponds to the number of correct answers in the post-test minus the number of correct answers in the pre-test. This score gives us a quantifiable measure of the effect of each treatment (gestures, no gestures, and text) on each student.

Our null hypothesis is that the three groups learned in similar ways. More precisely, under the null hypothesis we expect to see no statistically significant difference among the delta scores of the three groups. Our alternative hypothesis is that students learn better with gestures.

**RESULTS AND DISCUSSION**

RQ1) *Is there difference in the level of understanding of physics concepts when students (i) watch an explanation that contains gestures, (ii) watch an explanation that does not contain gestures, and (iii) read a transcript of the explanation?*

![Boxplot of delta scores for instructors in the three experimental groups.](image)

The results we obtained are depicted in Figure 3. This boxplot shows the delta score distributions for the three groups. The interquartile range (third quartile minus first quartile) of $G_{\text{gesture}}$ is higher than the others, showing more variability in the results. However, the $G_{\text{gesture}}$ has a higher third quartile compared to others (3.00 for $G_{\text{gesture}}$, 1.00 for $G_{\text{no-gesture}}$ and 0.75 for $G_{\text{text}}$).

In order to investigate our hypothesis, we first assessed normality using the Shapiro-Wilk test ($\alpha = 0.05$). The results showed that all three distributions were in fact normal ($G_{\text{gesture}}$ with $W=0.8565$ and $p$-value = 0.08782, $G_{\text{no-gesture}}$ with $W = 0.9129$ and $p$-value = 0.4558, and $G_{\text{text}}$ with $W = 0.8663$ and $p$-value = 0.2117). Therefore, we conducted the One-Way ANOVA test ($\alpha = 0.05$) to verify whether there is a statistically significant difference among the delta score of the three groups. We could *not* reject the null hypothesis ($F = 0.0729$, $p$-value = 0.9301). This result is consistent with a preliminary study we conducted (under review), in which we found evidence that gestures influenced only high school students, without any effect on higher education students.
Finally, even though we did not find statistical significance, we performed an effect size test using Cliff’s Delta. We reasoned about the Cliff’s Delta (d) using the thresholds introduced by Romano, Kromrey, Coraggio, & Skowronek (2006): negligible for $|d| \leq 0.147$, small for $0.147 < |d| \leq 0.33$, medium for $0.33 < |d| \leq 0.474$, and large otherwise. When comparing $G_{\text{gesture}}$ with $G_{\text{no-gesture}}$, we obtained $d = 0.20$, which is small. We reached the same conclusion when comparing $G_{\text{gesture}}$ with $G_{\text{text}}$, as we obtained $d = 0.25$ (small).

**RQ2) Do students who learn with gestures tend to explain the learned concept using more gestures compared to those who learn without gestures or by reading?**

When Instructors used examples that they got from the videos or text, they performed iconic gestures as a model for an object. This happened with all the Instructors, from all three groups. Moreover, the gestures seemed to follow a pattern, independently from the group the Instructor belonged to. An example can be observed in the image below (Figure 3). Instructors 1 and 2 were given an example about inelastic collision. Instructor 1 belonged to the Text Group and Instructor 2 belonged to the Without Gestures Group. Both instructors used the example from the original explanation they received, involving a crash between a truck and a car. In other words, even without having seen any gestures in the video or text, both instructors spontaneously executed virtually identical gestures.

![Image](image_url)

*Figure 4. Instructors from different groups exemplifying inelastic collision*
However, we have found that the instructors from the Without Gestures Group, during their explanation to the listeners, performed a greater amount of gestures than the instructors from the two other groups. Instructors from the Without Gestures Group performed about 69% of the iconic gestures that the teacher performed in the videos. In turn, the With Gestures Group performed about 44% of the gestures and the Text Group performed about 29% of them. We believe the smaller percentage of the Text Group is associated with the difficulty in transposing written language into oral form.

LIMITATIONS

In this section, we discuss the limitations of this research. As the students may already know the topics used in this experiment, we decided to analyze their performance in the pre-test. In the following scatterplot, we compare the pre-test score with the delta score (instructors only). We couldn’t find any discernible pattern between the two variables.

![Scatterplot of Instructors’ pre-test versus delta score](image)

Figure 5. Scatterplot of Instructors’ pre-test versus delta score (larger bubbles indicate 2 observations lying at the same coordinates).

However, we notice a huge amplitude in pre-test scores, which range from 2 to 11. Although the average pre-test score was 6.86, the standard deviation was 2.55. Hence, there is large variability in the pre-test scores. We conjecture that some participants may have participated in this research without much enthusiasm or focus, thus possibly impacting their performance in the pre-test and in the explanation given to listeners.

CONCLUSION

The results indicate that there was no significant improvement in the level of understanding of physics concepts when students watched explanations that leveraged gesture activity. This result is consistent with the evidences we obtained in a previous study where we found that gestures only improved the performance of high school students. Our results reveal that although there was no influence of gestures on the student’s performance, the students used gestures to teach others. Moreover, students spontaneously used similar gestures even though they had not seen any reference gestures. Researchers emphasize the importance of gestures
in teaching and learning. However, there is little evidence that shows a positive impact on students’ performance. In our research, this lack of improvement might have been due to the fact that we were testing some undergraduate students who had previously studied the topic they were being taught. It is undoubtedly true that gestures play an important role in the teaching-learning process. However, our paper also reveals a need for the science education community to further search for robust empirical evidence.

WHAT DO HIGH SCHOOL STUDENTS THINK IS IMPORTANT WHEN STUDYING SCIENCE AND HOW IS THIS DIFFERENT TO WHEN STUDYING THEIR OTHER SUBJECTS

Bruce White
University of South Australia, Adelaide, Australia

Students study skills are of interest for a range of reasons, including impact on achievement and teacher preparation. These are usually considered as generic skills associated with the student studying across a range of subjects. This paper will describe differences in student’s perceptions of study skills between Science and other subjects from one Australian high school. Students were surveyed and asked to nominate the subjects that they had their best and worst study skills in and then asked about their study skills in their best subject and how it differed from their worst. Initial results indicate, being interested and practice are the most important aspects of being successful while lack of effort and lack of interest were reasons most commonly given for not being successful in learning Science. There were some significant differences between subjects however the majority of criteria examined in this study were consistent across all subjects.

Keywords: study skills, learning,

LITERATURE

Student study skills have been related to academic achievement (Moreira, Dias, Vaz & Vaz, 2013; Jansen & Suhre, 2010; Sullivan & Guerra, 2007) and teaching approaches (Campbell, Smith, Boulton-Lewis, Brownlee, Burnett, Carrington, & Purdie, 2001). There is also evidence that indicates, when study skills were taught there was an impact on student outcomes (Hattie, Biggs & Purdie, 1996). Furthermore, that study skills should be taught incrementally within the subject rather than as a standalone course (Hattie & Donoghue, 2016).

Historically, the measurement of study skills initially started with the importance of student’s effort and application, its impact on academic achievement and that “good” study skills could be described (Entwistle & McCune, 2004). The work has been further developed and there are now several inventories of study skills, developed for different purposes and all based on different theoretical perspectives (Entwistle & McCune, 2004). One such inventory is the Approaches and Study Skills Inventory for Students (ASSIST) (Entwistle, McCune, & Tait, 2013) which was derived from the work of Marton & Saljo, Entwistle & Ramsden and Biggs (Entwistle, et. al., 2013). This inventory produces scores on Deep, Surface and Strategic approaches to studying and learning. Deep approaches are characterised by students seeking meaning, relating ideas, use of evidence and interest in ideas, surface approaches are characterised by lack of purpose, unrelated memorising and fear of failure, while Strategic approaches are characterised by organised studying, time management, achieving and alertness to assessment demands (Entwistle, et. al., 2013). The ASSIST inventory uses Likert scales, asking students to rate the extent of their agreement with a series of statements. A report on the use of the ASSIST inventory (Entwistle et al., 2013) indicated that there may be differences in
approaches to learning depending on the subject being studied, while other studies have indicated that the characteristics of different subjects’ impact on study skills (Curley, Estrin, Thomas, & Rohwer Jr, 1987, Husmann, Barger, & Schutte, 2016). There is some evidence to suggest however that changing study skills may have a detrimental effect on learning (Husmann, Barger, & Schutte, 2016).

This study sought to develop research in the area of student study skills by looking at the following questions. Are there differences in student’s study skills in Science and other subjects? Are there differences study skills between what students consider to be the subjects they have their best and worst study skills?

**METHODOLOGY**

Students in a large metropolitan high school in South Australia completed an online survey in November of 2016 (towards the end of the school year). The survey questions were developed in conjunction with the student leadership from the school and the survey was designed to look at the teaching and learning environment across the whole school. There were sections in the survey on, background (year level, age and gender), what students do that helps them learn, what teachers do that helps them learn, the teaching and learning environment, research skills and some questions about growth mindset. The survey was completed during school hours by 1442 students from a school population of approximately 1550.

This paper reports on the data from the questions regarding, what students do that helps their learning. In this section the students were asked to nominate the subject in which they had their best study skills and indicate on a Likert scale their level of agreement to a series of statements about what they do that helps them learn in that subject. They were then asked to nominate in rank order, six of these statements which they believed to be the most important to their learning. Finally, they were asked to nominate the subject in which they had their worst study skills and describe how their study skills were different to those in their best subject. The statements in the survey were focused on deep and strategic approaches (Entwistle et al., 2013). This was because this section of the survey was focused on study skills in their best subject and so statements relating to surface approaches were omitted in order to keep the total number of questions in the survey to a minimum and still get useful data.

The responses to the Likert questions treated as scalar data and the means are reported in Table 2, the importance responses were weighted (6 for a most important to 1 for sixth most important), totalled and ranked, with the rank being reported in Table 2. The text responses were categorized and the numbers in each category are reported in Table 3 and Table 4.

**RESULTS AND DISCUSSION**

Overall Science was selected by 20.6% of students surveyed, as the subject in which they had the best study skills. It was nominated by students in years 8 and 9 (approximate ages 12 &13 years old) as the third highest subject with their best study skills and this increased to the second highest subject indicated for best study skills, by students in years 10, 11 and 12 (approximate ages 14 – 17 years old). There was a sharp increase in the percentage of students selecting Science in year 10. Science in the school goes from being a compulsory general science to
being able to choose from discipline specific Science (Physics, Chemistry, Biology) or continue with general science in year 10. This element of choice and also specialist teachers may explain the increase in year 10.

</tbody>
</table>

In Table 2 it can be seen that the students who nominated Science as the subject with their best study skills, indicated that being deeply interested in the subject was the aspect that they considered to be the most important for success, followed by practice, wanting to understand and putting in effort. Not surprising these also were rated highly on the agreement scale, all having means above 4.

In Table 2 the statements that were ranked most important and where there was the strongest agreement, were more closely related to a deep approach (Entwistle, McCune, & Tait, 2013). Although practice does somewhat imply repetition and so could be considered as a strategic or even a surface approach, the statement does emphasise knowing well and therefore more closely related to a deep approach. A number of strategic approaches ranked quite highly, for example “I make a note of things that I don't understand very well in this subject, so that I can follow them up,” ranked 3 and “I set myself deadlines to complete activities and organise myself to meet the deadlines.” which ranked 6

In Table 2 it can also be seen that there are a few differences between the subjects indicated as their best study skills with seven of the seventeen statements having a significant difference. Students who nominated the Arts as the subject with their best study skills had the most differences in approaches to Science. There were six statements that were significantly different, four being stronger in agreement with the statement than Science and two where Science had the stronger agreement. The students who nominated the Arts indicated that they were more interested in the subject and were very confident that they could do well, however they used less online support and less note taking than the students indicating Science. This supports the conjecture that the characteristics of a subject impacts on study skills (Curley, Estrin, Thomas, & Rohwer Jr, 1987, Husmann, Barger, & Schutte, 2016) as Science has very different characteristics to the Arts.

The statements which had the strongest level of agreement with students who nominated Science were “I can get better at this subject if I put in the effort.” and “I am sure that I can do well in this subject.” indicates a high level of confidence in their ability improve and to be successful in Science as well as having their best study skills. The statement that was ranked most important was “I am deeply interested in this subject.” had a high level of agreement similar to all other subjects except the Arts, which had a higher level of agreement and Mathematics which had a significantly lower level of agreement. There was more agreement
to the statement “I make a note of things that I don't understand very well in this subject, so that I can follow them up.”, in Science than there was in English, HPE, Arts (Music, Drama, Art, Media etc.) which indicates that there are some strategic approaches that are used more often in Science that some other subjects.

* Results are based on two-sided tests assuming equal variances with significance level .05.
Students were asked to nominate the subject in which they had their worst study skills, and to comment on how the way they studied for this subject differed from the subject in which they had their best study skills. These comments were summarised by looking for common criteria and then grouped according to those criteria. Some examples of student comments and how they were categorised are given below.

**Examples of student comments (Science least successful)**

*I just understand concepts taught in mathematics more than in the natural sciences, and so I am willing to put more effort into doing maths homework.* (Not understanding, Lack of effort)

*In my most successful subject my teacher is very supportive and she helps me to improve while, in my least successful subject my teacher does not seem as enthusiastic to teach.* (Did not have a “good” teacher)

*It’s not because of the teacher I just hated science in primary in primary and i really struggle to be interested in it now* (Lack of interest)

*I don’t have a good way of studying for my least successful subject. Maybe because I don’t go over my study again to fully check if i understand the concepts, therefore, I don’t study much for this subject compared to my most successful subject.* (Organisation)

*This subject I don’t enjoy as much as my most successful subjects and so am less inclined to do extra study for it. I am currently doing chemistry which is very different academically (numerical, more logical) which I am not succeeding in as much as I would like. However, I am much more successful in drama and media (more creative, innovative) so I think I am just better suited to more creative subjects.* (Did not enjoy subject, Not understanding)

In Table 3 which summarises the comments made when Science was the subject nominated as the one with their worst study skills, the three most often mentioned differences Lack of effort, Lack of interest and Not understanding, could all be considered as being surface approaches to learning, and closely related to engagement with the subject.

**Table 3. Difference in study skills between students who nominated Science as the subject with worst study skills and the subject that they nominated as having their best study skills**

</tbody>
</table>
This indicates that there are very different approaches taken by students who consider Science as their best study skills subject (deep) and their worst study skills subject (surface). A number of students also mentioned a lack of strategic approaches when studying in their worst subject e.g. lack of organisation and not useful for their career, again highlighting the differences in approach.

The same process was used to categorise the student comments when Science was considered to be the subject in which they had their best study skills and another subject their worst. A similar set of criteria resulted and a similar pattern of responses with Lack of effort and Lack of interest being the most frequent responses.

**Examples of student comments (Science Most successful)**

*I find Science more interesting than Maths, and that makes it easier to learn and study. Maths doesn't interest me that much, especially because I don't get very good grades. I understand maths, but I just find it boring.*

(Lack of interest)

*I have less motivation towards this subject when I study but I still try my best to succeed. The way I am taught science is different and interesting. In English, I don't completely understand tasks and when and I don't receive help all the time which affects my learning. Science taught more passionately and in a variety of ways so that I can understand things better.*

(Lack of motivation, Did not have a “good” teacher, Not understanding)

*In science I can easily revise key terms whereas revising in English does nothing, it generally requires on the spot thinking which I'm not as good at.*

(Not understanding)

The pattern of more deep approaches for the subject with the best study skills and surface approaches for the subject with the worst was consistent across subjects. As indicated in Table 4, students who nominated Science as their best study skills subject also had more surface approaches to their learning in their worst study skills subject. There were less comments regarding strategic approaches for this group of students.

In Table 5 where the students nominated best and worst study skills subjects are summarised in relation to Science. Mathematics was the subject most selected (33%) by students as the subject they had the worst study skills when Science was nominated as the subject where they
had their best study skills. Conversely Science was selected 20.2% of the time when Mathematics was selected as the subject where they had their best study skills. This result is interesting, as these two subjects are often seen as being closely related, for example the current focus in Australia on STEM (Science Technology Engineering and Mathematics). The two subjects are at times taught in an integrated way particularly at a junior secondary (years 8-10) level. The results in Table 5 would indicate that many of the students would struggle to study for at least one part of a STEM subject, especially as other studies have indicated that having to use different approaches to learning can impact on learning outcomes (Husmann, Barger, & Schutte, 2016).

When the percentage of students (where Science was the subject with the best study skills) across a year level, that mentioned a particular criteria are examined (Table 6) some differences are evident. Interest is the most important in years 8 and 9 while effort and understanding were mentioned more often in years 11 and 12. Students elect to do Science in years 11 and 12 which may account for the change in focus.

CONCLUSION

This study indicated that the students who nominated Science as the subject with their best study skills considered deep approaches to studying Science as the most important for their success and they were the ones most enacted by these students. Where students selected Science as the one with their best study skills there were some differences in study skills between Science and other subjects and that these were more pronounced when the characteristics of the subjects were very different.
When students commented on their study skills in subjects with their best and worst study skills, differences were clearly highlighted. The differences most often mentioned by students were the surface learning approaches of; Lack of effort, Lack of interest, Found the subject difficult and Did not enjoy subject. These are more closely connected to engagement than specific study skills however this does highlight that students identified deep approaches to learning with their best subject and surface approaches with their worst.

This is a single study based in one high school and so the results can therefore not be generalised, however it does support previous studies that indicated that study skills differ across subjects, in particular those with different characteristics and that further research in this area is therefore warranted.

LEAVING CHEMISTRY: STUDENTS’ ACHIEVEMENT-RELATED CHOICES IN SECONDARY SCHOOL

Carolin Eitemüller and Maik Walpuski
University of Duisburg-Essen, Essen, Germany

Students’ educational choices in science are a matter of international concern. Like students in many other countries where natural sciences are optional, a majority of German students opt out of chemistry at upper secondary school and only few of them choose an advanced chemistry course. This study uses questionnaire data from German chemistry students in upper secondary school to identify predictors of course choice and students’ success in chemistry at secondary level. From literature, students’ interest, subject-specific knowledge, marks and their ability self-concept as well as the perceived relevance of the subject for their career aspirations were derived as possible influencing factors and were surveyed in a quasi-longitudinal study with two points of measurement spanning one academic year involving year 9-12 students. Findings indicate that students’ interest, ability self-concept and career aspirations play a significant role as predictor of chemistry choice while chemistry marks are less important.

Keywords: participation, interest, chemistry

THEORETICAL BACKGROUND

Over the last decade, science educators have monitored the high dropout rates of German students in chemistry at upper secondary school with growing concern (Ministry for School and Further Education, 2007; 2017). The steady decline in students’ chemistry enrolments has promoted a number of investigations about students’ subjects and study choices in the past few years. In terms of understanding how students decide about taking a course in upper secondary school, Eccles and colleagues have developed a general model of students’ decision-making process of choice, in which students’ expectations of success and several subject task values are understood to influence students’ decisions (Eccles & Wigfield, 2002) Figure 1. Subject task values include four components: interest-enjoyment value, attainment value, utility value and relative cost. Interest-enjoyment value is understood as students’ subject-specific interest and the enjoyment the individual gets from the subject. Attainment value is defined as individual importance, which is associated with a given task, to confirm important aspects of one’s self-rating. For example, it captures how important it is for a student to succeed in a specific subject. Utility value is determined by how well a task is suitable to reach other goals. Choosing a subject to achieve high marks for A-levels is an example for this component. Finally, relative cost includes all negative aspects which are directly linked to students’ choices. For example, this includes invested time and effort, which are necessary to be successful. Also, the risk of failure or parents’ disappointment, which might come from a wrong decision contribute to this component. In summary, all lost opportunities that result from making one choice rather in preference over another are conceptualized as relative cost.
Many studies have used this perspective to examine students’ motives of choice. According to the results of these surveys students claim to orientate their subject choices mostly along personal abilities and interests as well as on the basis of high marks from lower secondary level and career aspirations. Also, the idea to earn high marks for their A-levels evidently influences their choices (Abel, 2002). In this context critics complain that students are not able to reflect all factors, which could have influenced their decision-making process. Demographic factors like socio-cultural status and parents’ educational level as well as students’ gender and ethnic background also seem to be influencing students’ subject choices (Lyons, 2006). Further studies reveal that students’ study and course-level choices greatly vary between individual students. Depending on students’ self-confidence, talents and career targets, personal choices and decisions are experienced in different ways. High achievers’ motives of choice are mostly directed by interest whereas low achievers’ reasons diverge largely from intended motives of schooling system (Eilers, 1980). Moreover, differences could be found between secondary school students choosing different post-compulsory subject profiles (Bøe, 2011). The findings indicate that interest-enjoyment was less important for students with a science profile than for students who choose a combination of languages, social sciences and economics. Science students placed more weight on utility value for university admission, especially girls taking science. On the other hand, costs in terms of time and effort were much more important for students without science profile than for students with science courses. In addition, earlier results from Müsgens (1980) reveal that the decision-making-processes and the composition of the students in the subjects can be quite different. For example, the differences between marks regarding aspiring basic-level-course-takers and advanced-level-course-takers are much larger in physics and mathematics than they are in history at the end of the lower secondary level. Marks and competence beliefs, like TIMSS (2000) has shown, seem to predetermine decisions for or against certain subjects.
However, reliable data for the subject chemistry are missing so far and previous attempts of explanation appear to be incomplete if even students, who demonstrate high performances and value natural sciences as important for their futures, do not plan to study comparable courses (Bordt et al., 2001; Goto, 2001) and students who were interested in popular science magazines and television programs still claim science lessons were boring and uninteresting (Lindahl, 2003).

**METHOD**

The main goal of this study was to investigate which motives of choice influence students’ chemistry choices at upper secondary level and which factors can be identified as predictors of academic success in chemistry in order to counteract a declining number of chemistry students at upper secondary level by using these findings for future support frameworks.

**Research Questions & Hypothesis**

1. Which motives of choice are supportive for taking and for dropping chemistry at upper secondary level?

2. Which factors can be identified as predictors of academic success in chemistry?

It was assumed that a higher content knowledge, interest and self-concept of ability and a stronger desire to work in a chemical field increase the likelihood to choose chemistry at upper secondary level. Moreover, a higher content knowledge and self-concept of ability increase students’ success in chemistry.

**Study Design**

In accordance with predictors discussed in literature, students’ interest, subject-specific knowledge, marks and the ability self-concept as well as their career targets and the perceived relevance of the subject are surveyed. Furthermore, students’ explanations of their course level decision are surveyed with additional open items in the same questionnaire. With these findings, opportunities arise to compare motives of choice given by students themselves and all other personal variables.

To realize this research project, predictors of course choice and students’ success in chemistry were surveyed in a quasi-longitudinal study with two points of measurement within a period of one year from year 9-12 students (Figure 2). Therefore, all participating students were surveyed before their first subject selection at the end of lower secondary level, with students choosing chemistry in the next year being surveyed again at the end of grade 10 with an average age of 16 years (subsample I). After the basic- and advanced-level-course selections, students who continued chemistry courses were surveyed again at the end of grades 11 and 12 (subsample II). Both subsamples were realized in a longitudinal section, mean comparisons reflect a quasi-longitudinal section across all four cohorts. Altogether 1,800 students were surveyed at the first measurement point.
To assess chemical content-knowledge, multiple-choice items with a single select format were developed for the concept of chemical reactions, because this concept is fundamental to chemistry and test instruments and data regarding students’ performances for the lower secondary level already exist (e.g. AAAS, 1993) and a development of competence can be expected. Students’ interest was captured multi-dimensionally with scales for content-related interest and relying on validated instruments for subject-related interest and motivation by Schulz (2010) and van Vorst (2013). To investigate students’ ability-self-concepts an instrument by Dickhäuser et al. (2002) was administered. With the help of popular students’ motives of choice in literature closed items were constructed to capture factors of influence, which are given by the students themselves in the explanations of their course level decision. These items can be associated to Eccles and Wigfields (2002) subjective task values. All instruments were tested for applicability with a total sample of $N = 328$ students from all four cohorts (year 9-12) in a pilot study and could be valued good to very good with Cronbach’s $\alpha$ from .89 to .97. Only results of a Rasch analysis of the content-knowledge test suggested developing more easy items because some items could not be solved by the students. In addition, non-verbal scales of a cognitive ability test from Heller & Perleth (2000) served as control variable.

**RESULTS**

Because of limited space available, only the results of the students from year 9 are presented here. Findings of the main study reveal that the reliability of the item scales, which should capture students’ interest, ability self-concept and expectations of self-efficacy can be valued very good with Cronbach’s $\alpha$ from .90 to .94. Participants’ statistical results show that 55.4% of the students ($N = 1.425$, 50.8% female, 15 years) opt out of chemistry at the end of lower secondary level whereas 52.4% of the non-choosers are female. Looking for differences between the groups of chemistry choosers and non-choosers at the end of lower secondary school, t-tests were computed. There were
significant differences between the groups in extent of interest, ability self-concept, marks and utility value, which are shown in Figure 3.

![Figure 3. Comparisons between personal variables of students opting out for chemistry (grey bars) and students choosing chemistry (blue bars) for upper secondary school. *** p ≤ .001](image)

In order to identify predictors of course choice in chemistry correlation analyses between personal variables and students’ decision about taking chemistry courses were also calculated. The results reveal higher correlations for students’ interest ($r = .58, p \leq .01$) and ability self-concept ($r = .52, p \leq .01$) as well as students’ career targets ($r = .50, p \leq .01$) than for students’ chemistry marks ($r = .37, p \leq .01$) and their level of cognitive ability ($r = .18, p \leq .01$). While correlation analyses demonstrate the strength of the relation between performance and motivational variables and students’ decision about taking chemistry courses, further hierarchical regression analyses were calculated to reveal the nature of the relation between variables (Bühl, 2012) and to explain mediating and moderating effects.

Because students’ decision for taking or dropping chemistry at the end of lower secondary level is a dichotomous variable, which should be attributed to continuous variables, binary logistic regression analyses were calculated, in which students’ choice of chemistry was modeled hierarchically as a function of the predictors. Based upon the expectancy-value model by Eccles and Wigfield (2002) students’ interest, self-concept, marks and career targets were stepwise entered in the regression model. To interpret regression coefficients (exp[b]) more easily all predictors were previously z-standardized. The regression coefficient $R^2_N$ reported as part of the analyses indicates the percentage of variation in students’ choice that can be explained by the model. In terms of interpretation $R^2_N$ can be seen as similar to the $R^2$ in linear regressions (Field, 2013).

Table 1 provides a summary of the binary logistic regression analyses for all students from year 9. As indicated, model fit statistics improved with a stepwise inclusion of the seven variables in the model. In particular, 56 % of the variance in students' choices at the end of lower secondary level can be explained by the predictors included in model 5 (M5). Findings show, that students' subject-specific interest, ability self-concept and the perceived relevance of the subject for students' career aspirations are statistically significant predictors of course choice in chemistry (cf. table 1). Students' decision for taking chemistry at upper secondary level was 1.71 more likely for every one unit increase in students’ ability self-concept and 3.18 more likely for every one unit increase

Table 1
in students’ interest. Also, the chance to choose chemistry for upper secondary level increases if the perceived relevance of chemistry increases by one standard deviation.

Furthermore, regression coefficients indicate, that students’ motivational and performance-related characteristics may influence their decisions indirectly through mediation or moderation. Therefore, it has been tested whether chemistry marks have a moderating effect on the relationship between self-concept and chemistry choice, because the regression coefficient of chemistry marks (exp [b] = 2.41, p ≤ .001) remained significant after inclusion of students’ ability self-concept in the model as further predictor (exp [b] = 1.20, p ≤ .05), but were no longer significant in the model with the largest amount of explained variance (exp [b] = 1.22, n.s.). Results of a regression analysis show, that a moderating effect of chemistry marks exists, because the interaction term of marks and ability self-concepts became significant (exp [b] = 1.21, p ≤ .05). According to the expectancy-value model of achievement-related choices students’ subject-specific knowledge do not have a direct influence on students’ decisions about taking or dropping chemistry, but are mediated by students’ ability self-concepts. Like regression analysis confirm, the regression coefficient of students’ subject-specific knowledge became no longer significant (exp [b] = 1.03, n.s.) if students’ ability self-concept was included in the model as a predictor (cf. table 1 M3). Furthermore, it has been tested, weather students’ interest, which is understood as an important factor in theory of motivation (e.g. Rheinberg, 2010), mediates the relation between students’ motivation and course choice. As expected students’ motivation in learning chemistry is mediated by students’ interest like the results of the regression analysis confirm. To summarize the presented results, figure 4 shows a prediction model of students’ chemistry choices at the end of lower secondary level.

Further qualitative analyses of students’ explanations for course choice support and extend the findings generated by the logistic regression analyses. Findings show, that chemistry choosers as well as chemistry non-choosers claim that the aspect interest-enjoyment value was very important for their subject choice. In addition, their expectations of success were decisive for choosing and for dropping chemistry from their schedules whereas the perceived difficulty of the subject was relevant for non-choosers to drop chemistry. Moreover, attainment value was less important for students who did not continue with the subject at upper secondary school in comparison to the other subject task values. Regarding to the aspect utility value both groups have differing views on the extent of its influence. While students who choose chemistry for upper secondary level claim utility value was less important for their decision, utility value was more relevant for most of the students who opt out of chemistry (Figures 5 and 6).

**Figure 5. Motives of Choice at the End of Lower Secondary Level**
DISCUSSION AND CONCLUSIONS

This study contributes to the research on students’ choices of post-compulsory chemistry. It implies that students’ interest and ability self-concepts in chemistry as well as partly their career target play a significant role as predictor of course choice in chemistry for students from year 9. Regrettably, the findings also reveal that more than half of the students, who do not fulfill these requirements, already opt out of chemistry at the end of lower secondary school. These results and in addition students’ motives of choice permit the assumption that chemistry in lower secondary school fails in winning a large amount of students. Several students opt out of chemistry at the end of lower secondary school because they were overtaxed and bored. As a basis for further research, which aims to initialize natural science pathways, these results could be used to counteract the declining number of students. This study also makes a significant contribution for teachers to understand students’ choices of post-compulsory chemistry and to improve their own teaching although it is necessary to conduct more research to change the falling numbers of students in chemistry.

EPIGENETICS GIVES NEW KNOWLEDGE ABOUT LEARNING – THE EXAMPLE PHYSICAL EDUCATION

Birgitta Mc Ewen
Department of Health, Karlstad University, Karlstad, Sweden

New knowledge in biology accumulates fast. This has great implications, for example, for our views of learning. Brain research, as well as research in the new field of epigenetics, have been very intense during the last few decades, and will doubtless influence our view of learning. It is important to follow the development in biology, derive advantages from new insights, and to consider changed practices at school. This paper is an example of how an increased amount of physical education in the school timetable could increase performance in theoretical school subjects. This relation is discussed in the light of the recently discovered epigenetic mechanisms. Studies have revealed epigenetic modifications in the brain cells during learning. Learning, combined with physical activity, has revealed increased epigenetic modifications. Thus, it has been speculated that epigenetic mechanisms might explain improved results in theoretical subjects due to physical activity. This ought to have implications for the school timetable, and lead to more physical education at school. It is discussed that one of the easiest ways to improve results in theoretical school subjects could be to increase the amount of physical education in the school timetable.

INTRODUCTION

This paper has a theoretical approach, discussing how our understanding of prerequisites for learning has changed due to novel biological knowledge, and how this might have consequences in a school context. Noteworthy, knowledge about learning relies on what we know about biological processes in our bodies and particularly in our brains. During the last few decades, understandings about how the human brain works have accumulated quite rapidly (Huth et al., 2016; McNaughton et al., 2006). For example, it was long thought that the brain could not synthesize new neurons after childhood and adolescence. However, in 1998, Eriksson and colleagues (Eriksson et al., 1998) showed that new neurons are synthesized also in grown-ups. This was pioneering work, indicating that the human brain retains its ability to generate neurons throughout life, possibly leading to a changed view of learning.

Also included in this new biology knowledge is the concept of epigenetics, which is a molecular model explaining when genes are active or not. Thus, we now know more about the mechanisms for when different genes are “switched on” to be in an active state or when they are “turned down” to be passive or silent. This has a tremendous effect on the whole organism, and in practice decides its physiology. Learning is one of these processes where epigenetic mechanisms have been shown to operate. As we learn more about epigenetic processes, we also learn more about prerequisites for learning. Interestingly, it has been found that the environment could influence gene expressions. Through different environmental stimuli, molecules in our bodies transport and mediate a response to the cell machinery, to impact if genes should be active or not. Owing to the immense consequences that the knowledge of epigenetic mechanisms will have, many biologists have predicted epigenetics to result in a paradigm shift within biology (Gilbert & Epel, 2009).
Due to these new data, our comprehension about prerequisites for learning has changed. The aim of this paper is to highlight the importance of new knowledge and how it could be translated into practice at school. The chosen example is the school subject physical education.

It has been shown that an increased amount of physical education in the curriculum can improve results in theoretical school subjects (Chomitz et al., 2009; Fedewa & Ahn, 2013; Ericsson, 2012; Fritz, 2017; Käll et al., 2014; Raspberry et al., 2011; Spitzer & Hollmann, 2013; Van Dusen et al., 2011). In this paper, it is speculated that the correlation between improved school results and more physical education in the curriculum could be due to, at least partly, epigenetic mechanisms. This shows that we have to be acquainted with new biological knowledge and that this could change our view of prerequisites for learning.

**EPIGENETICS – DEFINITIONS, MECHANISMS, AND THE CONNECTION BETWEEN GENES AND THE ENVIRONMENT**

The word “epigenetics” was first coined by the development biologist Waddington in 1968 (see Van Speybroeck, 2002). The term described how an embryo develops, according to a well-defined pattern. A parallel origin came from Nanney (1958), who more specifically referred to it as the expression of genes. Since then, the term has been redefined. Gilbert and Epel (2009) defined it as “those genetic mechanisms that create phenotypic variation without altering the base-pair nucleotide sequence of the genes” (p. 12), and Riggs and Porter (1996) as: “the study of mitotically and/or meiotically heritable changes in gene function that cannot be explained by changes in DNA sequence” (see Allis et al., 2015, Chapter 1, p. 2).

“Epi” comes from the Greek word “over, above.” The word epigenetics aims at mechanisms acting “above” the sequence of base-pairs in the DNA. There are many types of epigenetic mechanisms (Kouzarides, 2007; Allis et al., 2015). The most studied are: DNA methylation, modification of histones, and epigenetic control made by small regulatory microRNAs (Semaan & Kauffman, 2013), see Figure 1. In principal, the different epigenetic mechanisms “open up” or “close” the genes. When they are “opened up,” they will be active, while silent when “closed down.” Whether genes are active or silent has a tremendous impact on what happens in an organism, and decides its physiology.

Besides taking place during development, epigenetic mechanisms are at work during the whole life of an organism (Szyf, McGowan, & Meaney, 2008). It has been suggested that epigenetic mechanisms occur during normal brain activity (Lipsky, 2013), both in youths (Essex et al., 2013) and adults (McEwen, Eiland, Hunter, & Miller, 2012).

Epigenetic mechanisms are dependent on the cell status and consequently its surroundings, i.e., the environment, comprised of both the internal (within the organism) and the external (outside the organism) environment. This means that the external environment influences the epigenetic mechanisms in the cells. It also means that the genes are not working alone, but are influenced by the environment, and explains e.g., why physical activity influences the cells in the brain. Actually, for the first time we now have a molecular model explaining how the environment could influence gene expressions. This is revolutionary knowledge and why many biologists talk about a paradigm shift in biology (Gilbert & Epel, 2009). This also gives clues to the classical debate about “what-is-due-to-genes” and “what-is-due-to-the-environment.” “Nature
“nature and nurture” is now replaced by “nature and nurture.”

Modified by Mc Ewen.

**PHYSICAL ACTIVITY AND LEARNING**

Meta-analyses have shown the positive relationship between physical activity and cognitive performance. Fedewa and Ahn (2013) pointed to significant and positive effects of physical activity on cognitive outcomes in 59 studies performed between 1947 and 2009. Raspberry et al. (2011) showed significant positive associations between physical activity and academic performance in slightly more than half of the 50 investigated studies. However, meta-analyses indicating no significant relationship between aerobic fitness and cognitive performance have also been found (Etnier et al., 2006). Thus, there are meta-analyses in the literature pointing to both positive and no effects of physical activity for cognitive performance, but the positive connections are more prevalent. Below, some examples of projects and studies describe the connection between physical activity and improved school results.

The Bunkeflo Project started in 1999 in a school in the southwestern part of Sweden. The curricula contained physical activity for every pupil each day from the first to the ninth grade. Several studies and some theses have been produced in the project. In his thesis, (Fritz, 2017) Fritz showed that 7% more of the boys in grade 9 reached qualification for upper secondary school (for the girls, the daily extra physical activity did not influence their qualification level; a result explained by the girls’ already high academic performance). Similar results were shown in another thesis from the Bunkeflo Project, where Ericsson (2012) presented that 96% of the boys reached qualification for upper secondary school in the intervention group compared to 84% in the control group. For the girls, the figures were 97% and 95%, respectively.
In a study by Käll and colleagues, the odds for achieving the national learning goals in Swedish, English, and mathematics in grade 5 were doubled for children participating in an intervention compared to a control group (Käll et al., 2014). The intervention consisted of an almost double amount of weekly school-based physical activity without changing the ordinary schedule. The extra physical activities were delivered by staff from a local sports club and were designed to be engaging, enjoyable, health promoting, and non-competitive. A meta-study from the U.S. showed that for circa 250,000 children in grades 3-11, fitness was strongly and significantly related to academic performance (Van Dusen et al., 2011). Chomitz et al. (2009) communicated a positive significant relationship between fitness and academic achievement, and Spitzer and Hollmann (2013) described positive effects on academic performance due to physical exercise. Furthermore, Spitzer and Hollmann (2013) informed about a positive effect on concentration and social behavior, besides that of academic performance.

Animal experiments have revealed that physical activity influences the hippocampus, the part of the brain where formation of memory takes place. Gomes da Silva et al. (2012) showed that adolescent rats, exposed to daily treadmill exercises, exhibited a changed hippocampal structure. The rats also displayed improved spatial learning and memory. Herting and Nagel (2012) reported on rodents with a larger hippocampal volume after having increased their aerobic fitness. Thus, animal experiments have shown that the structure of the hippocampus changes due to physical activity, and as the hippocampus is the part of the brain where formation of memory takes place, there seems to be a physiological link between physical activity and learning.

**PHYSICAL ACTIVITY, LEARNING, AND EPIGENETICS**

It would, of course, be interesting to understand more of the mechanisms behind the connection between physical activity and learning, and how this is coupled to that part of the brain, hippocampus, where the memory formation takes place. One conceivable mechanism is epigenetic processes. Different attempts to answer this question have been performed in various studies. The use of laboratory animals offers one way.

Abel and Rissman (2013) studied laboratory animals (adolescent male mice) running in so-called “running wheels” for one week. Compared to a control group, the epigenetic patterns of the hippocampus were changed in the “running” animals. Similarly, Gomez-Pinilla et al. (2011) showed that voluntary exercise changed rats' DNA methylation pattern in the hippocampus. Thus, these studies showed that epigenetic patterns in the brains of laboratory animals changed due to physical activity, and that the changes were localized to that part of the brain where memory formation takes place (the hippocampus). Abel and Rissman (2013) speculated about the plausibility that epigenetic patterns could also change in human brains due to physical activity.

Several researchers have suggested the involvement of epigenetic processes during learning and memory formation (Day & Sweatt, 2010; Levenson et al., 2006; Lipsky, 2013; Miller et al., 2010; Molfese, 2011). New synapses between neurons are built during these processes (Cortés-Mendoza et al., 2013). Lipsky (2013) showed that epigenetic processes are important when new synapses are built. Furthermore, epigenetic mechanisms are involved in cellular
processes during physical activity. Rönn et al. (2013) reported that within a group of healthy, but untrained, middle-aged men, epigenetic patterns changed in approximately 7,600 genes after a six month physical activity intervention. The activity consisted of two hours of spinning and aerobics each week, and was led by a certified instructor. Other studies have shown that epigenetic mechanisms were observed in the skeletal muscles after an intervention of physical exercise (Barrès et al., 2012; Lindholm et al., 2014; McGee et al., 2009). Accordingly, there is an occurrence of epigenetic processes during both learning and physical exercise. It is also conceivable that epigenetic processes are the mechanism that explains why physical activity supports learning. Future research will bring to light more about these relations.

**DISCUSSION**

Old masters of learning, e.g., Dewey, Piaget, and Vygotsky have had an enormous impact on our understanding of learning during the last 150 years, and still have. However, their knowledge was based on accessible facts of that time. Due to progress in research, a massive amount of knowledge has accumulated since these days. Whatever view we have on learning, the basis for our knowledge relies on understanding biological processes in our bodies, and particularly in the human brain. Thus, we ought to be aware of what these new findings could result in. When discussing learning, novel findings in brain research is especially important to consider, as well as its ability to build new neurons. It is also of great interest to focus on the newly unraveled epigenetic mechanisms.

A great number of studies have shown that physical activity increases academic performance (Chomitz et al., 2009; Fedewa & Ahn, 2013; Ericsson, 2012; Fritz, 2017; Käll et al., 2014; Raspberry et al., 2011; Spitzer & Hollmann, 2013; Van Dusen et al., 2011). In addition to increased academic performance, a positive effect on concentration and social behavior have also been reported (Spitzer & Hollmann, 2013). Thus, increasing physical activity in the school timetable seems to be one way to increase academic performance, and also perhaps to promote a more peaceful school atmosphere. There have been some reports of no effects of physical activity on cognitive performance (Etnier et al., 2006), but the positive connections are more prevalent in the literature. Moreover, there are numerous reports about the importance of physical activity for the overall human health (e.g., Berryman, 2010; Lindholm et al., 2014; Rankinen & Bouchard, 2007) in addition to the indicated positive effects of physical activity on academic performance.

A potential mechanism for the connection between physical activity and improved academic performance is the newly unraveled epigenetic mechanisms. These have been discovered in those parts of the brain where memory formation occurs, namely, the hippocampus (Day & Sweatt, 2010; Levenson et al., 2006; Lipsky, 2013; Miller et al., 2010; Molfese, 2011). Animal experiments have shown that increased physical activity changed the epigenetic patterns in the hippocampus, indicating a learning process (Abel & Rissman, 2013; Gomez-Pinilla et al., 2011). It has also been speculated that this takes place in the human brain (Abel & Rissman, 2013). Thus, there seems to be a connection between increased physical activity, learning, and changed epigenetic patterns in the brain.
The observation that physical activity seems to increase academic performance is important. It ought to lead to more discussions about increasing the amount of physical activity in the school timetable. As a complement to current discussions on how to improve school results, perhaps one of the easiest ways could be just to add more physical activities to the school timetable. Some researchers have expressed this in the following way: “In the light of these results, physical exercise should play a bigger role in school children’s daily curriculum” (Spitzer & Hollmann, 2013, p. 1), and “Exercise may prove to be a simple, yet important, method of enhancing those aspects of children’s mental functioning central to cognitive development” (Tomporowski et al., 2008, p. 111). Åberg et al. (2009) wrote: “… physical exercise could be an important instrument for public health initiatives to optimize educational achievements, cognitive performance, as well as disease prevention at the society level” (p. 20906). To summarize, by increasing the amount of physical activity in the school timetable, learning might be facilitated; thus, this is a good example of how to incorporate new knowledge to a practice at school.

CONCLUSIONS

Old masters of learning, such as Dewey, Piaget, and Vygotsky have had an enormous impact on our understanding of learning, but their knowledge was based on accessible facts of that time. This paper points to the importance of following current increasing knowledge in biology when discussing prerequisites for learning. In this study, this is exemplified with the rapidly evolving understanding of brain physiology and new insights into epigenetics. The positive correlation between increased learning and physical activity is highlighted. It is speculated that epigenetic mechanisms could serve as a molecular model to explain this connection. Phrased in a school context, one of the best ways to improve school results could be to increase the amount of physical activity in the curriculum. This is a good example of how to connect new knowledge about human physiology to practice at school.

ACCEPTING QUANTUM PHYSICS: ANALYSIS OF SECONDARY SCHOOL STUDENTS’ COGNITIVE NEEDS

Giovanni Ravaioli and Olivia Levrini
Department of Physics and Astronomy, University of Bologna - Alma Mater Studiorum, Bologna, Italy

In this paper we report some results obtained in classroom implementations of Quantum Physics teaching proposals, carried out in different school contexts. In particular, we observed significant cases of students who did not accept quantum physics as a personally reliable and convincing description of physical reality – cases of ‘non-acceptance’ –, even though they seemed to understand the basic concepts of quantum physics as they were proposed. A qualitative semantic analysis has been carried out on students’ interviews, so as to individuate the main cognitive needs emerging in learning quantum physics, and that have to be satisfied in order to make it acceptable, to a degree. We found three of them - need of visualisation, need of comparability, and need of ontology - emerging from students’ words, and used them to reread discourses of all students, despite their degree of acceptance. As this is a preliminary study, further work is suggested to better understand acceptance dynamics, to eventually operationalize its recognition in students’ discourses and to design instruction materials.

Keywords: acceptance, cognitive needs, quantum physics

INTRODUCTION

Most of the research on Quantum Physics (QP) teaching at a secondary school level has been on conceptual issues, mainly focused on students’ misconceptions; on the basis of these results, research groups have developed teaching proposals that aim at addressing the core concepts of QP (state, superposition, uncertainty, probability amplitude, measurement, entanglement, etc.) following different approaches. Beside these important results, research has recently moved to monitor also student epistemologies, mainly because QP epistemological/foundational issues are known to be raising basic questions about the sense of physical descriptions of reality and, more in general, about sense-making. These type of difficulties have been generally found to be independent of the personal confidence with the mathematical formalism. For example Greca & Freire (2003), referring to a course of engineering students, observed that for them “quantum concepts are fragmentary or mere mathematical expressions”, whilst Levrini & Fantini (2013) found students arguing that “formalism was necessary, but not sufficient to have the feeling of understanding”. Also Dini & Hammer (2017), monitoring a student’s variations in his personal epistemologies during a QP course, noted the persistence of his search for a connection between mathematics and a meaningful understanding of the physical world, aside from variations in how he engaged that effort. Baily & Finkelstein (2010) pointed out the relevance of teachers’ choices about interpretative issues, founding that an ‘agnostic’ stance can produce naïve realist interpretations in students. Thus, addressing epistemological issues in QP teaching seems to be crucial for students’ understanding, as the main difficulty could lie not only in the mathematical formalism, but in “accepting its consequences” (Levrini & Fantini, 2013).
In this paper we focus on a particular phenomenon that, even if not new in physics’ education research, has never been addressed in detail: the phenomenon of students’ non-acceptance of QP, that we observed in analyzing data from different high-school experimentations. For “non-acceptance” we refer to a specific reaction of students who explicitly did not accept QP as an adequate and personally reliable explanation of reality. Some cases are particularly interesting since they concern students who appeared to be rather confident with the formalism and to have appropriated the basic concepts of the teaching path as it was proposed (Malgieri, Branchetti, De Ambrosis, Levrini & Tasquier, 2018).

The main motivation of the study is the impression that students’ non-acceptance reaction could not always be interpreted in terms of an epistemological divergence, echoing the historical and authoritative realist positions who reacted against the Copenhagen interpretation. Instead we felt that, behind non-acceptance, ontological or cognitive needs, deeply implied in the fundamental mechanism of understanding, could be recognized. In light of these preliminary impressions, we decided to analyze the data so as to answer the following research questions:

(1) What needs QP does not satisfy and that can lead to non-acceptance? What is their nature?
(2) Can we support students’ acceptance by improving teaching or does the process of non-acceptance refer merely to QP per se and its intrinsic features?

CONTEXTS AND METHODS

In order to make the analysis reliable and as much as possible context-independent, we considered materials from different teaching experimentations. In particular, we refer here to experimentations conducted by the research group of the University of Bologna (that follows a spin-first approach) in 2012 and in 2015 in Rimini (already analysed by Levrini & Fantini (2013) and Lodovico (2016)), in 2015 in Bagno di Romagna and in 2016 in Castel san Pietro (Ravaioli, 2016); our data have been also contrasted with data coming from the experimentations conducted by the research group in physics education of the University of Pavia in 2014 and 2015, where the teacher followed a sum over path approach (Malgieri, 2015). The data are all taken from individual interviews carried out at the end of the teaching module. From a methodological point of view, a qualitative approach has been chosen. The analysis started by focusing on three cases of evident and explicit non-acceptance (see next Section), that came out in three different school contexts. Two of them had also showed a sensible degree of appropriation of the basic ideas of QP as they were proposed in the learning paths (Levrini & Fantini, 2013). Students’ profiles have been built so as to flesh out the key-words used by the students to describe their perplexities on QP, and to talk about the topics and concepts they found particularly puzzling. We then recognised the semantic fields to which students’ words belonged and formulated a hypothesis about students’ requirements (needs) underlying non-acceptance. The needs have been then used as lens to analyse students who accepted QP in order to check if and how they, however, clashed with similar needs and, in case, what way they found to satisfy them. Hence, after the recognition of the main needs showed by the non-acceptance cases, we re-analysed all students’ interviews by exploiting the needs as interpretive key.
THREE CASES OF EXPLICIT NON-ACCEPTANCE

In what follows, the three cases of clear non-acceptance of QP are considered, two of which from Bologna’s experimentations and one from Pavia’s. In order to investigate the nature of non-acceptance, we focused on students who appeared to grasp the sense and the basic rules of the formalism, and appropriate the fundamental concepts that were addressed (Malgieri et al, 2018); this allowed us to avoid cases in which non-acceptance was due to a lack of preparation and, hence, to focus on real cognitive and epistemic needs of the students (and, not, for example, to motivation aspects). As anticipation, we stress that the first two cases presented (Marco and Cheng) show typical epistemic refusal of the quantum description of reality, and still claim for a more ‘realistic’ theory to be found in future. Instead, in the third case (Alice), non-acceptance seems to have a slightly different – even though related - nature, as it emerges as a difficulty to understand physics without the support of spacetime visualizations.

Marco: postulating ‘well-defined properties’

Marco² is a student whose idiosyncratic idea of science is mainly founded in its utility and its possible applications: “science has to be used in technical field […] to create, let’s say, the great inventions”. Marco is considered by his classmates as a good and hardworking student, and the analysis reported by Lodovico (2016) shows that he appears to have generally appropriated the basic ideas of QP. Nevertheless, he consistently insists that he cannot accept QP as a complete explanation of the physical reality, and in particular as a reliable description of quantum objects. For example, when asked about the superposition principle (in the context of Stern-Gerlach experiments), during the final interview he answers as follows:

Marco: If I hypothetically can take a measure with a sufficiently sophisticated instrument, that object would have [would reveal] a well-defined property. The object itself does own a well-defined property, that’s what I believe. […] As Einstein, mine postulate is that an object has to embody well-defined properties. [E-1]

Or, for the uncertainty principle:

Interviewer: […] What was the most useful way for you to comprehend the meaning of quantum uncertainty in its revolutionary holding?

Marco: So... if I have to be honest, none.

Interviewer: None of these³?

Marco: All of these partly contributed, but none gave me a thorough explanation. Namely, what I was searching for as an explanation, I haven’t found it in any of these. […] I was in] a great confusion, not mostly because of the mathematic part, [in fact] I could understand the concepts the teacher was talking about, […] they were logically comprehensible. The point is that I couldn’t understand how couldn’t a body have

---

² Marco participated in the teaching experimentation carried out in Rimini 2015 the article by Levrini & Fantini (2013)
³ the uncertainty relations were addressed in class by discussing excerpts from the original pages of Heisenberg, the textbook, the metaphor of Brian Greene (Green,…), as well as the Stern-Gerlach experiments
Marco’s requirement of classical-like properties plays the role of a real postulate, whose strength probably comes from his personality and idiosyncratic idea of science. In this sense, the nature of this requirement is genuinely epistemic and it is an idea that generally produces in Marco a form of scepticism towards QP, affecting his acceptance of the uncertainty relation and superposition principle, but also of the concept of quanton and probability, as he states:

Marco: To me the word ‘probability’ is quite an ‘escamotage’ [trick] that we use to...to determine the phenomenon with certainty [...] But, indeed, these are the errors induced by this way of representing this fundamental issue, namely the one of non-defined properties.

Marco’s search seems moreover very interested in applications and technological developments, that serve him to partially postpone the problem of accepting QP in its implications. But in postponing the problem he always specifies his concern, for example, on uncertainty relation:

Marco: although I don’t agree with it, I understood that Heisenberg’s hypothesis [of uncertainty] in necessary in this moment. [...] I notice that considering the quanton as non-defined particle, even though I don’t agree, is in any event fruitful for the moment. Just like as your mother tries to convince you that black dogs are evil, and you know they’re not [...], but she gives you 50 euros every time you say: “yes, ok, ok”. [E-4]

Hence, although Marco’s idiosyncratic idea of science reveals a sort of empiricism, and the very reason that leads him to not accept QP is founded on epistemological requirements and considerations; he feels the necessity to “find a more epistemologically accurate meaning”.

Cheng: “I would like to know more about reality”

Cheng is a student from the experimentation of the group of Pavia, whose case has been extensively investigated (Malgieri, 2015; Malgieri et al., 2018). He seems to have well understood the disciplinary contents of the course and, on the basis of the markers proposed in Levrini and colleagues (2015) and re-elaborated in Malgieri et al. (2018), he seems to have also appropriated the basic concepts.

As it appears in Malgieri’s PhD Dissertation (Malgieri, 2015), Cheng correctly talks about the main historical developments of QP, describes the wave-particle duality from the point of view of some different scientists, and also explains in detail the most recent developments proposed in classroom (entanglement among the others). But, despite his confidence with all these issues, when interviewed he explicitly states that he cannot accept quantum theory as a ‘final’ explanation:

Interviewer: So you are not convinced by the idea of a quantum objects, which is neither wave nor particle (...) You believe a better explanation exists.

---

4 the term quanton, firstly proposed by Bunge, has been re-adopted by Levy-Leblond (2003) for categorizing quantum physical objects on the basis of the common quantum properties, so as to avoid classical categories to describe them. This choice has been extensively discussed with students in classrooms experimentations.
Cheng: I think it exists, but hasn’t been found yet […] I would like to discover why it is that way.

Interviewer: Is it my impression or there is something that you do not accept.

Cheng: Exactly. I would like to know more about reality.

Interviewer: So you don’t accept it. Sooner or later it will be discovered.

Cheng: Yes. Exactly.

Cheng doesn’t face any repulsion towards mathematics; on the contrary, he firmly believes in the explicating power of formalism: “Images can help you understand, while the mathematical model simplifies everything. If we know how it works, it makes us remember everything at a glance”.

This confidence with mathematics leads him to consider QP understandable, as he demonstrates when speaking about ‘Which Way’ measurements: “It is surprising because it does not follow the classical probability rule, but it’s not incomprehensible, because it follows the quantum probability rule. So it is surprising, but only because it is computed in a different way”. He shows also to have a precise idea of the relationship between physics and mathematics, as a description of intrinsic laws of Nature (which he demand to be the classical physics’ ones):

Interviewer: So you believe Newton’s formula for gravitation exists somewhere, and we just discover it.

Cheng: It exists, in the sense that it's intrinsic. But it's not mathematics. We mathematize it.

Hence, Cheng declares to understand QP and to be able to visualize, for example, Feynman’s model; furthermore he seems peaceful to momentarily accept QP for its results in calculations. But at the same time, confronting his idea with those of the most important scientists who developed QP, he is sure that this is not the final answer, as he explains:

Cheng: I believe objects to have a definite position and momentum. There is something that escapes our understanding. But it is not that uncertainty is due to measurement. It is due to some other reason. Something which we still don’t know.

As it was for Marco, this need of more ‘realistic’ properties affects his acceptance of the uncertainty principle, and of the nature of quantons. It is also interesting to notice that both Marco and Cheng consciously focused their attention on the formal apparatus and its relations with experimental devised, since they both consider QP useful and very effective for its technological applications. What they seem to keep faraway is the modelling game that the formalism seems to suggest to provide a new interpretation of the world.

Alice: “The ball is round, and the state?”

Alice is a student from the experimentation held in Castel San Pietro in 2016. Her personality shows to be always curious and ready to accept the challenge with every topic proposed in classroom. She likes to dialogue both with the teachers and her classmates, even if she is not
sure to have the right answers. Alice suffers a slight linguistic fragility, which often leads her to not fully comprehend the texts, and which weakens some of her logic arguments; for instance, she does not feel comfortable with most of the metaphors proposed in the course, mainly because of her tendency to read them literally and to miss the appropriate connections. Despite this slight difficulty, Alice is considered to be quite a good student and physics is her favourite subject matter, so that her final dissertation was about gravitational waves and general relativity. Alice showed a great interest towards QP course, and was the most active student during the lessons. Nevertheless, when interviewed, she expressed her difficulties in dealing with QP, some of which still remained unresolved. In particular, she felt bothered about the problem of imaging the quantum state:

Alice:  
Quantum physics has been difficult to comprehend with respect to the other physics fields, because...it’s a kind of physics that I cannot imagine, or contextualise [...]. When we talk about an electron, I know that I cannot see it but, at least, I imagine it as it is drawn in the textbook. Quantum physics instead...namely, the quantum state is much more difficult to be imagined.

Interviewer: [...] So, how did you imagine the state when we were talking about it in classroom?

Alice:  
...when you said that the [a particular] state comes to be defined only with a measurement...this shocked me a little, because that is not an ‘intrinsic’ characteristic, and so I really don’t know how to visualize it...

Alice’s idea of comprehension appears strongly influenced by the need of visualisation, as the example of the electron show. When trying to visualise the quantum state, she searches for an intrinsic property that can characterize it and let her to use the imagination. For the word ‘intrinsic’ what still claimed for Marco’s ‘well-defined’ properties, as they are indeed tacitly identified with properties held by a state or an object in a classical sense: properties that have a single, well-defined value to be revealed through measurement. In another extract, to get to the point, she enforces her argumentation through a metaphor:

Interviewer:  
So, what is your concern with the quantum state?

Alice:  
I would like to understand better what it is. We didn’t say: the state is this, or that...we only talked about some of its features...so to speak, the ball is round, and the state?

Consistently, the role of measurements in determining the state seems to be an awkward point for her conception of science:

Alice:  
I was used to think that all scientific subjects had to describe all the phenomena with certainty, but this issue of measurements changing the state...it makes a little bit perplexed”.

Even if not explicitly addressed by Alice herself, as it was instead for Marco and Cheng, we are prone to consider her case as a non-acceptance one. In fact, although she seems to have appropriated the basic concepts of the teaching proposal, she does not feel comfortable with QP’s description of the world, as clearly pointed out in the following:
Alice: I’m used to think about the world and about reality through classical physics. Sure enough, even with relativity I had some difficulties in imaging its ‘curvatures’...but for me quantum physics requires even a greater effort, because it’s a too small world...it’s too abstract. I haven’t fully grasped it yet...

The cognitive need of visualisation essentially emerges in the interviews as a sense of lack of mental images or metaphors to see physical objects or processes, or even to grasp concepts by intuition complains her difficulty in the lack of visualisation and of ‘intrinsic’ properties of the quantum state; she is trying to use the concept of state as a cognitive lens for understanding quantum phenomena, but she fails to finalise and establish such a shift due to this lack of visualisation.

QUALITATIVE ANALYSIS OF DATA: THE COGNITIVE NEEDS

A comparative analysis of the three cases of explicit non-acceptance shows some main evidences: (1) all the students mention three main conceptual topics against which their acceptance clashed, namely the concept of quantum object, the superposition state and the uncertainty relations; (2) the words used by the students to complain their difficulties can be grouped in three semantic fields, namely visualization/imagination, to know more/better, reality/existing. Some key expressions that mark problems of acceptance are “to know more about reality”, “to give meaning to the formulas”, or “compatibility with reality”, and reveal the need to strengthen or establish an interpretative and epistemological connection between the new mathematical structure and the world. In some sense it seems that the modelling dimension, that is the hypotheses and the features of the new paradigm, is not completely grasped or accepted.

In front of these evidences we hypothesize that behind non-acceptance dynamics lie some basic cognitive requirements, which we term cognitive needs, which emerge with strength in dealing with QP. We pointed out three of them: the needs of visualisation (to have a comprehensive view that can guide intuition), comparability (to have criteria to understand where and how the epistemological description/interpretation of QP is different from the classical one), and ontology (to attach a reliable and “realistic” meaning to new basic elements, like states, on which reasoning has to be developed). Whilst the nature of the latter can be considered typically epistemological, the first and the second can also be grounded in basic cognitive mechanisms of understanding. As introduced, we hypothesize that these needs do not belong only to those students who do not accept the theory, but traces of them can be found in many students’ discourses; simply, in dependence of other idiosyncratic or contextual factors, they can be activated with a variable strength. In what follows we provide a description of the cognitive needs, using also excerpts from other students from the three reported above.

Need of visualisation

The need of visualisation, expressed by Alice, is also stressed by Federico (experimentation in Rimini, 2015), who comes from another class. Federico seems to have appropriated the basic concepts but is not able to build a comprehensive picture/image that can sum up the logic connections between these concepts.
Anna (experimentation in Rimini, 2015), similarly, when asked about the quantum objects, answers as follows:

Anna: *In my head I’ve no ideas about the quanton [...], I’ve not a clear image in mind. [...] But I’ve made up the idea that this is quite a new stuff, and it seems almost unreachable, as it is not to be understood...* [E-12]

Although Anna seems not to be prevented by her need of visualisation in accepting quantum theory, she clearly considers the possibility to build up an image of the *quanton* at the same level of her understanding of the latter; as she cannot reach a clear image or idea of the ‘quanton’, it cannot be properly understood. One of the two classes under study in Levrini & Fantini (2013), where formalism was recognised from all the students as necessary to understand, generally recognized in the issue of *visualisation* of quantum phenomena a clear-cut point of detachment from classical physics. This generated a lively discussion in class, where different positions came to light. The case of Jessica is particularly interesting in this perspective.

Luca: *The picture of microscopic reality, in this case, is sufficiently supplied by the mathematical formalism. Therefore, in my opinion, to have a graphical representation is not important for scientific progress: What’s the use of the graphical representation? It may help in explaining the object as it is to children. But mathematics already explains it. [...] In my opinion anyway, the picture of microscopic reality is already described well enough by mathematics. It is enough to have the tools for comprehending it and it seems to me that everyone can do so...*  

Jessica: *[...] But for me it [visualization] is necessary in order to understand...*  

Luca: *Ah, but what if you can’t do it...*  

Jessica: *Because it is impossible to talk about something without trying to have a picture of what we are talking about, even unconsciously. It may help, in my opinion, also to give a meaning to formulas, because otherwise, even if we say that it is nonsense to represent the microscopic object, we make a picture anyway... I think so, although we decide not to draw it because we don’t want to give a model that... [...] it helps me, it helps me to remember. [...] honestly I can explain the Compton effect by keeping in mind the drawing, [...] we know that to be untrue but...*  

Pietro: *Ok, but it is just an icon, you could draw a little star to make a photon.*  

Jessica: *Yes, exactly.* [E-13]

Luca is accepting the impossibility to visualize quantum phenomena, founding his confidence in the possibilities of scientific progress, and refusing any other need of description. Jessica, instead, assigns to her need of visualization a critical role for understanding: the formalism has to be interpreted in terms of pictures that, being implicitly connected with classical world, allow for the use of an ordinary language. She restates many times that pictures does not have to be a *true representation* of physical reality, but visualisation, for Jessica, is an obliged way to travel through in order to face her necessity to “give meaning to the formulas”. The authors of the article point out that this personal requirement someway recall the position interpreted by Schrödinger in the historical debate about formulations of Quantum Mechanics, for whom
visualisability (Anschaulichkeit) is not only a useful way to comprehend the content of a theory but concerns the very aim of science research, as himself states: “Physics does not consist only of atomic research, science does not consist only of physics, and life does not consist only of science. The aim of atomic research is to fit our empirical knowledge concerning it into our outer thinking. All of this other thinking, so far as it concerns the outer world, is active in space and time. If it cannot be fitted into space and time, then it fails in its whole aim and one does not know what purpose it really serves” (de Regt, 1997).

This clear-cut line of though is not of course consciously accounted from students as a philosophical stance, and indeed neither entirely in its methodological and epistemological implications; nevertheless, their words evidence that, for someone, understanding and acceptance are tightly bound to visualisation. All these remarks led us to individuate the cognitive need of visualisation, that synthetically emerges in students as the need to have a comprehensive view that can guide intuition.

**Need of comparability**

The second cognitive need we pointed out concerns comparability, that emerges in students as the need to bridge, both formally and imaginatively, the quantum world to the classical one, so as to allow imagination to move from one to the other. The absence of an explicit demarcation line between classical and quantum domains often leads students to perceive them as completely detached from each other, and as it is for Marco and Cheng, the quantum formalism comes to be a ‘trick’ to account for the experimental results without really interpreting the world. Federico (experimentation in Rimini, 2015), for example, when asked to compare his studies about QP to the others, answers as follows:

**Federico:** [...] In the past two years [Federico was exposed to the experimentation about relativity in the previous year] my idea of physics has changed from the one where science had to determine everything, calculate, and tell us everything with certainty. Science has become an endless research of truths; truths that have to be proved wrong, or even made more true, by the following theory [...].

**Interviewer:** Yes. In fact in your essay you were claiming that it’s not clear yet how it is possible the coexistence between classical and quantum worlds, with such great differences...

**Federico:** Yes, that’s an issue I dealt with. [...] What I can’t explain is how could they can coexist, but just as how could relativity and classical mechanics coexist. [...] This is closer to philosophy than to physics! Or maybe this is true physics, I don’t know. [E-14]

In dealing with relativity and QP, as they were proposed in classroom, Federico’s idea of science has been enriched and enlarged from those limits that were given to be fixed in classical domains. Science’s development assumed the image of a dynamical process, where ‘truths’ are always to be questioned and deepened, and Federico comes to face his need for a ‘coexistence’ of the different theories, probably making the implicit assumption that all of them are needed to explain the whole reality. It is interesting, from this perspective, what Federico states about everyday reality:
Federico: The difficulty I encountered is, as I said before, that quantum concepts are so much distant from the Newtonian reality we experience every day.

What Federico is missing is an explicit connection between the daily experience, which is to him undoubtedly assumed to be Newtonian, and the new quantum concepts (like discreteness of the process or abstract spaces, as himself points out in other excerpts). Similarly, it is interesting what Silvia (Levrini & Fantini, 2013) points out during a discussion led in classroom:

Silvia: In relativity it was different [...] there you have a demarcation line. If you apply our velocity in formulas, you re-find our formulas. [In relativity] the two things are compatible, here not. [...] In relativity, in my opinion, there was a greater compatibility with reality.

As the authors highlight in their analysis, “without such a demarcation line and hence a comparative criterion, the quantum formalism risks becoming nothing but a ‘mechanism’, ‘a mentality’” (Silvia) to jump into, lacking what she felt to be a way for making the worlds comparable. Silvia was not compelling the impossibility of projecting classical images on the quantum world. She was instead manifesting the need of making the two ‘worlds’, however different, comparable, where comparability includes also the knowledge of where one fades in the other” (Levrini & Fantini, 2013). On the basis of these observations, the cognitive need of comparability can be defined as the need to find out criteria to understand where and how the epistemological description/interpretation of QP is different from the classical one, as to be able to move back and forth from one to the other.

Need of ‘ontology’

The name of this third cognitive need could be misleading for the various nuances the word ontology carries with itself, so firstly we try to describe what this requirement refers to from students’ words, and at the end of this paragraph we provide an explanation for its name. This need emerges quite systematically when talking about the quantum object, the superposition state and the uncertainty principle. Andrea (experimentation in Bagno di Romagna, 2015), for example, when asked about the nature of the quanton, answers:

Andrea: [This is] a word quite particular to describe it, but maybe it could be said to be mysterious, as up to now it’s difficult to define what it really is; we don’t know yet how to define it well, if particle, wave, or something which lies outside both natures. [...] ‘quanton’ is a totally new kind of thing, it’s difficult to tell its properties... it’s something that is not well definable.

In the attempt to find a definition of quantum objects Andrea implicitly makes the assumption that the words ‘property’ and ‘definition’ are strictly linked to classical quantities. In order to reach a more ‘realistic’ identification of the quanton, imagination searches for those classical-like properties on which students are used to rely and, thus, considered more ‘real’. Cheng in [E-5 and E-6] repeats the same requirement many times, and in a way very similar to that of Marco, as reported in the extract [E-2] about the uncertainty principle (“The point is that I couldn’t understand how couldn’t a body have its own properties, well-defined properties...”), and in [E-1] on the superposition state (“the object itself does own a well-defined property,
that’s what I believe. […] As Einstein, mine postulate is that an object has to embody well-defined properties”). Also in Alice’s interview the need of ‘intrinsic’ properties is mentioned in [E-8]. Another nuance of this requirement is that of determinism, raised up by Simone (Levrini & Fantini, 2013):

Simone: The hardest point to understand has been giving up classical determinism […] Deterministic physics was an exact science, at least at a theoretical level. Quantum mechanics is upsetting since it requires facing the knowledge problem, it makes you ask if what we observe is really what it is.

All of these statements somehow recall Einstein’s philosophical stance on the concept of quantum state, even though students are less conscious: “I am not ashamed to put the concept of «real state of a physical system» (‘existing objectively, independently of any observation or measure, and that can in principle be described through the means of expression of physics’) at the very centre of my meditation” (Einstein, 1953).

Nevertheless, we are prone to think that these students’ difficulties are not exclusively due to epistemological issues that immediately recall to mind the well-known debate about QP foundations; they can be ascribed also to a cognitive lack of a reliable ontology. With cognitive ontology we refer to those basic knowledge elements belonging to each theoretical formalism that allow to interpret the physical reality in a new reliable and fruitful way. With cognitive need of ontology we thus refer to the need to attach a reliable meaning to new basic knowledge elements, like states, on which reasoning has to be developed.

**DISCUSSION AND CONCLUSIONS**

We thus address the research questions as follows: (1) in the context of QP, students’ acceptance is strongly influenced by the emergence of some requirements: the needs of visualization, comparability, and ontology. The nature of these needs seems to be not only epistemological, but also cognitive (cognitive needs), and they can be activated in students with a variable strength, depending on their personality. (2) Identified these requirements, the work is to find ways to monitor their appearance and to accomplish them. In this direction, we propose some possible future work:

- to find an operative definition on acceptance, as to be able to better recognize it in its different nuances.

- to reform teaching materials as to accomplish the cognitive needs, and test their efficacy.

- to study (on the line of the work of Kapon (2016) about sense-making students’ self-evaluations) on one hand the strength of mechanistic explanations in QP students, as to get possible cognitive differences with other disciplines, and on the other, the relation of acceptance with framing.

- to study the relation of acceptance with understanding and appropriation (Levrini & Fantini, 2013; Levrini et al., 2015).

STUDENTS’ IDIOSYNCRATIC VOICES AND THE LEARNING OF QUANTUM PHYSICS IN SECONDARY SCHOOL: A CASE STUDY OF APPROPRIATION

Massimiliano Malgieri¹, Laura Branchetti², Anna De Ambrosis¹, Olivia Levrini³ and Giulia Tasquier³

¹Department of Physics, University of Pavia, Pavia, Italy
²Liceo Statale “G. M. Colombini”, Piacenza, Italy
³Department of Physics, University of Bologna - Alma Mater Studiorum, Bologna, Italy

In this talk we report selected results from a study on the processes of appropriation in students’ learning of quantum physics, organized jointly by the universities of Bologna and Pavia. In the study, experimentations of learning paths on quantum physics were carried out in secondary school classes. The experimentations were based on different educational reconstructions of the content, but were designed according to common guiding principles, shared some crucial activities aimed at building a non-authoritarian, inclusive and complex learning environment, and used jointly designed data collection instruments. The primary goal of the study was to promote and identify those processes (which we call, in the spirit of Bakthin (1981) and following Levrini et al. (2015) processes of appropriation) through which students attribute personal meaning to the words and expressions of scientific discourse, loading them with nuances which reflect their individual epistemological positions. In the talk we will focus on the case of two students. For such students we will report on the methodological process by which appropriation can operationally be recognized: the identification of an idiosyncratic “voice” of the student from the analysis of a semi-structured interview, and the search, in the remaining data including crucially disciplinary tests, for proof that such voice a) is recognizable beyond the interview, and in particular b) guides the student in attributing meaning to the scientific discourse. The case study will allow us to show how appropriation can adequately interpret the complex interactions between students’ identities and science learning, with a dual value for science education. On one hand, it helps identifying epistemological obstacles in the disciplinary content, with positive reflexes on educational design. On the other hand, it shows how science learning can help students in constructing and refining their personal identity at a crucial time in the development of their personality.

Keywords: Appropriation, students’ epistemologies, quantum physics

INTRODUCTION

Learning quantum physics is a complex educational problem, in which cognitive difficulties related to its sophisticated mathematical model are intertwined with epistemological difficulties in understanding what the model represents, and in accepting its epistemological implications. While conceptual learning difficulties, as traditionally intended, are very well studied, epistemological issues have received less attention. Baily and Filkenstein (2010) focused on the relevance in the educational process of the epistemological position of the teachers, concluding that their interpretational stance can have non-trivial consequences on educational outcomes. On the other hand, a consolidated result from conceptual change studies is that an ontological shift (Hadzidaki et al., 2000) from a classical to a quantum ontology is required for educational success, although the precise details of such ontological shift remain a function of the approach used by the teacher.
Our study focuses on how individual students appropriate quantum theory, i.e. how they make sense of it, and to a degree, how they reinterpret it so that it makes sense for them. Appropriation, as defined and operationalized in Levrini et al. (2015), is a holistic construct, which involves cognition, affect and behavior, and places the emphasis on the role of students’ will and intentions in learning. The present article will focus on the case of two students, chosen among several ones that we are analyzing in our study in order to exemplify both methodological aspects of how appropriation can be recognized in students’ discourses, and issues which are specific of the process of appropriation in quantum physics.

METHODS

A necessary condition for studying the individual and idiosyncratic character of sense making in science learning is that students feel legitimated to find their own route to the construction of meaning. Thus, an essential part of the preliminary work for this study concerned the design of non-authoritarian, inclusive and properly complex learning environments, built around the principles of longitudinality, multidimensionality, and multi-perspectiveness (Levrini et al., 2014). Guided by the above principles, parallel experimentations, whose skeleton was based on the different educational approaches to quantum physics of the groups of Bologna (Levrini and Fantini, 2013) and Pavia (Malgieri et al., 2014, 2017), were enriched with a set of shared core activities. Two extended periods of open class discussion, the first one following a questionnaire aimed at stimulating metacognitive and epistemological reflections, the second one based on material concerning historical debates on the foundations of quantum physics. Common data collection instruments were also designed, such as a semi-structured protocol to be used for interviews carried out at the end of the sequence, and a conceptual questionnaire, composed of open response items requiring students to develop articulated scientific argumentations.

The analysis of individual students’ data has been carried out in order to recognize cases of appropriation and it proceeded according to the general guidelines stated by Levrini et al. (2015). The authors define five discourse markers as necessary to infer that a student’s discourse reveals appropriation. More specifically, a student’s discourse is argued to reveal appropriation if it is: an expression of a personal “signature” ideas (marker A); grounded in the discipline (marker B); thick, in that it involves a metacognitive and epistemological dimension (marker C); non-incidental, in the sense of being consistently used throughout classroom activities (marker D) and a carrier of social relationships, in that it positions the student within the classroom community (marker E).

The analysis we carried out on the quantum physics experimentations was performed in two steps. First, the interviews were considered, with the aim of identifying the idiosyncratic “voices” of the students. The search for students’ voices started from objective linguistic features of students’ utterances, such as frequently repeated terms, consistently avoided terms, language slips or misplaced words; and proceeded with the search for an underlying thread, in the form of a key idea or fundamental epistemological position, capable of conveying the overall sense and sound of the student’s discourse. This step incorporates the markers A and C of Levrini et al. (2015). If all the researchers came to an agreement on the recognized voice, the remaining data (audio recordings of lessons, written productions including the disciplinary
test) were considered for each student. Aim of this second step is to check whether the voice could be recognized beyond the interview, and whether it played a significant role in orienting the student in the attribution of meaning to the scientific content, in a way respectful of the rules of the discipline. The second step incorporates markers B, D and E of Levrini et al. (2015).

In order to reach an acceptable level of internal validity, the data were analysed through a process of triangulation among different researchers by crossing data from the two experimentations (Anfara et al., 2002). Each of the group of scholars from the two contexts carried out the analysis by separately, then the scholars exchanged and checked their work separately, before discussing each case of the sample together. The work was repeated several times and the special cases were collectively discussed. This process of triangulation led to a progressive refinement of the profiles.

The process of testing appropriation markers against different data and of refining them allowed us to redefine the appropriation construct by deepening the relation with the discipline, and thus to construct students’ profiles which reliably bring out students’ voices within the rules of the discipline.

RESULTS

In this paper we limit the discussion to the cases of two students whom we call Filippo (from one of the classes following the Bologna path) and Cheng (from the Pavia experimentation). The two students were both revealed as cases of appropriation, and both obtained extremely good results in disciplinary tests. However, while Filippo seems to have no special problems in accepting the epistemological implications of quantum physics, Cheng very explicitly refuses to do so, stating clearly and repeatedly that there must be something we don’t know yet about Nature. The problem of students’ acceptance of quantum physics is, in itself, quite complex, and has been studied more thoroughly in a different contribution presented to the ESERA 2017 conference (Ravaioli and Levrini, 2017); in the present context we take the dichotomy acceptance/non-acceptance to mean whether the student seems, or doesn’t seem, convinced that quantum theory can be regarded as a true fundamental theory about nature.

It is worth specifying that that the two outcomes presented are not meant to be correlated to the path followed (Bologna or Pavia), in the sense that we could have chosen students playing very similar roles from opposite experimentations. Extended analysis (Malgieri, 2015; Lodovico, 2016) revealed cases of appropriation and not appropriation in both contexts.

First step of the analysis: recognizing students’ voices

Filippo’s voice

Recurring words in the interview of Filippo are “discourse” (which appears 13 times), “approach” (9), “reason/reasoning” (5), “conceptual/conceptualize” (7), “process” (6). The word “process” is occasionally used slightly out of place, like in “a process of uncertainty” or “our process” (to mean something akin to “our learning path”). Filippo’s interview is generally centered on describing the change in physical theories as a global process which involves, at the same time, a change in the concepts and objects used in the description but also, at a deeper level, a change in the way of reasoning. In this sense, a sentence which may be especially
revealing of Filippo’s thought is the following: “After having destroyed one’s convictions, new ones must be created and, after that, one needs to be perseverant in order to be able to enter the new method of reasoning”. The idea of perseverance is reiterated in another passage, in which Filippo states that mathematics and physics do not require only conceptual understanding, but also time and effort to accept and test a new method of reasoning. In another important passage Filippo describes how his idea of physics changed in time: “After these two years my idea of physics has changed, from the science which has to calculate everything, tell everything with certainty, physics became like an endless search for truth..., truths which are later proved wrong, or rendered even more true by a later theory”. At the time of the interview, Filippo appears concerned with the problem of finding a perspective for seeing both the classical and quantum descriptions as part of a whole, consistent discourse, and he recognizes that, for him, some pieces of the puzzle are still missing (for example, he is lacking familiarity with mathematical aspects). However, he appears to see in principle no obstacle to the task, provided that enough effort is put into it. Unlike other students, Filippo does not highlight aspects related to logic or paradox (both words are never used), nor he ever mentions intuition; his epistemological interest seems concentrated at the level of the verbal (“discourse”) and mental (“reasoning”, “conceptualizing”) structures associated with a physical description.

Putting all these elements together, we were able to recast Filippo’s voice as follows: “Physics is a never ending process, through which our discourse about Nature evolves. The approach to studying physics must be to challenge one’s certainties and build a new way of reasoning, based on new conceptualizations. One must be prepared to discard intuition, and to cast doubts on any rule or law he believed immutable. The process needs perseverance and effort, but at the end of it the whole construction will appear as consistent, because it is our way of reasoning, which defines the criteria for its own consistency.”

Cheng’s voice

Cheng is a first generation Chinese immigrant, he has been in Italy for five years and the interview is slightly hindered by linguistic barriers as his spoken Italian (contrarily to his written productions which are indistinguishable from those of an Italian student) is good but not perfect; he expresses himself through very short sentences and often asks to repeat questions. Recurring words in the interview are “experiment” (which appears 13 times), “exact” and “precise” (4 and 3 times), “reality” (5) and “it seems” (8 times). Recurring expressions, with slight variations, are “we don’t know yet”, “we haven’t found yet”, which appear about ten times globally. Cheng very openly expresses doubts on quantum mechanics, stating clearly that in his opinion a better theory hasn’t been found yet. When asked to describe what he would say to a friend to convince him that quantum mechanics can be understood, he offers the following answer: “[I would say] that we have found experiments which seem to work this way. That we can compute exactly certain things. Using formulas from quantum mechanics.” Cheng has very good results in mathematics and in the interview he states that the most important element to make a theory comprehensible is that it has a working mathematical model; however, he also complains at one point that the mathematical model of quantum physics disturbs him because it is not precise. Elsewhere, he says that in his opinion a theory even more precise will be found. By using this term, he presumably does not mean
(since he has explicitly stated the contrary) that quantum physics is not capable of providing accurate results for experiments, but that the model does not accurately reflect the structure of the underlying reality.

Thus, Cheng’s voice can be summarized as follows: “The scope of physics is to understand precisely how reality works. So, not only it must allow to compute exactly the results of experiments, but the mathematical models it builds to compute such results must also reflect accurately the underlying mechanisms and their cause-effect relationships.”

**Second step of the analysis: Students’ appropriation of quantum physics**

In order to check whether the student’s voice could be recognized beyond the interview (marker D), and whether it played a significant role in orienting the student in the attribution of meaning to the scientific content (marker B), we mainly considered data from the written task and, to a lesser degree, from the interviews. Among the problems of the written tasks, we took into account problems and questions that had the following features:

a) they required articulated answers;  
b) they allowed a comparison of the answers coming from the different contexts.

According to these criteria, we selected a problem about the Mach-Zehnder interferometer from the written task of Pavia’s path and a problem about Stern and Gerlach experiments from the written task of Bologna’s path. The topics of the problems were addressed during the respective paths to: (i) strengthen the concept of quantum state, (ii) discuss the meaning of quantum measurement and (iii) apply a basic quantum probabilistic reasoning to foresee measurement results that cannot be explain through classical reasoning (Malgieri, 2015; Lodovico, 2016).

The problems were built with the same structure, that is the students were asked to: a) explain the measurement results in different experimental configurations (see Figures 1-2-3-4-5-6) and b) highlight the main features that make quantum description different from the classical one.

From the interviews, the data that appeared particularly rich and informative concern the answers to the first question: What are the concepts that you understood better? And what are those you understood worst?
Figure 1. Setup for the first item of the Pavia path: the Mach-Zehnder experiment and its results (the two arms of the interferometer have the same length)

Figure 2. Setup for the second item of the Pavia path: the Mach-Zehnder experiment and its results with an intermediate which way detector C (the detector reveals whether the photon passes through the lower arm without destroying it)

Figure 3: Setup for the first item of the Bologna path: the experiment of Stern and Gerlach ("preparation" stage)
Figure 4: Setup for the second item of the Bologna path: experiment of Stern and Gerlach, results with a magnet oriented along the x direction

Figure 5: Setup for the third item of the Bologna path: articulated experimental set-up with three Stern-Gerlach apparatuses in “cascade”.

Figure 6: Setup for the fourth item of the Bologna path: at the output of the Stern-Gerlach X, the two beams are recombined in a coherent superposition.

In the following we present the results of the analysis by comparing, respectively, a case of appropriation with acceptance (Filippo), and one of appropriation without acceptance (Cheng).

**The case of Filippo**

Filippo’s voice, expressing his strong epistemological focus on “discourse” and “reasoning”, almost naturally helps him progress in quantum physics. By analyzing his disciplinary test it is possible to show that Filippo consistently performs an ontological shift from “object” to “state”, and pays continual attention to the dialogic relationship between reality and the game of modelling and reasoning. Furthermore, his voice re-emerges as a key to understand how he infuses physics with personal meaning when describes the outcome of the Stern-Gerlach experiment: here, the narrative choice he makes is to comment each step of reasoning in terms of whether it could be also explained through a classical logic, and the predominant emotion
which he shows through is fascination for the idea of comparing two radically different ways of thinking.

Filippo, in his written task, analyses the Stern-Gerlach setup. He starts by stressing what the experiments show (“two states for the spin”, the “probability of measuring each of them”) and he introduces the sensible “hypothesis” that, before measurement, the objects “result in a superposition state that collapse only at the moment of measurement”. Then he describes the new probabilistic reasoning and the role of measurement to “confirm” it.

"So, with the Stern and Gerlach experiment, quantum properties are highlighted: the existence of the Electron spin, which is not verifiable except through measurement. It is the act of measurement which makes the electrons "collapse" in such state since, if it were not so, the experiment could not be explained. Thus, we must advance the hypothesis that electrons are in a "superposition of states" which only collapses at the moment of measurement."

Filippo carefully focuses on stressing the difference between the classical description and the quantum one.

The properties resulting from experiment 3 [Figure 4] would seem to follow a classical logic (...) Experiment 4 [Figure 5] on the other hand highlights how electrons, prepared in the Stern and Gerlach Z, then made to pass through the S&G X, "forget" the initial preparation on Z.

Then Filippo reaches a "crucial" experiment, which he says marks the complete "decay" of classical logic, and explains its outcome at a remarkably high level of formal complexity (see also Figure 7):

"[The Stern-Gerlach experiment in Figure 6 of this paper] highlights the complete decay of classical logic in predicting quantum phenomena. Classical logic would have predicted 50 and 50, while the Stern and Gerlach X appears as almost "non-existent" and results analogous to experiment 2 [Figure 3] are found. Thus, it is no longer possible to reason with classical logics.

Figure 7. An excerpt of Filippo’s answer to the written task

This detail of Filippo’s argumentation is where his voice appears not only an epistemic stance, but a key idea to grapple with science contents and attach personal sense to them. In the words of Bakhtin, Filippo’s argumentation shows that he turned quantum physics discourse from
“authoritative” into “internally persuasive” (Bakhtin, 1981; Levrini, Levin, Fantini, Tasquier, under review). His personal interest in testing the new conceptualization and the new discourse against the old ones re-emerges here as a key to understand physics and to infuse it his personal meaning. In the model of appropriation of Levrini et al. (2015), this specific aspect is fundamental to conclude that the student appropriated scientific discourse and it is summed up by marker B, which requires idiosyncratic voice to be “grounded in the discipline”. The occurrence of the same key points in several activities (both the final interviews and the conceptual written task) shows that Filippo’s voice is also non- incidental (marker D).

Based also on the analysis of other cases, two main aspects, the state-ontology and the dialogical dynamics between models and reality, seem crucial for accepting the quantum description.

**The case of Cheng**

It is perhaps more surprising that also Cheng, with the essentially mechanistic position expressed by his voice, also displays appropriation. However, by analyzing Cheng’s disciplinary test one can see that he also abandons an “object-ontology” and consistently focuses his attention on the experimental set up and its measurement results, effectively adopting an “experiment-ontology”. Experimental setup and outcome are connected in Cheng’s answer by mathematical statements, with few additional comments. We may argue that such strategy allows Cheng to maintain his inner doubts on the definitive nature of quantum physics, while accepting, and focusing on, what is good in quantum physics for him: the possibility to compute accurately experimental results.

When Cheng is required, during the interview, to comment the disciplinary path, he seems to feel the need to stress his discomfort in talking about a quantum object of which we cannot say to know “all the properties”. The aspects that he thinks to have better understood are the uncertainty relations and the wave-particle dualism. They are said to represent the main points that characterise the description of quantum objects with respect to the classical one.

“I think that those I understood better are the uncertainty principle, the fact that they look both like waves and particles, those discussions [...] quantum object display wave-particle duality, but in everyday reality we find nothing like that [...] eh, because a solution has not yet been found, thus this dualism is used”

His answer to the Mach-Zehnder problem of the written task is very essential but precise and complete. What characterizes Cheng’s answer is the attention on the experiments results and on the mathematical calculations. He starts with a description of the experimental set-up (Figure 1):

“In the Mach-Zehnder experiment 2 beam-splitters, 2 mirrors and 2 detectors are used.”

After that, the phase shift is calculated to explain the experimental results and the formal expression of the classical probability is used to argue why the “which way” configuration leads to different results.

In the language of conceptual change, we can state that also Cheng, like Filippo, arrived to focus his attention on what really counts for understanding quantum physics. Also Cheng, in
the written task, does not show any attachment to an “object-ontology” and he consistently focuses his attention to the experimental set up and its measurement results. We call this type of ontology “experiment-ontology”, since the basic pieces of knowledge to which Cheng attaches as sense of reality and on which he built his reasoning are the experimental results and the experimental apparatus. He also shows to be able to manage the needed mathematical tools.

Case b) [Figure 1] does not follow the classical probability rule, but it is not incomprehensible because it follows the quantum probability rule \( P(A+B) = |\psi(A) + \psi(B)|^2 \) which depends on the phases \( \psi(A) = kx \) which in turn depend on the path distance. Thus, it is surprising because it is computed in a different way.

For all these reasons, we can conclude that we are here in front of another case of appropriation, accompanied by an ontological shift (Hadzidaki, Kalkanis e Stavrou, 2000).

Our analysis, however, stresses essential differences between Cheng and Filippo: Cheng neither uses a modelling language to justify mathematical calculations nor uses a contrastive strategy to discuss quantum reasoning (with respect to the classical one).

Cheng, in his answer, doesn’t provide any substantial comment and doesn’t even develop any argument: he simply describes the set-up and provides mathematical calculations.

After having built Cheng’s profile, we were able to recognise, in these features of the written task, Cheng’s voice, including his discomfort in accepting the inner interpretation of quantum physics.

**DISCUSSION**

The comparison between Filippo and Cheng highlights important aspects.

From the perspective of conceptual change, their learning processes are characterized by an ontological shift (Hadzidaki, Kalkanis e Stavrou, 2000). In the case of Filippo, the shift is from classical object to state; in the case of Cheng, the reasoning, instead of being focused on the object, is built around the source-detector setup (experiment-ontology).

Their learning, as seen from the point of view of appropriation, shows idiosyncratic aspects and their voices are recognizable. This specific analysis led us to see a problem in the model of Levrini et al., (2015), concerning marker E that, in this different context, was neither easy to be observed, nor necessary to conclude about appropriation.

The novelty of this analysis, besides the application of the construct of appropriation on new teaching contexts, is the possibility of crossing fruitfully appropriation and conceptual change. When these two research perspectives are crossed, we as researchers can find new arguments to infer if of how the mechanism of conceptual change can be enhanced. In our cases, for example, we found that students’ learning shows that their voices have been "productive" in orienting them to focalize their attention on significant and essential aspects of quantum physics.

By considering the cases of Filippo and Cheng we may draw two provisional conclusions: a) The learning processes of the two students show idiosyncratic aspects in which their voices are recognizable, and such voices were also productive in focusing their attention on essential
aspects of quantum physics which could be meaningful to them. b) The epistemological obstacles encountered by students in learning quantum physics may depend on their idiosyncratic ideas in a non-trivial way, with the consequence that a unique approach to a “correct” quantum epistemology may not suit all students equally well. In the interview, Cheng expresses discomfort in talking about the “quantum object”, and does not adopt a state ontology. However, the “experiment” ontology offers him a viable alternative, which he can accept, to a degree, without renouncing his inner convictions.

As counter-examples, cases of non-appropriation - that we found but that we are not able to report here for a matter of space - reveal that students’ voices led them to focus their attention on unproductive pieces of knowledge that hindered any ontological shift (Levrini, Malgieri, De Ambrosis, Tasquier, Branchetti, in preparation).

The problem of accepting quantum physics

In two cases, one from both experimentations (Cheng and a student of Bologna, Marco), students who refused to accept quantum physics shifted the focus of their discourse on the experimental apparatus, and the experimental outcome, which became the central element of their ontologies.

These students share a very strong image of science, and in both cases they acquired significant skills in predicting and describing the experimental outcomes. However, in their reasoning they do not display the perception of a dialogical relationship between model and reality. They are uncomfortable with using the term "quantum object", which remains in the background or does not appear in their descriptions.

The extension of the construct of appropriation to the case of quantum physics has allowed us to uncover peculiar relationships between interest and conceptual change which did not emerge so clearly and explicitly with themes of classical physics. For example, if a student only appropriates the non-deterministic character of quantum physics, this may be seen as a case of failed conceptual change (Ferrari and Elik, 2003). On the other hand, the refusal to accept quantum physics may follow from the recognition of the objective epistemological non-neutrality of quantum physics. Thus, as in the case of some scientists of the 20th century, appropriation can happen without acceptance, as the epistemological changes required by quantum physics can be refused on the grounds of personal epistemologies that don’t fit in the vision of science offered by quantum physics.

Thus, lack of acceptance does not necessarily imply non-appropriation. The in-depth analysis of marker B in the case of non-acceptance, like Cheng, helped us to focus on the issue.

CONCLUSIONS

In this paper we considered the construct of appropriation that Levrini et al. operationalized from a teaching experiment on thermodynamics and we applied it to analyse teaching experiences on quantum physics. The study has implications on at least three research issues: a) the feedback on the construct of appropriation; b) the interaction between students’ epistemological and conceptual change; c) the relationship between science learning and the development of personal identities.
As for the first issue, this study feedbacks on the definition of appropriation, by showing that the markers can work to orient the analysis of rich data where several dimensions of learning are involved: disciplinary and conceptual, epistemological, affective, social. Yet, the study showed that marker E revealed to be anomalous in the list and difficult to be recognised. This point deserves further analyses and maybe the definition of appropriation reported in Levrini et al. (2015) needs to be refined.

Regarding the second issue, more explicitly than in the case of thermodynamics, the analysis shows that the construct of appropriation is effective to point out the dynamical aspects of the interaction between students' epistemologies and the learning of disciplinary content (conceptual change). In particular, the study showed examples of how the epistemological attitudes which allow a more "productive" approach to the subject can be highlighted and this has positive reflexes on the re-design of future implementations.

Finally, the creation of an open and non-authoritarian learning environment allowed us to uncover and study in depth the issue of students refusing to accept quantum physics (Levrini et al., 2008), through the open discussion of epistemological and foundational issues which are generally considered a hidden curriculum in quantum physics (Baily e Filkenstein, 2015). In this rich and complex context, the construct of appropriation revealed to be adequate to highlight how, and through which processes, disciplinary learning can become an important context for the development of the student’s personal identity (Levrini, 2014).

Understanding and stimulating such ambitious process where the learning of physics does contribute to developing personal identity is maybe the most relevant overarching objective of our research.

STUDENTS’ USE OF REPRESENTATION AND PARTICLE MODELS FOR DISSOLUTION

Shingo Uchinokura
Kagoshima University, Kagoshima, Japan

The particulate nature of matter is a core idea in science that mandates that students learn the use of particle models and develop representational skills. This study included 185 participants who were eighth-grade students in Japan, and it investigated the students’ understanding of the use of particle models for dissolution through Paper Pencil Testing. The students were divided into two groups: the model-use prompted and the non-prompted groups. Their answers were categorised based on several aspects such as level and mode of representation, and features of the models. Model-use prompted students were encouraged to use representations and build particle models to enhance their explanations at the submicro level, although this concept had not been applied to the phenomenon that they had studied only at a macro level. They not only had to recall earlier models that they had studied but they also had to change some of their elements to suit the requirements of the new models. This change provoked typical misconceptions. Faced with the mode of representation, they depicted their models using diagrams supplemented by text-based descriptions. Apparently, the model-use prompt affected the students’ actual use of representations for their models. The results implied that the students’ lack of spontaneity was related to their low awareness about models and modelling. The study shows that it is necessary to enrich the students’ contextual knowledge of models and modelling as part of their metamodelling knowledge in order to engender their transition to different levels and/or modes of representation.

Keywords: models and modelling, representations, particle models of matter

INTRODUCTION

Role of models in science and science education

It is a known fact that models and modelling play an important role in the history and current practice of science (Hesse, 1966; Giere, 1988; Nersessian, 2008; Bailer-Jones, 2009). Scientists’ methods of reasoning are characterised as model-based reasoning in which the practice of analogical modelling, visual modelling and thought experimenting (simulative modelling) are frequently used together (Nersessian, 2002). This implies that the practice of modelling in science is closely related to the different practices of mental and material representation.

Models and modelling are also recognised as one of the most important topics of science education (Erduran & Duschl, 2004; Clement, 2008; Gilbert & Justi, 2016). International trends in educational reform known as competency-based education acknowledge models and modelling as a requisite core-competency of children’s science learning (Lehrer & Schauble, 2006; Michaels, Shouse, & Schweingruber, 2008; NGSS Lead States, 2013). Gilbert and Justi (2016) characterised approaches to learning about models and modelling in science as a spectrum from model-based teaching to modelling-based teaching. That is, model-based teaching focuses on the use of existing models by students, while modelling-based teaching focuses on the development and use of models by students. The core elements of these learning
practices are constructing, using, evaluating, and revising models. Additionally, metamodelling knowledge as a type of epistemological knowledge (Schwarz et al., 2009) and visualisation skills of various representations (Gilbert, 2008) or metarepresentation (diSessa, 2004) play significant roles in these learning processes.

**Particle models of matter and representation in chemistry**

The particulate nature of matter is a core idea in science. Therefore, it is vital that students learn the uses of particle models and representational skills so that they can visualise sophisticated models over time (Tsaparlis & Sevian, 2013). A hypothetical learning pathway is conceptualised as a *learning progression* (Duschl, Scheingruber, & Shouse, 2007). Mastering abstruse knowledge and skills is hardly easy for school children. Over the course of a few decades, various researchers have reported on the alternative conceptions of students regarding the particulate nature of matter (Garnett, Garnett, & Hackling, 1995; Taber, 2002; Barke, Hazari, & Yitbarek, 2009).

Merritt and Krajcik (2013) reported that a greater number of students built better models for particulate matter after the implementation of the inquiry program of smell phenomenon. Contrarily, longitudinal studies by Johnson (1998) discovered that some students improved and developed more scientific particle models while others regressed to less-sophisticated particle models. This suggests that learning about models and modelling might follow different pathways. Essentially, since teaching about particulate matter might follow various possible pathways, particular models are chosen depending on the chemical processes learnt. (Eilks, 2013).

Some studies have explored the use and generation of analogies and models by students (Wong, 1993; Clement, 2008), and by scientists (Dunbar, 1995; Clement, 2008). The term *spontaneous analogy* is used when students use and generate analogy voluntarily while *self-generated analogy* is what they do by themselves but with this difference – they utilise instructions and/or cues. Studies show that *spontaneous analogy* does not occur with great frequency (Haglund, 2013). Studies focused on the use of spontaneous models by students when learning chemistry are also limited. Selly (2000) found that students are able to give meaningful explanations and spontaneously develop particle models for dissolution without any prompting even when they have not been taught a specific model for dissolution; but many of these models contained errors and weaknesses. The difference between the students’ use of models in spontaneous situations and induced (self-generated) situations is unclear under this framework.

Although not all representations are models, still it is beneficial for students to be proficient in drawing in science (Tytler et al., 2013; Ainsworth, Prain, & Tytler, 2011). While diagrams are one of the most common modes of representation when teaching chemistry, linking the macroscopic and submicroscopic levels is not easy for students (Davidowitz & Chittleborough, 2009). Additionally, Cheng and Gilbert (2009) implied that it will be difficult for students to alternate between different modes of representation within a single level of representation. Hence, this study explored the extent of understanding shown by students regarding the usage of previously taught particle models and representations for the study of dissolution. The study was driven by these research questions:
• Does the model-use prompt engender students’ use of different modes of representation and particle models?,
• How do the students use particle models in a different context with a different level of representation to those previously taught when they explain dissolution?,
• Which levels and modes of representation do students prefer to use when explaining the phenomenon?.

When compared to previous studies on the students’ use of particle models of dissolutions, this study focuses further on the students’ use of the modes of representation in each of the spontaneous and induced (self-generated) situations.

METHOD

Subjects and learning context

The study was conducted in a lower secondary school in southern Japan. It is a public school attached to the university and students wishing to study there have to pass an entrance examination held by the school. Generally speaking, the students of this school are highly motivated and have higher academic achievements than those of neighbouring public schools. Participants of the study belonged to the eighth grade science class, were 13-14 years old and included 89 males and 97 females. The students belonged to four different classes and were taught by three teachers who each had 8-14 years of teaching experience. No significant differences in achievement were seen between the classes from the perspective of the teachers.

According to the national science curriculum of Japan (the Ministry of Education, Culture, Sports, Science and Technology, 2008), integrated science is taught at the primary and lower secondary levels (from Grade 2 to Grade 9). Primary school children are taught basic chemistry at a macroscopic level; this changes to the submicroscopic level in the lower secondary school. By the eighth grade they have already learnt about the physical and chemical changes of matter at both the macroscopic and submicroscopic levels, including lessons about dissolution and the use of particle models. This phenomenon was their first formal exposure to models in their science classes. They were taught the simple particle model (Cheng & Gilbert, 2017).

Data collection and analysis

The Paper Pencil Testing (PPT) contained five questions to evaluate the extent of the students’ understanding regarding the use of particle models for dissolution:

• Q1. describing the difference between unsaturated and saturated water solutions of alum,
• Q2. determining the minimum mass of water needed to dissolve the solute,
• Q3. explaining the concept of convection by heating water in a beaker,
• Q4. explaining the change in solubility of the solute with the rise in the temperature of water, and
• Q5. evaluating the alternative explanation—which focuses on the volume change of water—for the change in solubility upon heating.
One group contained 115 students as the model-use prompted group (MP), and the other contained 71 students as the non-prompted group (NP). The explicit prompt for the use of a model was given to the MP group only. Students were distributed arbitrarily within each group based on their classrooms. For qualitative and quantitative data analysis, the answers were categorised by several dimensions defined in this study: (1) level of representation (macroscopic, submicroscopic, symbolic), (2) mode of representation (text, diagram, graph etc.) (Gilbert, 2008), and (3) features of models (particle, non-particle, etc.) (Selly, 2000). Statistics such as Fisher’s exact test were used to test the differences between the two groups, as well as to determine the differences between the groups’ responses to each question. The PPT procedure followed was the same for both the groups apart from these differences.

RESULTS

Selected level and mode of representation by students

Based on the students’ description and/or drawing for the saturated/unsaturated solution, convection and solubility change, students selected the levels of representation as shown in Table 1.

Significant differences were observed between the levels of representation selected by the MP and NP students to explain the difference between unsaturated and saturated solutions ($p < .05$, two-sided). Although many students from both groups described this phenomenon and/or drew diagrams at the submicroscopic level, the MP students tended to select the higher level of representation better than NP students did. In terms of the implemented curriculum, students were familiar with learning the particle model of matter in similar problem-setting situations.

A similar significant difference in the level of representation was found between the two groups when they were asked to explain the change in solubility with the rise in temperature ($p < .05$, two-sided). While the MP students preferred to describe and/or draw at the submicroscopic level, the NP students did so at the macroscopic level. Students were puzzled by this question because of unfamiliar context despite having learnt to use particle models of matter in this

phenomenon earlier in their regular classes. Nearly half the students of both groups were unable to answer this question. Those students who recognised the use of the model in relation to the level of representation explained the concepts at the submicroscopic level.

On the other hand, when the students explained the heating process of water, their focus stayed at the macroscopic level irrespective of their group since they have learnt this phenomenon at the macroscopic level in their primary science course without the use of the particle model of matter. Most students did not try to translate their understanding at the macroscopic level into the submicroscopic level.

Table 2 shows the results of the modes of representation selected by students to explain dissolution and convection. In all three explanations, significant differences were observed between MP and NP students pertaining to the modes of representation selected by them ($p < .05$, two-sided).

The MP students tended to prefer the use of diagrams, or a combination of diagrams and text, as a mode of representation. Whether their explanations were acceptable scientifically or not, they displayed their preference for a diagrammatic mode of representation and/or multimodal representation compared to NP students. For example, the students explained the solubility change caused by heating with the combination of diagrams and text (Figure 1). In this case, both representations implied the same meaning, with semantically equivalent expressions.
Strand 2

Figure 1. Students’ multimodal representation of the change in solubility caused by heating.

When the interpretive meaning of the diagram differed from the text description, the context of the text seemed to be correct but the connotation of the diagram was problematic.

It is possible to combine diagrams and graphs as diagrammatic representation but this was seen only in a few responses (Figure 2).

A very limited percentage of MP students used only text descriptions whereas a greater percentage of NP students relied heavily on text descriptions to explain concepts when faced with unfamiliar situations.

Figure 2. Students’ diagrammatic representations such as combination diagrams and graphs.

Students’ models and its ‘Model-of’

In describing and drawing the dissolution at the submicroscopic level, most students used the simple particle model. At the macroscopic level, students were found to use the area model, where the mass of the solute is represented by area or area-related concepts (Figure 3).

Figure 3. Students’ area model at the macroscopic level.

Additionally, along with their usage of models, some students generated the spontaneous analogy. The study detected 35 answers including students’ analogies among all answers to all questions. MP students were once again seen to introduce their analogy more than the other students. Among many popular analogies reported in chemistry (Harrison & Coll, 2008), the analogy of musical chairs to the change in solubility is a well-known one to Japanese science teachers who often see it in the secondary science textbook (Figure 4).
The change becomes like the musical chair game.

Figure 4. Example of students’ analogy; the musical chairs game.

Table 3 shows that students used different referents for their particle models at the submicroscopic level depending upon the situation. Students from both groups explained unsaturated and saturated solutions using the particle model of matter and represented the solute as particles (Figure 5-a). It was normal to select this kind of particle model for the students who were taught about it. The significant difference was found in the use of models ($p < .05$, two-sided). But the students of both groups seemed to be familiar with this kind of model (88% and 73%, respectively).

The models showing that the solvent was also expressed as a particle appeared to be in the more demanding category for the students (Figure 5-b). However, this change was mainly found in the MP students. The NP students hardly used a particle model. The significant difference was found in this kind of model representation ($p < .05$, two-sided).

Figure 5. Students’ particle model of matter.

The majority of the students’ models were simple particle models but there were several variations (Table 4). The core of the model was the nature of particulate matter but they added other elements to their models. Both groups, the MP and the NP, expressed the mass ratio of solute between the two solutions through the model. In addition to this, the MP students tried
to depict the concept of solubility as space-filling (Figure 6-a) (11%) or one-to-one correspondence (9.0%).

In explaining the solubility change caused by heating, the MP students explained the phenomenon as space-filling (12%), size change of solute particle (Figure 6-b) (10%), the increase in the volume of solvent (7%), and as moving particles (6%). A few students explained it as the melting or stirring of particles. When confronted with puzzling situations, they revised and constructed particle models to ‘save the phenomenon’. These inferred meanings are not accurate scientifically.

Students’ mathematical understanding and evaluating the alternative explanation

The study found no significant difference between MP and NP students with reference to their mathematical understanding and evaluation of the alternative explanation (Table 5). Almost all the students used a proportional calculation to determine the minimum mass of the solvent. Students utilise the proportional equation to represent the relation between the unsaturated and saturated alum solutions (Figure 7).

Although statistical difference was not found, it was not so easy for students of both groups to evaluate the alternative analogical explanation properly.

**DISCUSSION AND IMPLICATIONS**

**Spontaneous model use in students’ explanation**

While both the students’ groups have learnt to use representation and particle models for dissolution in the same way, their method of using their knowledge in other contexts was different. When faced with a familiar context, both groups of students used particle models to describe and/or draw dissolution, and the model-use prompt was not a factor. When confronted with unfamiliar contexts, prompted students were able to use representations and particle models to build their explanation for dissolution at the submicroscopic level. Conversely, the non-prompted students tended not to use the particle models and to represent the phenomenon at the macroscopic level. Non-prompted students displayed a spontaneous use of models in a limited way and then only with familiar content. The results of observing the students’ modelling and representative practices imply that low awareness of these concepts will inhibit the students from practicing them spontaneously. Therefore, a simple and trigger such as asking them to use models, i.e., to prompt them for model use influenced the students’ actual use of representations and models. However, the prompt effect did not apply to the situation of explaining the convection theory that they had learnt only at the macroscopic level. In some cases, the transition from the macroscopic level to submicroscopic level means to transition between the learning contexts.

The result of this study shows that the students are not necessarily able to transition representationally. With respect to the transition, it is a promising opportunity for the students to reflect on the same phenomenon from different levels of representation, especially when they learn it at the macroscopic level. Additionally, it is necessary to enrich the students’ contextual knowledge of models and modelling; that is, knowledge about when, where, and how to use models as part of metamodelling knowledge (Schwarz et al., 2009).
Ways in which students use models

Students used *the simple particle model* in familiar situations provided that they could recall what they had already learnt. The students in the study who could access their knowledge base and/or the instructional prompt could use the particle models. It might be challenging for the students as novice model-users to be proficient, but model-based teaching can achieve this scope of learning when focused on the use of existing models by students.

On the other hand, in unfamiliar situations, the students changed some elements of the model to suit the new requirements. Some of the changes of the model provoked typical misconceptions (Garnett, Garnett, & Hackling, 1995). These misconceptions were nearly in line with those reported by Selly (2000). The students revised their models freely in order to respond to the situation but they did not know enough to process the modelling in the form consistent with the related scientific knowledge base. It can be surmised that they hardly re-examine their explanations by relating them to other scientific concepts and the original definition of the particle model of the matter. As well as using models, some students generated analogies spontaneously. Some of their analogies were material or physical but the others were anthropomorphic. The study shows that students can perform analogical modelling, visual modelling and simulative modelling together through science learning just like scientists do (Nersessian, 2002). Similarities such as the spontaneous use of analogy in the construction of explanation between experts and novices has long been known but experts pay special attention to the process of evaluating and revising their analogies (Clement, 2008). Emphasis on the aspects of the modelling cycle such as generating, evaluating and modifying successively is necessary when learning science. It is important to note that models must be recognised not only in terms of how they represent phenomenon (*model of*), but also with respect to the aims and intentions of a cognitive agent (*model for*) (Gouvea, J. & Passmore, 2017).

Modelling competence and metarepresentation

In conjunction with the use of models, the students depicted the phenomenon by using diagrams and text. It is arguable that the students’ selection of the mode of representation was closely related to their ideas about models and representation in science and science learning. Another study on the students’ ideas of models found that 9th-grade students in the same school had some relevant—although not complete—knowledge of metamodelling and metavisualisation through science learning (Uchinokura, 2016). They thought that a model in science functions to explain invisible things, and the replication of a phenomenon as alternative experimentation; a model is represented by the diagram mode. However, the students did not use diagrammatic representation like arrows properly except in the case of mathematical representations like proportional equations. Arrows are used more often in science but have various representational roles (McTighe & Flowers, 2012). The students’ use of the models and representation was not quite as functional (Ainsworth, 2008) but was just superficial or just drawings. Referring to the representation competence model (Kozma & Russel, 2005), the students in the study seem to be placed in the lower level: *representation as depiction and early symbolic skills*. As if in response to increasing model and modelling research, the focus of research on diagrams shifted from learning *from* to learning *with* visual representation recently (Tippett, 2016). Thus emphasising the model and modelling more. This study suggests that
Further study must be conducted to enhance students’ modelling competence and metarepresentation, for examining students’ comprehension of the relation between the use of a model and the use of diagrammatic representation, and for investigating students’ knowledge of diagrammatic conventions as well as their scientific knowledge (Novick, 2006).

CHILDREN’S DRAWINGS ABOUT “RADIATION”—A REPLICAION STUDY FIVE YEARS AFTER FUKUSHIMA

Thomas Plotz and Fanny Hollenthoner
University of Vienna, Vienna, Austria

The aim of this study is to investigate school students’ perceptions of the concept “radiation” (German: Strahlung) prior to their exposure to the topic in class. This work should fulfil two purposes. We try to reproduce the studies carried out by Neumann and Hopf (2013) and also expand their results. The method employed in both studies was identical. Students drew pictures associated with the concept under observation. The resulting motives were subsequently categorized and compared. Firstly, this study focuses on the investigation of whether school students still associate the Fukushima Nuclear Disaster with the concept of radiation, even though it has been five years since the accident at the power plant. Secondly, we investigated the extent to which the results of the current study correspond or disagree with the previous study. Thirdly, we looked for new motifs in the drawings of the children and we tried to investigate the link between media coverage and drawings is plausible. This study demonstrates that children barely associate the concept of “radiation” with the Fukushima Nuclear Disaster. Moreover, a number of differences could be realized when compared to the reference study. For instance, significantly more students drew cell phones and computer monitors in the current study. Additionally, a greater number of drawings related to radioactivity could be observed. Overall, the findings of this work indicate that not only are students exposed to the media at a much younger age, but also more frequently. This leads to the conclusion that more and more children build their own understanding of a particular subject, which might potentially result in misconceptions.

Keywords: children’s drawings, radiation, students’ conceptions

INTRODUCTION

Students’ conceptions about radiation are a field of little interest in empirical science education research. However, this topic influences our everyday life on a broad basis. From mobile phone radiation to X-rays in medicine, we are surrounded by radiation every day. Neumann and Hopf investigated the drawings of over 500 children to answer the questions: what motifs do the children and do these motifs change over time draw? This study replicates the study by Neumann and Hopf and expands their research question. After five years the presence of the topic radiation and Fukushima in the media has disappeared. Therefore, it is interesting to find out if the increase of motifs related to radioactivity, documented by Neumann and Hopf, is visible today. We used the same design and method to analyse the drawings. We included children from the original schools in Vienna and in addition children from a rural area to compare their drawings.

PREVIOUS FINDINGS

There are studies in the mid-nineties (H. Eijkelhof & Millar, 1988; H.M.C. Eijkelhof, 1996; H. M. C. Eijkelhof, Klaassen, Lijnse, & Scholte, 1990; Lijnse, Eijkelhof, Klaassen, & Scholte, 1990; Millar, 1994; Millar & Gill, 1996; Millar, Klaassen, & Eijkelhof, 1990) that revealed
frequent misconceptions (false conceptions) on nuclear radiation. They documented problems with the concept of contamination and irradiation or the concept of activation: an object emits radiation after being exposed to radiation. Additional, students linked the effects of nuclear radiation to other environmental issues like the greenhouse effect or the ozone layer. A lot of these misconceptions can be found today. Sen and Ince (2010) reported in their study that those misconceptions are widely spread on the Internet. So the information students find on the internet can stabilize their misconceptions.

Other studies focusing on invisible radiation as distinct from nuclear radiation came up with very concerning results. Rego and Peralta (2006) found that students were unable to distinguish between non-ionizing and ionizing radiation. Most of the students could not tell the difference between various types of radiation. Libarkin, Asghar, Crockett, and Sadler (2011) focused in their study on infrared (IR) and ultraviolet (UV) radiation. The majority of students (age 10 to 16) believed that the sun is the only origin for UV-radiation. They also described UV as “light,” “bright light,” “strong rays,” “very violet,” “a color like red, blue, purple light,” or “harmful rays.” Concerning IR-radiation a lack of knowledge was revealed; scarcely anybody had heard of this kind of radiation.

In his review Plotz (2017) summarized conceptions for nuclear radiation and various types of electromagnetic radiation. He provides an overview of the recent literature. Most of the mentioned studies dealt with misconceptions and associations linked with radiation. Overall we see a nonpoint picture of the students’ conceptions. There is a clear gap in the knowledge about students’ conceptions in the field of radiation.

Due to the design of this study, the most important findings are those of Neumann and Hopf. They showed first and foremost, that children are likely to draw the sun when they are asked to draw something about radiation. About 70% of the students (age 9 to 12) drew a picture of the sun or sunlight. In Figure 1, the results from Neumann and Hopf can be seen. Overall, Neumann and Hopf showed, that the motifs are often connected to visible light and to sources of radiation like mobile phones and monitors. There was also a shift in motifs from younger (sun, visible light) to older children (artificial light sources).

![Percentage of Drawings that Include ... as a Motif](image)

**Figure 3. Frequentness of motifs in 2009**

In addition to the first study in 2009, they investigated the change in motifs in 2011 after the nuclear accident in Fukushima. In Figure 2, the change in percentage of motifs connected to radioactivity is visible. The change can be connected to the enormous amount of coverage of the accident in Fukushima in the media. This connection has been documented in the drawings.
and in interviews with the students after they drew the first set of pictures. According to this connection there should be a significant lower percentage of drawings about radiation in 2015 compared to 2011.

![Figure 4. Change of motifs between 2009 and 2011.](image)

**METHOD**

There is a long tradition of using children’s drawings in psychology research. Drawings are used to analyse the developmental stage and emotional states of children (Thomas & Silk, 1990). They provide an insight into the thoughts and feelings of children. Drawings are also used in learning psychology and teaching practice to investigate students’ understanding (Hope, 2008; White & Gunstone, 1992). Looking to science education, there is the famous “Draw-A-Scientist” test (Chambers, 1983; Finson, 2002) that is used to find out about students’ conceptions about the nature of science. Markic and Eilks (2008) investigated student teachers’ beliefs about learning and teaching by analysing drawings. The method of analysing drawings has also been implemented in various fields of science education, for instance biology education (Dikmenli, 2010), environmental science education (Barraza, 1999), technology education (Rennie & Jarvis, 1995) and earth science education (Dove, Everett, & Preece, 1999). Most studies use drawings as an additional form that gives students the chance to express their ideas and conceptions beyond writing texts or answering interview questions.

As described by Neumann and Hopf, we implemented the same procedure to collect drawings from the students. The students received a blank sheet of paper and the word “Strahlung” (the German word for radiation, as used in the term “elektromagnetische Strahlung”) was written on the board in the classroom. The teacher or we asked the students to draw whatever comes to their minds, whenever they read or hear the word. During the period of drawing, the teacher did not answer any subject-specific questions and the students were encouraged to draw any motif. After 10 to 15 minutes the drawings were collected. To analyse the drawings, we categorised the motifs using the five main categories from Neumann and Hopf.

- The sun
- Artificial source of light (lamps, flashlight, …)
- Motifs related to radioactivity (nuclear power plants, radioactive warning sign…)
- Mobile phones
- Monitors (all types of different screens like, TV, computer or laptop)
In addition to those categories, we found new motifs, which we grouped into several side categories.

In this study, we collected drawings from 459 students (age 9 to age 12) from seven different schools. Three schools are located in Vienna and four schools are in the countryside of Upper Austria. The drawings were made and collected in December 2015. As shown in Figure 3 the process of data collection was done four years after the second and six years after the first study. To be able to compare our data to the previous study of Neumann and Hopf we decided to collect drawings in two schools (both in Vienna) from their study. We also collected Data from four other schools not represented in the original study.

![Timeline of the different studies](image)

To conclude the setting of the replication study was as near to the original study as possible to be able to compare the numbers. However, there was a major change in the data collection process. We did not differentiate the gender of the students. This decision was based on the fact that the results did not vary significant for most categories in the original study. We focused more on the overall numbers and the variation between the different age and location of our students. We addressed the following research questions.

- What do younger students (age 9 to 12) associate with the term “radiation”?
- Do those associations change with the age of the students?

As mentioned above we also searched for new motifs in the drawings.

**RESULTS**

In this study, we collected drawings from 459 students (age 9 to age 12) from different schools in Vienna and two smaller towns in the countryside. Our observations showed, that completing the task was easier for younger than older students. In Figure 4, the results are shown for the five main categories.

The percentage of drawings picturing the sun ($\chi^2 = 1.145, df = 1, p<0.01$) and radioactivity ($\chi^2 = 1.317, df = 1, p<0.01$) has not changed in a significant way. What stands out is the vast increase of pictures of mobile phones ($\chi^2 = 38.1, df = 1, p<0.01$) and monitors ($\chi^2 = 30.99, df = 1, p<0.01$). Both doubled the percentage from 2011 to 2015.

We assume, that the different accessibility to mobile phones and computers are the main reasons for this increase. Our hypothesis, that the increase in radioactive motifs from 2009 to 2011 should vanish, can be rejected, due to the slight but not significant increase in the
Strand 2

percentage (to about 35%). More interesting was the appearance of laser and laser swords in about 11% of the drawings (see Figure 5). However, there was a difference in the grades. The younger children drew the motif more often (27%) than the older one (5% in grade 6). In the months prior and during the data collection process, a huge media campaign for the new Star Wars film occurred, so we assume there was a connection between this event and the observed drawings.

![Figure 4. Comparison between the different studies.](image)

![Figure 5. Pictures of Lasers and Laser swords](image)

In addition to the appearance of LASER-themed drawings we identified two interesting subcategories. Neumann and Hopf found, that the vast majority (81.4%) of the drawings related to nuclear radiation had a negative connotation, especially after the accident in Fukushima. They even pointed out that only three drawings showed positive aspects of radioactivity. Although our results showed a similar amount of drawings related to radioactivity, we also found in 13.7% of our drawings positive aspects related to radioactivity or radiation in general.
The second subcategory we called the etymology category. To fit into this category the motifs should contain a connection to the word radiation or radiate. One example for those motifs was a picture of a smiling face (Figure 6). The German langue uses normally the term “to radiate with joy” instead of “to beam with joy”. So therefore there is a connection for the children to the word radiation. The same argument can explain the appearance of the number line in some drawings (Figure 7). The German translation would be “Zahlenstrahl” (number ray). We found those motifs in about 4.1% of our drawings.

CONCLUSION AND DISCUSSION

Overall, the results correspond with the previous study and the overall trend in the appearance of the different motifs, although there are some interesting exceptions, like the picture of lasers from above. Due to the fact that laser swords were part of the everyday life of the students at the time of the data collection, it is reasonable to link the appearance of this topic relate to radiation in the media to the frequency of the pictures of this topic in our research. This link is also a possible explanation for the increase of motifs for radioactivity in the original study. Neumann and Hopf hinted this link in their discussion as they wrote:

“The analysis of the interviews reinforced our hypothesis that the reason for this change in the students’ associations could be found in the tragic events of Fukushima.” (Neumann & Hopf, 2013, p. 1546)

However, we are not able to explain the result that in 2015 the frequency of radioactive motifs is as high as in 2011. The media coverage has rapidly decreased in the years after 2011 and so there should be a decrease. The results did not show much of a connection to the nuclear
disaster of Fukushima. The slight increase in the radioactivity category maybe occurred, because of the pictures of applications like cancer treatment that were linked to nuclear radiation. We think that this point should be investigated further in the future.

In our analyses we found pictures with smiling faces or the number ray and we decided to put those motifs into a new category. We called it the etymology category. Neumann and Hopf also discussed the impact of the language to their results.

“We assume that these results are strongly influenced by the German language since the German word Strahlung (radiation) is commonly used in everyday speech, especially in connection with the word ‘sun’.” (Neumann & Hopf, 2013, p. 1546)

In a similar fashion knowledge of the German language is necessary, to understand the connection between a smile and radiation. The phrase “A shining smile.” means, the face is radiating in German. And the “Zahlenstrahl” contains the word “Strahl” which can be translated with ‘ray’. Keeping those explanations in mind it seems obvious, that further research is necessary. Therefore we plan to conduct a study in different European countries (Denmark, Italy, France, … ) to validate the hypotheses that there are different motifs depended on the language and others that are independent (for example the motif of the sun). Due to the very simple instruction to the students the collected data should be comparable and we hope to get a better insight into the conceptions of children concerning radiation.

Overall we think, that this study helped to solidify some results from the original study. Therefore, we strongly recommend, that more replication studies should be conducted. We also see a possibility and a necessity to investigate this topic further.

ACKNOWLEDGEMENT

We would like to thank all the teachers and students participating in this study. We also like to thank Dr. Martin Hopf for his advice throughout the study and Dr. Susanne Neumann for providing us with additional unpublished information about her study.

ASSOCIATION BETWEEN THE ACADEMIC PERFORMANCE OF SECONDARY SCHOOL PUPILS AND THEIR EMOTIONS WHEN THEY ARE LEARNING PHYSICS AND CHEMISTRY

Mª Antonia Dávila Acedo, Florentina Cañada Cañada, Jesús Sánchez Martín and Diego Airado Rodríguez
Department of Science and Mathematics Education, University of Extremadura. Avda. de Elvas s/n, Badajoz, Spain.

The aim of this study was to determine the association between the academic performance (grades) in Physics and Chemistry of Spanish Compulsory Secondary Education (ESO) pupils and the emotions they experience relative to learning those subjects. The sample comprised 431 ESO pupils, distributed over three levels – 2nd, 3rd, and 4th of ESO – in various state and charter schools in the city of Badajoz (Spain) during the 2014/2015 school year. A descriptive research method was used based on an anonymous questionnaire that the participants completed concerning the emotions they experienced when learning Physics and Chemistry. They also reported the grades they had obtained. In overall terms, the results showed that the higher the grades, the more positive emotions the pupil experienced, and the lower the grades, the more negative emotions.

Keywords: emotions, academic performance (grades), secondary education, physics and chemistry.

INTRODUCTION

Teaching and learning are strongly charged with beliefs, attitudes, and emotions stimulated and directed towards people, but also towards values and ideals. Nonetheless, as Garritz pointed out (2010), science is mainly represented in schools as an area of the rational, analytical curriculum, with hardly any relation to emotions. For years, social, cultural, and emotional factors have been excluded, being labeled by the dominant positivist orientations as improper or unscientific, being contrary to the objectivity of science (Alsop & Watts, 2003; Vázquez & Manassero, 2007).

The transmission of science as a set of finished and indisputable truths has removed science from the pupils' concerns and from the emotion that historically marked the moments of the construction of knowledge (Mellado et al., 2014). Nonetheless, there are reasons to also believe that in the history of science "conceptual change is emotional as well as cognitive" (Thagard, 2008, p. 385).

Numerous studies (Hargreaves, 1998; Hargreaves, 2003; LeDoux, 1999; Ritchie et al., 2011; Shapiro, 2010; Sutton & Wheatley, 2003) have shown that both cognitive and affective aspects should be considered as influencing the process of teaching and learning. The reason is that the subjective and emotional world that we all develop from the external reality gives meaning to our relationships and allows us to understand the place we occupy in that reality. There are current lines of research focused on the importance of emotions in our society (Gardner, 2005; Punset, 2010), as well as on science teaching in particular (Hong, Lin & Lawrenz, 2012; Hugo,
Marbá & Márquez, 2010; Mellado et al., 2014; Vázquez & Manassero, 2007a, 2007b; Zembylas, 2005).

To help Physics and Chemistry teachers reflect on and plan their teaching so as to make it more effective, it is necessary to know what are their pupils' emotions towards Science in general, and towards those two subjects in particular (Cheung, 2011).

Teaching and learning scientific content is far more than just a cognitive process. Teaching is powerfully charged with beliefs, attitudes, and emotions that are directed not only towards people but also towards values and ideals. In this line, Garritz (2010) states that in primary and secondary schools, and in universities, science is for the most part symbolized as being an area of the rational, analytical, and non-emotive curriculum. In addition, curricular documents and science teachers both normally present images of science and its content that are far removed from anything related to the emotions.

Learning science is much more than a cognitive process because, in order to learn, it is necessary to be able to do (skills, knowledge, and capabilities) and to want to do (disposition, intention, and motivation) (Bacete & Betoret, 2000). If, as pointed out by Bisquerra & Pérez (2007), academic knowledge is learnt better when the pupils have emotional competencies then it is necessary to analyse both the cognitive and the affective aspects of learning different scientific content (Garritz, 2009). Diagnoses of the emotions that occur every day in secondary classrooms will therefore provide a basis for intervention in the improvement of science learning by designing activities that promote more positive emotions (King, Ritchie, Sandhu & Henderson, 2015), since positive emotions foster learning whereas negative emotions limit the ability to learn (Pekrun, 1992; Vázquez & Manassero, 2007).

In learning, the emotions that pupils experience depend on whether the perception they have is of success or of failure. Positive emotions from a sense of achievement will lead to increased effort and self-esteem, but when a pupil does not perceive those possibilities of achievement they will give up trying (Weiner, 1986). Because of this, in the context of schools and learning, an individual's motivations can influence their behaviour, strategies, and relationships.

Given this background, the objective of the present study was to determine the association between the emotions experienced by Spanish Compulsory Secondary Education (ESO) pupils when learning Physics and Chemistry and their academic performance (grades) in that area.

**RESEARCH OBJECTIVE**

This research is aimed at achieving the following objective:

- To determine the relationship between the emotions experienced by ESO pupils when learning Physics and Chemistry and their academic performance (grades).
RESEARCH METHODS

Sample

The sample consisted of 431 pupils of 2nd, 3rd, and 4th year Compulsory Secondary Education (ESO) from various schools in Badajoz (Spain) during the 2014/2015 school year. Table 1 lists the distribution of the pupils by year.

Table 7. Distribution of the pupils by year.

</tr>
<tr>
<td>4th ESO</td>
<td>130</td>
<td>30.1</td>
</tr>
</tbody>
</table>

Of the pupils, 47.1% were girls and 52.9% boys. Their ages were between 13 and 17 years, with the average being around 14-15 years.

Instrument

A questionnaire-based descriptive method was used for the study. The questionnaire was elaborated by the researchers, taking into account some of the ideas in the questionnaire used by Borrachero (2015) which sought the opinions of prospective secondary teachers on what they remembered of their emotions towards Physics and Chemistry during their own period as learners at school.

We classified the pupils' emotions on the basis of the categorizations described by various authors (Bisquerra, 2009; Borrachero, 2015; Casacuberta, 2000; Damasio, 2010; Francisco, Gervás & Hervás, 2005). Table 2 lists the 7 positive emotions (joy, trust, fun, enthusiasm, satisfaction, surprise, tranquillity) and the 7 negative emotions (boredom, anxiety, disgust, fear, nervousness, worry, sadness) selected for this research. These emotions were measured on an 11-point Likert scale where "0 = never" and "10 = maximum frequency". A Cronbach’s alpha of 0.824 was obtained for the reliability of both the positive and the negative emotions.

<td>Sadness</td>
</tr>
</tbody>
</table>

The respondents were also asked to establish numerically their final grades in the previous course (in Nature Sciences for the 2nd of ESO pupils, and in the subject of Physics and Chemistry for the 3rd and 4th of ESO pupils) within the range from 0 (minimum score) to 10.
(maximum score). The data were processed using the statistics software package SPSS 22.0 for Windows. The Pearson correlation test was used to check for significant relationships between the emotions experienced by the ESO pupils when learning Physics and Chemistry and the grades they obtained, applying a 95% confidence interval.

RESULTS

In this section, we shall present the results of the analysis of the emotions experienced by the Compulsory Secondary Education pupils when learning Physics and Chemistry, and their academic performance (grades).

Table 3 lists the Pearson correlation coefficients and the significance levels obtained for each emotion, both positive and negative. For all of the positive emotions experienced by the pupils when learning Physics and Chemistry, there were positive (r>0) and significant (* p≤0.010, ** p≤0.050) correlations. Thus, higher grades obtained by the pupils corresponded to greater frequencies with which they experienced the positive emotions, and lower grades corresponded to lower frequencies.

Table 3. Pearson's correlation coefficient between positive emotions and academic performance.

</tr>
</tbody>
</table>

In the case of the negative emotions (Table 4), there were negative (r<0) and significant (* p≤0.010, ** p≤0.050) correlations for boredom, anxiety, disgust, fear, worry, and sadness. In this case therefore, higher grades obtained by the pupils corresponded to lower frequencies with which they experienced those negative emotions, and lower grades corresponded to higher frequencies.

CONCLUSIONS

From the results of this research, one can state that there is a relationship or association between the emotions these Compulsory Secondary Education pupils feel towards learning Physics and Chemistry and the grades they get in this area.

Thus, pupils with high grades experienced greater frequencies of the positive emotions and lower frequencies of the negative ones. Conversely, when the grades obtained were low, the frequencies with which they experienced positive emotions were lower and those of the negative emotions higher.

These results are consistent with the study by Goetz, Frenzel, Hall & Pekrun (2008) of 5th and 6th year Mathematics pupils on the relationship between their academic performance in that subject and the emotions they feel. The pupils with better performance experienced more positive feelings towards activities related to Mathematics, with a reduction in the anxiety that this subject usually generates in pupils.

In a study involving 1st year undergraduates doing different degrees, Borrachero, Davila & Costillo (2016) found an association between their course marks and their recall of the emotions that they had experienced as secondary school pupils when learning scientific subjects. The students with high marks recalled having experienced positive emotions towards the sciences, and those with low marks, negative emotions.

GENDER BIAS IN THE ASSOCIATION BETWEEN LONG-LASTING LEARNING AND PAST ACADEMIC EMOTIONS

José María Marcos-Merino¹, Rocío Esteban Gallego¹ and Jesús Gómez Ochoa de Alda²

¹Science and Mathematics Education Department (Faculty of Education, University of Extremadura), Badajoz, Spain; ²Science and Mathematics Education Department (Teacher Training College, University of Extremadura), Cáceres, Spain.

Emotional state and learning are reciprocally conditioned. To ascertain if this relation is maintained in the long-term, we studied the association between learning outcomes acquired since compulsory education (such as prevalence of misconceptions and key concepts of Cell Biology and Genetics) and emotions experienced in two academic settings (lectures and practices) of 152 students enrolled in a course of science education for prospective teachers. Results support a long-lasting interplay between emotions experienced in these academic settings and learning outcomes, being this association gender biased.

Keywords: academic emotions, academic setting, gender bias.

INTRODUCTION

Classroom is an emotional place: there is virtually no major human emotion not experienced in academic settings. In spite of this diversity, most academic emotions have been largely neglected by educational research for years (Pekrun, Goetz, Titz and Perry, 2002). Cognition (such as memory, attention, language and problem solving) and emotions are integrated in the brain in critical areas for regulating the flow of information between regions. Moreover, it is well known that emotional information is preferentially remembered (Kensinger and Corkin, 2004) since people are motivated to remember details of emotional events as this information is useful for controlling future events (Dunsmoor, Murty, Davachi and Phelps, 2015). In addition, emotions are expected to have important effects on students’ learning since control their attention, influence their motivation to learn and modify their learning strategies. To understand students’ emotions, it is necessary to consider that emotions can vary across school subjects (Goetz, Frenzel, Pekrun, Hall and Lüdtke, 2007), settings and time, even within each individual student (Pekrun, 2014).

The complexity of emotional processes and the diversity of physiological responses make difficult to integrate emotions in a single discrete measure. Nowadays, measurement of self-reported emotions is among the most commonly method used, since it is easy to implement, it hardly affects the development of classroom’s activities and provides measures of subjective and verbalized emotional experiences. However, these measurements must be carefully interpreted since some biases may occur between momentary self-reported emotions and beliefs about past academic emotions (Robinson and Clore 2002).

Since the pioneer work of Pekrun and co-workers, academic achievement emotions, those concerning achievement activities and outcomes, have been one of the most studied (Goetz, Sticca, Pekrun, Murayama and Elliot, 2016), since they are significantly associated to learning outcomes. However, this association, in the long-term, is rarely explored. For that purpose, in
this contribution we developed a quantitative self-report test to estimate students’ emotions, validated through factor analysis. Results show that emotions felt by a group of prospective teachers during Secondary Education were correlated with learning outcomes corresponding to this educational stage. We also provide evidences of a gender bias.

**METHOD**

**Participants**

A sample of 152 volunteers (64% female, average age 22) was obtained from three groups of students enrolled in the Bachelor in Primary Education at University of Extremadura in its two campuses in Cáceres and Badajoz (Spain). Study participants answered two questionnaires before a practical activity related to Cell Biology Education: one on the emotions they felt in different academic settings and one routine assessment on core Biology concepts. Prior to participation, students were informed about the goals of the research, duration, procedure and anonymity of their data. Participation was voluntarily and it was possible to withdraw participation at any time. All participants provided verbal informed consent prior to data collection.

**Assessing academic emotions and core Secondary Biology concepts**

Based on Pekrun’s contributions (Pekrun *et al.* 2002), we developed a simple and fast quantitative self-report questionnaire measuring ten academic emotions (joyful, trusting, satisfied, enthusiastic, fun, worried, frustrated, uncertainty, nervous, bored). The order was randomized and kept constant. In line with recent works (Goetz *et al.*, 2016; Gogol *et al.*, 2014), academic emotions were assessed using single items since, compared to longer multi-item state measures, provide enough validity, require less time and are less intrusive with emotional responses of participants. Emotions were rated on a Likert scale from 1 “not experienced” to 5 “intensely experienced”. Students reported their emotions associated with two past academic settings: class lectures and practices either at laboratory or field. In this way, we expected to collect information of trait (habitual) emotions. By contrast, to collect state (momentary) students’ emotions, we asked their emotions before an incoming practice (a DNA extraction using common household items).

Biology fundamental concepts were assessed through true/false questions about common misconceptions of Cell Biology and Genetics in Secondary school (Banet and Ayuso, 2003; Chattopadhyay, 2005; Caballero, 2008; Wood-Robinson, Lewis and Leach, 2000) as well as multiple-choice questions extracted from TIMSS (Trends in International Mathematics and Science Study), which is designed to estimate science achievement in Secondary Education pupils, aged 12 and 16 (Foy, Arora and Stanco, 2013).

**Statistical analysis**

Data were compared using non-parametric statistical tests (Wilcoxon and Spearman correlation tests) since they did not fit a normal distribution. The data of the three groups of students were grouped into a single one after verifying the absence of significant differences between them. The normality tests (Kolmogoro-Smirnov and Shapiro Wilk), the correlation analysis
(Spearman) and the exploratory factor analysis were performed with the software SPSS v19 (IBM software). For the extraction of the factors were used generalized least squares and oblimin rotation. Once calculated, the factors were stored as centered variables. Sample adequacy, reliability and fit of factorial models were assessed using Kaiser-Meyer-Olkin, Cronbach's alpha and $\chi^2$ tests, respectively. The non-parametric tests used to compare groups and graphs were performed using the Kaleidagraph v5 program (Synergy software).

RESULTS

Exploratory factor analysis: factors associated to positive and negative academic emotions

Data of the intensity of emotions experienced by students were subjected to a factor analysis (Table 1). It was performed before analyzing intercorrelations between emotions, studies that showed that:

- Positive and negative emotions correlate low, which support discriminant, construct validity (we are not measuring the same)
- Significant correlations among positive and negative emotions (which suggest the presence of an underlying common factor)

According to a reliable exploratory factor analysis (sample adequacy measure KMO>.8, Cronbach's alpha >.7 and $\chi^2$ tests>.05), emotions experienced by participants in each academic setting can be modeled into two factors: one for positive emotions (factor 1) and one for negative emotions (factor 2). This allowed us to extract six factors (Table 1).

Boredom showed, in all cases, an intermediate behavior since it negatively correlated with factor 1 and positively with factor 2. This situation has been observed by previous studies (Pekrun et al. 2002).

Table 1. Factor analysis performed with emotion intensity data. It is shown the sample adequacy measure (KMO), the test $\chi^2$ (p-value) and the structure matrix in which the highest correlations are highlighted in bold.

Distribution of emotions’ intensity across different trait and state academic settings: evidences of a gender bias

Results evidence the ability of students to differentiate the intensity of their emotions across different past and present academic settings (Figure 1). Compared to practices, lecture setting was characterized by higher boredom and frustration and lower intensity of positive emotions such as joy, enthusiastic, trusting and fun. A gender bias was observed in this effect, in particular for positive emotions (Figure 2).

Figure 1. Distribution of positive (A) and negative (B) self-reported emotions in lectures (empty boxes) and practices (gray boxes) (**p-value < 0.001, Wilcoxon test). The horizontal thick line inside each box is the median, and the top and bottom are the 25th and 75th percentiles. The top and bottom ends of the vertical lines approximate the 95th and 5th percentiles, respectively.

Then, females experienced more joy, trusting, satisfaction, enthusiastic and fun in practices than males. This pattern also appears with all inquired positive emotions for a state biological practice (DNA extraction). Within negative emotions, nervousness was more experienced in practices. There are no significant evidences of gender bias in this sort of academic emotions (Figure 3), excluding frustration in a state practice (males thought that they will feel more frustrated than females performing this laboratory practice).

Regarding analysis of trait and state academic emotions, males distinguished between some habitual and momentary emotions during practices, such as enthusiasm and boredom (Figure 2). Females, by contrast, were able to differentiate more habitual and momentary emotions (such as joy, nervousness, boredom, and worry) (Figures 2 and 3). This suggests that our test also informed about trait and state emotions.
Figure 2. Distribution of positive emotions self-reported by females (empty boxes) and males (gray boxes) during past lectures (L) and laboratory practices (P) of Biology, and just before a practical experience of DNA extraction (D). The lines above the boxes connect groups of emotions evidencing gender bias for a given academic setting (GB), and groups of emotions significantly different in males (M) and females (F) in different academic settings (Wilcoxon test, ***p-value < 0.001, **p-value < 0.01, *p-value < 0.05). The horizontal thick line inside each box is the median, and the top and bottom are the 25th and 75th percentiles. The top and bottom ends of the vertical lines approximate the 95th and 5th percentiles, respectively.

Figure 3. Distribution of negative emotions self-reported by females (empty boxes) and males (gray boxes) during past lectures (L) and laboratory practices (P) of Biology, and just before a practical experience of DNA extraction (D). The lines above the boxes connect groups of emotions evidencing gender bias for a given academic setting (GB), and groups of emotions significantly different in males (M) and females (F) in different academic settings (Wilcoxon test, ***p-value < 0.001, **p-value < 0.01, *p-value < 0.05). The horizontal thick line inside each box is the median, and the top and bottom are the 25th and 75th percentiles. The top and bottom ends of the vertical lines approximate the 95th and 5th percentiles, respectively.
Analysis of the interplay between emotions and Secondary Biology knowledge: evidences of a gender bias

Spearman correlations detected significant associations between the mark obtained in the assessment of Cell Biology contents taught at Secondary Education and the intensity of single academic emotions. Students who showed a better previous knowledge were those who experienced less nervousness, worry and uncertainty in lectures and less boredom, frustration and worry in practices. Moreover, these students experienced more joy, satisfaction and enthusiasm in practices and less enthusiasm and fun in lectures. The correlation analysis as well as the linear regression graphs (Figure 4) between previous Biology knowledge and emotions factors supported these results. There is a significant negative correlation between negative emotions and previous knowledge in both lectures and practices and a significant positive correlation between positive emotions experienced in practices and previous Biology knowledge.

Figure 4. Linear regression between Cell Biology previous knowledge and factors of positive (continuous line) and negative (dashed line) emotions

Regarding gender analysis (Table 2), in females positive emotions during lectures (joyful, enthusiastic and fun as well as factor associated to positive emotions experienced in this academic setting) were negatively associated with long-term learning outcomes whereas in males this association was not significant. In contrast, male outcomes were positively associated with positive emotions for practices (joyful and satisfaction in the case of single
emotions) and negatively associated with negative emotions during lectures (nervousness, frustration and worry in the case of single emotions) and practices (only worry if we study single emotions). Studies of Spearman correlation using factors associated to each sort of academic emotions in each academic setting support these results.

Table 2: Spearman correlations (**p-value<0.01, * p-value<0.05) between knowledge of Cell Biology concepts and single emotions (left) and factors (right) in females (F) and males (M) in different academic settings. Bold highlights significant correlations.

**DISCUSSION AND CONCLUSIONS**

First of all, we develop a fast and simple quantitative test to assess academic emotions, which was designed following previous works in relation to selected academic emotions (Mellado, Borrachero, Dávila, Melo y Brígido, 2014) and regarding its construction: a self-report (Robinson and Clore, 2002) questionnaire of simple items (Goetz et al., 2016; Gogol et al., 2014; Pekrun et al., 2002). This test shows construct validity and reliability, since has been validated through an exploratory factor analysis, obtaining similar results than Pekrun and co-workers’ studies.

Results evidenced the ability of students to differentiate the intensity of their emotions across different academic settings, confirming previous findings about the diversity of academic emotions (Pekrun et al., 2002; Raccanello, Brondino, and Bernardi, 2013), although one latent factor is associated with each valence and academic setting. Regarding trait and state emotions, students (especially females) are able to differentiate between the intensity of some academic emotions in a past academic setting and in an equivalent academic setting of present. This is in contrast to studies of Robinson and Clore (2002).

Moreover, our results support a long lasting interplay of academic emotions and learning (Pekrun et al., 2002), since we observe a long-lasting link between Biology Secondary learning outcomes and academic emotions experienced by students at this educational stage, at least five years ago. Since emotional information is better remembered (Kensinger and Corkin, 2004), learning could be encouraged if negative emotions, in all academic settings, were reduced and positive emotions experienced in practices were increased. Regarding gender bias analysis, the negative association of positive emotions to female achievement raises questions about how students’ positive emotions might be regulated effectively so that they remain focused on the intended learning (Pekrun et al., 2002; Goetz et al., 2016).

STRAND 3: INTRODUCTION
SCIENCE TEACHING PROCESSES

The contributions to strand 3 “Science Teaching Processes” shed light on current trends in science education research with a focus on the relations between teaching practices and students’ cognitive and affective development. In the majority of cases, the projects report on the design of research-based teaching interventions and their role for learning outcomes. Methods are supposed to embrace multiple approaches including video analysis in science education.

The twelve contributions submitted to strand 3 of the ESERA 2017 ebook consist of eleven accounts on research and development projects from all over Europe and Asia as well as a Swedish teacher workshop that was conducted at ESERA 2017 conference. The eleven research and development papers can roughly be divided into three groups with different foci of investigation: While the majority of papers evaluate a novel or adapted teaching intervention and their impact on students, such as different modes of inquiry-based student activity or differentiated learning environments, others focus on teacher competencies and their progression through interventions or relate teacher beliefs and student outcome with each other. Methodologically, the studies show a diverse scope from case studies collecting and interpreting qualitative data to experimental studies with pre-post-test designs using instruments to measure cognitive and/or affective variables.

In terms of teaching approaches, a slight focus can be found on the evaluation of inquiry-based student activities: While the mode of laboratory activity and its effect on student knowledge is investigated in interdependence with teacher beliefs in two papers (Muth & Erb; Weber et al.), a third contribution focuses on the role of teacher feedback during inquiry-based student activities (Eckes & Wilde). The papers report on data that show the effects of the intervention on student affective and cognitive variables while the intervention itself is not monitored by data collection.

Another three papers investigate novel or adapted teaching approaches with the aim of fostering student affective and/or cognitive outcomes. For teaching at school level, a digital educational scenario is presented that aims at motivating interdisciplinary problem-solving on the basis of gamification (Theodoropoulou et al.), while the approach “Ladders of Learning” adapted from India is examined with regard to its potential as a differentiated learning environment (Hauerstein & van Vorst). For higher education, Kraus and colleagues evaluate a physics course on general relativity which focuses on a model-based and conceptual rather than a mathematical approach (Kraus et al.).

It is interesting to note, however, that these studies investigate students’ responses to a variety of interventions without investigating the implementation of the actual intervention by means of process analysis. The interplay of student and teacher interaction in the learning process is only observed by one paper (Ha & Kim). They examine teachers’ responsive practices to support students’ epistemologically productive practices by means of argumentation analysis. The interdependence of teacher beliefs and student outcome is also investigated in a
A correlational study using quantitative data (Korom et al.) reports on the relationship of teaching strategies and student reasoning skills.

Focusing on the part of the teacher, one paper reports on multiple studies on teacher topic-specific content knowledge in the area of chemical bonding (Rollnick et al.). Eliciting pre-conceptions, the authors report on ways to diagnose and professionally develop scientifically correct views on the topic.

Concerning the used methods, it is striking that little process analysis, such as video-based analysis in the classroom or intervention group, is used to tackle and explain the learning processes that lead to certain student affective or cognitive outcomes. On the other hand, a number of papers pursue the goal of explaining the effects of the intervention on students by directly relating it to teacher beliefs such as the preferred teaching strategy investigated through questionnaires.

The combination of papers also underlines the trend that the selection of specific scientific topics for the investigation is not necessarily justified by the authors. The scientific topics rather become a vehicle to study the respective intervention which is often based on general educational principles (e.g., digital learning, feedback). Exceptions can be found in the course on relativity (Kraus et al.) and the symposium paper on chemical bonding (Rollnick et al.).

Sabine Fechner and André Tiberghien
INFLUENCE OF THE POSTPROCESSING-PHASE OF AN EXPERIMENT IN THE PHYSICS CLASSROOM

Laura Muth and Roger Erb
Institute for Physics Education, Goethe-University, Frankfurt, Germany

The preparation and postprocessing of experiments in the physics classroom and their embedment in the course of the lesson have a great influence on the quality of the lesson (Tesch and Duit, 2004). However, only few studies are concerned with the structure of these two phases. A study by Winkelmann (2015) could prove that learners increase their knowledge during the postprocessing-phase of an experiment. The present study should follow up at this point. Within the framework of a comparative study, it examines the question how the postprocessing-phase of an experiment in the natural science classroom should be structured in order to achieve the best results in the increase of physics knowledge and growth of experimental competencies of students. Therefore, three variations of postprocessing with a different degree of student activity are contrasted. Furthermore, the importance of teachers’ beliefs concerning scientific inquiry and the school subject physics for the students’ learning progress is evaluated. This field study is designed in a pre-post-test design and conducted in physics lessons in schools to ensure a natural learning environment.

Keywords: science learning, postprocessing of experiments, teacher influence

INTRODUCTION

Research findings of the last years have shown that the experiment plays a major role in the natural science classroom. Not only the conducting-process, but also the preparation and the postprocessing of an experiment have a great influence on the quality of the lesson (Tesch and Duit, 2004). However, research does not provide much evidence on how these two phases of the experiment (preparation and postprocessing) should be designed in order to achieve the best increase in physics knowledge. Still, a study by Winkelmann (2015), who investigated the difference between practical work and teacher demonstrations in the conducting-phase of the experiment, could find out that students also increase their knowledge significantly during the postprocessing-phase. Therefore, it seems interesting to take a closer look at the postprocessing-phase by contrasting several postprocessing situations with different degrees of student activity. As an addition to the competence area of physics knowledge, the development of the experimental competencies of the students should be analysed.

As another result, Winkelmann (2015) could determine the relevance of the interdependency between the experimental situation and the teacher. He could find out that apparently (with a small effect), it is less the experimental situation itself that plays a role, but rather which teacher decides which form of experimentation to use. Therefore, data about teacher beliefs concerning scientific inquiry and the school subject ‘physics’ is collected in this study, in order to draw conclusions about the role of teachers’ beliefs and the interdependency between teacher and experimental situation.
THEORETICAL BACKGROUND

Teacher Beliefs

Teachers and their beliefs have a great influence on the quality of teaching and thus on the learning and the motivation of the students (Helmke, 2012). In an experiment, the activity of the students can vary from simple observations to completely independent work. Thus, the role of the teacher can vary from strongly guiding to loosely supporting. For this reason the beliefs of the teachers on the school subject ‘physics’ and on scientific inquiry appear particularly interesting. A distinction should be made between teachers with rather constructivist and teachers with rather transmissive beliefs.

In order to categorize the teachers, a questionnaire by Lamprecht (2011) was used, who could identify three types of teachers: the so called instructivist, the constructivist and the mediator. In addition to a different understanding of scientific inquiry, the three teacher types differ in their constructivist beliefs:

1. Instructivist: These teachers emphasize students learning by detailed instructions of the teacher and oppose autonomous learning of students.
2. Constructivist: These teachers emphasize the importance of autonomous learning of students and do not support students’ learning by detailed instructions of the teacher.
3. Mediator: Mediators emphasize the importance of autonomous learning of students but do also support students’ learning by detailed instructions of the teacher.

Therefore, the instructivist has the strongest transmissive and the constructivist the strongest constructivist beliefs. The beliefs of mediating teachers are positioned in between.

The experimental process

Research on experiments is extensive, but not always consistent. As a basis of the present study, the definition of the natural science experiment according to Millar (2010) is used, who describes the experiment as an activity, ‘[...] which involves an intervention to produce the phenomenon to be observed or to test a hypothesis’ (Millar, 2010, p. 109 according to Hacking, 1989).

In many studies, the science experiment is split into three phases:

1. preparation or planning,
2. conduction and
3. evaluation or postprocessing.

Regarding the components of the experimental process the Scientific Discovery as Dual Search (SDDS) model by Klahr and Dunbar (1988) is used frequently. Klahr and Dunbar (1988) describe the experimental process as a problem solving process. Therefore, an initial state is to be converted into a desired target state through problem solving. This is done in three steps:

1. search in the hypothesis space,
2. testing of hypotheses / search in the experiment space,
3. analysis of evidence.
By considering this and numerous other models, Vorholzer et al. (2016) could identify three central sub-competencies of scientific thinking and experimental techniques that are compatible with the three phases of the experiment (Table 1).

Table 1. Phases of the experiment and related competencies concerning to Vorholzer et al. (2016)

<table>
<thead>
<tr>
<th>Phase of Experiment</th>
<th>Sub-competencies concerning to Vorholzer et al. (2016)</th>

</tr>
<tr>
<td>Conduction-phase</td>
<td>plan and carry-out the experiment</td>
</tr>
<tr>
<td>Postprocessing-phase</td>
<td>analyse and interpret data.</td>
</tr>
</tbody>
</table>

While research shares the understanding of these central competencies, the associated abilities and skills of the learners are rarely clearly specified or differ enormously. Therefore, the first step of this research project was the conception of a suitable model that concretises the competencies for the postprocessing-phase of a school experiment.

After careful examination of the state of research (Asay and Orgill, 2010; Börlin, 2012; Chinn and Malhotra, 2002; Doland and Grady, 2010; Glug, 2009; Klahr and Dunbahr, 1988; KMK, 2004; Mayer, 2007; Schreiber, 2012), a model was designed which divides the postprocessing-process into three phases. In the first phase the preparation and processing of the measurements data takes place, followed by the formulation and interpretation of results in the second phase. In the third phase, measurement errors are to be considered.

In order to examine whether the developed model was also accepted by experts from theory and practice, it was subjected to a survey involving education experts from universities, school teachers and teachers in training. In this expert survey, three questions should be answered:

1. Are the components of the designed model relevant for the postprocessing-phase of an experiment?
2. Is the model complete?
3. Do teachers and education experts at the universities appreciate the components similarly relevant?

A questionnaire with 19 items was developed in which the experts should assess the components on a 4-level Likert scale with regard to their relevance. 95 experts participated in the survey of which around 3/4th could be classified as scientists from universities (Figure 1).

The survey showed that almost all the components presented were considered relevant by the experts. Two items classified as less relevant were removed from the model, two missing components were added. There were no significant differences in the response behavior between teachers and education experts from universities. The final model of postprocessing competencies of a natural science experiment with the three phases mentioned above and the associated abilities and skills is presented in Figure 2.
RESEARCH QUESTIONS

Building on the findings of Winkelmann (2015), the study covered several research questions, including:

Q1: In how far do postprocessing situations of experiments in the physics classroom with different degrees of student activity affect the development of the students in the areas of physics knowledge and postprocessing competencies?

Q2: What influences do the beliefs of teachers concerning scientific inquiry and the school subject ‘physics’ have on the development of physics knowledge and postprocessing competencies of students?
METHOD

Setting

The study is designed as a comparative study that investigates the development of students’ knowledge and competencies through guided and autonomous evaluation of teacher demonstration experiments. It is a quasi-experimental intervention-study in physics lessons in grade seven. A complete randomization could not be realized due to practical reasons. Therefore, the tests and interventions were carried out in the usual classes by the usual teachers. To test the learning effect of the designed lessons, a paired t-test is carried out followed by an Analysis of Variance (ANOVA) to determine possible differences in knowledge growth between the comparison groups. In the ANOVA, the “teacher” and the “postprocessing situation” are fixed factors while the “physics knowledge” and the “postprocessing competencies” are the dependent variables.

Treatments and comparison-groups

To answer the research questions above, three postprocessing situations with different degrees of student activity were developed:

1. Teacher demonstration: The postprocessing-phase is guided and carried out by the teacher.
2. Guided: The postprocessing-phase is carried out by the students in small groups. The students are guided by detailed instructions on work sheets.
3. Autonomous: The postprocessing-phase is carried out by the students in small groups. The process is not guided in any way.

In the conducting-phase of the experiment, teacher demonstrations are realized. Therefore, the study is realized as a 1x3 design with three comparison groups as shown in Table 2.

Table 2. Differentiation between comparison groups by acting party

<table>

</tr>
<tr>
<td>Teacher Demonstration</td>
<td>Teacher</td>
</tr>
<tr>
<td>Guided</td>
<td>Teacher</td>
</tr>
<tr>
<td>Autonomous</td>
<td>Teacher</td>
</tr>
</tbody>
</table>

For reasons of simplicity the first two phases (preparation and conduction) should be referred to as conduction-phase for the rest of the paper.

Course of the study

The study is realised in a pilot and a main study. The pilot study was carried out in winter 2015/2016 with the aim of testing, analyzing and, if necessary, revising the developed measuring instruments. Results of the pilot study can be found in Muth & Erb (2016). In winter 2016/2017, the revised measuring instruments were used to carry out the main survey, in which
the students’ knowledge increase in the areas of physics knowledge and postprocessing competencies as well as the teachers' beliefs concerning scientific inquiry and the school subject ‘physics’ were collected.

The intervention comprises ten 45-minute lessons. In the first two lessons the pretest and an introduction are carried out. In this introduction, the teacher performs an experiment as an example with the students. The learners should observe how the teachers plan and carry out the experiment and what steps should be taken during the postprocessing-phase. This is intended to ensure that pupils who are to evaluate the experiments autonomously in the next sessions get an idea of how the postprocessing of an experiment is usually carried out. In the following six lessons, the actual intervention with six experiments takes place. In each lesson one experiment is carried out and evaluated. In the final lesson, the posttest is completed.

**Measuring instruments**

Table 3 provides an overview of the five measuring instruments used in the main study and their associated application times:

</tr>
</tbody>
</table>

In order to be able to allocate the teachers to the three teacher types according to Lamprecht (2011), they complete a questionnaire concerning their beliefs at any time during the intervention.

In the first lesson, the students complete a cognitive performance test and a questionnaire on personal data. This serves to estimate the homogeneity or heterogeneity of the sample afterwards. Since these data is considered to be stable, it is sufficient to collect them at only one measurement time. These tests are followed by a physics knowledge test according to Winkelmann (2015) and a test for postprocessing competencies. In order to be able to differentiate the influence of the postprocessing-phase from the impact of the overall experiment on the physics knowledge increase, the students complete an intermediate test after the conduction but before the postprocessing of each experiment. These six intermediate tests
sum up to be exactly the pre or post physics knowledge test. At the third point of measurement, the students complete the questionnaire on physics knowledge and postprocessing competencies again. The three times of measurement are intended to test the learning progress between pre- and post-test (knowledge increase due to the entire experiment) as well as between intermediate tests and post-test (knowledge increase due to the postprocessing-phase).

RESULTS

In total, 376 students in 18 classes (Teacher Demonstration: 6, Guided: 6, Autonomous: 6) with 10 teachers took part in the study. These numbers show that although the sample is satisfactorily high on student side, the number of teachers is still very small with only 10 participants. For this reason, the results concerning the teachers must be interpreted with utmost caution. Among the 10 teachers, four could be identified as instructivists, three as constructivists, and four as mediators. Table 4 shows that not all factor combinations could be filled. Therefore, results on the interaction between teacher and treatment should not be interpreted for the current sample.

Table 4. Distribution of the teacher types on the treatments

<td>2</td>
<td>2</td>
<td>2</td>
</tr>
</tbody>
</table>

The results of the t-tests could show that the students increased their physics knowledge in both the conduction (\(p < .001, \eta^2 = .2\)) and the postprocessing-phase (\(p < .001, \eta^2 = .02\)) significantly (Figure 3). A significant increase between pre- and posttest (\(p < .001, \eta^2 = .02\)) was also found in the postprocessing competencies (Figure 4).

Regarding the treatment, Figure 5 and 6 indicate an advantage for the guided treatment. However, the results of the ANOVA show that the differences in knowledge increase are not significant for both physics knowledge and post processing competencies. The test-power \(\beta\) is sufficiently high.
In the course of the demonstration experiment, instructivist teachers were able to generate the most growth in physics knowledge, followed by the constructivists ($p < .001$, $\eta^2 = .16$). A contrasting picture is obtained for the postprocessing-phase. In this phase mediators were able to achieve the greatest increase in physics knowledge, followed by constructivist teachers ($p = .001$, $\eta^2 = .035$) (Figures 7 and 8). The differences between the mediators and the other two teacher types are significant in both cases.

With regard to the postprocessing competencies, students with teachers from the mediating type could benefit the most. However, the differences between the three teacher types are not significant in this case. The test-power $\beta$ is sufficiently high.

Figure 5. Increase in physics knowledge by teacher in the conduction phase (CP) and the postprocessing-phase (PP) of the experiment

Figure 6. Increase in postprocessing competencies by teacher
DISCUSSION AND CONCLUSION

The results of the t-tests could show, that the designed lessons are beneficial for the knowledge increase for both subject knowledge and postprocessing competencies and that students increase their knowledge significantly during the postprocessing-phase of the experiment. However, the larger effect with $\eta^2 = .2$ could be found in the planning and conduction phase.

With regard to Q1, it can be stated that students who have completed the postprocessing-phase autonomously have been able to increase their physics knowledge and post processing competencies to the same extend as students who have evaluated the experiment together with the teacher. This could mean that teachers should let the student work independently more often. The learners can acquire knowledge just as good as in a teacher guided scenarios, but at the same time autonomous work promotes the development of other competencies (for example social competencies) as well.

For Q2, it could be shown for the present sample that instructivist teachers were particularly successful in the conduction-phase of the experiment. However, mediators were most successful in the postprocessing-phase. Since the actual intervention with treatment variations only took place in the postprocessing-phase, this could indicate that teachers with transmissive beliefs can teach particularly well in teacher-oriented situations (here demonstration experiments), while teachers with both constructivist and transmissive beliefs (=mediators) can respond more flexibly to teaching situations with different degrees of openness. However, it must be stressed here that the sample with only 10 teachers is clearly too small to make generalizable statements. The interpretation can only refer to the present data situation.

It seems worthwhile to carry out further research at this point in order to increase the sample on the teachers. Thus, on the one hand, research question Q2 could be answered more meaningfully, on the other hand an interaction analysis between teachers and treatments could be carried out.

SUBJECT KNOWLEDGE IN GEOMETRICAL OPTICS: TESTING AND IMPROVING STUDENT’S KNOWLEDGE

Jeremias Weber, S. Franziska C. Wenzel, Jan Winkelmann, Mark Ullrich, Holger Horz and Roger Er
Goethe-Universität Frankfurt, Frankfurt am Main, Germany

In physics education experiments are used quite often and take up a lot of time in the classroom. For something which is as important as this, it is still unclear which kind of experimental situation (ranging from teacher demonstrations to hands-on student experiments) is the best approach to improve student learning. In this project, the following situations were compared: Demonstration experiments done by the teacher, cook-book-experiments done by the students and free-form experiments done by the students. To measure the improvement in subject knowledge, an IRT-scaled test was constructed: Items from previous works were used in a pre-study to estimate difficulty and item-total-correlation. These were then used to construct a pre-post-test study design which was given to ca. 1000 students which were also submitted to the various experiment approaches. Results from previous research suggest that there is an interaction between teacher’s concepts, the specific experimental situation and the improvement of subject knowledge: If the teacher uses a situation which fits his own concepts, students improve significantly better. In order to investigate this further, cognitive ability as well as subject knowledge in geometrical optics and current interest in physics was measured. In addition, the teachers were asked to fill out a survey, which should identify their concepts about physics education. First results, based on the data collected so far, will be presented to emphasize for the variegated impact of classroom experiments in physics education.

Keywords: physics education, geometrical optics, IRT

THEORETICAL BACKGROUND

Motivation

Experiments are an important part of many national physics curricula. This is not only grounded in physics as a subject of experimental research, but was also already called for by Wagenschein (1976) and, more current, by Merzyn (2008, 2010). Also, most teachers see experiments as central for science education and assume that they are an important factor for further improvement of subject knowledge and conceptual understanding (Welzel et al., 1998; Abrahams & Millar, 2008).

Therefore, it is not surprising that in a video study, conducted by Tesch (2005), around two thirds of class time in physics lessons is taken up by experiments (with necessary preparations and analyses). Most of the observed experiments were conducted by students, which is also observed by Duit and Wodzinski (2010). Duit and Wodzinski criticize at the same time that students often don’t have the time or the opportunity to plan or interpret their experiment but instead use “cook-book lists of tasks” (also mentioned by Hofstein and Lunetta, 2004, p. 47).

In addition, various authors are demanding a more inquiry-based approach to teaching, with less guidance (Bunterm et al., 2014; Hofstein and Lunetta, 2004; Koksal and Berberoglu, 2014; Wodzinski et al., 2007). They argue that more open learning situations demand more cognitive effort of learners, and therefore increase the amount of learning time for the particular subject
and hence facilitate better learning. They also believe that open learning situations are more conducive for learning in heterogeneous groups because students can profit from each other and don’t have to rely solely on the teacher. Results of flipped classroom concepts, which rely on the same principles, are very positive (Crouch and Mazur, 2001).

But, according to Hofstein and Lunetta (2004) as well as Lazonder and Harmsen (2016), it remains unclear if there is a specific amount or a specific type of guidance in experimental situations which can enhance learning. This was also the result of a previous study by Winkelmann (2015).

**Previous Studies**

Winkelmann (2015) formulated various experimental situations (demonstration experiments, cook-book-experiments and guided experiments) and investigated their impact on the learning success of students. Those experiments differed in the amount of guidance during planning and execution and which person would conduct the experiment, as seen in the following table.

**Table 1. Description of experimental situations**

All experiments had light refraction as a topic, especially the following phenomena:

a) Refraction of light on a water surface,
b) Refraction of light on a glass surface,
c) Total internal reflection in glass,
d) Focusing of light in lenses,
e) Image formation in lenses.

Winkelmann (2015) reported that the student experiments had no significantly different impact on the students’ learning success, compared to the demonstration experiments. At the same time, he found a small interaction between the experimental situation and the teacher who conducted it. He also found a small advantage for students with high and low abilities in experimental situations with strong guidance, compared to students with medium ability, which profited more from open experimental situations.

**Research questions**

Based on the motivation and the previous studies, the following research questions were formulated:

1.1. What impact have different experimental situations in physics classes on subject knowledge?
1.2. What differences can be shown in heterogeneous learning groups due to the different experimental situations with regard to subject knowledge?

2. What impact has the interaction between characteristics of the teacher and the experimental situation on subject knowledge?

METHOD

Study design

To answer these research questions, a study called “Testing and improving student’s competencies in diverse learning groups by using an experiment-based physics curriculum” (funded by the German Federal Ministry of Education and Research) was proposed.

Three different experimental situations were chosen to be compared: Teacher demonstration, small group practical work with detailed instruction (Cook-book-experiments) and small group practical work with little instruction (Guided). These situations were the same experimental situations as in the previous study by Winkelmann (2015). The three treatment groups were respectively composed of randomly assigned classes. An overview of the length of the Pre-, Post- and Post-2-Tests (Follow-Up-Test) as well as the whole study duration, can be found in the Table 2:

For the Post-2-Test a Planned-Missing-Design (Little & Rhemtulla, 2013) was used. In this, not all participants are tested at every measurement date, but only on one of the three Post-2-Tests and therefore participants completed three of the five overall tests. The participants, still grouped in classes, were randomly assigned to the different measurement dates. This is deemed appropriate, due to the sample size, which is large enough to ensure satisfactory test power.

Measures

In the pre-test, students’ sociodemographic characteristics as well as students’ subject knowledge were measured (CAT-V3, -N2, Heller & Perleth, 2000) to estimate the heterogeneity of specific classes.

At the same time the teacher’s characteristics were determined (Lamprecht, 2011). The results of this questionnaire should give insight in the beliefs about teaching and the science of physics of the various teachers. Those beliefs are suspected to impact how teachers teach and therefore
give an idea about which experimental situation could be the best fit for their respective teaching style.

In the post-test the students are asked about their current interest in physics (Schulz, 2011). The answers to this particular part of the questionnaire can lead to a deeper understanding which experimental situation is most motivating for students as this is one of the goals of using experiments (Merzyn, 2008, 2010).

To measure a potential nonlinear development of the subject knowledge and scientific literacy, tests for those areas were administered at all five measurement dates. To measure the scientific literacy an already existing IRT-scaled test by Glug (2009) was used. To measure the development of the subject knowledge a new IRT-scaled test was constructed, drawing on Winkelmann (2015). The development of these two areas is not only important to answer the research questions but are also important indicators for the individual growth of the student’s competencies.

**Construction of an IRT-scaled subject knowledge test (geometrical optics)**

As a first step, the 44 items which Winkelmann (2015) used in his study were analyzed with models of the Item-Response-Theory (van der Linden & Hambleton, 2013). By using Winkelmann’s data, the item difficulty could be scaled and the personal ability estimated. By checking various psychometric criteria, the items were reviewed for their usability in the study. These criteria were Itemfit, Item-Total-Correlation and differential item functioning for gender (Osterlind & Everson, 2009). 33 items were selected for the item pool, but those were generally rather difficult. For this reason, 33 additional items with intended lower performance requirements were developed by an expert group.

In a second step, the 33 new items, together with 18 previously selected items, were used in a pre-study with 301 participants. To get as many participants as possible, the test time has been minimized by using a balanced incomplete booklet design (Frey, Hartig & Rupp, 2009). The resulting data was again reviewed using models of IRT, in the same way as mentioned before. The item analyses (selection by using the aforementioned criteria) lead to a total item pool size of 60 items (out of 66 items overall), which were available for the construction of the subject knowledge test.

Test-Booklets for all measurement points were constructed in a third step. To minimize repetition and to adapt test difficulty according to the levels of students’ learning progress, only a part of the items was used during each measurement point. Every booklet included a set of anchoring items (which were repeated at two dates) and date-specific items. This approach permits to match the ability estimation of students over the three times of measurement without using the exact same items.

**FIRST RESULTS**

After reviewing the results from the main study, data from 44 teachers and 1094 students were analyzed. The average class included 25 students, ranging from 14 to 31 students. The students were averagely 14 years old. Students were mostly in the seventh grade (73%), but more than
a quarter of the students were in the eighth grade (27%). Of the 978 students who indicated their gender, 49% were male students and 51% were female students.

Subject Knowledge

The subject knowledge was measured before and after the different treatments. In all treatment groups the subject knowledge of the students grew after the treatment significantly and with a sizeable effect (partial $\eta^2 = 0.365$). It should be mentioned that the estimated ability of the students was highest directly after the treatment and afterwards declined slightly. The treatment group who experienced the teacher demonstration experiments differed at the pre-test measurement date slightly from the other groups (cohen's $d = 0.21$ between Demonstration group and Guided group and cohen's $d = 0.29$ between Demonstration group and Cookbook group), but this difference stayed unchanging over all measurement dates and was therefore not influenced by the treatment itself.

![Figure 1. Development of subject knowledge (estimated ability) of students in all treatment groups](image)

No significant difference could be found in the growth of the estimated ability of the students between the treatment groups. As seen in Figure 1, the overall progression in the estimated ability in the area of subject knowledge seems to be similar for students of all treatment groups.

It should be noted, that the sample size for this analysis consisted of 867 students after eliminating all non-complete data sets (Demonstration group: 302, Cookbook group: 291, Guided group: 274). The difference between the Cookbook group and the Guided group, which seems to emerge at the time of the Post-2-test was significant, but very small (partial $\eta^2 = 0.02$).

Current interest

Subsequent to the intervention the students were asked to rate their current interest for physics on a five point Likert scale, from “uninterested” up to “interested”. While this doesn't have a significant difference for male students over all treatment groups, female students show a significantly different interest between the Demonstration group and the two other groups can be seen in Figure 2.
Figure 2. Current interest of students in all treatment groups, divided by gender

The difference between male and female students is insignificant when both were part of a treatment group who did student experiments. Female students showed no differing interest after conducting student experiments with more or less guidance. However, the difference between male and female students in the Demonstration group is significant and has a moderate effect size (Cohen's $d = 0.38$, $p < 0.05$).

To further analyze these findings, the ratio of male to female teachers in each treatment group was examined. This showed no significant deviation in the ratios of male to female teachers over all treatment groups.

Due to the elimination of incomplete data sets, the sample size in this analysis consisted of 978 students.

CONCLUSION

Findings

As found in previous works, the subject knowledge rises after the treatment, but no significant difference was between the treatments. At this point, it can be concluded, that experiments with very low guidance have no significant negative impact on the learning success of students, in comparison to situations structured by the teacher. This is important because most teachers prefer more structured learning environments to closely control the learning outcomes. As no significant advantage of one experimental situation could be found, it is doubtful if the learning success in the area of subject knowledge could be the deciding factor to choose one experimental situation over another.

More importantly, current interest is closely related to positive and open engagement with the subject and therefore is believed to be conductive for better learning (Merzyn, 2008, 2010). As student experiments elicited a significantly higher interest from female students, this should be an important factor in the teacher's decision for or against a particular experimental situation.
Further analysis

At the moment, the data is still being analyzed. Further work should deliver a more in-depth analysis of the first results which are reported here.

The data will be analyzed:

a) On interactions between teacher's characteristics and the experimental situation and the impact on subject knowledge,

b) On interactions between class heterogeneity and the experimental situation and the impact on subject knowledge,

c) On interactions between teacher's characteristics and the experimental situation and the impact on conceptual understanding,

d) On interactions between class heterogeneity and the experimental situation and the impact on conceptual understanding.

This will be done by using multilevel analyses to provide for the nested structure of our data.

Future Research

The subject knowledge test which was constructed for this study can be used in other IRT research settings. After the main study, most items showed a good quality, only 4 of the 12 anchor items and 7 of the other 36 items had to dropped, due to item misfit. By using data from this study, the item difficulty could be estimated and it is mostly of a moderate difficulty.

ACKNOWLEDGEMENT

The study was funded by the German Federal Ministry of Education and Research.

THE BENEFITS OF STRUCTURING TEACHER BEHAVIOR IN BIOLOGY LESSONS WITH EXPERIMENTS

Alexander Eckes and Matthias Wilde
University of Bielefeld, Bielefeld, Germany

Experimentation is among the methods of inquiry in biology, and it is the most important form of scientific inquiry. The corresponding scientific problem-solving can be framed by the central elements that are posing questions, establishing hypotheses, planning the experiment and interpreting the findings. In this study, this problem-solving is framed through scientific discovery learning. Conducting experiments in class may pose challenges. Students may fail in selecting relevant information, and they may in turn become confused, lost and frustrated. Being potentially unable to effectively or successfully interact with the working materials in the learning environment might lead to students perceiving themselves as not competent. Competence, alongside autonomy and relatedness, is one of the three basic needs of the Self-Determination Theory of Motivation (Deci & Ryan, 2002; Ryan & Deci, 2017), and the fulfilment of the three needs is related to positive qualities of motivation. The need for competence is the focus of this study. As it is an invaluable tool in guiding students through discovery settings, feedback was used to structure teacher behavior. Feedback can support students’ perception of competence. Supporting students’ competence may balance the requirements of scientific inquiry and students’ abilities. We hypothesized that informative tutoring feedback facilitates positive qualities of motivation and knowledge acquisition. In a pre-post-design, this study aimed to investigate the effects of basic and informative tutoring feedback (cf. Narciss 2004, 2006) on motivation and knowledge acquisition. 183 high school students from sixth and seventh grade (M_age = 12.02 years, SD_age = 0.68 years) from schools of medium and high stratification levels took part in the study. Students received an introductory lesson as well as two consecutive lessons on experimentation. Students’ motivation was assessed using an adapted version of the Intrinsic Motivation Inventory (IMI; Ryan, 1982). Reliabilities of the subscales were satisfactory and ranged from Cronbachs α = .67 to α = .85. Offering informative tutoring feedback showed beneficial effects on intrinsic motivation. Findings for knowledge acquisition were not conclusive.

Keywords: feedback, motivation, discovery learning

INTRODUCTION

Scientific discovery learning

This study uses Bruner’s (1961, 1970) approach to discovery learning, as it provides a framework for experimentation in an open learning environment. More specifically it focusses on scientific discovery learning and infers to conducting experiments as the central characteristic (de Jong & van Joolingen, 1998). Experiments are the most important method of scientific inquiry, as they develop scientific discovery learning environments through framing of the central elements of scientific problem-solving by posing questions and hypotheses, planning experiments and interpreting the findings (Abd-el Khalick et al., 2004; Koslowski, 1996; Klahr, 2000; Hammann 2004). The open discovery environment enables students to work independently and self-determined, yet it may also put extra strain on students (Tuovinen & Sweller, 1999). Central elements of scientific problem-solving may pose problems to students, through which they might not be able to work effectively. Problems such as not being
able to choose relevant information (Mayer, 2004) may occur. Thus, students may not feel competent while working on the respective task at hand, and might become frustrated and confused (Brown & Campione, 1994; Hardiman, Pollatsek, & Weil, 1986).

Structure

To manage the potential problems mentioned above, teachers can apply structure to support students working on scientific inquiry in an open learning environment. Teachers can facilitate structure by providing clear, comprehensible, explicit and detailed instructions through setting clear expectations by initiating the students’ activities with an action plan and by giving students constructive feedback (Brophy, 1986; Skinner & Belmont, 1993; Skinner et al., 1998). Structure can be viewed as a continuum ranging from chaos to high degrees of structure (Jang, Reeve, & Deci, 2010). Teachers facilitating chaos do not communicate clear rules and expectations, or how to accomplish these expectations. This may make things unclear for the students. Provisions of structure can be used by students to better choose tasks that may be well suited to their abilities and their competence (Ryan & Deci, 2002). In this way structure might support scientific inquiry.

Feedback

Feedback has been shown to be an effective tool in discovery settings (Kirschner, Sweller & Clark, 2006; Moreno, 2004). This study focuses on feedback as a provision of structure to guide students in such a setting. Taking Hattie and Timperleys (2007) analysis into account, feedback is one of the ten major determinants of achievement. Feedback provides students with information that allows them to verify their current working practice as well as the correctness of their responses. This can enable them to improve their thinking and behavior, and facilitates better learning performance (Shute, 2008). Here, informative tutoring feedback was implemented to provide students with strategic information on how to complete the tasks at hand, and how to apply efficient strategies (Narciss, 2004, 2006). Components of strategic information may be: cues for retrieving facts, analogies, hints on possible sources of information, hints on errors and successful strategies as well as Socratic questions (Narciss, 2004; Narciss & Huth, 2004). Feedback can have an impact on students’ perceived competence (Connell & Wellborn, 1991; Grolnick & Ryan, 1987; Jang et al, 2010; Taylor & Ntoumanis, 2007). According to the Self-Determination Theory of Motivation (SDT) (Deci & Ryan, 2002) this can affect students’ quality of motivation.

Self-Determination Theory of Motivation

SDT describes a continuum that distinguishes two types of motivation, extrinsic and intrinsic motivation. Extrinsic motivation can be observed in behaviors that are conducted with instrumental intent (Deci & Ryan, 1993). In contrast, intrinsic motivation is autotelic and defined by curiosity, exploration, spontaneity, and interest in the task itself (Deci & Ryan, 1993). SDT states that competence, autonomy and relatedness are the three psychological needs that are inherent to every human being. Relatedness is the need to feel connected to and accepted by significant others. Feelings of autonomy arise when the locus of causality is internal, and actions are based on an inner desire for self-determination (Reeve, 2002; Ryan &
Deci, 2002). The need for competence represents the need to feel effective and to successfully interact with one’s surroundings (Deci & Ryan, 2002; White, 1959). It is satisfied when a balance between ability and requirements is met (Danner & Lonky, 1981; Deci & Ryan, 1993). The satisfaction of these three needs is essential to fostering positive qualities of motivation (Deci & Ryan, 2002).

In this study, informative tutoring feedback is utilized to facilitate competence in students. Working on tasks that correspond to a person’s abilities in compliance with the requirements of a task may influence the satisfaction of the basic need for competence (Grolnick & Ryan, 1987; Skinner et al., 2008) and in turn might contribute positively to intrinsic motivation (Ryan & Deci, 2002).

**Learning in scientific discovery learning**

Scientific discovery learning is likely to increase the personal relevance of a subject matter as actions are undertaken in a self-determined manner, thus supporting perceptions of autonomy. There is very strong evidence to suggest that support in autonomy leads to performance gains (Boggiano, Flink, Shields, Seelbach, & Barrett, 1993) and conceptual understanding (Benware & Deci, 1984; Flink, Boggiano, & Barrett, 1990; Grolnick & Ryan, 1987; McGraw & McCullers, 1979). In addition, offering feedback and thus supporting competence can lead to positive qualities of motivation. Satisfying the basic needs for competence and autonomy can lead to self-determined, motivated students that can acquire more differentiated knowledge and are better able to apply it (Deci & Ryan, 1993). This can lead to more intense contact with the subject matter as well as a deeper understanding of the subject matter acquired during the problem-solving processes (Bruner, 1961).

The aim of our study was to investigate the effect of two degrees of structuring feedback – basic and informative tutoring feedback – on students’ intrinsic motivation and knowledge acquisition in biology lessons with experiments.

**HYPOTHESES**

Informative tutoring feedback can help facilitate structure in biology lessons with experiments by enabling students to interact with the tasks in the scientific discovery learning environment in a meaningful way. Therefore, feedback is assumed to facilitate students’ perceived competence. Support for perceived competence may promote positive qualities of motivation.

H1: In biology lessons with experiments, positive qualities of motivation can be facilitated to a higher degree through informative tutoring feedback rather than basic feedback.

Scientific discovery learning might support positive qualities of motivation in problem-solving processes through perceptions of autonomy, personal relevance and engagement with the materials. Students may then achieve more intense contact with the task, leading to deeper understanding (Benware & Deci, 1984; Boggiano et al., 1993; Müller & Palekčić, 2005) and a more in-depth examination of working materials, which can lead to higher knowledge gains (Deci & Ryan, 2002).

H2: In biology lessons with experiments, knowledge acquisition can be facilitated to a higher degree through informative tutoring feedback rather than basic feedback.
METHOD

Sample

The sample consisted of 183 students (91 females, $M_{age} = 12.02$ years, $SD_{age} = 0.68$ years). Participating students were in grades six and seven and were from schools of medium and higher types of tracking. In this quasi-experimental study, classes were randomly assigned to the control group “F” (n=102) in which teacher trainees offered a basic level of feedback, or to the experimental group “F+” (n=82) in which teacher trainees offered informative tutoring feedback. In both treatments teacher trainees worked in tandem. The teacher trainees were biology students of advanced semesters. All of them were trained in several meetings prior to the intervention in providing feedback and in the autonomy-supportive teaching style. In this study teacher trainees were deliberately chosen over the students’ regular biology teachers for several reasons. Teacher trainees show interest in new teaching strategies and have not yet established strong teaching habits (Hoy & Woolfolk, 1990). More experienced teachers tend to use rather defined styles of teaching which may vary greatly. In contrast, teacher trainees have just begun to develop their own teacher personality. Most importantly, teachers and teacher trainees may differ in respect to offering feedback. Teacher trainees’ feedback seems to be very valuable (Cho & Schunn, 2007), whereas expert feedback can be perceived as less helpful or even hard to understand (Cho & Schunn, 2007).

Study design and treatment

This study examined problem-oriented experiments in an open environment with the topic of bird flight in biology lessons. Emphasis was put on formulating and testing hypotheses, analyzing data and drawing conclusions (cf. Abd-el Khalick et al., 2004). Experimentation as a method was chosen deliberately in this study as it offers plenty of situations to offer feedback while students work on the experiments. Students used an experiment set containing an abundance of possibilities for experiments on bird flight. Students used a flow chart to frame each of their experiments. The flow chart was adapted from Walpuski and Sumfleth (2007) and was created to visualize the steps of scientific reasoning. It depicts scientific reasoning in the form of a circle, starting at a problem and continuing along the steps of inquiry, leaving room for students’ notes. The intervention consisted of three lessons. Students participated in an introductory lesson, in which an experiment (thermal lift) was demonstrated by the teacher trainees. This experiment and the corresponding scientific reasoning was explained using a flow chart for the experiment. The introductory lesson was followed by two lessons in which students conducted experiments in groups of three to four students. In both treatments students worked together with their teacher trainees to form research questions or hypotheses. They chose which experiments they wanted to work on, planned the experiments themselves, worked independently on the experiments they chose, evaluated their findings and drew conclusions. The interpretation was finally checked with the class and the teacher trainees at the end of the lesson. Classes were randomly assigned to the control (F) and to the experimental treatment (F+). In both treatments feedback was given if students asked the teacher trainee or because it was obvious to the teacher trainee that a group had problems. In the basic feedback treatment (F), students were given the necessary information and expectations needed to work properly. Basic feedback was defined by teacher trainees in such a way that if a group had problems...
working on one of the experiments, the teacher trainees promoted discussion inside the respective group without the further involvement of the teacher trainees. If the problem persisted, teacher trainees suggested that students might work on another experiment and that problems were going to be discussed at the end of the lesson. In the informative tutoring feedback (F+) treatment, students received informative tutoring feedback (Narciss, 2004), providing information about students’ performance and error correction information. Teacher trainees asked students first about their current position on the flow chart. Then the feedback was specifically given corresponding to the current position on the flow chart continuously, using clear explanations of working materials. To elaborate on the aspect of tutoring, the reflective toss (Van Zee & Minstrell, 1997) was used. It is defined as a sequence consisting of a student statement, a teacher question and a student elaboration. In a reflective toss, the teacher’s question tries to “catch” the meaning of the student statement and “throws” the responsibility for thinking back to the student (Van Zee & Minstrell, 1997). In using the reflective toss, teachers encourage students to elaborate independently on their own questions, making their thinking more visible and allowing teachers to use it as the basis for adaptive feedback.

**Questionnaires**

This study used a pre-post-test design. Questionnaires used a five-point rating scale that ranged from ‘0 - not at all true’ to ‘4 - very true’. Internal consistencies were reported as Cronbach’s $\alpha$. Students’ self-determination in biology lessons was assessed in the pre-test using an adapted version of the Academic Self-Regulation Questionnaire (SRQ-A; Ryan & Connell, 1989; 4 subscales) to check for potential differences in regulation types between treatment groups. The Relative Autonomy Index (RAI) was derived from the subscales of the SRQ-A: *intrinsic* (5 Items, $\alpha = .88$), *identified* (4 Items, $\alpha = .82$), *introjected* (4 Items, $\alpha = .70$) and *external* (4 Items, $\alpha = .48$). The RAI provides an indicator of whether a child is working autonomously or controlled during regular biology classes at school. Additionally, a knowledge test consisting of five multiple choice items was assessed in the pre-test.

In the post-test, an adapted version of the Teacher as a Social Context Questionnaire was used (TASCQ; Belmont, Skinner, Wellborn, & Connell, 1988). The TASCQ (13 Items, $\alpha = .88$) examined the implementation of structure. Additionally, an adapted version of the subscales *interest/enjoyment* (7 Items, $\alpha = .85$), *pressure/tension* (5 Items, $\alpha = .67$), *perceived choice* (5 Items, $\alpha = .67$) and *perceived competence* (6 Items, $\alpha = .79$) of the Intrinsic Motivation Inventory (IMI; Ryan, 1982) was used. The knowledge test was applied again in the post-test.

**RESULTS**

In this study, the effect of basic and informative tutoring feedback on the motivation and knowledge acquisition of the students was examined. The data was assessed using analysis of variance.

To assess the operationalization of feedback, we tested the implementation of teacher structure using the TASCQ in the post-test. The students of treatment F+ perceived a significantly higher degree of structure than the students in the F treatment ($F(1,174) = 20.807, p \leq .001, \eta^2 = .107$).
The provision of informative tutoring feedback was perceived as being more structured than the basic feedback.

To test for potential motivational differences between the two treatment groups, the Academic Self-Regulation Questionnaire (SRQ-A) was used in the pre-test. Derived from the four subscales of the SRQ-A, the Self-determination index (SDI) was calculated (Ryan & Connell, 1989). Analysis showed that there was no difference between the treatment groups ($F(1,149) = 0.03, p = ns$). Both groups showed similar motivational pre-conditions regarding biology lessons.

To examine motivation, the Intrinsic Motivation Inventory (IMI) was assessed in the post-test. Four subscales were used. The interest/enjoyment subscale can be considered the self-report measure of intrinsic motivation. The perceived choice and perceived competence are positive predictors, whereas the pressure/tension subscale is a negative predictor of both self-report and behavioral measures of intrinsic motivation. The analysis of the IMI revealed that students provided with informative tutoring feedback perceived themselves as more competent and perceived more interest and enjoyment as well as less pressure while working on the experiments (table 1). For the subscale perceived choice, we found no difference between basic and informative tutoring feedback (Table 1).

Table 1. Mean scores (M) and standard deviations (SD) for subscales of the IMI are shown separately for basic feedback (F) and informative tutoring feedback (F+). Results of an ANOVA for each of the subscales of the adapted IMI follow. P-values are reported in the following α levels: $p < .001$, $p < .01$, $p < .05$ and not significant (ns), $p > .05$. Effect sizes are reported as partial eta square ($\eta^2$).

</table>

For the analysis of the knowledge tests assessed on pre- and post-test a mixed ANOVA was used. The descriptive data showed that the treatments F ($M = 11.58, SD = 2.79$) and F+ ($M = 13.27, SD = 2.68$) already differed in the pre-test. These differences are repeated in the post-test F ($M = 13.91, SD = 2.62$) and F+ ($M = 14.69, SD = 2.84$). The results for the mixed ANOVA were: Main effect for time ($F(1,163) = 49.00; p \leq 0.001; \eta^2 = .231$), main effect for treatment ($F(1,163) = 13.90; p \leq 0.001; \eta^2 = .079$) and interaction ($F(1,163) = 2.92; p = 0.09; \eta^2 = .018$). Students did acquire knowledge regarding bird flight. The interaction is marginally significant.
The rather small effect size suggests that there might be an interaction between knowledge gain and treatment.

**DISCUSSION AND CONCLUSION**

The preliminary results showed that the operationalization of structure using feedback was effective. The large effect for informative tutoring feedback is in line with the importance that can be deduced from the meta-analysis of Hattie and Timperley (2007), putting feedback in the top ranking influences on achievement. This study succeeded in creating a very effective form of teacher instructional structure in the form of informative tutoring feedback. Additional teacher structure had a positive effect on three of the four subscales that were used to measure intrinsic motivation. Informative tutoring feedback led to higher support in perceived competence as well as interest/enjoyment in comparison to basic feedback. The subscale perceived competence was the most prominent one and can be directly linked to structure (Connell & Wellborn, 1991). The interest/enjoyment subscale is considered the self-report measure of intrinsic motivation. Students, in addition, perceived less pressure/tension when supported by informative tutoring feedback. The subscale perceived choice showed no effect for provision of teacher structure, which is not surprising as the scale is related to autonomy, which was constant in both treatments. Using informative tutoring feedback and structuring the lessons beforehand motivated students to a significantly higher degree in comparison to support through basic feedback. The first hypothesis can be supported. The results of the perceived competence subscale of the IMI notably suggest that the effect of informative tutoring feedback is achieved through students’ perception of competence while working on experiments in an open learning environment.

Without taking the treatment into account, the results for the knowledge test showed knowledge gains for participating students. There were already differences between both treatments in the pretest. In the pretest students in treatment F+ scored higher than those in the treatment F. These differences have to be taken into account for the interpretation of the interaction between treatment and time. The result for the interaction suggests that there may be a dependence of knowledge gain regarding affiliation to the basic or informative tutoring feedback treatment. The interaction is marginally significant and shows a small effect size. The differences between both treatment groups in the pretest may impact the results of the interaction and must be considered. A follow-up study with a larger sample size is needed to analyze the connection between the provision of feedback and knowledge acquisition.

The results of the study suggest that the provision of informative tutoring feedback was more effective and led to significantly higher perception of competence, higher interest and enjoyment as well as lower perception of pressure and an unimpeded perception of choice. The knowledge test showed an overall knowledge gain for both treatments and evidence for an interaction between the factors provided feedback and time.

ARCHIMEDES AND THE TIME MACHINE: A DIGITAL EDUCATIONAL SCENARIO OF A.R.G.

Christine Theodoropoulou¹, Yannis Psaromiligos² and Symeon Retalis³
¹Platon I.B. World School, Athens, Greece
²Technological Education Institute of Piraeus, Athens, Greece
³University of Piraeus, Athens, Greece

The current study presents an Alternate Reality Game, designed for 4th Graders, as a form of formative evaluation of Competences developed through the school year. The story of Archimedes engages students in a journey in time and space. Their journey involves collecting clues in real world activities, but also accessing information from the internet through their tablets. This playful digital educational scenario is based on transdisciplinary learning, linking astronomy, math, language and history, while the Greek Curriculum is interrelated with I.B. learner skills in the P.Y.P. Students apply Competences and exercise Life Skills, such as critical thinking, organizing information and relationship management while working in active gaming. Finally, the game leads to a straightforward invitation to participate in a continuum of gamification lead by the students. The assessment of this educational scenario is based on class observation. Problem solving situations, Internet applications, and scaffolding procedures created a unique experience for the students. Students beginning from level ‘Comprehend’ of the reversed pyramid of Bloom’s Taxonomy were led to level ‘Create’ by encouraging students to create their own riddles and to document their own ideas for a new game hence the continuum.

Key words: alternate reality games, cooperative learning, competences

BACKGROUND

Alternate Reality Games (A.R.G.) fall into the category of digital games and is an interactive networked narrative that uses the real world as a platform and employs transmedia storytelling to deliver a story that may be altered by players' ideas or actions. (Szulborski, 2005). ‘The Beast’, the first A.R.G., was created in 2001 for marketing promotion for the movie A.I. (Artificial Intelligence) (McGonigal, 2007). Ever since A.R.G. are famous, not only for their originality but also for their educational value. They engage players in various interactive and teamwork challenges with riddles that gradually unfold a storyline.

The current study presents the development of an A.R.G. with an inter relation between Greek Curriculum and I.B. learner’s skills in the P.Y.P. There is also a strong interdisciplinary thread linking astronomy, math, language and history. This educational scenario was developed and assessed through classroom observation.

METHODOLOGY

Development and context

‘Archimedes and the time machine’ is based on competences (Sigrid Blömeke, 2013) and was originally addressed to 4th Graders, though eventually 5th Graders participated as well. Students were interfaced with A.R.G. and mobile devices in classroom for the first time. The implementation of the game took 3 teaching hours, which is approximately one and a half
hours. It was designed according to the principles of Instructional Scaffolding Learning and it demands of students working in groups. It is significantly important to mention in that it was designed as a formative assessment tool and does not intent to teach students new knowledge. Therefore, learning objectives of the 4th Grade are mainly to be found in the context of the game. A.R.G. took place in ‘Platon I.B. World school’, a co-operatively- based environment that apply the cooperative method Jigsaw (Aranson, 1992).

**Aim of the study**

The present study aims to develop, implement and assess an Educational scenario. The assessment was based on class observation. Therefore, five teachers participated in the implementation of the A.R.G.

**THE PLOT**

The game begins with the narration of Archimedes’ story, without letting students know it’s actually a game. They think it is a typical language lesson. Students are already separated into groups, as they work that way during the whole school year. The story of Archimedes’ is about a 4th Grader that loses enthusiasm of learning in school and his teacher accuses him of not trying at all and always being day dreaming. So his parents decide to send him spend some time with his grandfather. His grandfather is a very strict man with a love for knowledge. During his stay at his grandpa’s Archimedes finds out that his grandpa owns a very strange machine. A time machine! Thereafter he begins his journey, but unfortunately he forgets the chest that will allow him to return and gets trapped in space and time. He asks through a message shown in the classroom board help from the students to be set free. The aim of the game is for the students to collect various clues, while travelling in time in groups, in order to unlock a chest. The chest contains the date Archimedes set out for his journey and this is the only clue that will allow him to return.

![Figure 1. Group 3 Challenges](image-url)
IMPLEMENTATION

The duration of the journey is about 50 minutes and in case of difficulty student groups are required to help each other. Every group consists of 4-5 members and is given a miniature suitcase, which contains a riddle, an object, an answer sheet, a map and a tablet. Students form six groups, with each group travelling in a different time and space and are required to deal with different instructional objectives. If students have difficulty in collecting a clue they have the right to access the emergency button, which is located in the center of the classroom. When the buzzer is hit all the groups stop working and the group in trouble chooses which member of each group should convene (the managers, the pacifiers e.t.c.) They also have the right to ask for teacher’s help, but only once! Additionally, for every app there is a tutorial video inside the tablet, because students aren’t familiar with any of these apps.

Figure 2. The Cooperative Group Roles table displayed in classroom

Group 1 receives a suitcase with an illustrated map, the answering sheet, a riddle, a map with the cities named after Alexander the Great and a tablet. The map with the cities named as “Alexandria” informs the group that they are travelling in the past and particularly in the era of Alexander the Great. The answering sheet asks students to select a name for their team and to delegate the responsibilities of every member (manager, pacifier, facilitator, assessor). The riddle is written backwards, so the students use the classroom mirror to decode the message. The riddle refers to the city of Alexandria in Egypt, which is the most known city named after Alexander the Great. The last challenge involves examining the application ‘Planimeter’ where students are asked to calculate the distance between Thessaloniki in Greece and Smirni in Turkey through mathematical procedures with decimal numbers. This is the final clue that group 1 has to provide for unlocking the chest.
Figure 3. Group 1 challenges

The second team receives a suitcase with an illustrated map, the answering sheet, a mathematical riddle, a paper spacecraft and a tablet. The paper spacecraft informs the group that they are travelling to another planet. The answering sheet asks students to select a name for their team and to delegate the responsibilities of every member (manager, pacifier, facilitator, assessor). The mathematical problem focuses on the time needed by a spacecraft to travel from Earth to Mars. Students perform actions of round numbers, applying critical thinking, in order to find out the exact month and year that the spacecraft will land on Mars. Subsequently, they examine the application ‘Globe Mars’ which provides them with an abundance of information about planet Mars in English. Through this App they are required to locate the name of spacecraft that landed on Mars on August 2012, named ‘MSL Curiosity’. This is the solution of the problem and the final clue that Group number 2 has to provide for unlocking the chest.

Figure 4. Group 2 challenges
The suitcase of the third group contains an illustrated map, the answering sheet, a tablet, a mathematical riddle, a photo of Acropolis of Athens and a poem. The mathematical problem refers to how many kilos of marble were used by ancient Greeks to build the Ereththio temple, performing actions of fractions. The photo presents all of the temples that are located in the Acropolis and students are asked to locate the place of sacred battle between Athena and Poseidon, according to Greek Mythology. Afterwards, they use the ‘Acropolis 3D’ app in order to observe the temple of Erethtion and answer how many Kariatides they see. The Kariatides are the names the ancient marble sculptures of young women who were used as columns of a building standing next to the Parthenon on the Acropolis. In the 3D app they will find six. Then, they proceed to read a poem that refers to a Kariatida who’s been missing and they will have to write a sentence about what would they say, if they were in her place. The missing Kariatida has been housed in the British Museum since 1801. The phrase is the clue that Group 3 has to deliver to the class.

Group 4 travels back in time to the naval combat of Salamina, where ancient Greeks defeated the Persian fleet. Students are given a riddle, a photo of a sail ship in full sail, the answer sheet and the tablet. Their first task is to put the sentences in the right order so the paragraph will make sense. The paragraph refers specific details about the naval combat and is taken from the ‘Salamina’ app. After the paragraph is complete they are given instructions to locate the specific paragraph in the App by using the divisibility rules of number 3, which reveals the exact number of page and number of paragraph. Subsequently, they explore the app, which provides them with a 3D presentation of the ancient Greek ship, named the Treiris. Then, students have to find out what the name of the part of the ancient ship shown in the picture they are given is called. The part of the sails is called ‘mega istiaio’ and it is the clue Group 4 has to deliver to the class.
The fifth group of students visits Egypt in the present time. Their suitcase contains a hieroglyph message, two different Egyptian hieroglyphic vocabularies, a picture of a clock and two pictures of flags of foreign countries, the illustrated map, the answering sheet and the tablet. The first challenge of this group is to decode the message written in hieroglyphic language. Students must combine the two different vocabularies in order to reveal the phrase ‘Ancient Egypt’ in English. Their next step is to find out in which countries the two flags refer to, using their own knowledge or by searching information through the internet. The flags belong to Egypt and Canada and they have to use the app ‘City Clocks’ in order to find the time difference between the two countries performing sums in round numbers. This is the final clue for this group.

Figure 6. Group 5 challenges

The last group travels to the cities of future. Their suitcase contains three pictures of buildings of strange architecture, a word puzzle, a cube design, the illustrated map, the answer sheet and the tablet. Students talk about the strange buildings they see in the pictures and make calculated guesses as to where they are travelling. Afterwards, they examine the word puzzle which hides the phrase ‘cities of the future’ among other irrelevant words such as lawyer and cat. When locating the phrase ‘cities of future’ they write in down in their answering sheet. Their next challenge is to create the Rubric cube from scratch. Therefore, after forming the cube, following the directions of the design given, they use information through the internet to learn about the special characteristics of the Rubric cube and paint their own cube the same way. Finally, students explore the app ‘Measure Map Lite’ which shows a picture of our school as it is presented from satellite. Group 6 is asked to calculate the perimeter of the athletic fields of our school performing actions of decimal numbers. The arithmetical number is the final clue for opening the chest.
The chest opens only after all six clues have been gathered correctly. At this point the narration of the second part of Archimedes’ story follows. Archimedes is finally set free, goes back to school and has the chance to repair his relationship with his teacher and also cooperate with her to make the lesson more interesting with all of new ideas he has obtained during his journey. After that a discussion in the class about what students think keeps them motivated and what they would change follows. Finally, teacher asks students to go to their portfolios were all the transdisciplinary projects are kept and they find a thank you letter from Archimedes for their precious help. In this letter, he also assigns them with a new task, which involves for every group the development of a new riddle, with a form and context of their choosing. The teacher uses these riddles to develop a new A.R.G. and create a never-ending continuum of gamification within the classroom.
RESULTS

Based on the class observations students could easily recall prior knowledge, taught through the school year. What is remarkable is the fact that some students with learning difficulties have participated actively. Bear in mind that during the school year they seemed particularly discontent when asked to edit written text. Furthermore, students were asked to apply through playing organizing skills that have developed through the school year and enhance interpersonal relationships management. Feedback from the students was included in the formative amendment of the game. For example, students noticed that allowing student group access the emergency button as many times as a group needed, created a delay in the progress of the game. They proposed having just three opportunities would be more helpful. Furthermore, the first group of 4th Grade students that participated was involved in the further implementation of educational scenario as helpers. Finally, students made remarkable statements about their experience such as ‘I was scared that I might break the iPad, so I was trying the whole time to hold it gently’, ‘The riddles were perfect’, ‘It is only now that I understand why our parents keep telling us that they are working and not playing while using their tablet’.

CONCLUSIONS

Problem solving situations, Internet application, and scaffolding procedures created a unique experience for the students. Students beginning from level ‘Comprehend’ of the reversed pyramid of Bloom’s Taxonomy (Krathwohl, 2002) were led to level ‘Create’, by encouraging students to create their own riddles and to document their own ideas for a new game. Consequently, Alternate Reality Games in the classroom appear to be particularly useful, as they motivate students and, concurrently provide teachers with the opportunity to go beyond evaluation of instructional objectives and focus on skills and competences when students work in an active gaming.

ACKNOWLEDGEMENTS

I would like to thank my colleagues at Platon I.B. World School for their participation and feedback in this study, as well as the School Administration for their trust and support. Most of all I would like to thank my students for inspiring me.

THE EFFECTIVENESS OF ‘LADDERS OF LEARNING’ IN CHEMISTRY EDUCATION

Marie-Therese Hauerstein and Helena van Vorst
University Duisburg-Essen, Essen, Germany

School classes are dominated by heterogeneity in terms of differing prior knowledge, interests and cognitive abilities. During lessons, teachers have to deal with this heterogeneity to support individual learning. The concept ‘Ladders of Learning’ constitutes a teaching method which aims fulfilling these demands. It structures learning processes, divides the learning content into several parts and allows the integration of phases with differentiated instruction. The aim of this study is to analyse the effectiveness of ‘Ladders of Learning’ in terms of students’ cognitive and affective variables. First results of the pilot study reveal satisfying test instrument reliabilities and significant increases in students’ learning outcomes.

Keywords: structuring, differentiated instruction, chemistry education

INTRODUCTION AND THEORETICAL FRAMEWORK

Problem Statement

Students are diverse, for example in terms of prior knowledge, cognitive ability and interest. Caring for successful individual learning processes of every single student, it is necessary to address these differences in school lessons (Dixon, Yssel, McConnell & Hardin, 2014). An opportunity to handle this challenge is offered by the concept called ‘Ladders of Learning’ which structures both the learning process and the learning content. Furthermore, it integrates phases of differentiated instruction. Thus, Ladders of Learning combine a high degree of structuring with differentiated instruction.

How Ladders of Learning affect students’ learning outcome, interest and motivation has not been examined so far. Furthermore, it is not clear to what extent structuring and differentiated instruction interact with each other and which effects result from a combination of both.

Differentiated Instruction

Over the last decades, numerous approaches for handling heterogeneity in the classroom were developed. They can be summarized under headings like individualised instruction (e.g. Fletcher, 1992), adaptive instruction (e.g. Wang, 1980), and differentiated instruction (e.g. Tomlinson, 2003). Most studies focusing on these methods show positive effects on students’ learning outcomes. Taking a closer look at these studies, differences in the realised ways of differentiation can be identified. For instance, the use of differentiated learning material and a variation of the learning pace lead to positive effects in terms of students’ learning achievement. In a study conducted by Slavin & Karweit (1985) maths classes were divided into a high-ability group (around 60 % of the students) and a low-ability group (40 %). The teacher had to differentiate the material and the learning pace, especially to raise the learning pace for the high-ability students. The material was differentiated by involving ‘a high ratio of active instruction to seatwork […], teaching mathematics in the context of meaning, frequent questions and feedback, and management strategies’ (Slavin & Karweit, 1985, p. 355). As a
result, the students of the intervention group learned significantly more than the students of a control group.

In a study conducted by Kallweit (2014), the use of a self-evaluation sheet in chemistry education showed positive effects in terms of students’ learning outcomes. While the treatment group worked on exercises concerning the topic of chemical reactions by using a self-evaluation sheet in a 90-minute chemistry lesson, the control group worked without this sheet but with the same material and in the same time. The study showed that the students of the treatment group benefited from the work with the self-evaluation sheet significantly.

Anus (2014) analysed the effectiveness of an individualised assessment on students’ achievement within a learning situation. Her results show significant effects on students’ learning gains when they are assigned to exercises individually based on a diagnosis.

However, Gruehn (2000) concludes that differentiated instruction leads to negative effects on students’ learning outcome when it is accompanied by a great amount of organizational efforts. As a reason for this, Gruehn assumes students to have potentially less time on task when dealing with this extra effort.

Studies concerning differentiated instruction show that not every student benefits from differentiated instruction in the same way: i.e. high-ability students profit more than low-ability ones (e.g. Kulik & Kulik, 1992, Mavarech & Kramarski, 1997). As low ability students are overstrained by too independent learning settings, they rather benefit from highly structured lessons (Snow, 1989).

**Structuring**

Structuring in general is one characteristic of high-quality teaching (Kounin, 2006). According to Meyer (2014), general indicators for a well-structured lesson are a plausible subdivision of the learning content and clear-cut lesson phases.

In order to enable successful learning of all students, sequencing of the learning content should take students’ learning development into account. Students’ understanding and learning progress are described within so-called *learning progressions*. *Learning progressions* provide ‘empirically grounded and testable hypotheses about how students’ understanding of, and ability to use, core scientific concepts and explanations and related scientific practices grow and become more sophisticated over time, with appropriate instruction’ (Corcoran, Mosher, & Rogat, 2009, p. 8). They consist of different components: a lower anchor (meaning those abilities students already have when starting the learning sequence), an upper anchor (meaning the knowledge goals to be achieved) and several stages of progress in between (Duschl, Schweingruber, & Shouse, 2007). The concrete stages of progress are assumed in advance and validated afterwards (e.g. Stevens, Delgado, & Krajcik, 2009).

Apart from the sequence of the learning content, the content itself should be presented to the students in a structured way (Helmke, 2014). An opportunity to structure lessons are structuring auxiliaries such as advance organizers, concept maps, or *Ladders of Learning* (Ausubel, 1960; Nesbit, & Adesope, 2006; Meyer, 2014; Müller, Lichtinger, & Girk, 2015). Advance organizers date back to the 1960s and David Ausubel. In his original concept, Ausubel described advance
organizers as a textual summary of a new learning content. Furthermore, in a study by Holländer (2010), advance organizers were used as a figural summary. Advance organizers are presented to the students to facilitate the following learning process. They have the characteristic of structuring the learning content, but they do not set the structure of the learning process in advance. In previous studies, advance organizers achieve significant increases in students’ learning outcomes (e. g. Ausubel, 1960; Holländer, 2010).

Concept maps are diagrams that node-link different terms, adding a description of the linked terms’ relation. Just like advance organizers, concept maps only structure the learning content, without giving any information about the order of the learning phases (Nesbit & Adesope, 2006). Meta-studies by Nesbit and Adesope (2006) and by Horton and coworkers (1993) come to the conclusion that the use of concept maps leads to positive effects on student achievement. Students of different educational levels benefit from concept mapping in the same way.

A structuring auxiliary that sets the sequence of the learning phases in advance, considers students’ learning progression and includes phases of differentiated instruction has been put forward in the form of Ladders of Learning.

**Concept ‘Ladders of Learning’**

The concept Ladders of Learning was developed in India in the 1980s to establish school education in rural areas. It focuses on an increased structuring of school lessons and illustrates it to the students. The Ladder of Learning organizes the learning content into several parts, called ‘milestones’, which are based on each other. Each milestone has an inner process structure which systemises the corresponding school lesson (Müller, Lichtinger & Girg, 2015).

For this study, learning material for the chemical topic ‘Bohr’s atomic model’ has been developed. The related Ladder of Learning contains three milestones (Figure 1) that fit the steps of progress proposed and reviewed in a ‘Structure of Matter’ learning progression by Weber, Emden, & Sumfleth (2016).

Every milestone starts with the introduction of a new learning content. This part is called Introductory (Figure 2). Subsequently, students work on exercises to practice the basic knowledge necessary for the lesson (Basic Exercise) before they go through a self-evaluation phase to diagnose their individual learning achievement (Self-Evaluation). Based on the results, they are assigned to exercises on three different levels of difficulty (Individualised Exercise). In order to realise a systematic variation of the levels of difficulty, these exercises have been constructed following the structural competence model for scientific inquiry developed within the project Evaluation of Standards in Science for Secondary School (ESNaS) (Köller et al., 2008). The part Individualised Exercise aims at reinforcing or transferring the new learning content and is conducted in the form of an individualised practice phase. Each milestone is completed by a short content knowledge test and a PowerPoint presentation repeating the learning content of the current milestone (Final Evaluation).

The Ladder of Learning-related learning material used for this study was developed within the North Rhine-Westphalian project Ganz In in cooperation with several teachers from upper secondary schools. Around ten 90-minute chemistry lessons are needed to implement the material in school. The material contains worksheets with exercises that require to be
completed in different cooperative learning arrangements. For instance, they include educational games designed to develop a conception of atomic models or to improve the jargon of chemistry. Furthermore, students have to develop models, for example for the periodic table, and compare them.

Figure 1. The developed ‘Ladder of Learning’

Figure 2. First milestone of the developed ‘Ladder of Learning’
METHOD AND DESIGN

Research Questions

This study focuses on the following research questions:

**RQ1:** To what extent does **structuring** by *Ladders of Learning* have an effect on students’ learning outcome, interest and motivation?

**RQ2:** To what extent does **differentiated instruction** within the *Ladder of Learning* enhance students’ learning outcome, interest and motivation?

**RQ3:** To what extent does the combination of both treatments, **structuring** and **differentiated instruction**, have an effect on students’ learning outcome, interest and motivation?

Study Design

To answer these research questions, an intervention-control group study in a 2x2-design is conducted. As can be seen in Figure 3, three treatment groups and one control group are realized within the design: intervention group A receives both treatments, structuring and differentiated instruction, while group B and group C receive only one of these two treatments. Group D serves as a control group and receives neither structuring nor differentiated instruction.

Figure 3. 2x2-design of the study

This means group A and group B work with the developed learning material of the *Ladder of Learning* (Table 1). Instead of using the exercises with the three different levels of difficulty in the element of *Individualised Exercise*, all students of Group B work with the material that has the average level of difficulty. Group C works with material prepared by the teacher and supplemented by learning tasks of the *Ladder of Learning* for realizing the intended differentiation. In group D, the teacher uses his or her own material for this unit.

Table 1. Treatments of the four groups
Participants
In winter 2016/2017 a pilot study with two groups of the study design was conducted in order to test the quality of the developed learning material for the Ladder of Learning (group A) and to examine the feasibility of group C. The developed learning material and the material for the differentiated instruction have been implemented in one class of 8th grade each from the same upper secondary school in Germany. Both classes were taught by the same teacher and had no significant differences in terms of the tested variables at the pre-test. The participating students (n_A = 24; 54.2 % female; n_C = 20; 60 % female) were between 13 and 14 years old on average.

Test Instruments
In order to investigate students’ learning achievement before and after the intervention, a topic-specific multiple-choice questionnaire in a single-select format has been developed and tested within the pilot study. Additionally, students’ self-concept, their motivation and individual interest in chemistry at school as well as their interest in the relevant topic ‘Bohr’s atomic model’ have been surveyed as control variables with the help of a Likert-scaled questionnaire, adopted from Fechner (2009) and van Vorst (2013). For illuminating the development of students’ content knowledge and situational interest during the intervention, the relevant variables have been surveyed after every milestone with the help of a questionnaire adopted from Fechner (2009) and Holländer (2010). As can be seen in Table 2, the reliabilities of the used items are good to excellent (.86 ≤ α ≤ .91), except for the pre-test scale for content knowledge. The poor reliability of the pre-test scale can be attributed to the fact that the tested items refer to the content of ‘Bohr’s Atomic model’ that students learn during the intervention, hence the items are too difficult for them at the first point of measurement. The purpose of this questionnaire is to detect students’ prior knowledge. With regard to their score in items that correspond to the probability of guessing (Table 3), it can be said that they nearly have no prior knowledge in terms of the current topic.

FIRST RESULTS AND CONCLUSIONS
Between the two groups A and C, only the kind of structuring is varied. While the students of group A work with the developed learning material of the Ladder of Learning, the students of group C work with the material prepared by their teacher and supplemented with the Ladder of Learning-related material for the intended differentiation. Hence, the differentiated instruction was systemized for both groups.
Content knowledge

The results show significant knowledge gains for both groups (A: $t(23) = 9.896$, $p < .001$; C: $t(17) = 9.488$, $p < .001$) with large effect sizes (A: $d = 2.29$; C: $d = 1.69$). In the content knowledge test, 45 points were the maximum. The reached points of the two groups are listed in Table 3 and Figure 4 for both points of measurement. Between the two groups, there are no significant differences in terms of knowledge gains.

Figure 4. Knowledge gains of group A and group C

Self-concept

Further results in terms of students’ self-concepts are summarized in Table 4 and Figure 5. The self-concept questionnaire was Likert-scaled from 1 (= very bad) to 4 (= very good). As can be seen, there are significant gains in students’ self-concept of group A ($t(22) = 2.631$, $p = .015$) with a small effect size ($d = .42$). In group C there is no significant change in students’ self-concept ($t(14) = 1.980$, $p = .068$, $d = .25$). Group A differs from group C in the kind of structuring. As the lessons of group A were structured by the Ladders of Learning related material, the lessons of group C were structured by the teacher. The results indicate a benefit of structuring by Ladders of Learning. Due to the small sample size, the results cannot be generalized before the results of the main study are available.

Individual Interest and Intrinsic Motivation

Figure 6 and Table 5 summarizes the results for students’ intrinsic motivation and individual interest in chemistry. The related questionnaire was Likert-scaled from 1 (= absolutely wrong) to 4 (= absolutely right). In both groups, there is no significant change from the pre-test to the post-test (A: \( t(23) = .785, p = .441, d = .12 \); C: \( t(18) = .128, p = .899, d = -.02 \)). The tested variable seems to be too stable to be affected by this intervention.

**Effects for different ability groups**

As described above, the students of both groups were assigned to three different ability groups for the phase of differentiated instruction. This assignment was based on students’ results in their self-evaluation sheet and therefore oriented on their content knowledge. That is why in the following, the effects on students’ content knowledge are described for different ability groups.

To see whether there are any differences in terms of content knowledge increase between low-, middle- and high-ability students within one group (intervention or control group), the sample was divided into different ability groups based on the students’ last chemistry grade. The German grade system distinguishes between six different grades, with 1 being the best grade. Figure 7 and Table 6 summarize the results. Because of the fact that the differences between the groups are not statistically significant for the first point of measurement, the content knowledge gains are reported from a descriptive perspective.

The low-ability students of group A have an average knowledge gain of 14.17 points. The low-ability students of group C reach 13.00 points more at the second point of measurement than at the first point of measurement. The difference between the two groups measures 1.17 points. Hence, students who learn with the material of the *Ladder of Learning* have a content knowledge gain that is in average 1.17 points larger than the one of the students learning without this material.
The average total score of the middle-ability students of group A have an average content knowledge gain of 13.7 points. The middle-ability students of group C gain 13.5 points in average. The difference of the two groups measures 0.23 points. Hence, there is nearly no difference between the two groups.

Looking at the high-ability students of group A, their average content knowledge gain is 15.57 points. The high-ability students of group C gain in average 13.13 points. Comparing the two high-ability groups, there is a difference of 2.44 points for the benefit of the students of group A.

</tbody>
</table>

Because of the fact that every ability group has knowledge gains, it can be concluded that the material is appropriate for each level of ability. Compared to the students of group C, especially the low-ability and the high-ability students of group A seem to profit from the Ladder of Learning-related material. Both groups work with the individualised exercises, hence, the small descriptive benefit of the group A students could come from the structure provided by the developed Ladder of Learning.

Implementation of the material

In the conducted study, the self-evaluation questionnaire assigned too many students to the highest level of difficulty. The reason for this seems to be the length of the questionnaire which is clearly too short. The students only have two or three abilities in which to self-evaluate. In case the students consider themselves as competent in terms of these items, they are assigned to the exercise with the highest level of difficulty. To distribute the students between the different levels of difficulty more evenly, the self-evaluation questionnaire has been revised as to include more different abilities. Besides this, all abilities are formulated more like short tasks to avoid too abstract phraseologies.

In addition to that the teacher’s content structure in the lessons of group C was very similar to the one of group A. It might well be that the teacher has been influenced by the structure of the Ladder of Learning material.
CONCLUSIONS

The use of the developed learning material for the *Ladder of Learning* leads to significant knowledge gains. Nevertheless, the material will be partly revised for the main study. Especially the self-evaluation sheet will be re-examined and extended. The reliabilities of the test instruments are satisfying.

To generate further information about the influence of differentiated instruction on the tested variables and to examine interaction effects of structuring by *Ladders of Learning* and differentiated instruction, the main study is conducted in winter 2017. The sample of the main study is expected to consist of about 500 students from the 8th grade from 12 upper secondary schools in Germany.

Furthermore, in the main study, measures will be taken to minimize influences of *Ladder of Learning*-related material (used in groups A and B) on the structure of the lessons without this material planned by teachers (groups C and D): From each school, two classes taught by the same teacher will be assigned to either groups A and B or groups C and D (Figure 3). Thus, the combination of groups with and without the *Ladder of Learning* structure is avoided.

ACKNOWLEDGEMENT

The material was developed in cooperation with the North Rhine-Westphalian project *Ganz In* and founded by the Stiftung Mercator.

A MODEL-BASED GENERAL RELATIVITY COURSE FOR PHYSICS TEACHERS

Ute Kraus, Corvin Zahn, Thomas Reiber and Stephan Preiß
Hildesheim University, Hildesheim, Germany

The general theory of relativity is one of the foundations of today’s physical worldview and should therefore be part of the education of physics teachers and also of the school curricula. We present a general relativity course for pre-service physics teachers that is model-based and conceptual rather than mathematical. The course is comparatively short, uses only elementary mathematics, and has a focus on the basic concepts and on the physical phenomena. We also present an evaluation of the course based on written exam papers of students at Hildesheim University over several years of teaching the course. The teaching strategy relies on the fact that general relativity is a geometric theory. Graphic constructions are used to study the properties of curved spacetime. This is made possible by the use of sector models (Zahn & Kraus, 2014) as tools to represent curved spaces and spacetime true to scale. The evaluation is focussed on students’ ability to construct and use sector models.

Keywords: general relativity, astrophysics, teacher education

INTRODUCTION

The general theory of relativity is one of the foundations of today’s physical worldview. Its importance lies both in the fundamental concepts, forming the physical notions of space, time, and gravity, and in the relativistic phenomena that are of major importance in cosmology and astrophysics.

However, in the university education of pre-service physics teachers in Germany, a course in general relativity usually is not part of the curriculum. The existing courses in general relativity are aimed at future theoretical physicists. They involve learning an extensive mathematical apparatus and therefore require a substantial amount of time. In the German teacher education, where future teachers study two subjects plus education science, such a comprehensive general relativity course does not fit into the time available for studying physics. Also, the standard course is an approach that cannot be transferred to school since it involves mathematical concepts that are way beyond the elementary mathematics taught in school.

Teacher education requires a general relativity course sui generis: a short course, with a focus on conceptual understanding rather than on the mathematical formalism, and with an emphasis on the physical phenomena and their astrophysical significance. In this contribution we describe a general relativity course along these lines. It has been developed and evaluated in the physics teacher education at Hildesheim university.

TEACHING STRATEGY

John Wheeler summarized the basic ideas of general relativity stating that “Spacetime tells matter how to move. Matter tells spacetime how to curve.” (Wheeler, 1990). Thus, the basic concept is curved spacetime and its properties, notably its geodesics (being the paths of freely falling particles and of photons) and its curvature (being related to the distribution of matter).
It is apparent that general relativity describes gravity with geometric concepts. These are familiar in the special case of Euclidean geometry, where geodesics are straight lines and the curvature is zero. When questions are geometric in nature we can often use intuitive geometric insight or we can find solutions by graphic construction.

Our teaching strategy for a short and conceptual general relativity course is to use graphic construction and by doing so to aim at developing geometric insight for non-Euclidean geometries. Graphic construction in curved spaces and spacetimes is made possible by using a novel tool developed for this purpose. Sector models (Zahn & Kraus, 2014) are physical models of curved spaces and spacetimes. They are constructed true to scale so that the geometric properties that are inferred from the models are quantitatively correct.

The sector models are two-dimensional (e.g. the symmetry plane of a spherical star), three-dimensional (e.g. the curved three-dimensional space around a black hole), or 1+1-dimensional (i.e. a spacetime with two spatial dimensions suppressed, like in the Minkowski diagrams of special relativity). They permit to construct geodesics with pencil and ruler and to determine curvature components by the measurement of deficit angles with a protractor (Zahn & Kraus, 2014; Kraus & Zahn, 2016).

COURSE DESCRIPTION

The general relativity course at Hildesheim University is taught within a seven week period with a weekly lecture (90 minutes) and a weekly tutorial class (90 minutes). Homework problems are set each week and students are required to work on them on their own prior to discussing results in the tutorial. The course has been developed over several years in cycles of teaching, evaluation, and redesign. It is part of the physics curriculum of pre-service physics teachers.

LECTURE

This sections gives a summary of the lecture (see Table 1 for an overview) with a comparison between the model-based course and standard introductory courses.

Part I Introduction

The introductory chapters of the model-based course are similar to those of many introductory texts on general relativity (e.g. Hartle, 2003; Natário, 2011).

The course starts with the principle of equivalence. The well-known thought experiments about a laboratory system in free fall are used to show that light deflection and gravitational red shift are consequences of the equivalence principle. This section then goes on to give a description of the basic ideas of the general theory of relativity: Gravity is geometry, and a curved four-dimensional spacetime gives rise to the gravitational phenomena.

Next, basic geometric concepts are introduced by studying curved surfaces, in particular the sphere (Figure 1). Curvature is described in a qualitative way that permits to distinguish between positive, negative, and null curvature by inspection (Rindler, 2001). The criterion for positive curvature, for instance, states that a small piece of the surface, when flattened in the
plane, must tear. Geodesics are defined as lines that are locally straight, i. e. lines that locally keep their direction. Using a globe as a physical model, geodesics are studied on the sphere. Geodesics are then used to highlight the non-Euclidean geometry of the sphere (e. g. by showing that two initially parallel geodesics converge, Figure 1). The concepts of coordinates and metric are introduced using the Euclidean plane in polar coordinates and the sphere in spherical coordinates as examples.

Figure 1. Introduction to non-Euclidean geometry: The geodesics of the sphere are the great circles, initially parallel geodesics converge.

Part II The geometry of curved surfaces

This part of the course introduces the tools for studying a curved surface specified by its metric. From the given metric, the geodesics and the curvature are to be determined. At this point, the course deviates from the traditional approach and takes a new path. It does not introduce the geodesic equation and the curvature tensor like the mathematically minded courses (e. g. Hartle, 2003). Instead, sector models are introduced. Again using the sphere as an example, its sector model is constructed and is then used to determine geodesics and curvature. Figures 2 and 3 give a summary of the procedure (for details see Zahn & Kraus 2014; Kraus & Zahn, 2016): The sphere is subdivided into small elements of area (Figure 2a, b). Then, using the metric, the lengths of the edges of all quadrangles are calculated. Finally, quadrangles with the same edge lengths (and the same symmetry properties) are constructed in the Euclidean plane (Figure 2c). These are the sectors that make up the sector model. Each sector can be thought of as a nearly true-to-scale map of the corresponding part of the sphere. Figure 3 illustrates the use of the model: Geodesics are constructed as locally straight lines with pencil and ruler (Figure 3a). In the case of initially parallel geodesics, e. g. this reproduces the fact that two
initially parallel geodesics on the sphere converge (Figure 3b, Figure 1). The geodesics obtained with this graphic method are approximate solutions of the geodesic equation with an accuracy depending on the resolution of the sector model. Curvature is determined by applying the criteria for positive, negative, and null curvature on the level of the discrete model. Figure 3c shows “tearing” of a small part of the surface made up of four sectors sharing the central vertex, thus indicating the positive curvature of the sphere.

Figure 2. Construction of the sector model of a sphere. The sphere is subdivided into small quadrangles defined by their vertices (a, b). Quadrangles with the same edge lengths are constructed in the Euclidean plane (c); these are the sectors that make up the sector model.

Figure 3. Use of the sector model of a sphere. Geodesics are constructed as locally straight lines (a), reproducing the properties of geodesics on the sphere (b, see Figure 1). The criteria for the qualitative determination of curvature are applied to the discrete model, showing the positive curvature of the sphere (c).

Part III The Schwarzschild spacetime

The Schwarzschild spacetime, describing the exterior of a spherical star or a black hole, is arguably the most frequently and extensively treated example in textbooks on general relativity. This course is no exception and is strongly focussed on the gravitational phenomena occurring close to a black hole. Besides its importance, this example has the advantage that gravitational effects are large in the vicinity of a black hole and are therefore clearly visible in the sector models.

The spacetime in the exterior region of a black hole is studied by applying the methods developed in part II to subspaces of dimension two and three of the Schwarzschild spacetime. In the process, the methods are extended from two spatial dimensions to three spatial dimensions and to a spacetime with one spatial and one temporal dimension.

The equatorial plane

The objective in studying the equatorial plane of a black hole is to convey a conceptual understanding of light deflection. This understanding is actually reached by way of an analogy,
because this section is limited to geodesics in space (as opposed to photon worldlines in spacetime).

Due to the spherical symmetry of the Schwarzschild spacetime any geodesic lies completely within a plane of mirror symmetry, in the following called an equatorial plane.

A sector model of the equatorial plane is computed based on its metric and geodesics are drawn across the sector model. This proceeds exactly as described in part II, substituting the Schwarzschild metric of the equatorial plane for the metric of the sphere (Kraus & Zahn, 2016).

The main result is the observation that a geodesic is, on the one hand, a straight line by construction (Figure 3), i.e. a line that at no point exhibits bends or kinks. On the other hand, when a geodesic is constructed that passes close to a black hole, the direction "far behind" the black hole turns out to be different from the direction "far ahead". Transferred to light rays: A light ray is everywhere straight. When it passes through a region of curved spacetime, the asymptotic directions before and after are different. The graphic construction visualizes that these two observations are in accord. Further constructions on the sector model are used to study more details, e.g. the formation of double images. The results are the basis for a discussion of gravitational lenses using both astronomical observations and computer visualizations.

The spacetime of a radial ray

By suppressing two spatial dimensions (as in the Minkowski diagrams of special relativity) and considering the spacetime of a radial ray, the worldlines of light and particles in radial motion can be constructed (Zahn & Kraus, 2018a, 2018b). The goal of this section is to infer gravitational redshift from the Schwarzschild metric and to study vertical free fall in comparison with the Newtonian description.

In this section, a spacetime sector model is computed. The procedure is similar to that described in part II, but must take into account that the metric is not positive definite, so that negative intervals are computed for timelike sector edges (or for spacelike edges, depending on the choice of signature).

To show gravitational redshift, two radial null geodesics are constructed on the sector model. They represent light signals that are emitted at the same radial distance from the black hole, one a short time after the other. The construction shows that signals moving outwards arrive at a larger radial distance with an increased time delay. When the two geodesics are interpreted as the worldlines of wave crests, this translates into an increase in period, i.e. a redshift.

Vertical free fall is studied by constructing timelike geodesics corresponding to objects released at some distance from the black hole with some initial velocity. When the object is thrown upwards, e.g., intuition tells us that it will reach a maximum height and then fall back down (provided it starts with less than the escape velocity). In the general relativistic description, the path of the object is a geodesic, i.e. a straight line. The construction shows nicely that these two descriptions are perfectly in accord.

The construction of geodesics is similar to the spatial case shown in Figure 3a. There is an additional requirement, though, because spacetime sectors must be submitted to Lorentz
transformations in order to continue geodesics across the borders between neighboring sectors (Zahn & Kraus, 2014).

**Space around a black hole**

The focus of this section is the study of a three-dimensional curved space and its curvature properties. Its goal is a qualitative understanding of curvature in three dimensions and, based on this, of the field equations.

This section makes use of a three-dimensional sector model that represents the space around a black hole. To this end, the methods described in Part II are extended from two to three dimensions: The space is subdivided into blocks (corresponding to the elements of area in Figure 2b). In case of the black hole sector model the blocks are chosen to be frustums. To test for curvature, sectors are assembled around a common edge (corresponding to being assembled around a common vertex as in Figure 3c).

The test for curvature by means of the three-dimensional black hole sector model shows that curvature must be described not by a single quantity but by three components (Zahn & Kraus, 2014). This understanding paves the way for a qualitative description of the field equations, linking curvature to matter content (Kraus & Zahn, 2018). For the purpose of illustrating the field equations, a simple neutron star model as an example for a non-vacuum spacetime is also studied via its sector model. The neutron star sector model and its use in teaching general relativity will be presented elsewhere.

**Part IV Cosmology**

The course includes a section on observational cosmology that is similar to the treatment in other introductory texts. Cosmological redshift in the Friedman-Robertson-Walker cosmological model is then studied in more detail. To this end, a sector model is computed for the cosmological spacetime, suppressing two spatial dimensions, and redshift is demonstrated by constructing geodesics. The construction and the handling of the sector model closely correspond to the procedure described in section ‘The spacetime of a radial ray’.

**PROBLEMS AND TUTORIALS**

As described above the lectures are accompanied by homework problems and tutorials. The questions regarding the parts of the course that are presented in the standard way are similar to problems found in standard introductory texts.

Here we will describe the problems that are solved with the sector model approach. They include the construction of additional sector models, both for curved surfaces (e.g. the torus) and for two-dimensional subspaces of curved spacetimes (e.g. the equatorial plane for a simple neutron star model). They also include problems that require handling sector models to study geodesics or curvature. These models are partly constructed by the students on their own (see above) and partly provided as work sheets (in particular spacetime models including Lorentz transformed sectors).

We give two examples of problems that students can work out based on this course by using sector models as tools:
Consider a spacetime with metric $ds^2 = -c^2 dt^2 + (t/14 T_0)^2 dx^2$. Two observers with world lines $x = \text{const}$ exchange light signals. Will they observe a redshift?

The metric of the equatorial plane of a Morris-Thorne wormhole is given by $ds^2 = dl^2 + (b^2 + l^2) d\varphi^2$, where $-\infty < l < \infty$ and $0 \leq \varphi \leq 2\pi$. Two long, straight rigid rods are pushed radially into the wormhole with an angle of 90 degrees between them. Will the rods collide?

LEARNING OBJECTIVES AND ASSESSMENT

Learning objectives can be grouped in three subject areas.

1. Get to know important gravitational phenomena and their significance in astrophysics and cosmology, including light deflection, gravitational lenses, gravitational (cosmological) redshift.

2. Develop understanding for the basic geometric concepts used in general relativity, including non-Euclidean geometry, curvature, geodesics, and metric.

3. Acquire a set of tools to study the physical properties of a (two- or three-dimensional) subspace of a spacetime. This includes the construction of sector models (in two spatial dimensions and in one spatial/one temporal dimension) for a given metric. It also includes the use of sector models for constructing geodesics and for a qualitative determination of curvature (in two and in three dimensions).

The course ends with a written exam with questions of the same type as in the homework problems, addressing objectives of the three subject areas with emphasis on the third. The course is followed in a subsequent semester by a seminar on teaching modern physics in school. Students who completed the course described above then hold workshops on special or general relativity for secondary school students (aged 16 to 19), including among other topics the model-based approach to explain light deflection. Their contributions in this seminar reflect their learning outcomes in subject areas one and two.

In the following section, we present an evaluation of the learning outcomes in subject area three by a combined analysis of the relevant questions in the written exams over several years of teaching this course.

EVALUATION

Participants

The course described above was evaluated using written exams. It was held in the years 2009-2017 with groups of six to thirteen students, resulting in 85 participating students in total. The students were prospective physics teachers in the fourth or fifth semester of their Bachelor studies.

Method

The exams included several complex tasks that led from the construction of a sector model to the determination of the curvature. In some cases, geodesics had to be constructed on a sector
model. To quantify the students’ understanding of the relativistic concepts taught in the course, we re-evaluated the written exams. For that matter, 22 items in total were developed, which were then rated with a scale ranging from 0 to 4 points. In this scale, 4 points were rated if the task was completely fulfilled. If minor errors, like computational inaccuracies, occurred, a rating of 3 points was made. 2 points were achieved if the answer was partially correct. A rating of 1 point has been made in cases an answer contained an important feature but major errors and 0 points if the answer was completely wrong. Also included in the rating are students that gave no answer to an item or answers that could not be classified. Out of the 22 items, only 11 were used for this evaluation, because they had the best statistics and contained the relevant aspects for this discussion. The items were assigned to four categories (see Table 2). While some items were exclusive, i.e. a student had to do only one of the tasks (M1 or M2; S1 or S2; GA or GB), other items were summarized (C1 and C2; GA1-3; GB1 and GB2). Here, the rating for a student was obtained by taking the average of the single ratings (rounded off). To test for inter-rater reliability, after the first definition of the items and the scale for rating the answers, 6% of the exam papers were evaluated by five investigators in parallel. The results were discussed and the process led to a minor adjustment in the item definitions.

Results

In the following sections the items are presented together with the corresponding tasks. We also discuss the main sources of errors in the respective task.

The following problem is an example task that was given in one of the exams, probing M1 and S2: The metric

\[ ds^2 = [1 - (by)^2]d\lambda^2 + d\eta^2 \]  

with \( b = 0.1 \) was given on the region \( 0 \leq \lambda \leq 10, -5 \leq \eta \leq 5 \). The region had to be subdivided into sectors with coordinate length 5 both in \( \lambda \)- and \( \eta \)-direction. Then, the edge lengths of the sectors had to be computed and the sectors constructed in the shape of symmetric trapezoids. The items concerning the subdivision of the region and the use of symmetries of the metric will not be discussed here. With this task, the students could show their conceptual
understanding of the metric by using it for length calculations (M1). The maximum mathematical complexity of this kind of task was an integration of an elementary function. Overall 88% of the students got a rating of 3 or 4 (see Figure 4, category “Metric”). Here, the reductions in the ratings mainly result from errors in the computation.

The task also showed the students’ ability to construct a sector model. The knowledge of the lengths of the four edges (computed using the metric) is in general not sufficient for the unique construction of a sector. The shape of the sectors is usually a trapezoid which is symmetrical with respect to its central axis (e.g. Figure 2c). This symmetry was always mentioned as additional information. The category “Sectors” could be completely fulfilled by 51% of our students (see Figure 4, cat. “Sectors”). In this case, many errors arose because the imposed symmetry was used incorrectly. In Figure 5, a correct answer to this task is displayed. It corresponds to the metric (1).

The following part of this investigation is focussed on the application of sector models. A main feature of the 2D spatial sector models is that the curvature at a certain vertex can easily be verified to be positive, negative, or null (e.g. Figure 3c). In the exams, the students had the task to apply the criteria for the determination of the curvature at a vertex in a given sector model, either in the constructed sector model from the previous task or in a model that was provided. In our study, firstly, we investigated if the students were able to phrase the curvature criterion themselves (C1) and secondly, if they were able to apply the criterion correctly (C2). The ratings of these two items were averaged and are displayed in the “Curvature”-bar in Figure 4. Here, it is shown that 60 of 85 students (71%) could achieve a rating of 3 or 4 in this category.

Another important application of sector models is the construction of geodesics. In the exams, students had to construct geodesics across a sector model. To do this, geodesics have to be continued from one sector to its neighbor (Figure 3a). There are three important items that are needed to correctly do this construction. At first, a geodesic in a single sector is a straight line (GA1), as we have shown above (see Figure 3a). Secondly, when a geodesic hits the edge of a sector, it starts at the same point on the common edge of the neighboring sector (GA2). And lastly, the geodesic keeps the direction (angle) with respect to the edge (GA3). Similar items can also be applied for the construction of lightlike geodesics on a 1+1D (space and time) sector model. The peculiarity about light rays in these models is that they always have a 45° angle to the space and time axis (GB). In this analysis both versions have been tested. The typical task in this category is to start with two parallel geodesics in one sector and continue both to the other end of the sector model. The construction needed to be done either on a given model or the students had to use the model they created in a previous task. In the latter case, problems arose if the construction of the model was incorrect. Again, the ratings for the above-mentioned items have been averaged. The result obtained here is that 58% of the students have completely fulfilled the task to construct geodesics in a sector model (see Figure 4, category “Geodesics”). The fact that the geodesic is to be continued with the correct angle was a main error source in this task.
Figure 4. Evaluation results. Tasks addressing the categories “Sectors” and “Geodesics” were not contained in every exam.

Figure 5. Solution for the construction of a sector model. The sectors are symmetric trapezoids.

DISCUSSION AND OUTLOOK

We have devised and evaluated a general relativity course suitable for physics teacher education. It is a conceptual course with a focus on geometric insight and it is a comparatively short course. The mathematical level is elementary, the metric being the only concept that is beyond standard school knowledge.

The main purpose of the evaluation of this course was to validate if the participants were able to use the tools taught in the course. We assume that with the help of these tools the students can learn the basics of general relativity and improve their conceptual understanding of difficult theoretical building blocks like curved spacetime and the motion of particles on the curved spacetime.

In this analysis, we can show that in the context of our course the concept of the metric is well-known to the students and that the majority of the participants is able to construct a sector model from a given metric of a curved space. We notice that there is a significant difference between the abilities to calculate and to construct a sector model. There is clear evidence that the students in this study are able to deal with the concept of curvature and the results also
show that most of the participants of the course have a good understanding of the concept of geodesics. Since these features are important parts in the treatment of general relativity, the course using sector models seems suitable for teaching this subject.

A possible reason for the difficulties that some students had with the tasks discussed above is lack of attendance in the tutorial classes. We have made the observation that active participation in the tutorials is essential for gaining understanding and expertise in handling the sector models. Attendance at tutorial classes is, however, not obligatory and some students attend sporadically or not at all. We expect that this explains a significant part of the incorrect and missing answers. A future evaluation should, therefore, include data on attendance in class.

As we have pointed out, the construction of geodesics on sector models can be used to visualize astrophysical phenomena like light deflection or cosmological redshift. Unfortunately, we have yet too small statistics to conclude if the conceptual understanding of these phenomena can be improved with the tools used in this course.

Besides prospective physics teachers, other students can profit from the model-based approach, e.g. those who study physics as a minor subject. The course can also serve as a supplement to a standard general relativity course and help to strengthen geometric insight.

The course has been developed over several years in cycles of teaching, evaluation, and redesign. Future work will add to the contents of the course (e.g. particles in non-radial orbits, interior region of a black hole) and will also analyse more closely the development of geometric insight through the model-based approach.

Closely related to this work is the question of how to teach general relativity in school that is attracting increasing attention (Natário, 2011; Henriksen et al., 2014; Pitts et al., 2014; Zahn & Kraus, 2014; Kraus & Zahn, 2016). The model-based approach used in the course for physics teachers is also suitable for use in school. A section of the teachers’ course has been used in a number of workshops (2 to 4 hours duration) with school classes grades 10 to 13. The approach has been presented at in-service teacher courses both at Hildesheim University (annual “Einstein days”) and elsewhere. The development of a course for physics classes in schools is under way.

RESPONSIVE TEACHING ACTIVATING STUDENTS’ EPISTEMOLOGICAL RESOURCES IN SMALL GROUP ARGUMENTATION

Heesoo Ha and Heui-Baik Kim
Seoul National University, Seoul, Republic of Korea

This study aimed to explore how responsive teaching activates students’ epistemological resources and affects their epistemological practices in small group argumentation. The participants were a middle school teacher and 53 students in two eighth-grade classes. Students were divided into small groups to develop group arguments. We chose two cases of teacher intervention that showed the teacher’s responsive practices when leading the students through epistemologically productive practices. We qualitatively analysed the transcriptions of whole-class recordings and of each group’s discourses during the lessons. The analyses showed that the teacher used eliciting questions to understand the students’ thinking behind their responses and to support the students in modifying their justifications, leading to epistemologically productive practices. The teacher’s responsive moves with conceptual support led the students into deeper discussions and maintained the students’ productive practices until they had developed arguments and rebuttals. These findings suggest that teachers need to understand students’ thinking by using eliciting questions and support students’ epistemologically productive practices. Teachers also need to engage in responsive teaching with conceptual support to help maintain students’ epistemologically productive practices. This study contributes to laying the groundwork for teachers’ responsive teaching to foster epistemologically productive small group argumentation practices.

Keywords: responsive teaching, epistemological resources, scientific argumentation

RESPONSIVE TEACHING AND STUDENTS’ EPISTEMOLOGIES

Responsive teaching is an instructional practice that asks teachers to elicit students’ thoughts and respond to them with the purpose of taking in students’ ideas in the course of constructing scientific idea (Levin, Hammer, & Coffey, 2009; Pierson, 2008). Kang and Anderson (2015) stated that responsive teachers continuously engage in the cycle of eliciting, attending to, interpreting, and responding to students’ thinking throughout the course of instruction at the scale of in-the-moment interactions. Responsive teaching has been explained in various ways, but this study aimed to shed light on responsive teaching grounded in the resource perspective, which asserts that students possess potential thoughts that could be activated and advanced to scientific ideas and practices if they were situated in the proper context (Hammer, Goldberg, & Fargason, 2012). By acknowledging and investigating students’ potential, the resource perspective underpins teachers’ responsive teaching practices. By applying this resource framework, responsive teaching can be explained as a form of instruction that elicits students’ potential resources in the proper context, leading to scientific ideas through a productive process (Hammer et al., 2012).

Students’ resources are not confined to the conceptual aspect; they also include an epistemological aspect. To explain the context-dependent nature of students’ epistemologies, the resource perspective considers students’ cognition regarding the nature of knowledge and
learning as constituted by fine-grained and context-sensitive elements (Hammer & Elby, 2002; Louca, Elby, Hammer, & Kagey, 2004). In line with the contention that teachers need to consider the epistemological aspect of students’ practices (Duschl, 2008; Osborne, 2010), there has been growing attention to students’ activation of diverse epistemological resources in differing contexts (e.g. Berland & Hammer, 2012; Louca et al., 2004).

Although responsive teaching has been proposed for authentic science learning, most of the studies about responsive teaching have focused on responsive practices involving students’ conceptual resources, considering students’ productive epistemological framing as a larger context (Radoff & Hammer, 2015). Thus, the understanding of how teachers’ responsive teaching provides support for students’ epistemologically productive practices in science classes still remains limited. Therefore, to expand the understanding of responsive teaching, we explored (1) how responsive teaching practices are carried out and (2) how these practices activated students’ epistemological resources and affected their practices in an argumentation activity.

**METHOD**

The data came from eighth grade mixed-gender classes in a Korean middle school. The research participants were one science teacher (Ms. K) and 53 students from two classes. The students formed seven small groups in each class, with three to four students per group. The teacher majored in biology education and showed a cooperative attitude towards adopting the argumentation activity in her science classes.

During each lesson, the students engaged in argumentation activities that were designed by the researchers. We analysed lessons about eyes and vision. We selected two teacher intervention cases that included the teacher’s responsive practices and clearly showed the students’ activated resources. In the first case of the teacher’s intervention, the students identified the existence of their blind spot through a hands-on activity. They were given a paper containing images of a magician and a mouse. They were asked to continue to focus on the magician while bringing the paper closer and to see what happened to the mouse’s image. Then, in the next argumentation activity, a squid eye model and a human eye model were provided, and the students were asked to choose which eye model could explain their experience in the blind spot activity. The models were contrasted in the existence of blind spot, which led to the next argumentation activity about the evolution of eyes in the second case. In the second case of the teacher’s intervention, the students constructed claims about which of the two kinds of eyes they would say was more evolved. An argument in the worksheet claimed that the squid eye is more evolved than the human eye. Evidence cards providing scientific concepts about the eye structure of squids and humans were provided to support students’ argumentation practices.

We transcribed video and audio recordings of the whole-class discourses and of each small group’s discourses and conducted semi-structured interviews with the teacher after each lesson. Finally, we qualitatively analysed the videos, transcriptions, and the students’ worksheets.

The data analysis passed through three stages. First, we revised the responsive practice framework proposed by Kang and Anderson (2015) so that it would be suitable for explaining responsive practices to the students’ epistemological aspects in the argumentation activity. We
analysed the teacher’s responsive practices based on the revised responsive practice framework, with some inductive modifications to the description of each aspect of responsive practice (Table 1).

Table 5. Teachers’ responsiveness to students’ epistemological framing in the argumentation activity

<table>
<thead>
<tr>
<th>Aspects of responsive practice</th>
<th>Description</th>

<tr>
<td>Interpreting</td>
<td>Inferring students’ epistemological framing based on the students’ responses that the teacher attended to (e.g., how they think the knowledge claims arise, their stances towards the ideas they encounter, or the type of activity they think they are engaged in)</td>
</tr>
<tr>
<td>Responding</td>
<td>Providing support for students to shift to a more productive epistemological framing and engage in more productive epistemological practices</td>
</tr>
</tbody>
</table>

Second, we analysed the students’ epistemological practices and their activation of epistemological resources, using a revised epistemological resource framework (Hammer & Elby, 2002) suitable for analysing students’ argumentation practices. The categories of the revised framework and the resources in each category are presented in Table 2.

Table 6. Categories of epistemological resources in the argumentation activity

<table>
<thead>
<tr>
<th>Category</th>
<th>Resources</th>
</tr>
</thead>
</table>
| Resources for understanding the nature and sources of knowledge | Knowledge as a propagated stuff  
Knowledge as a fabricated stuff |
| Resources for understanding epistemological forms          | Argument with justification  
Argument with coherent justification based on the data  
Argument with justification and qualifier |
| Resources for understanding epistemological stances        | Acceptance of an epistemic authority  
Critical evaluation of justification based on the data  
Proposal of resources relevant to the argument |
| Resources for understanding epistemological activities    | Accumulation of information  
Construction of an argument through discussion |

Finally, we analysed how the teacher’s responsive practices affected the students’ activation of epistemological resources. We used triangulation to enhance the validity of our research.
RESULTS

The teacher’s responsive practices to support epistemologically productive practices were shown in two cases; the students’ epistemological practices in the argumentation activity differed depending on these responsive moves.

Case of small group 1: Responsive practice for modifying justification

Before the teacher’s intervention, the students’ discussion focused on the differences between the squid eye model and the human eye model (Table 3), using scientific terms for each part of the eye without any critical evaluation of each other’s ideas. In addition, although StA also proposed his own thoughts in their construction of a justification (line 138), he copied what StA wrote down on his worksheet (line 140). This transfer of conceptual resources reflects StA’s dependence on StB to make sure he recorded the “correct answers” on the worksheet. We can infer that the epistemological resources activated in this context were knowledge as a propagated stuff, acceptance of an epistemic authority, proposal of resources relevant to the argument, and accumulation of information.

Note. (): Students’ actions. []: Researchers’ additional interpretation of students’ intended meaning.
StC rarely engaged in the discussion but occasionally provided counterarguments or suggestions about his framing of the activity as constructing a justification for their hands-on activity based on the eye models (line 145). This reflected StC’s activation of the epistemological resource of *argument with justification based on the data*, unlike StA and StB, who focused on a simple comparison of the two eye structures. However, the other students did not pay attention to StC’s suggestions and mostly disregarded his framing of the activity.

When the teacher approached the group during her classroom monitoring, StB asked her what they were supposed to discuss, pointing at the activity question on the worksheet. This implies that StB had also been considering the epistemological framing of the activity. Ms. K attended to this consideration and interpreted that the students were having trouble engaging in the argumentation practices with the activation of productive epistemological resources. She started to engage in the students’ discussion, guiding the students to elicit and further their thoughts step by step (Table 4).

</tbody>
</table>
Ms. K asked the students to explain the results of the blind spot activity and then asked for a justification of the results based on the eye model that the students had chosen (lines 159-163). Such questions indicated how the teacher framed the students’ process of constructing a justification. However, StB asked Ms. K about what they were supposed to justify (line 164), indicating that the students did not share the same epistemological framing as Ms. K; in particular, they were unable to activate the epistemological resource such as argument with coherent justification based on the data. To support the students’ activation of this resource, Ms. K guided the students in reframing their results in the hands-on activity as the data in their argument (line 165).

StB provided his ideas as justification, focusing on using scientific terms that they had previously learned in the lesson about eye structure. Ms. K repeated StB’s words with a tone that implied an evaluation of conceptual correctness. It led the students to keep searching for different parts of the eye structure to construct other justifications, without critically evaluating their reasoning. Ms. K reflected on this moment in her interview after the class;

The best advantage of this activity I felt in this class was that I could understand what kind of concept the students possess and what kinds of thoughts they were having at the moment. I didn’t care about students’ everyday thoughts before, but as I was eliciting their thoughts [in this class], I kept trying to figure out what they were thinking … and then support them with additional questions to advance their thoughts. … when
the kids mentioned scientifically incorrect ideas, I kept asking additional questions as I used to do before. So they could have noticed [that their thoughts were scientifically incorrect] through this kind of difference in my practices. … So it remained an unsolved question, how much support would be appropriate for me to provide to the students.

From the interview, we can infer that Ms. K was constantly concerned about the balance between eliciting the students’ everyday thoughts as productive resources and leading them to the scientific concepts. Although Ms. K constantly repeated StB’s words, which indicated that she focused on the correctness of the students’ ideas, she started to shift her attention towards the intention behind StB’s words (line 173). To further elicit StB’s ideas, Ms. K asked for a critical evaluation of the idea within the group (line 177). Moreover, she demonstrated how they could critically evaluate the idea to modify the justification. Specifically, she asked for a more precise description of StB’s everyday experience that was transferred in the discussion, revealing his conceptual resource more concretely. Through these discourses, we can infer Ms. K’s intention to foster a context for the students to activate the epistemological resources knowledge as a fabricated stuff, critical evaluation of justification based on the data, and construction of an argument through discussion. She then asked, in the form of a rebuttal of the student’s idea, for a comparison of the activated resource and the phenomenon they experienced in the blind spot activity (line 185). This supported the shift in their attention from a conception about the eye structure to the logical validity of the justification based on the data. Overall, by interpreting the students’ confusion about the epistemological framing of the argumentation activity, Ms. K tried to support the students so that they could share a critical evaluation of their ideas to construct a valid argument.

At the end of the intervention, StC engaged in a discussion where the group adjusted their data so that they could use it to construct an argument, showing an effort to engage in the critical evaluation of the argument. Right after Ms. K’s intervention, StA told StB, “Your confidence went down” indicating that the student’s perception of StB’s authority had diminished. StB then started to ask the other students for ideas and said, “Let’s interpret these models as we want to. It’s okay to construct justifications on our own, and we can express our thoughts in our own words.” These practices demonstrate the students’ activation of epistemological resources, which the teacher tried to support in her intervention.

Although the students occasionally shifted back to asking for a transfer of the “correct answer” and relying on epistemic authority such as textbooks when they could not propose new ideas (line 285), no one provided definitive answers and they kept proposing new justifications and sharing critical evaluations of them (Table 5). However, when the students did not complete the construction of a group argument and the teacher announced their lack of time for discussion, they stopped this productive practice and shifted back to filling in the blanks on their worksheets, which indicated the activation of the epistemological resources accumulation of information and acceptance of an epistemic authority once again.

Note. (): Students’ actions. [ ]: Researchers’ additional interpretation of the intended meaning.

Case of small group 2: Responsive practice for developing justification and rebuttal

In small group 2, before the teacher’s intervention, the students discussed whether they agreed with a claim provided on the worksheet that said, “Squid eyes are more evolved than human eyes because they don’t have a blind spot.” StE suggested that they needed to develop a justification for this claim that included a comparison of squid eyes and human eyes, starting a discussion to construct a justification (Table 6).

The students’ discourse indicates that the difference between the activated epistemological resources of StD and StE persists. Unlike StD’s consideration of a form of valid justification, StE continued to assert that there should be a comparison of squid and human eye structures because the argumentation question involved a comparison of these two subjects (lines 372-374). This indicates that StD and StE activated different epistemological resources in the category of “understanding epistemological forms”, with StD activating argument with justification and StE activating argument with justification and qualifier to uphold the claim against the counterargument. They did not resolve this issue, and StD stopped trying to discuss it with StE. Instead, she asked for corroboration of her argument from a student in another group in an attempt to prove the validity of her thoughts (lines 375-382).

<td>StD</td>
<td>It cannot distinguish colours but … they can see multiple things [with a wider view] since they don’t have a blind spot.</td>
</tr>
<tr>
<td>414</td>
<td>StE</td>
<td>No, please hear me out. The reason I’ve put this evidence card here [as the one supporting her claim] is this one [human eye] has blind spots but that one [squid eye] doesn’t. That’s what we are supposed to explain … because there’s a possibility that both of them possess it [a blind spot]. But we are telling them that this one has it [a blind spot] but that one doesn’t. Do you get it?</td>
</tr>
</tbody>
</table>

Note. (): Students’ action. []: Researchers’ additional interpretation of the intended meaning.

Without aligning their activation of epistemological resources for understanding epistemological forms, the students continued to discuss how the existence of a blind spot would affect vision (lines 400-409). They focused on activating various conceptual resources in their discussion, showing the activation of the epistemological resource proposal of resources relevant to the argument, but they did not respond to each other’s ideas, showing a limitation on activating the resource critical evaluation of justification based on the data. Then, after StE pointed out her thoughts on constructing a valid justification again (line 414), the students ended the discussion, writing down on their worksheets an argument that was not agreed upon. This showed a change in their activation of epistemological resources for understanding epistemological activities from construction of an argument through discussion to accumulation of information. StB then asked for Ms. K’s help (Table 7).

</tbody>
</table>

Note. (): Students’ actions. [ ]: Researchers’ additional interpretation of the intended meaning. (()): Unintelligible recording. |: Discourses spoken at the same time.

Ms. K started to join the discussion by responding to StE’s question. She responded by asking the students whether thought that noticing colours was a factor that determine the more evolved eye structure. This reflected her epistemological framing of the activity, constructing an argument by discussing a factor that could determine which eye structure was more evolved. This implies the necessity to consider the respective features of squid and human eyes, supporting StE’s activated epistemological resource of argument with justification and qualifier.

StD then asked another question about the existence of a blind spot. Ms. K attended to the conceptual aspect of StD’s justification, interpreting that the students did not understand the concept of a visual pathway. She tried to elicit the concept from the students by asking them what they need to get a rear view. The students’ answers varied, and the teacher attended to the range of the answers, interpreting that the students did not know which specific structure was necessary for visibility and that their speculation was based on this confusion. Furthermore, she could interpret that the students did not reach a consensus on an argument, which indicated a lack of activation of the epistemological resources argument with coherent justification based on the data and construction of an argument through discussion. She responded to them with
conceptual support by pointing out that the direction of the light coming into the eye is the factor that determines range of the vision. It also provided the students another example of justification that incorporates consideration of the difference between squids’ and human eyes, facilitating activation of productive epistemological resources.

After the teacher’s intervention, the students shared Ms. K’s and StE’s epistemological framing and started to discuss the justification based on a comparison of squid and human eye structures (Table 8). StE constructed a rebuttal of the provided claim (line 444) and developed its justification further with specific conceptions about eye structure and visual cells. The students also fostered their justification by bringing up their everyday experiences, proposing critical opinions about each other’s ideas. Such discussion after the teacher’s intervention demonstrated the activation of productive epistemological resources, namely knowledge as a fabricated stuff, argument with coherent justification based on the data, critical evaluation of justification based on the data, and construction of an argument through discussion, indicating their epistemologically productive practice.

Note. (): Students’ actions. [ ]: Researchers’ additional interpretation of the intended meaning.
CONCLUSIONS AND IMPLICATIONS

The cases showed the teacher’s efforts to the attend to students’ thinking behind their utterances and how she elicited and responded to the students’ epistemological features to facilitate productive practices. Specifically, the teacher supported the students’ activation of productive epistemological resources by eliciting and interpreting the students’ thoughts in terms of how they constructed their arguments. She paid more attention to how the students justified the results of their activity, such as their everyday experiences that were applied to the justification or the conceptual resources they focused on as an important factor to support their claim. She then responded to the students’ arguments by rebutting the incoherence of their ad hoc justifications, guiding the students to further reconsider their justifications instead of imposing her thoughts over their thoughts. The teacher’s responsive teaching fostered the context for the students to modify their justifications by advancing the epistemological aspects of their argumentation practices.

This research identified a teacher’s responsive teaching approaches to argumentation, which is a core practice of authentic scientific practice and has a significant effect on students’ epistemological support. The study expands the understanding of the role of responsive teaching in supporting students’ epistemologically productive practices and authentic scientific practices.

MTA-SZTE Science Education Research Group

An increasing number of countries in the world admit the outstanding importance of high-quality teachers. Studies have started to focus on teachers’ effectiveness through the examination of the relationship between teaching strategies and student performance. The first aim of our research is to examine whether the strategies favoured by Hungarian teachers are consistent with the international findings; then, we will explore the relationship between the identified strategies and children’s scientific reasoning skills at classroom level. We hypothesize a correlation between classroom teachers’ teaching strategy and children’s performance. Our research consists of two parts: (1) a teachers’ questionnaire about teaching and (2) an assessment of students’ reasoning skills. The online data collection was carried out in 2015 among 237 classroom teachers and 4010 primary school students in Grade 4. The teachers’ questionnaire consists of 30 items; the scientific reasoning test consists of 64 items. The reliability of both assessment instruments was good (questionnaire: Cronbach’s alpha=.81, test: Cronbach’s alpha=.85). We have directly linked each teacher to his/her classroom; therefore, we received more accurate results than school level-based studies. In line with international findings, we identified three subscales of teaching strategy by using factor analysis (KMO=.785): teacher-directed, cognitive-activation and active learning strategy. The most commonly used instructional strategy is teacher-directed, which is followed by the cognitive activation and the active learning strategy. Active learning is the only strategy that shows correlation with the scientific reasoning test (r=.22, p<.05), and teachers who have participated in in-service training programmes about teaching science subjects use active learning methods more frequently (r=.18, p<.01). Considering these results, we have to offer more opportunities for teachers to expand and improve their teaching techniques to encourage active learning strategies in the classroom.

Keywords: teaching methods, primary school, scientific reasoning

THEORETICAL FRAMEWORK

The success of education is influenced by many factors, and one of the key elements is the teacher. The outstanding importance of high-quality teachers is more and more recognised all over the world. Several research projects focus on the study of teachers’ knowledge, beliefs and self-efficacy, and an increasing number now focus on teacher’s effectiveness through the examination of the relationship between teaching strategies and student performance, e.g. Catalano, Perucchini and Vecchio (2014); Samson, Enderle and Grooms (2013). Due to international student assessments, many background studies started to examine the extent of different effects on student performance. Schroeder, Scott, Tolson, Huang and Lee (2007) looked at the effects of teaching strategies on student achievement in science. They analysed sixty-one studies and identified 8 teaching strategies. The main message of this study is that
alternative teaching strategies exerted a positive influence on student achievement when compared with the traditional teaching methods used in the instruction of the control groups. The direct antecedent of our research is the OECD’s ‘Teaching Strategies for Instructional Quality’ research, which is based on the analysis of the TALIS-PISA link database (OECD, 2016). The OECD linked the PISA 2012 mathematics results to the teaching strategies part of the TALIS questionnaire to gain some insight into teachers’ effectiveness in the 8 participating countries. This research identified three main teaching strategies at school level: active learning, cognitive activation and teacher-directed instruction (Table 1). Student discussions, teamwork, cooperation and both peers’ and tutor’s reflexions play a key role in the use of active learning. The cognitive activation strategy uses instructional methods that create challenges for students engaging their higher order thinking skills to solve the problem. Teacher-directed instruction is clear, simple and easy to follow; requires no complex thinking skills.

<tbody>
<tr>
<td>Consists of promoting the engagement of students in their own learning.</td>
<td>Refers to the use of practices capable of challenging students in order to motivate them and stimulate higher-order skills, such as critical thinking, problem solving and decision making.</td>
<td>Refers to teaching practices that rely, to a great extent, on a teacher’s ability to deliver orderly and clear lessons.</td>
</tr>
<tr>
<td>Under this strategy, students’ discussions, group work, co-operation, reflection and the necessary support to foster these activities play a central role.</td>
<td>This strategy not only encourages students to find creative and alternative ways to solve problems, but enables them to communicate their thinking processes and results with their peers and teachers.</td>
<td>Making explicit the learning goals, providing a summary of previous lessons or asking short, fact-based questions are examples of practices that help to structure lessons.</td>
</tr>
<tr>
<td>Furthermore, the inclusion and use of information and communication technologies (ICT) in the classroom can help to foster an interactive and individual learning environment.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

According to the TALIS-PISA results, students learning through the cognitive-activation strategy achieved significantly better results than others. The teacher-directed strategy is mostly used among lower-performing students. Thus, the teacher-directed strategies can help students succeed on easier tasks, but they may not be the best strategy in the long run to prepare students for more complex tasks. The study did not find any significant connection between the strategies used and the level of students’ engagement. Teachers working at the same school tend to use similar strategies, and the teachers in schools with students from disadvantaged socio-economic background tend to have fewer opportunities to attend further training. This research focuses on mathematics teachers and the mathematics performance of 15-year-old students. For the development of our teachers’ questionnaire, we took the TALIS-PISA link data analysis into account, but we also examined younger students, and the students’ scientific
thinking. Our research is highly relevant because very little data is available about the instructional methods used by Hungarian classroom teachers and their impact on students’ scientific knowledge. Most importantly, we have examined one of the main components of scientific knowledge: scientific reasoning skills.

There is a growing need to learn the methods of science along with science content. Scientific reasoning is an important component under the cognitive strand of 21st century skills and is highly emphasized in the new science education standards (Zhou et al., 2016). There is a greater emphasis on general reasoning skills needed for open-ended scientific inquiry (Bybee & Fuchs, 2006). Scientific reasoning can be defined as international knowledge-seeking and coordination of theory and evidence (Kuhn, 2002). This process of knowledge acquisition change encompasses the abilities to generate, test and revise theories and hypotheses, and to reflect on this process (Kuhn & Franklin, 2007; Wilkening & Sodian, 2005; Zimmerman, 2007). Scientific reasoning skills include the ability to systematically explore a problem, formulate and test hypotheses, control and manipulate variables, and evaluate experimental outcomes (Bao et al., 2009; Zimmerman, 2007). Scientific reasoning is important for participation in the knowledge society as an autonomous, critical thinker and is a key part of so-called 21st century skills (Fischer et al., 2014; Osborne, 2013). Traditionally, developmental psychologists argued that scientific reasoning skills emerged only during adolescence (Inhelder & Piaget, 1958). In contrast, in the last 20 years developmental research has found plenty of evidence for the existence of early competencies (Bullock, Sodian, & Koerber, 2009; Zimmerman, 2007). Research findings indicate the appearance of basic experimentation and evidence evaluation skills in preschool and elementary school children.

AIMS

The aim of our study was to twofold. First, we explored the underlying factors of teachers’ teaching strategies in 4th grade science class. Secondly, we looked at the effects of the teaching strategy used on students’ scientific reasoning performance. In line with the OECD research, we hypothesized that teacher-directed strategies and cognitive activation strategies are used the most by the teachers, while active learning strategies are used less often. We predicted a connection between teaching experience and the strategies used. As the test measured scientific reasoning skills and inquiry skills, we expected students using cognitive activation and active learning strategies to perform better.

METHODS

Sample

The sample of the present study was drawn from the Hungarian Education Longitudinal Program (HELP), in which 4010, 4th grade students of 206 classes of 113 schools participated (Table 2). The sex ratio in the students’ sample is balanced.

The teachers’ questionnaire was completed by the science teachers working in the participating classes, and all together 237 primary school teachers participated in our research. The average age of teachers in the sample is high; half of the teachers are older than 50 years and have more than 30 years of experience (Table 2). The sample is reasonably typical of Hungarian
conditions (Eurostat database, 2017). The average age of Hungarian teachers is high (around 40 years old), most of them are women; there is a shortage of male teachers and science teachers as well. Most of the lower elementary teachers in our sample have a degree from a teacher training college and teach in Grades 3 and 4. Only 5% of our sample has got a university degree. Almost 80% of the teachers participated in in-service teacher training in the past 3 years. Based on the available data, we linked and analysed the achievement data of 2618 students and the teaching strategies of 135 teachers.

**Measurements**

To explore teaching strategies, we composed a self-reported questionnaire based on the TALIS items (OECD, 2014). Besides background variables (gender, age, qualifications, professional experience, in-service training) we identified the use of instructional methods using 22 items. 9 of the items were the same as those used in the TALIS study. The questionnaire consists of three subscales with one subscale for each of the three strategies. Six items belonging to the active learning subscale examine the frequency of the students’ experiments, short presentations, projects and the out of school social activities during science classes. Nine items of the cognitive activation subscale measure the use of discussions, debate, problem-based assignments, the presentation of the connection between science and everyday life; and seven items of the teacher-directed strategy subscale assess the emphasis teachers put on the transfer of the curriculum, on highlighting the essential elements, on practicing the assignments and on helping students lagging. We used a four-point Likert scale (1 = never, 2 = rarely, 3 = often, 4 = always).

The online Scientific Reasoning test consists of two subtests (Table 3). One of the subtests measures some basic reasoning skills with 29 alternate or multiple-choice items. In order to complete the tasks students had to operate different thinking processes such as conservation; proportional, correlational, probabilistic reasoning and classification skills in science context (Figure 1). These reasoning skills are the general components of thinking, and they play a fundamental role in the acquisition of scientific knowledge.

The inquiry skills subtest consists of 35 items assessing different types of inquiry stages: identifying research questions and hypothesis, designing experiments, interpreting data and drawing conclusions (Figure 2). These skills are important components of scientific knowledge and the knowledge acquisition process.

- 5 minutes
- 7 minutes
- 10 minutes

Figure 2. Analysis of the experiment and drawing conclusion – A sample item for measuring the inquiry skills in the Scientific Reasoning test
Data collection was carried out in May 2015. The assessments were carried out in the schools’ ICT rooms by means of the eDia (Electronic Diagnostic Assessment) system. Students completed the online tasks by clicking on or moving objects on the screen by dragging-and-dropping. Immediate feedback was given after test completion.

RESULTS

The reliability of the questionnaire was good (Cronbach’s alpha=0.81). As a result of the exploratory factor analysis (KMO=0.785), we identified three subgroups in line with the TALIS-PISA link report (OECD, 2016): active learning, cognitive activation and teacher-directed strategy. During the analysis, we summed the scores of the items belonging to the same subscales. The most commonly used instructional strategy is teacher-directed, which is followed by cognitive activation and the active learning strategy (Table 4).

Table 4. The frequency of teaching strategies uses among teachers (N=237)

</tr>
<tr>
<td>Teacher-directed strategy</td>
<td>80.2</td>
<td>9.5</td>
</tr>
</tbody>
</table>

The correlation analyses between teaching strategies revealed that the strongest correlation is between the use of active learning and cognitive activation strategy (r=0.47, p<0.01), while the teacher-directed strategy shows a stronger correlation with the cognitive strategy (r=0.31; p<0.01) than with the active strategy (r=0.14, p<0.05).

We found no difference in strategy use based on age or teaching experience. For the background variables, the only correlation is in the case of in-service professional training: those who have participated in in-service training programmes on teaching science subjects, are the ones who use active learning methods most frequently.

The scientific reasoning test proved to be reliable (Cronbach’s alpha=0.85). The results of the inquiry skills subscale are significantly higher than the reasoning skills measured on scientific content (paired samples statistics t=-20.252 p<0.01). Broken down by gender, girls’ performance is higher on both the complete test and on the subtests as well (Table 5).

</table>
To examine the correlations between teaching strategy and science test results, we compared the teachers’ total scores on the three subscales to the results of the 4th grade students’ who they taught (N=2618). Only the active learning strategy shows a significant correlation with the scientific reasoning test (r=.22, p<.05) and the inquiry skills subtest. and the inquiry skills subtest (r=.24, p<.05). Among the examined 22 items, performance is positively correlating with 3 subscales of active learning: ‘We make student presentations.’ (r=reasoning skills=.34; r inquiry skills=.32; r total test=.34 p<.01); ‘We conduct student experiments according to my instructions.’ (r=reasoning skills=.25; r inquiry skills=.25; r total test=.26 p<.01); ‘We visit out of school places (e.g. zoo, museum, nature trail).’ (r=reasoning skills=.25; r inquiry skills=.25; r total test=.21 p<.01). The teacher-directed item of ‘I help those, for who the learning material is too difficult.’ correlates negatively with the test performance (r=reasoning skills= -.23; r inquiry skills= -.28; r total test= -.27 p<.01).

DISCUSSION AND CONCLUSIONS

Our data suggest that Hungarian primary teachers in the science lessons prefer frontal methods with teacher-directed processing and practicing of the instructional material. The cognitive activation strategy, in which students are given the opportunity to discuss the issues raised and to get to know the social relevance of the learning material, is used with a similar frequency. The least typical strategy in the classroom is a method relying on students’ active participation (e.g. student experiments, project work, presentations, inquiry-based learning). This could be explained by the learning material, which is a large amount and is very much knowledge-oriented already in the early phase of learning, which has an effect on teaching strategies. Teachers concentrate on the transmission of knowledge and to teach the basic terms and relationships, therefore, they have little time for an active student activity, for inquiry, examination and to discuss experiences.

The other factor that influences the differences found on the use of diverse instructional strategies could be teachers’ preparedness and their existing methodological knowledge. Our results are in accordance with previous research results (see for example Hódi, B. Németh & Tóth, 2017; Rice, 2010). They show that teaching experience has less influence on the instructional methods used by the teachers, it only plays a role during the initial phase. Our data show that the in-service training programmes have a higher impact on the use of active learning strategies – which are the most effective in the development of scientific reasoning –, than teaching experience has. Our research draws attention to the importance of in-service teacher training, and to the key importance of the integration of modern teaching methods into classroom practice.

We would expect that in the development of scientific thinking both cognitive and active strategies have a demonstrable effect. Our data, however, only confirmed the role of active learning strategies. This can be explained by the nature of the test. The inquiry skills subtest measured such skills, of which development can be promoted by active learning methods, like student observations, examinations, student experiments facilitated by the teacher.

LIMITATIONS

The teachers’ questionnaire used self-report. As a next step, we could analyse actual teaching practice through video-analysis on a smaller sample, and it would be necessary to ask the students on the applied teaching and learning methods during science lessons. The examined
teaching strategies explain the differences between students’ performance to a small extent. To understand the further effects, it would be necessary to reveal students’ affective features and socio-cultural background, and other features of the learning environment. Our research focused on the early phase of scientific learning, when according to age characteristics, both the nature of the curriculum and the teaching strategy is different than in the latter phases. Teachers’ qualification varies as well. From 1st to 4th grade, mostly teachers with college degree teach science, while from 5th grade – with the beginning of the disciplinary education – subject teachers with scientific qualification participate. Therefore, it would be advisable to extend the research to the upper elementary school and to secondary school as well.

ACKNOWLEDGEMENT

TEACHERS’ KNOWLEDGE FOR TEACHING CHEMICAL BONDING: SCOPE AND TRAJECTORIES

Chemical Bonding is a central concept in the study of chemistry. It is foundational in that it is difficult for chemistry students to progress without understanding how and why atoms bond. Research over several decades shows multiple conceptions and misconceptions of bonding in the student population. Given the abstract nature of the topic these incorrect ideas must originate in teaching. This paper thus focuses on the extent to which teachers succeed in taking student ideas into account through their topic specific knowledge for teaching the topic, also known as Pedagogical Content Knowledge (PCK). The paper analyses three aspects of teacher knowledge from three studies – how their PCK for teaching chemical bonding develops through their career, whether short term workshops can make an impact on their PCK and how a group of teachers sequence material for teaching chemical bonding. The findings show that events over the careers of teachers can play a significant role in shifting their teaching approaches, from being textbook bound and teacher-focused, to including students’ ideas into their teaching strategies. Significant events include professional development opportunities, teaching experience and the input from colleagues and students. The attendance of short term workshops can show both short and long term gains. The long term gains depended on whether they taught the topic shortly after the workshop. Changes in the curriculum also played an important role in determining classroom practice with sequencing of concepts being a key issue. In the study reported teachers do not get much assistance from curriculum documents and evolve their sequencing largely from their determination of student difficulties from research on teaching and learning and the logic of the content structure. Overall the findings connect well to the components of the model used in the first study and show that events throughout the careers of teachers can play an important role in shaping the career trajectories

Keywords, chemical bonding; sequencing, PCK

INTRODUCTION

Feiman-Nemser (2001) views learning to teach as a life-long endeavour, a learning continuum that starts with pre-service training and ends when a teacher permanently leaves the profession. Teacher learning can therefore be viewed on a trajectory over an entire career, some learning being planned and intentional, for example participating in formal professional development activities, but more likely entailing learning that is incidental and unplanned, as a result of larger and smaller events that happen on a daily basis. Mapping the scope and trajectories of teachers’ knowledge for teaching, by investigating the impact of significant events, such as professional development activities, the influences of changes in the curriculum, and the impact of classroom experience, can provide insight into how to better support teachers and shorten the route to expertise. These influences may lead to changes in patterns of sequences in teaching
a particular topic or shifts in knowledge of different explanatory frameworks after a topic specific workshop.

This paper investigates the above changes in the context of chemical bonding, a crucial component of high school chemistry courses which needs to be rigorously taught to avoid confusion in later studies. The topic is taught using a variety of explanatory frameworks (Taber, 2002). Teaching this topic requires thoughtful application of such frameworks. Chemical bonding is abstract hence misconceptions held by learners are likely to arise from teaching.

The paper considers two aspects of teacher knowledge development - the career trajectories of their knowledge for teaching chemical bonding and the influence of significant events, such as participation in professional development activities, changes in the curriculum, and teaching experience on their PCK for teaching the topic. The study was guided by the following research questions.

1. How can teacher learning trajectories for teaching chemical bonding be mapped?
2. What is the impact of a one-day workshop on teachers’ knowledge for teaching chemical bonding?
3. What patterns of learning sequences do teachers use for teaching bonding?

LITERATURE

Chemical bonding is a topic where understanding is developed over time, through multiple models. Students need to be able to interpret multiple symbolic representations of a chemical bond (Tan & Taber, 2010). One of the goals in science teaching is to facilitate deeper understanding of the science content amongst students. Students start off with a very basic understanding of bonding, but, over time, they expand their understanding by including more sophisticated models (Taber, 2003). The teaching of chemical bonding should therefore facilitate this expansion of students’ content understanding, shifting their understanding beyond viewing bonds as shared or transferred electrons to seeing bonding as electrostatic interactions, and then as interactions between orbitals (Taber, 2002).

There is evidence that students’ difficulties with chemical bonding may emanate from the use of certain teaching models. For example, Levy Nahum, Mamlok-Naaman, Hofstein, and Taber (2010, p. 185) argue that students had difficulties ‘finding a model of melting and vaporization, which enabled bonds to form when particles were in close contact.’ Dhindsa and Treagust (2014) argue that the difficulty in understanding chemical bonding is linked to a teaching sequence that starts from ionic, covalent and polar covalent bonding. In most countries, curricula are designed based on a constructivist approach which favours a sequence starting from covalent, polar covalent and ionic bonding.

The investigations were framed theoretically by the understanding that teachers transform their knowledge of a specific topic (Content Knowledge, or CK) using their knowledge of learners to develop specialised knowledge for teaching, referred to by Shulman (1986) as pedagogical content knowledge (PCK). Despite debates surrounding PCK (Kind, 2009) there is now substantial agreement that PCK is topic specific (Aydin, Friedrichsen, Boz, & Hanuscin, 2014; Gess-Newsome, 2015) and can be differentiated as either personal or collective (Gess-
Collective PCK relates to shared teacher knowledge while personal PCK refers to knowledge implemented in practice taking context into account. A necessary precursor of PCK is knowledge of the relevant content of the topic to be taught (Kind, 2009).

PCK has been modelled in various ways (e.g. Gess-Newsome, 2015; Magnusson, Krajcik, & Borko, 1999) and multiple components have been considered essential for its development. Common to most models are two components emphasised in the intervention in this study, namely knowledge of student prior knowledge and conceptual teaching strategies. These two components are considered canonical knowledge as they appear in the Topic Specific Professional Knowledge (TSPK) box of the Gess Newsome (2015) model. Toerien (2017) modifies this model slightly to include a topic specific content component in the second box which she renames as Topic Specific Knowledge for Teaching (TSKFT).

![Figure 1: Adapted Model of Teacher Professional Knowledge and Skill, including PCK (Toerien, 2017)](image)

Teaching is a complex endeavour with many different long term and short term experiences playing a role in the growth of knowledge. Long term influences include teaching experience (Hashweh, 2005) and gaining further qualifications (Toerien, 2017). Other influences may be short term single events such as a one-day workshop on a specific topic.

Daehler, Heller, and Wong (2015) draw several lessons from their experiences with three interventions in science education, the most recent being “Making sense of science”. They conclude that professional development activities can be employed to improve teacher PCK, outlining several key ingredients that contribute to PCK growth, including the intertwining of science learning with teaching, high quality teacher learning experiences that model exemplary instruction, an emphasis on deep conceptual understanding of the content in both teaching and
learning and the leverage of collaborative sense making. Luft and Hewson (2014) argue that it would be useful for future professional development interventions to investigate how teachers learn about a concept. In this paper we look at a conceptually based short term intervention based on chemical bonding.

METHOD

To answer the first question, the learning trajectories of a group of experienced chemistry teachers in South Africa were mapped with respect to their topic specific knowledge for teaching (TSKFT) chemical bonding (Toerien, 2017). A multiple case study design was followed with in-depth interviews providing insight into the events which played a role in the teachers’ perceived shifts in their knowledge for teaching. Ten high performing experienced teachers were selected from 60 respondents to a validated TSKFT questionnaire on chemical bonding to take part in 90-minute long story-line interviews (Nilsson & van Driel, 2011). In the interviews teachers reflected retrospectively over their careers to identify and elaborate on significant events that played a role in the perceived shifts in TSKFT. Teachers also drew story-line graphs for each of the knowledge components (Student prior knowledge and conceptual teaching strategies under investigation here) to help them remember the influence of past events. A grounded analysis of the individual interview transcripts and story-line graphs preceded a cross-case analysis to identify significant events and shifts in teacher knowledge, and identify the trajectories for the group of teachers.

To answer the second question, the impact of a one-day workshop on content knowledge and PCK of teachers was investigated in a small-scale case study. Although we were aware that short interventions may have limited impact (Supovitz & Turner, 2000), we were persuaded that tightly focused content and the centrality of the topic to chemistry would contribute to positive impact, as teachers respond well to interventions that have potential to improve student learning outcomes (Guskey, 2002). Twenty-one teachers of varying experience and qualifications attended a one day interactive workshop on aspects of teaching and learning chemical bonding.

As a pre-test, participants answered a previously validated instrument comprising 25 four response multiple-choice questions testing their understanding of chemical bonding concepts. During the workshop they were exposed to research findings on learners’ misconceptions about aspects of chemical bonding and provided with opportunities to plan and deliver mini-lessons focused on addressing these. Participants answered the same knowledge test instrument after the workshop. Three months later nine teachers answered Toerien’s TSKFT questionnaire (Toerien, 2017). In the intervening period, part of this group had taught chemical bonding to their students in schools. The knowledge tests were analysed using traditional item analysis such as facility percentages and the TSKFT test was analysed using a validated rubric.

To answer the third research question, on the impact of a change in the curriculum, and the accompanying introduction of new curriculum documents on the sequence in which chemical bonding was taught, 227 physical science teachers answered a survey in which they were asked about their approach to sequencing topics in chemical bonding. From this group, 11 experienced physical science teachers were interviewed. In the interviews teachers were asked
for details on their teaching approaches and planning, particularly the strategies they use to ensure understanding of chemical bonding by learners. The interviews were analysed using the Model of Education Reconstruction (Komorek & Duit, 2004).

RESULTS

In response to the first research question, one of the ten cases, Doreen’s, is presented below to illustrate the findings.

Doreen had 16 years’ teaching experience. She graduated with a bachelor’s degree in botany and zoology. Although she wanted to become a biology teacher, she accepted a post teaching chemistry and physics. Her teaching strategy at the beginning of her career was influenced by the opinions of her more experienced colleagues at the school which were strongly textbook bound. ‘I was scared that if I missed a word from the textbook, they [the students] would fail. ... In our school there was very little emphasis on prior knowledge, so you would have to just start pumping them full of information.’ Over time, as she gained teaching experience, she was able to shift her attention to what her students were saying. She indicates this as ‘learners’ answ[ers]’ in her story-line in Figure 2.

![Figure 2. Doreen’s story-line of her perceived shifts in knowledge of student prior knowledge](image)

Post-graduate studies in education later in her career increased her knowledge about how students learn and provided her with knowledge about topic specific misconceptions to interpret her students’ ‘incorrect’ answers. She reflects on this as follows: ‘And only recently I know that an answer is not just correct or incorrect. If it is incorrect, there is a reason why it is not there …there is something causing that reasoning of the child to think that he is right’. The feedback from students and further studies later in her career increased her knowledge of students’ ideas, which she could incorporate into her teaching strategies by moving away from the textbook, and becoming more student-focussed.

As a result of the frequent curriculum changes in South Africa, Doreen had the opportunity to attend curriculum training workshops. The workshops challenged her knowledge of curricula and supported the move away from textbooks to developing her own teaching sequence: ‘...because I knew the content, and I was confident… I don’t teach from the textbook at all.
anymore. I am teaching a section that I know I am supposed to be teaching for the day, and I teach it with a structure that I consciously planned to teach’. Doreen indicated this event as ‘curriculum change’ on the story-line in Figure 2.

Analysis of Doreen and the other teacher’s experiences identified three prominent themes or events which they perceived to have had significant influence on their knowledge for teaching - the influence of professional development activities, changes in the curriculum, and teaching experience. This led to the studies for research questions 2 and 3.

To answer the second research question regarding the professional development workshop, the diagnostic pre- and post-tests were analysed by calculating overall scores, averages and standard deviations, as well as teacher performance on each item. Results showed improvement in the test score average from 60% (pre-test) to 88% (post-test) with a stable standard deviation. Facility indices on specific questions ranged from 16% to 95% (pre-test) and 52% to 100% (post-test). Improvements in correct responses of greater than 50% on individual questions were observed for six questions. For example, Figure 3 shows responses to question 11: “Why do atoms form bonds?”, a fundamental concept in chemical bonding. A shift towards the correct response of 64% was observed. The correct response is shown using an asterisk.

Question 15 (“What happens in the jar?”) showed the poorest performance, generating a negative change between pre- and post-test. Nevertheless, figure 4 shows that a majority of teachers provided the correct response pre- and post-test. However, post-test an appreciable number gave the incorrect response D and some shifted from the correct response B to A. Responses show that some teachers retain the notion that sodium chloride comprises molecules, a misconception documented by Taber (2002) despite the fact that this was dealt with in the workshop.

11. Why do atoms form bonds?
A. This is what they want to do
B. Forming bonds makes atoms more stable
C.* Forming bonds is energetically favoured
D. Atoms are happiest with full shells of electrons

![Question 11](image)

Figure 3: Pre- and post-workshop distribution of responses to “Why do atoms form bonds?”
15. Hot sodium reacts violently with chlorine gas in a gas jar. An exothermic reaction occurs that spatters sodium chloride on the sides of the jar. Which description best fits what happens in the jar?

A. Sodium chloride molecules form by electron sharing between sodium and chlorine atoms
B. An ionic lattice forms from sodium and chloride ions
C. A giant covalent lattice of sodium chloride forms
D. Sodium and chloride ions form by electron transfer which bond to make sodium chloride molecules

**Figure 4: Pre- and post-workshop responses to “What happens in the jar?”**

TSKFT data for the 9 teachers were analysed using a rubric to obtain competence, and identifying explanatory frameworks used by participants to describe chemical bonding in different contexts (Taber, 2002). The items were scored using a previously validated rubric on a four point scale of 1 (limited), 2 (basic), 3 (developing) and 4 (exemplary). The CK portion of this delayed test was scored using a validated memo.

CK scores of seven of the nine teachers ranged between 58% and 98%. Two scored below 50, one (28% and 48% respectively). The latter had evidently not engaged with the questionnaire providing only one or two word answers where explanations were required. The former, a masters’ student with a poor CK background and no teaching experience showed contradictory knowledge of concepts emphasised in the workshop. This teacher had scored 93% in the multiple-choice post-test, suggesting that learning from the workshop was superficial and short-lived. The delayed test required explanations, rather than multiple choice answers. Of the other seven participants, five were practising teachers who had just completed teaching chemical bonding. The two remaining respondents were faculty members in physics and physics education, both with previous exposure to undergraduate chemistry.

The TSKFT test generated an overall score of 3, grading most group members as “developing”. Three teachers scored at the basic level and one at exemplary TSKFT. The two components emphasised in the workshop, learner knowledge and conceptual teaching strategies, scored consistently at 3 (developing). Qualitative analysis of responses showed a move towards more sophisticated explanatory frameworks, for example, from an “octet” type to adopting a “minimum energy” principle.

The findings on the third question, regarding sequencing patterns for teaching chemical bonding, were obtained by comparing teaching sequences analysed from various sources – survey and interview data from teachers, curriculum documents and prescribed textbook. The learning sequences obtained from different data sources are given in Table 1.
Table 1. Patterns of chemical bonding learning sequences from survey, policy documents and textbook

From Table 1 it is clear that the curriculum policy document is not explicit on a learning sequence of topics for chemical bonding. This may indicate either that sequencing is not viewed as critical by policy makers, or that there is further need to refine the policy instruments whose ostensible premise is to support a constructivist approach (Department of Education, 2006). The analysis showed that there are differences between the chemical bonding sequences suggested by teachers to the one vaguely proposed in the curriculum policy document. Based on these findings, it is therefore recommended that an appropriate teaching sequence for chemical bonding should be included in policy documents.

In the interviews, the 11 teachers did not agree on a single learning sequence for chemical bonding. For example, four teachers re-organised the content sequence in a similar way to that suggested in the survey, starting with attraction forces, covalent bonding, Lewis notation, ionic bonding, metallic bonding, and molecular shapes. Two teachers mentioned using chalk and talk approaches and a further teacher focused on using prior knowledge to make science accessible to learners.

Eight teachers referred to chemical bonding as a problematic topic, because it is too abstract and difficult for learners to understand and three teachers spoke about the importance of prior knowledge during teaching and learning of chemical bonding and how prior knowledge facilitates learners’ understanding of the topic.

The analysis of interview results indicate that the majority of the interviewed teachers think broadly about science content to be taught and restructure the science content before planning a learning sequence. The teachers also think about issues that might hinder learning of the topic by the learners thus showing the use of two components from the Model of Educational Reconstruction (Komorek & Duit, 2004). Despite, the fact that the majority of the teachers planned learning sequences that were in line with the framework, there were some teachers who failed to include the issues of learners’ preconceptions about chemical bonding at the planning phase.

**DISCUSSION AND CONCLUSIONS**

In the space available, it has only been possible to give an account of one of the ten teachers interviewed and their trajectories overall. The case of Doreen illustrates her learning trajectory, also found in other teachers that teachers shifted from teacher-focussed towards student-focussed teaching approaches.
A combination of events, over an extended period of time, played a role in Doreen’s perceived shifts in her knowledge for teaching. Early in her career, Doreen gained confidence in what she knew about the subject by teaching the same content year after year. She could then shift her attention to her students, realising that they had prior knowledge which could give her insight into how her learners understood the content. Later in her career, post-graduate studies in education gave her knowledge about how students learn and their alternative conceptions they may have. She was then able to incorporate this new knowledge into her teaching, shifting her teaching strategies to become much more student-focused, and interpreting her students’ ‘incorrect’ answers as tools to guide her teaching, and help her students understand better.

The link between awareness of student thinking and teaching strategies is evident in the second part of research addressed by the second research question and has also been highlighted as an important quality indicator by several researchers (e.g. Jin, Shin, Johnson, Kim, & Anderson, 2015). The workshop on chemical bonding offered to teachers targeted the link between these components. Teachers with sufficient teaching experience would benefit optimally from the workshop, particularly if they had the opportunity to teach the topic immediately after the workshop, which was the case for five of the nine teachers who provide additional data.

The findings reveal that the strategies utilised in the workshop impacted positively on teachers’ knowledge and misconceptions of chemical bonding. The CK scores of the nine teachers who returned the three-month delayed post-test questionnaire demonstrated a moderately successful long term impact of the workshop on content knowledge. In terms of their knowledge for teaching, the two components emphasised in the workshop showed moderately good scores, with a majority of teachers at the “developing” level. Overall the study shows that if focused on a well-defined topic, one day workshops can have a medium impact on teacher knowledge.

The study of sequencing patterns revealed that the general idea for teaching chemical bonding is first to teach attraction force then types of bonding starting with covalent bonds followed by Lewis notation/theory and lastly, molecular shapes. The findings of the study are represented in a similar manner to what Levy Nahum, et al. (2008) term the “bottom up framework”. Data showed that teachers were clear on which concepts for teaching chemical bonding should be at the beginning of the sequence. Their ideas imply that when teaching chemical bonding the concept of covalent bonding should be introduced first, in contrast with the suggestion of Taber and Coll (2003) who felt that ionic bonding should the taught at the beginning of the sequence but in line with the argument proposed by Dhindsa and Treagust (2014) to start with covalent bonding.

This paper has tried to provide illustrative research to amplify teacher learning trajectory identified in question 1. The two game changing events identified by Doreen - awareness of student thinking and an understanding of curricular issues including sequencing we played out in the research related to questions 2 and 3. Teachers did benefit from the short workshop, but learnt more if they taught the topic soon afterward, and teachers’ ideas about sequencing topics in chemical bonding are influenced mainly by their perceived structure of the content and their knowledge of student thinking.

MECHANICS PROGRAMMES UNDER THE JAPANESE INSTRUCTION THEORY HEC

Koji Tsukamoto
Chiba Institute of Science, Choshi, Japan

Around 1950, Dr. Kiyonobu Itakura of the Japanese National Institute for Education, a historian of science and educator, conducted a study of Japanese students’ understanding of scientific knowledge, concluding that they clung to intuitive concepts acquired through their daily experience. To overcome these intuitive concepts, Itakura advocated Kasetsu Jikken Jugyo, or Hypothesis Experiment Class (HEC) in English, in 1963. The lesson plan ‘Spring and Force’, developed and published in the early days of Itakura’s work, remains highly effective at teaching statics in schools, even today.

Keywords: mechanics, conceptual understanding, learning theory

INTRODUCTION

In 1963, Dr. Kiyonobu Itakura (a senior scientist emeritus at the Japanese National Institution for Education) advocated an instruction theory called the Hypothesis Experiment Class (HEC) based on his study of the history of science and scientific epistemology (Itakura, 1963). Over 50 lesson plans, termed Jugyosho (H-E Classbook in English, or Classbook for short) that created enjoyable science classes were published. These plans cover a wide range of fields, from biology to mathematics, even to social science.

Although the concept of HEC is acknowledged in Japan as a fruitful achievement, it is little known outside the country since its basic literature has not been published abroad in any foreign languages. In this paper, we will introduce an outline of the Classbook for ‘Spring and Force’, which was Itakura’s initial representative work and an achievement of Itakura’s thesis.

COGNITIVE RESEARCH AND HEC

Around 1960, Itakura published the results of his study of students’ understanding of scientific knowledge, based on his prediction that the confusion about scientific knowledge conception in the history of science would also be seen in the confusion of students in science class (Itakura, 1964; Itakura & Kubo, 1965; Iwaki, Kamikawa, & Itakura, 1959). A sample of the research done by Itakura is shown below (Figures 1 and 2).

[Problem 1] (Target: 93 students in a public school, 13 years old) If this were a smooth table, and air resistance and friction were vanishingly small, sliding the block will lead to which of these results?

(i) The block will run to the end of the earth.
(ii) The block will stop after a little because of its weight.
(iii) The block will stop for another reason.

Figure 1. Problem 1 with results
[Problem 2] (Target: 77 students in a private high school, 16 years old)

A disk is moving horizontally on ice.

i. Indicate all forces acting on the disk.

ii. Indicate these force on the figure.

(In all, 39/77 students placed an arrow pointing ahead)

iii. How much distance will the disk go if its initial speed is 2.8 m/sec and the coefficient of kinetic friction is 0.02.

(Correct answers were given by 10 students; 8 answered correctly on all questions)

Figure 2. Problem 2 with results

After realising that even privileged private-school students could not answer these problems correctly, Itakura characterised students as believing in medieval impetus or vis impressa mechanics.

He published his results on research into frictional force (Figure 3).

[Problem 3] (Target: 93 students at a public school, 13 years old)

There is a stone of about 100 kg. If there is friction, how much force is needed to move this stone horizontally.

Figure 3. Problem 3 and results – (Frictional Force)

Most students (45%) thought that friction + 100 kgw or more is needed to move the block. Itakura noted that this result is similar to Bradwardine and Buridan’s mechanics from the mid-fourteenth century. Though Buridan accepted inertia, he thought that the force applied needed to be greater than the weight of the object which was being moved.

He also published his results on statics (Figure 4).
[Problem 4] (Target: 93 students in a public school, 13 years old)

There is a metal bottle with a vacuum inside. When hydrogen is put in this bottle, the weight of the bottle is

i. lighter than the bottle with the vacuum.
ii. heavier than the bottle with the vacuum.
iii. the same weight.
iv. dependant on the weight of hydrogen put into bottle.

Figure 4. Problem 4 and results – (Statics)

For this problem, 40% students answered i (It is lighter than vacuum bottle), an answer consistent with Aristotelian mechanics.

From his research, Itakura concluded that the students’ common or intuitive concepts sometimes prevented them from understanding scientific concepts.

STRUCTURE OF HEC

Basic idea of HEC

To overcome students’ intuitive concepts and bring them to a true understanding of science, Itakura began advocating HEC in 1963 (Itakura, 1963). Itakura stated that to overcome students’ concrete intuitive concepts, the conflict between scientific logic and common intuitive logic must be made clear, so that students realize the superiority of scientific logic and concepts (Itakura, 1967).

Classbook

The fundamental concept of HEC is that ‘all preparation should be supported, so that any teachers who is not master or veteran but is eager to perform good instruction can achieve their goal’. To realise this, Classbooks, which have the multiple functions of instruction manual, textbook, and notebook, are prepared. Using a Classbook, anyone have good lessons.

Evaluation of the class

The goals of HEC are as follows (Itakura, 1966).
1. The concepts and laws taught in the Classbook will be mastered by the students.
2. All students will enjoy science and their lessons.

To evaluate the first goal, the average score on the final test should be 90%. To achieve the latter goal, more than half of students will respond to a questionnaire that they like science or the HEC lesson, if the questionnaire is conducted after an HEC lesson, and none (except for two or three anomalous students) would answer that they dislike it.
**Procedure of HEC**

A Classbook is composed of a series of problems and readings. In the ‘problem’, all students or pupils must expect a certain result and see their expectation was right. The problem consists of four steps: problem statement, expectation, discussion, and experiment (Itakura, 1967).

In the problem statement, all procedures for conducting the experiment are given. The teacher sets up the experiment as instructed in the statement and explains it to the students. When students understand what is being asked, they choose their expectations of the result of the experiment.

The expectation should be chosen from multiple given options. At the beginning of the lesson, the students may choose their expectation based on their intuition without any specific reason, as they have not studied the subject yet.

The teacher requests the students to raise their hands for the option they choose, counts how many students have chosen the option, and writes the numbers up on the board. The teacher asks the students why they have chosen their option. An open discussion should be conducted if needed. After asking the students if anyone wants to change his or her expectation, the teacher conducts the experiment.

The teacher should confirm what option is correct, not explaining why this result occurred and goes on to the next problem. Since people often interpret experimental result to favour themselves, teacher should not explain until the students have acquired a true understanding of scientific concepts. A number of experiments is needed to teach each law or concept in the HEC.

When almost all students have acquired a scientific law or concept, the law or concept is explained in detail through the reading in the Classbook, which often contains the episode within the history of science.

All of this occurs in the Classbooks.

**THE CLASSBOOK ‘SPRING AND FORCE’**

‘Spring and Force’

Over 50 Classbooks have been published; these cover not only physics and chemistry but also social science. We introduce the classical Classbook ‘Spring and Force’ which aim to teach statics published in 1967 (Itakra, 1967).

As has been mentioned, Classbooks contain a number of problems and readings. The one for ‘Spring and Force’ consists of almost 40 problems and readings and is over 60 pages long. For this reason, we cannot describe all of it here, only being able to introduce it briefly.

**Aim of ‘Spring and Force’**

‘Spring and Force’ teaches the static concept of force. The intuitive concept of force acquired in daily experiences is based on the sense of human force and ad hoc reasoning. However, the scientific concept of force is based on coherent logic. Using various experiments, to create a
conflict between the intuitive concept of force and the scientific concept is the aim of this Classbook.

**Introduction of the concept of force**

Usually, the concept of force is introduced by gravitational force since almost all students today know gravitational force. However, although people are able to understand the concept of force through understanding an equilibrium of forces, it is difficult to teach equilibrium with gravitational force. The force of the human relates to the feeling of exhaustion and tension, so normal force is difficult to understand.

This Classbook introduce the concept of force using the equilibrium of gravitational and magnetic forces.

**Introducing normal force by using spring model of matter**

After introducing the concept of force, normal force is introduced through the idea that all matter has the nature of a spring.

Since normal forces are often logically introduced through the formal balance of forces, students tend to think that mechanics is a system of sophistry. Even if students can answer correctly on a paper test, they do not believe it in their minds. To render the concept comprehensible, normal force is introduced using a model of matter as a spring. To make this idea concrete, students are instructed that even very strong springs will be deformed by a little force and that a deformed sponge under a book will produce force due to its deformation, as described in this Classbook. (Figure 5a).

The fact that even a desk will be deformed by a small force, since it is composed of atoms, is described in the reading. Students thus realize the concept of normal force themselves (Figure 5b).

![Figure 5a. A book on the sponge](image1)

![Figure 5b. Deformation of the desk](image2)

**Experimental conflict between the scientific principle and the intuitive idea**

Students accept scientific concepts through problems that lead to conflict between the intuitive idea and scientific logic. One of these problems presented in this Classbook is given in Figure 6.
[Problem] A spring is extended by two weights hanging on both of its sides. If we fix one side of the spring and hang a weight on the other side, how far will it be extended?

- i. half the length
- ii. the same length
- iii. double the length

Figure 6. Classbook Problem - Spring extended by two weights or a weight.

In this problem, most students choose i. Since the weights are reduced by half, it is natural to expect that the length of the extension of the spring will also be half. However, the result of this experiment gives ii. Using such experiments whose results dramatically conflict with intuitive concepts, students can learn the effectiveness of the logic of science over intuitive ideas.

EVALUATION

Result of the final test

As noted, the Classbook under discussion consists of a number of problems. We have only briefly introduced part of it. To go through the whole of this Classbook, 12–13 class hours are needed (a class hour is 45 minutes). According to Itakura’s thesis, a final test, made by another researcher, which was used to evaluate their (another researcher’s) lessons was used. In the researcher’s report, the average of the final test for students taught by their lessons was 46/100. However, the averages on the final test after the HEC lessons was 87–97/100 (Itakura, 1967).

Students’ motivation

In HEC, the result of questionnaire determining whether the class was enjoyable was given more value than the results of the final test. Even if the students acquired correct scientific knowledge, this would be meaningless if they did not enjoy learning. The students were thus asked for their evaluation of their degree of enjoyment of the class.

Degree of enjoyment

5. Very enjoyable
4. Enjoyable
3. Neither enjoyable or not.
2. Boring
1. Very boring.

If over a half of students answer 4 or 5, and few answer 2 or 1, the lessons are judged to have succeeded. For Itakura’s work in 1967, over 90% of students chose 5 or 4 (Itakura, 1967).
CONCLUSION

We have briefly introduced the basic theory for HEC and the classical Classbook ‘Spring and Force’, developed in the early days of Itakura’s research. Cognitive study of scientific knowledge has been conducted systematically around the world, beginning in the 1980s. Lessons have been improved using this cognitive research. Some of the results are similar to HEC.

However, one special feature of HEC remains the concept of the Classbook. The theory of HEC is little known outside of Japan, because the basic literature for HEC has not been translated into English.

Our colleague is preparing to publish an English translation of Itakura’s thesis this year. We expect that HEC will attract attention outside of Japan.

New Classbook that introduce dynamics are in development. We hope to present these in the future.

ACKNOWLEDGEMENTS

We offer special thanks to Dr. Kiyonobu Itakura for his encouragement. The establishment of HEC theory was performed by Itakura alone.

The authors would like to thank Enago (www.enago.jp) for the English language review.

We also thank Kaya Sakashita for modifying figures and tables.

FINDING THE ’RHYTHM’ IN A SCIENCE CLASSROOM: ANALYSING TEACHER’S SPATIAL POSITIONS AND THE INTERACTION DURING TRANSITIONS

Miranda Rocksén
University of Gothenburg, Gothenburg, Sweden

In this presentation, the contributions and constraints from a methodology based in dialogical theories of communication, is illustrated and discussed. The purpose of the study is to investigate the details of how a discursively changing environment is achieved in a science classroom. The approach was enabled by investigating video data from a sequence of 11 lessons about evolution in a grade 9 (15 years) in which a suitable pattern of activity, alternating between small group and whole-class activities, was established. Using data from four simultaneous cameras, the analysis focused on teacher movements and spatial positions in the classroom and how the interaction between the teacher and the students was sequentially organised. The results show how during transitions between activities the teacher used a set of signals such as repeating the question and backing away from the students, in the communication. The students responded to these signals by shifting their focus of attention resulting in a coordinated classroom communication with smooth transitions between whole-class and small-group activities. The described details of the interaction and the sequential organisation provided by the study illustrate some of the main contributions from using the methodology. The focus on the embodied communication evokes constrains with regard to developing aspects of the subject matter being taught and learnt. Also, this methodological approach does not support conclusions about teaching effectiveness. Further research focusing on classroom activities is needed in order to show empirical examples from different settings and develop the understanding of how activity patterns are interactively achieved.

Keywords: classroom discourse, video analysis, science education

INTRODUCTION

"In a nutshell, how helpful is it for a science teacher and students to be exposed to the genre of scientific argumentation, when their normal, daily lessons are based on a routine of teacher presentation? Our view is that the priority must be, first of all, to make these existing practices more ‘visible’, and then to point towards how they might be extended by employing the different kinds of interactions we discuss." (Mortimer & Scott, 2003, p 5)

I will in the presentation illustrate and discuss contributions and constrains from a methodology based on a case-study design and within a framework of dialogical theories of communication. This is a research approach that may contribute to make visible the practices of science classrooms for the benefit of researchers’ and science educators’ further investigations and development of that practices. The purpose of the current study is to investigate the details of how a discursively changing environment is achieved in a science classroom. In the title, I have chosen to define this as a ’rhythm’, which consists of relations between two components, one spatial and one temporal. In science education, the nature of the interaction between teachers and students is emphasised as one critical aspect with the potential to significantly contribute to students’ meaning making (Mortimer & Scott, 2003). Still, studies that approach the spatial
and temporal aspects of science teaching practices and provide empirical examples of how this can be achieved in different settings, are rare. In this Introduction, I briefly present some examples from the field of education that expand on these two components as a background to the reader. The theoretical framework and some of the basic assumptions that are shared among dialogical approaches are then presented in the section Theory. In Methods, I describe the special interest for this particular study and provide some details about how data was generated and some ideas about what it might imply to use and work with this methodology in video-analytical studies. The Results summarizes the study results. Finally, in the Discussion, I consider some contributions and constrains from using the methodology.

**Addressing questions of time and space**

Teachers’ gestures and movements have previously been investigated for example in studies influenced by the approach to proxemic behaviour (Hall, 1963, 1969). Hall investigated for example the use of space in public and in private and between different cultures. This approach to the study of gestures and movements in social interaction seeks to establish meanings, and is based on the assumption that there is the possibility to assign certain meanings to bodily movements and behaviour.

Lim, O’Halloran, and Podlasov (2012) investigates two teachers’ moves in front of their respective classes. The traces from the individual teacher’s movements show characteristic patterns in how each individual use the classroom space during a lesson. In one of their empirical studies, Sensevy, Gruson and Forest (2015) investigates one teacher’s interaction with children sitting in a small-group around a table learning a memory game. Here, the teacher’s gestures are seen as partly contributing to how the didactical contract is maintained in the interaction.

Studies have also investigated gestures (Arnold, 2012; Rosborough, 2016) and the performance of science concepts during lectures (Pozzer-Ardenghi & Roth, 2007). To different degrees, all these approaches take into account spatiality, in terms of types of embodiment, as well as temporality. However, several authors have asked for further investigations into the temporal aspects of teaching and learning (e.g Mercer, 2008; Roth, Tobin, & Ritchie, 2008).

Alhadeff-Jones (Alhadeff-Jones, 2017) presents a review of the study of time and theorizes about time in educational research. In this book physics and biology exemplify contrasting disciplinary conceptions of time that are reflected in conceptualisations of time in education. In physics time is more linear while in Biology time is more circular and emergent. Rhythm characterises the relationships between changes: “Rhythms refer to the specific way we perceive the signals (e.g.,visual or auditory) and signs (e.g.,language) characterising the experience of time” (Alhadeff-Jones, 2017). Two studies that shares the focus on the relation between the use of space in relation to aspects of time, in particular the role of interaction during shifts between classroom activities, are (Icbay, 2011) and (Jacknick, 2011). Icbay (2011) applies the concept of tying signals and investigates the restoring of classroom order after transitions. Jacknick (2011) investigates teacher initiated shifts between activities and the interactional work required of students to challenge such shifts. The present approach
investigates the embodied aspects of science teaching, such as physical positions, gestures and gaze in the interaction with students.

THEORY

The study is based in dialogical theories of communication (Bakhtin, 1986; Linell, 1998, 2009). One possible characterisation of some of the approaches based on the framework – is as studies of naturally occurring data that produces results in the form of detailed descriptions of empirical cases. Shared among dialogical approaches is the assumption that human action, communication and mind remain reflexive, intersubjective and context-dependent. Also, the elaborated view on spoken language and social interaction embraced by the framework facilitates the analysis of video-data from classrooms. Emphasised in this view is the sequential production of utterances, that spoken language is embodied and that linguistic resources – for example words and subject-specific terms – have meaning potentials and that meaning is jointly constructed. These ways in which the nature of spoken language differs radically from the nature of written language, are significant to verbal communication in different contexts.

The analysis is developed based on the assumptions about the dialogical nature of human action, communication and mind. The purpose here is to investigate the details of how a shifting environment is interactively achieved in a science classroom. Focusing a shifting pattern of activity, established by a previous study (Rocksén, 2017), this study seeks to answer the following questions: How is the shifting pattern of activity sequentially organised? What significant gestures and moves can be identified in the teacher’s interaction with the students during the transitions between small-group and whole-class activities? What are students’ responses?

METHOD

The particular case under investigation is the teaching of a unit in biology in grade 9 (15 years) in a particular classroom where an established shifting activity pattern was described by an earlier study (Rocksén, 2017). According to Yin (2009), case-study may be a particularly feasible design in the work of defining boundaries between a phenomenon and how this appears in the real world. Further, Silverman (2010) describes how case studies identify these boundaries, define the unit of analysis, delimit a research problem that focuses on some features of the case, and still preserve the “integrity of the case” (Silverman, 2010, p. 138).

The project developed an application for vetting of ethics and the teacher and students gave their informed consent to participate. The particular data set was re-used for this study. It included 38 hours of video covering 11 lessons. Each lesson lasted 50 minutes and was planned and conducted by the teacher.

Four simultaneous cameras were used for the recordings (Clarke, Mitchell, & Bowman, 2009). Two of the cameras provided close-ups on two different student groups, one camera followed the teacher and one camera provided an overview of the classroom. The data was stored on a separate server and retrieved through Transana multiuser software. Transcripts in combination with time-based coding were used in order to capture, investigate and analyze the details of the transitions between activities. Transcripts of speech as well as visual conduct, emphases and
overlapping speech were developed for the selected episodes and included frames from the video (see Heath, Hindmarsh, & Luff, 2010). The transcripts were iteratively revised by returning and repeatedly looking at the video, and became key data (Derry et al., 2010, p. 20).

The methods for analysis involved an iterative process of repeated watching of the video – developing transcriptions, identifying sequences that were found relevant to the specific focus of interest. Then building a collection of sequences, developing more detailed transcriptions, using the theory and theoretical concepts within the framework in order to understand the unfolding of particular events.

In a process of analytical induction (Erickson, 2012) the physical positions, gestures and gaze in the interaction between teacher and students were established and documented. The focus of interest was the transitions between different activities, and how the shifting pattern of activity is constituted, in an attempt to reveal what cues the teacher provides to the students and what the nature of any irregularities to that pattern mean in the interaction. In order to do this, the phases of transitions between activities were focused: transitions from whole-class to small-group activity, and transitions from small-group to whole-class activities. During the final lesson, there are three small-group activities, and in particular this caught my interest. The next step was to study these phases of transition. The final part implied to identify and represent the results in text, and text combined with frames from the video – including excerpts showing the details of empirical data. The next section includes a summary of the results.

RESULTS

The results show the details of the classroom interaction during transitions between whole-class and small-group activities along the eleven lessons. A sequential organization could be described in detail including phases of transition before and after the small-group activities. The introduction and ending of small-group activities are indicated by the teacher’s different physical positions in the classroom and shifts in the students’ attention.

One example of how a small-group was initiated is when the teacher picks up on a contribution previously made by one student talking about sun radiation causing spots in the skin. The teacher asks:

“but okay do you think, do you think that such mutations in a small, let’s say a mutation happens in a muscle cell, will this be transferred to your kids? Think about this now. Talk with the person next to you. I do not just want a finished answer at this point.”

A few seconds later, the teacher leaves the front of the classroom and the students shift their focus of attention, Figure 1.

This particular introduction represents about 20 seconds; however this single example represents a recurring situation in the classroom. Like in the example, during the transitions, the teacher in this particular classroom asks questions for the students to discuss standing in the front position but the time and exact formulation of the question is a consequence from the interaction with the students happening immediately before this moment.

The teacher’s use of a set of tying signals to which the students respond by shifting their focus of attention. Identified tying signals are: Instant reformulation of contribution in whole-class,
Repeating the question, Gestures highlighting concepts noted on the white-board, Gestures requesting response. When shifting back to whole-class activity this transition is faster: Nomination of students, Loud voice, Re-taking classroom front-position, with body and gaze oriented towards nominated students. Students shifting focus of attention is shown in their body position, talking without raising their hands. This did not only occur in small-groups but also across groups getting ideas, some more vivdely, some more silent and not as focused. This phase is also characterised by the more informal character of talk about the issue at hand with the teacher when she approaches.

In the introduction of the third small-group activity a discrepant instance is identified. Here, the transition is delayed and teacher re-starts using the tying signals a bit differently. In this particular situation, the question is not timely repeated. When students do not respond by shifting their focus of attention, the teacher reformulates and writes down the question on the white-board and then students turn to each other to discuss the assigned task.

**DISCUSSION AND CONCLUSION**

The study was facilitated by the quality of the video-data and the already established pattern of activity. One general conclusion based on the study results is that during phases of transition a joint attention to the topic involves gaze, facial expression, gesture and physical position. The study shows that movements, gestures and voice is associated with shifting physical positions. For science education a discursively changing environment implies particular teacher challenges. For example, it requires flexibility in the communication with students with timely reformulations of contributions made in whole-class. In the investigated classroom, the repeating of a well-defined question was critical.

Descriptive case-studies are not useful for answering every question. They may however respond to the question of how teachers and students interact in a science classroom and therefore contribute important understandings of the challenges involved. Single-case studies also benefit from systematic and high quality approaches to the collection of data. This would
be a reason for shared principles and quality criteria for video-analytical studies could be further developed by researchers in the field.

Illustrated in this study is a methodological approach based on video-analysis of the interaction in classrooms. The study displays detailed patterns in the classroom ecology of action (Erickson, 2012) of how one teacher and a group of students coordinate their interaction into a shifting environment where small-group activities are embedded in whole-class teaching on a regular basis.

The theoretical framework embraces a view on interaction as embodied and involving several temporalities, which enables the analysis to include embodied aspects of the communication in the classroom. Altogether the theoretical framework is found suitable for analysing video due to the elaborated view on spoken language and social interaction.

One of the constraints of the dialogic and interactive approach to teaching and learning in general is that content may be downplayed (Ongstad, 2004). The focus on gestures and moves may take the attention from the scientific concepts in focus. The content is embedded in the interaction and requires specific analytical solutions, units of analysis etcetera.

This is not a type of research that prescribes best teaching practices, but a framework potentially useful for making comparisons across classrooms. Most of all the described methodology enables expanding conceptualisations of teaching and learning, new descriptive units, aspects of space and time, and is therefore promising.

The nature of the interaction between teachers and students is emphasised as one critical aspect with the potential to significantly contribute to students’ meaning making in science. Although this highlights the benefits from developing a variation of discourse patterns in science classrooms few research studies show detailed examples from different settings. By illuminating the details of how this can be achieved in different settings research can provide the empirical base necessary for bringing discussions further in teaching practices and teacher education.

ACKNOWLEDGEMENT

I am grateful to the participating teacher and students, and to Andrée Tiberghien for introducing me to proxemics. The study was financially supported by LinCS research environment at the University of Gothenburg.

SCIENCE INTEGRATED WITH AESTHETIC EXPRESSIONS FOR BETTER UNDERSTANDING OF SCIENCE SUBJECT MATTER

Ulrika Tobieson¹ and Ann Mutvei²

²Södertörn university, School of Natural Sciences, Technology and Environmental Studies, Huddinge, Sweden

Teachers have to create a variation of learning situations to increase the understanding for theories and abstract models in science. We have experiences of combining aesthetic expression with science in pre-service teacher programme for more than ten years and have seen the benefits of embodying abstract theories with dance, art, music or drama and better understanding of science subject matter. The integration of science and aesthetic forms of expressions have support in the Swedish curriculum both for preschool and the compulsory school and it is therefore important to include exercises using aesthetic expression in the teacher education program. The purpose of the workshop was to give examples of how art can be used to study phenomena in science. The workshop was divided into three parts. In the first part the participants were doing different exercises embodying concepts in physics and creating relations with each other. In the second part the participants in groups constructed a kinetic mobile. In the third part, the participants reflected and discussed their experience and understanding of phenomena during the workshop. Examples of assessments of the construction process were presented. Here we also present the planning and theoretical background to the work with aesthetic expression of science.

Keywords: aesthetic expression, integrating art with science, learning outcome

INTRODUCTION

Every student is unique as well as every learning experience is particular in its own way and therefore is conducive to a joint future where our common agreements affect our habitual experience of the world. Martha Graham, innovator of modern contemporary dance expressed the concept of uniqueness and the ability to partake actively (Halprin, 2003);

There is vitality, a life force, an energy, a quickening, that is translated through you into action and because there is only one of you in all time, this expression is unique.

And if you block it, it will never exist through any other medium, and will be lost.

As a teacher it is crucial to have the opportunity to create a variation of learning situations in order to deepen, broaden and crystalize the understanding especially addressing complex phenomena and abstract concepts together with models and theories.

John Dewey pointed out the importance of achieving experience in order to acquire knowledge, a sort of “experience through learning” (Pugh & Girod, 2007) which can be understood as an embodied integrated knowledge received through active participation. In Canada Learning through the arts was created as a national educational program (Smithrim & Upitis, 2005). This program showed an evident increase both in student engagement in other subjects than art as well as a higher level of motivation in learning. Visual and performing arts called Arts-
Infused Learning has been found to be important for different subjects, besides art in school such as language, math, science, and history/social studies courses (Lorimer, 2011). It was shown that using art in order to understand complex phenomena in science increased student’s concentration of the exercise as well as their understanding (Lorimer, 2011). It was also noted that Arts-Infused Learning encouraged intercultural collaborations and trans-disciplinary understanding. Music has also been described to successfully integrate other subject where young children in preschool could better understand the meaning of different concepts (Economidou Stavrou, et al., 2011). Education of artists together with pre-service teachers in teacher education also showed the advantages of integrating different professional disciplines as well as different disciplines in art together with the subject matters. These types of student collaboration increased their enthusiasm about teaching and it broaden their perspective on learning in and outside the classroom (Ketovuori, 2011).

SUPPORT IN CURRICULUM

In Sweden students in pre-school and compulsory should learn to express their knowledge in using art. In the curriculum of Swedish preschool this is expressed as

The work team should give children the opportunity to develop their ability to communicate, document and describe their impressions, experiences, ideas and thinking processes by means of words, concrete materials and pictures, as well as aesthetic and other forms of expression (Skolverket a, 2011, p. 11)

Further, in the aims of the subject biology, physic and chemistry in the curriculum for compulsory school:

Teaching should contribute to pupils developing the ability to discuss, interpret and produce texts and various forms of aesthetic expressions with scientific content (Skolverket b, 2011, pp. 105, 120, 135).

Therefore, it is important to include this type of activity as well as knowledge of the art itself to be able to use these tools to create a diversity of learning situations. This skill described in the Reporting Guidelines for International Teaching Placement for professional development of teachers used during placement express:

Commands and uses various communicative abilities (for example, body language, drama, music, pictures).

EXPERIENCES FROM TEACHER EDUCATION

At Södertörn University the science teachers have worked together with artists in teacher education during the last 15 years with the purpose to create an education from a more diverse intercultural perspective. Disciplines of Art such as dance, art, drama and music have been used, e.g., to visualize hydrogen bonds between water molecules by dancing, forces and balance in producing kinetic mobiles, details of biological material by drawing, drama exercises showing the pump of blood and digestion and singing songs about the cycle of water creating clouds and rain.
In 2011 Södertörn University teacher education hired a group of artists in order to teach what was now mentioned as Aesthetic Learning Processes. Examples of aesthetic expressions in 2- and 3-dimensions in a science course for pre-service preschool teacher is shown in Figure 1. During the aesthetic exercise students recalled the content of the science course with examples like frictions from shoe soles on ice, insulation of a snow and the effect of gravity on a door hinge. They then created a world where night and day, planet system, seasons or the phases of moon also should be included (Figure 1).

Figure 1. Closing of workshop with artefacts created by pre-service preschool teacher students

After the course, two years later, the students were evaluating the course by answering questions like:

Describe how Aesthetic learning processes have supported and/ or enhanced your understanding of different phenomenon, concepts and abstract models?

Here are a few randomly picked answers:

“Through talking around the concepts and making a conclusion at the end of the session”.

“Through giving knowledge a different and new dimension”.

“Through the process and creative thinking outside the box during the art-making process I have gained a deeper understanding.”

“Go beyond the theories, express my thoughts not only through written text. I have learned to share my thoughts and to be openminded toward others”

“Aesthetic learning processes have supported to transfer our theoretical knowledge into practical action”

“I have understood the meaning of different concepts especially the difficult one. Practicing practical exercises that reveal what we are reading have developed my understanding of different areas. And learning each other's learning "
THEORETICAL BACKGROUND TO THE STRUCTURE OF THE WORKSHOP

Intermodal theory – modalities of imagination

Joseph Beuys argued that “Everyone is an artist” and we all strive for coherence, connection and Beauty as we struggle to construct meaning, direction and shape our lives, in our habitual world experience. Beauty as the term is used in the understanding and the implementation of Intermodal theory refers to a distinct response to an artistic act and/or an artwork that stirs us and which we associate with Beauty (Knill, 2003). The response has a bodily origin, which sometimes describes as ‘moving’, ‘touching’ or ‘breath-taking’. Most languages suggest this sensory effect even if we do not always experience the effect literally. The notion of Beauty is closely linked to the phenomenon when a ‘quite-right’ image emerges as a felt sense, an image that matches and resonates with the psychic condition of the individual person or group working together on the shaping and constructing of knowledge inherent in the subject matter. This is followed by a shift in awareness often experienced and described as a sharpened understanding and change in the notion of time and the conception of the learning process. This shift is often linked to a shared ‘aha’ -moment or experience. The phenomenon occurs whether the experience of Beauty is intensely joyful and pleasurable or is characterised by pain, confusion and perplexity (Knill, et al., 2005). The contrary quality to an embodied Aesthetic response (Figure. 2 left) would not be the idea of ugliness but rather dullness and an apathetical inability to respond (Knill, 2003).

M Consider the Material, its shaping tool and frame, in the instruction.
O Organize a direction of discovery that motivates.
R Restrict the frame and the field of play.
E Sensitize toward the Emerging shapes.

Figure 2. A structural didactic map of Aesthetic Learning Process (ELP) to the left, MORE – guidelines of intermodal work process (Knill, et al., 2005) upper right and Intermodal arts model (Halprin, 2003) lower right.
We sometimes have a preconceived notion that very well may situate us in the narrow manner of thinking and acting that marks the helplessness around a ‘dead-end’ situation. This position may originate from both imaginary and/or actual external factors such as the number of students, the timetables, the surroundings, social- and economic conditions, various disciplines and subject matter and the ability to reach the goals and quality of the curriculum. Focusing on the problematic situation has a tendency to produce more of the same and tends to worsen the situation. On the other hand, a Decentering induced attitude (Figure 2 left) and approach moves away from the fixed position offering a variety of possible and unexpected solutions. Decentering is used in order to slow down, find balance, stability and flow. In order to leave the time-sequence of literal reality controlled by a linear game-structure to a circularity movement of improvisation and play full of coincidences and synchronicity. The phenomenon of play is experienced in the ‘doing as if’ and in the here- and-now connected to all Alternative world experience (Figure 2 left). This phase is always framed by an entrance and an exit. The characteristics of all the ‘in and outs’ of the Alternative world experience are at the same time aspects of Decentering and contributes to the Range of play, the area of unconstructed movement of body, feelings and thoughts. Whereas creativity is often explained as an ability that allows people to discover a new solution to an old problem, Art-making is a multitude of perspectives, which alters into new knowledge. When provided with Range of play (Figure 2 left) the situational restrictions experienced by preconceived, stereotyped and normative thinking are contrasted.

However, restriction in the field of play is essential and may lead to further discovery and depth of subject matter. Restriction in for example constriction of material or time together with distinct and direct guidance providing directions of exploration in order to sensitise towards what is being experienced makes for a deeper understanding (Knill, et al., 2005).

Various theories of Imagination explain that imagination is not totally controllable; it is predictable only in its unpredictability. We can distinguish three realms of imagination: the dream space – (phantasy), the daydream and the artistic activity/play. The artistic activity combines the dream space and the daydream as the force of longing, which belongs to imagination as it yearns for the moment to manifest itself in the real world. The difference between imagination and phantasy is the embodiment of materiality with the former and the immaterial quality of the later (Levine, 1992).

The artistic activity is always a shared experience, in between group members, within a community and/ or individual, the tools and the materiality of the Emerging shape. The sharing happens not only through verbal description and communication but also through multiple sensory modalities (Knill, 2003).

Any art discipline, because of its connection with imagination, can evoke and find further expression in any other modality of imagination. Among all art disciplines we find a variety of sensory channels and imagination modalities. For example, within the visual arts the sensorimotor and tactile senses are engaged when we paint and a painting communicates not only through the visual image, but also through other imagination modalities. A painting may evoke a rhythm and a sound from which a story appears that depicts an act and a dance unfolds. In a similar way a poem can evoke sounds and movement (Knill, et al., 2005).
To educate in an integrated way one therefore must allow a synthesis that sharpens the sensory modalities seeing that the human instinct is multisensory.

Aesthetic Learning Process

An Aesthetic Learning Process based on Intermodal Theory (Figure 2) always consists of a five-part process. At the ESREA- conference 2017 our workshop was designed with the conference in mind and therefore with a focus on the middle parts of an intermodal Arts model process. The framework was the setting of the conference itself using the pre-understanding and predisposition of the participants as an agreement of shared literal reality (Knill, 2003; Halprin, 2003). This was the ethical starting point for the workshop at ESERA.

An Intermodal Expressive Arts five-parts process

The first part (identification) begins with an opening of the workshop by introducing the theme or subject matter, connecting these to the framework, in which the distribution of time is included and Literal reality (Figure 2 left), which can be described as a static and limited yet a familiar situation and cognizance (Knill, et al., 2005).

The second part (confrontation) is the BRIDGE. This phase is where the guiding and sensitising toward the qualities and characteristics to the theme and/ or subject matter happens. This approximation is done in an organized, clear and distinct direction of discovery using corporeal expression as a medium on the path to a broader and deeper awareness and adding layer on layer. The responsiveness and perception is thoroughly investigated both individually and together with others. It is equal important for the participants to start to discover one another as well as the subject matter or /and theme. It is also during this part where the Rang of play must establish a good enough spatial room for movement of body, feelings and thoughts (Figure 2).

The third part (release) consists of the Alternative world experience. This phase cannot start until the Range of play is sufficient in scope, depth and balance. The phase of Art making and Play is ready to begin provided that an agreement has been reached in regard to the materials, tools, oneself and the other participants. Then the Art making takes place - shaping the emerging forms. When the shaping act is followed by a shift in awareness often experienced and described as a sharpened understanding and change in the notion of time and conception of the learning process. The Imaginal reality (Figure 2 left) is an active part of the driving force in both receiving and welcoming of the emergent form.

The fourth part (change) is the BRIDGE again, but in this phase the crossing is from the Alternative world experience and Art making. In this step it is crucial to recognize and create awareness of the Imaginal reality and its motivation to co-exist. A good way of reaching a level of understanding is the Aesthetic response and analysis, which are both significant parts of Harvesting (Figure 2 left).

The fifth part (growth) is recollecting the Effective reality, connecting back to the beginning evaluating and reflecting over the process from the first step to the last. (Knill, et al., 2005).
An intermodal arts model is used during and within every sequential step as the Aesthetic learning process moves through the five part-work processes, looping, descending and ascending in-between and between the three levels of awareness and response, the Mental level, the Physical level and the Emotional level (Halprin, 2003). The three levels are equivalent significant components in the driving force behind this sometimes astute and exhaustive faculty that grasps, perceives, differentiates, distinguishes, integrates and conceptualizes the complexity of forms and patterns throughout and within the entire work process of Aesthetic Learning (Halprin, 2003) (Figure 3).

WORKSHOP

The workshop at ESERA -17 was directed by an art- and a science teacher and included examples of phenomena in science integrated with art performances in order to create deeper understanding through the construction of artefacts.

We constructed the workshop based on the setting of the conference as being a context of shared participation. We therefore incorporated the topic from one of the Conference Keynote speakers; the pivotal moment and we focused our work as a sort of play in three acts; the opening, the middle and the closing act. The mental image being a stroke out of a poem Lifting Belly by Getrude Stein; “...a rose is a rose is a rose..” as a form of direction of discovery (Figure 2 upper right and Figure 3). The work was carried out in three main parts:

Part 1. Opening and introduction to the workshop followed by Bridging.

In the first part the participants were doing different exercises embodying concepts in physics and creating relations with each other. Exploring the Range of play – organically forming groups of four quartets.
Part 2. Art-making

In the second part the participants constructed a kinetic mobile in groups of four.

Part 3. Bridging and *Harvesting*.

In the third part, the participants reflected, discussed and analysed their experience and understanding of different phenomenon, which had been addressed during the work process.

Altogether, 16 persons from different countries participated in the workshop.

**First part**

In order to achieve experience of concepts in physics such as gravity, friction, density, equilibrium and forces by aesthetic expressions, the workshop started with the participants standing in a circle in the centre of the aula. The following steps were improvisational work on the floor. Movements were done to feel gravity and to find the equilibrium in their own bodies (Figure 4 left). The instruction was to focus their own awareness as they moved and felt the space and the concept of “sliding” and then imagine and ask themselves if “sliding” has the colour of white, black or more a greyish nuance in between the white and the black. The next step was to find the spot where they sensed and felt the colour of “sliding”. After finding the spot, the next step was to turn to the person, whom at the moment was physically closest to them and share what they had become aware of during the exercise. We then went on to explore other concept such as “heavy” and “light” in the similar manner. The participants told their impression of the concepts to the person next to them and finally to all members of the group.

Examples of descriptions were: “black, it is fast in the dark when driving”, “white - all colours together when it spins quickly”.

The next instruction was to collect a piece of large white cotton sheet, a black crayon, a white crayon and a white panel with canvas structure. They were told to find and prepare a drawing area in somewhere in the aula - a place that made them comfortable enough. The following step was sensitizing towards the materials as well as to the surroundings by taken the white crayon in one hand and the black crayon in the opposite hand. Letting the crayons transform into dancers and themselves into world-renowned choreographers famous for creating choreographies representing different pivotal-moments. (This connects the work in progress to the outer framework of the conference and particularly to the topic raised by one of the Keynote speaker). They were then told to breathe and let the body, arms and torso get heavy as they opened their listening (ears) while they were instructed to close their eyes and let the dancers start dancing using the white square panel with structured canvas surface. The group members were instructed to share with another member of the group and then come together in the respective quartets observing and comparing their dance drawings within finding connections and similarities between their respective “blueprints” of the various choreographies (Figure 4 right). The blueprints of the dance were then used in opening up the second part of the workshop, the *Art-making* and construction of the quartet’s kinetic mobile.
Figure 4. Participants expressing different concepts in physics using their body (left) and crayons and panel.

Second part

The participants in groups of four used their blueprints to build a kinetic mobile. The instructions were to construct the mobile in at least two levels with two wooden sticks using the material presented on a table (Figure 5). All material was carefully planned to have different physical properties for example material with different elasticity such as rubber bands and to awake imagination. The mobile should also contain hanging things. The instruction was also that each person should think what the mobile tells them and the group was supposed to give it a name (Figure 6). This phase of Alternative world experience often draws group members closer to one another creating and bonding with a closeness in the relationships emerging during this phase. The relationships emerging are several, in between group members, in between the subject matter and the physical artefact leaving preconceived notions aside. The last step of in the Art-making and an Alternative world experience is Aesthetic response, the reflections were first done individually and then in small groups.

Figure 5. Material presented on a table.
Strand 3

Third part

We reconected and reflected upon to the second and first part through Aesthetic analysis over the shared and achieved experience, recollecting the Effective reality, the learning and the altering of perspective and new insights that has taken place during the one-and-a-half-hour Workshop.

Figure 6. Example of kinetic mobiles constructed in the workshop.

Comments from participants:

Amazing that we created something from our mind.

Art is linked in the same way as curiosity in science.

Warming up is good to let go of the conference.

Needed several steps – not until we drew the dance – and I let go of the idea of doing right and wrong.

It takes a while before the thought comes.

I have never thought that I could create something like this along with people I do not know.

With such activities you can distinguish patterns.

It was an important and informative piece of the instructions about the hardness of the pen, 6B - I realized then that different hardness on pens can be investigated in chemistry and that the different grind of the canvas panel structure gives different results.

For the final evaluation of the exercises two questions were presented:
-What moment during the workshop awoke your curiosity or surprised /amazed you?

What new knowledge or experience will you bring with you?

“A surprise that came from the meanings that emerged.”
“The black and white sequence. Then my mind opened for your instructions. I think I needed some time to disconnect from the reality of the conference.”

“Bringing me an unexpected context. Not understanding the purpose, I opened up, it wakened my inspiration – with reduced experience like that can wake up hidden ideas.”

“White movement above is invisible.”

“I started to be very curious when we had to find the good place on the line between the grey and the white colour. My body decided for me what was the best place for me”

“The necessity to find a dialogue between the authenticity (defined by our own body) and the truth (defined by the science).”

**PERFORMANCE ASSESSMENT OF PRACTICAL EXERCISES**

The Swedish curriculum in the subjects of science have changed from being centred on reproducing facts to performance of skills when students should show their ability to use their knowledge in a context. One example is from the curriculum knowledge requirement in physics for grade E (passable) year 9 (Skolverket b, 2011, p. 127):

- Pupils can compare results with their questions and draw simple conclusions with some connection to the models and theories of physics. Pupils apply simple reasoning about the plausibility of their results and contribute to making proposals on how the studies can be improved.

- Pupils have basic knowledge of energy, matter, the structure and development of the universe and other physics contexts and show this by giving examples and describing these with some use of the concepts, models and theories of physics. Pupils can apply simple and to some extent informed reasoning where phenomena in daily life and society are linked together with forces, movement, leverage, light, sound and electricity, and show easily identifiable relationships in physics.

The teachers must create different learning situation to train these skills and to make it possible to assess performances. One possibility to assess practical exercises is to use an assessment rubric, here created from the knowledge requirements in physics in the Swedish curriculum for compulsory school and student’s examples (Skolverket b, 2011) (Table 1). Such rubric is also useful during exercises integrating science subject matter with aesthetic expression where knowledge can be visualised (Mutvei & Mattsson, 2013).

By formation of a rubric for performance assessment with possible student answers provide opportunities for the teacher to participate in practical exercises in physics integrated with aesthetic expression. The teacher can investigate the knowledge of the students by listening to their discussions and how they solve problems while creating artefacts. The assessment rubric is a valuable tool for the teacher to evaluate their teaching and to give students more precise feedback (Mutvei & Mattsson, 2013).

**SUMMARY**

The participants of the workshop performed designed practical aesthetic activities as examples on how to reach a deeper, wider level of scientific understanding with several perspectives and layers of experience and knowledge. The workshop also gave examples of how to plan, implement and assess outcome of aesthetic learning activities in order to promote the development of the students’ science knowledge content.

Strand four focuses on science learning in digitally enriched environments. Papers in this strand cover designing, enactment, and reflection of teaching as well as digitalized assessment. Teachers’ views, experiences and aspects of professional learning are crucial to enhancing digital resources in classrooms. Further, the papers characterise digital resources and potentials of educational technology for science teaching and learning. The strand includes research on digitalization, artificial intelligence, learning with mobile devices, online learning environments, simulation and modelling tools as well as virtual laboratories. Self-regulation, reflection and collaboration in digital learning environments are also examined.

This section of the e-proceedings on digital resources for science teaching and learning includes 14 papers offering an overview of the diversity of research in this strand. Further, research on digital resources for science teaching and learning is truly international. Papers are from almost all continents. There are papers from Brazil, Germany Greece Ireland Japan, Korea, Portugal, Spain, Thailand, and US.

As the scope of the strand is rather wide, papers in the e-proceedings illustrate the same diversity of digital resources. There are papers focusing on computer animations, digital content workshop design, app usage, assessment, presentation applications, mobile tools, digital narratives, national language app evaluation, multimedia learning, interactive whiteboards, digital laboratories, as well as technology mediated home-school collaboration. Science topics cover all sciences including health education.

In the future, we hope that strand four provides a forum for those who are interested in science teaching and learning in digitally enriched environments to share findings and exchange ideas to improve the future science education.

ACTIVITIES WITH PARENTS ON THE COMPUTER: SCIENCE TEACHERS’ VIEWS

João C. Paiva¹, Carla Morais¹ and Luciano Moreira²

¹CIQUP, UEC, DQBD, Faculdade de Ciências, Universidade do Porto, Porto, Portugal
²CIQUP, DEI, Faculdade de Engenharia, Universidade do Porto, Porto, Portugal

An ecological framework, named activities with parents on the computer (APC), was proposed in order to promote the collaboration between school and home and, through this way, contribute to improving new literacies as well. In this study, we address science teachers’ views on APC. Nine science teachers who have attended courses on multimedia in science education (pre- or in-service) were inquired via email. Their statements were submitted to content analysis. Results revealed a plethora of reasons why APC was not being used, including technological, socio-economic, and educational policy reasons. Teachers attributed the cause of their behaviour to the external environment and not to their own internal dispositions. The findings urge us (i) to ask for environmental changes that may increase the legitimacy to interconnect home and school via APC; (ii) to design specific training on APC that can promote reform-minded identities so as to accept the amplification of teachers’ field of action and to encourage them to interact and collaborate with other community partners; and (iii) to think of activities with partners on the Internet, in order to favour the usage of mobile devices, especially in disadvantaged milieus.

Keywords: collaborative construction of knowledge, computer-based tasks

SCHOOL AND HOME COLLABORATION: AN ECOLOGICAL FRAMEWORK

Nowadays, the society expects teachers to be key players in fostering collaboration and bridging school and home contexts. Even if teachers – within the four walls of the classroom – could offer identical learning contexts and opportunities to each and every student, socio-economic backgrounds (including family) would bring back imbalance and inequality. We already know that students’ academic performance is not equally affected by summer vacation (Cooper, Nye, Charlton, Lindsay & Greathouse, 1996). Furthermore, from an ecological point of view, development occurs when the subject carries learning from one setting to another (Bronfenbrenner, 1979). All considered, school has to establish bonds with the community. With Hohlfeld, Ritzhaupt, and Barron (2010), we may rightly claim that schools have a social responsibility before their communities.

Structured tasks, like homework, can help to establish productive bonds between different settings and offer students and their parents structured opportunities to collaborate. Homework has been used by educators with different purposes, ranging from personal development to punishment (Epstein & Voorhis, 2001). Quality homework not only helps school to be more effective, enhancing students’ achievement (Dettmers, Trautwein, Lüdtke, Kunter & Baumert, 2010), but it can also help to connect schools and homes, involving parents and caretakers in their children’s academic life. After Hoover-Dempsey et al. (2001), one can say that ‘parents decide to become involved in students’ homework because they believe they should be involved, believe their involvement will make a difference, and perceive that their involvement
is wanted and expected” (p. 206), influencing homework through modelling, reinforcement and instruction.

The question of parental involvement has been thoroughly investigated and the process/program named Teachers Involve Parents in Schoolwork (TIPS) developed (e.g., Epstein, Van Voorhis, & Batza, 2001). According to Epstein et al. (2002), TIPS are activities designed by the teachers aiming at establishing a teacher-parent partnership in order to help the families to be up-to-date with their children’s learning activities at home and to become involved in the process. Research shows that when parents get involved children do better in school, but most families need information and guidance on how to do it in a profitable way (Epstein, et al., 2001).

However, when trying to involve parents, teachers “may contend with pragmatic, psychological, and cultural barriers to parental involvement” (Hoover-Dempsey, Walker, Jones, & Reed, 2002, p. 844). Hurdles include lack of support, limited experience or skills, reluctance if previous experiences have been perceived negatively.

According to Lewin and Luckin (2010), technology can be a means that is able to connect the school and home contexts, and help parents to perceive what their children are doing both at school and at home. As Yu, Yuen and Park (2012) argue “one of the barriers of parents’ involvement in students’ use of computer at home is their lack of a comprehensive understanding on how to get involved appropriately” (p. 19). That is why the assigned activities must be structured and parents need to have guidance (Lewin & Luckin, 2010).

Even if technology alone is not the panacea for all the problems, it may be used to develop new literacies (Leu, Kinzer, Coiro, Castek, & Henry, 2013). The activities with parents on the computer (APC) consists of an ecological framework to guide teachers fostering school-home collaboration via digital technologies.

APC builds on Bronfenbrenner’s (1979) ecological model and on the techno sub-system proposed by Johnson and Puplampu (2008) (Figure 1).

Figure 1. Techno-subsystem (Johnson & Puplampu, 2008)
The techno sub-system (Johnson & Puplampu, 2008; see also Johnson, 2010a; 2010b) fits within the micro-system and helps to deal with the "continuously increasing complexity and availability of childhood technology" (Johnson & Puplampu, 2008, para. 11). It “includes child interaction with both living (e.g., peers) and nonliving (e.g., hardware) elements of communication, information, and recreation technologies in immediate or direct environments. From an ecological perspective, the techno-subsystem mediates bidirectional interaction between the child and the microsystem” (Johnson & Puplampu, 2008, para. 11).

We have defined APC as “pedagogical tasks – based on socially relevant disciplinary contents – adopted or designed, assigned and evaluated by teachers, aiming to promote home and school connection, parents and students collaboration, digital and domain-specific literacy skills” (Paiva, Morais, & Moreira, 2017, p. 3).

The APC is divided in six parts:

(i) invitation to the parents (or other relatives) to participate, explaining to them the goals and the process (this step tends to disappear as parents get more used to the APC);

(ii) context of the learning activities and proposal of the activity;

(iii) individual work area where students should work on their own (with or without computers) revising the structural concepts involved in the task(s);

(iv) collaborative work area where parents and students work together;

(v) follow-up activities: further research which will open and extend the APC;

(vi) self-evaluation of the quality of the work.

As one can see in Figure 2, digital literacy and, ultimately, knowledge are the main goals of APC. It a knowledge-centred approach. By bridging school and home contexts, APC should promote changes in the actors’ position. According to Bronfenbrenner (1979, p. 26) “an ecological transition occurs whenever a person’s position in the ecological environment is altered as the result of a change in role, setting, or both.” Furthermore, “to demonstrate that development has occurred, it is necessary to establish that a change produced in the person’s conceptions and/or activities carries over to other settings and other times. Such demonstration is referred to as developmental validity” (ibidem, p. 35). The model is plastic enough to allow exchanges in roles and tasks.

The actors at the vertices of the triangle are teachers, students and parents. Each side represents a different microsystem (school; home; meetings between parents and teachers). If, at the very heart of the triangle, we introduce APC, we may find a way to improve access to home or school, and also to transform the traditional roles of each actor. APC becomes a true mesosystem.

In our seminal work (Paiva, Morais, & Moreira, 2017), however, teachers showed mixed feelings or ambivalent attitudes towards APC. Furthermore, teachers who undertook training on APC, in spite of acknowledging their value, seemed reluctant in applying them in their professional practice (Paiva, Morais, Amaral-Rosa, Moreira, & Eichler, 2017).
In the current study, we tried to gain more knowledge about the teachers’ views on APC after they had attended courses on multimedia in science education. We wanted to know if they had used APC with their students, and, if they had not, what kind of reasons would they present to explain their decision.

**METHODS**

In this section, we give detailed information about the participants, instruments and procedures used in the study.

**Participants**

The participants in this research are teachers who had attended a course on multimedia in science education two to three years before. The training included a topic on APC. Nine teachers (eight females and one male) accepted the invitation to participate. Six were Portuguese and three were Brazilian. Four participants had only had the opportunity to teach for one year and at the moment of the study were not employed as teachers.

**Instruments**

In this study, we decided to use questionnaires with the participants. When compared to interview, this option is not only less time-consuming but also allows the participants to answer in their own time. The questionnaire falls into two parts according to the participants’ situation:

- If you have ever used an APC, please indicate: how many times, subject(s), level(s) of teaching, year(s), context(s), level(s) and quality of students, and the overall assessment of the experience(s) carried out.

- If you have never used it, please indicate why you did not, detailing as much as possible your response.

**Procedures**

The questionnaire was sent to the participants by email. Each response was first read by one of the authors who suggested – if necessary – additional questions to obtain more detailed
information. The suggestions were then analysed by another author and sent back to the participants in reply.

RESULTS

To begin with, it must be said that none of the nine teachers had used an APC after the course. Teachers offered a plethora of reasons in order to explain why that happened.

The more general reason was the perceived scarcity of opportunities for implementing APC. Teachers also pointed out more specific reasons:

(a) lack of computers and broadband access, either at school or at students’ home;

(b) socio-economic status;

(c) inequality. If students come from different milieus and not all of them have computers available, then, according to the teachers, APC would only reinforce the gap between those who have a computer and those who do not.

However, if teachers were to use APC one day, it would be because they perceived them as valuable activities for:

(a) bridging school and home contexts,

(b) increasing digital literacy, and

(c) contributing for the collaborative construction of knowledge.

One teacher claimed that APC would work fine at primary school or with high achievement classes at secondary school. The lack of parental support at home was referred by two teachers but with different meanings: on the one hand, as a motive for implementing APC, but, on the other hand, an excuse for not implementing it.

To wrap up, reasons for not using APC are rooted in technological, socio-economic, and educational policy fields. All these reasons converge in the measure that they exempt teachers’ professional practice. An exception to this externalization of control in using APC can be found in a brief statement from one of the participants that said that she was not ready to move on from her comfort zone. On the other hand, reasons for using APC come only from the education policy goals (e.g., increasing digital literacy).

DISCUSSION

In this exploratory study, we tried to understand if teachers who had attended courses on multimedia in science education had used APC with their students, and, moreover, if they had not, we wanted to understand why that happened and how they supported their decision. With this purpose in mind, we questioned nine science teachers.

The most striking finding is that none of the teachers have ever used an APC in his pedagogical practice. Nonetheless, we should not be surprised to learn that teachers had not used APC. This result is in line with the results of a study by Paiva, Morais, Amaral-Rosa, et al. (2017). The authors used the theory of planned behaviour to assess the behavioural intention about using the digital tools and strategies of the participants (physics and chemistry teachers) of a
professional development course. The level of behavioural intention about using APC was much lower than about using webquests, exploration guides, Moodle platform and web 2.0 tools.

The current findings should not discourage us, though, as if only APC was difficult to adopt. We know that digital technologies are highly challenging for teachers, as they are “protean, unstable, and opaque” (Koehler & Mishra, 2009, p. 61) and often encounter resistance. For example, in a review of 48 empirical studies on pedagogical integration of technology, Hew and Bush (2006) highlighted 6 types of barriers, namely, resources, knowledge and skills, institution, attitudes and beliefs, assessment, and subject culture.

According to Donnelly, McGarr and O’Reilly (2011), change in ICT-based practices may occur due to two fundamental reasons. On the one hand professional development can help teachers to transit from contented traditionalists teachers to selective users and inadvertent users to creative adapters. On the other hand, only changes in environmental factors (e.g., assessment) can help teachers to transit from contented traditionalists to inadvertent users and selective users to creative adapters. As far as we understand, training has not been successful in changing our participants’ mind about using APC. Thus, we can reason that environmental mandates are required.

However, before we advocate for environmental changes, let us remember that the arguments used by teachers to not use APC are, almost without exception, external as they come from the technological, socio-economic and educational policy fields. In terms of attribution theory (Jones & Nisbett, 1971), we can say that teachers attributed the cause of their behaviour to the external environment and not to their own internal dispositions. According to Jones and Nisbett (1971), the actors are more aware of external circumstances that may interfere with their behaviour while observers, on the contrary, emphasize the actor’s autonomy. It seems that APC – considered as a pedagogical strategy – touches on a sensible nerve as it pushes teachers to new challenges increasing their responsibility. In fact, teachers often claim that students’ achievement depends on their natural aptitudes or on their social milieu. This line of thought seems to free teachers from questioning their competencies and, moreover, creates a sort of buffer that helps them in preserving their own self-esteem.

If environmental changes are necessary to increase the perceived legitimacy to implement APC, it is also necessary to rethink professional development. Until know, training on APC aimed at increasing the levels of technological-pedagogical-content knowledge (TPACK), as formulated by Koehler and Mishra (2009). Now, in turn, we comprehend that in order to implement APC requires more that knowledge from a teacher. It asks for a new vision of what it is to be a teacher. The formation of a teacher’s identity is a task for a lifetime (Alsup, 2006) and informal science environments seem to promote reform-minded identity (Avraamidou, 2014). APC can be understood as a link between formal (school) and informal (home) settings. For this reason, APC require teachers to step outside the classroom, amplifying their scope of action and, consequently, affecting the way they usually define themselves as teachers. As such, training on APC must include means to promote reflection about teachers’ professional identity and ways to promote reform-minded identities.

Finally, it is important to share some thoughts about mobile learning. In spite of some
enthusiasm and expectations about the affordances of mobile devices, some hurdles can be identified. In Portugal, for example, the use of mobile phones in the classroom is even forbidden in some schools. Again, this problem asks for policy changes. Meanwhile, in the absence of school norms and/or clear national policies, the adoption of mobile devices depends on the teachers. In this study, teachers did not consider the possibility of using mobile devices to implement APC. An additional explanation can lay on the very name of our framework. As they read computer on the name of the framework, teachers may think that it is mandatory to use the computer and not mobile phones or tablets as alternative means. One should remember that mobile phones are most likely to be found among people with lower socio-economic status (Chen, 2015), and, therefore, could be mobilized for teaching purposes. In order to favour a broader understanding and protean view of APC, perhaps we should talk of API, i.e., activities with partners on the Internet.

The limitations of this study lay essentially on the number of participants which is small even for an exploratory study. An obvious consequence of this observation is the need for carrying out further and larger studies focused on teachers’ social representations and practices around digital technologies and APC, in particular. Furthermore, a new line of research can be devised for addressing the relation between social representations, practices and teachers’ identity.

CONCLUSION

Although APC can be presented as a useful strategy to help teachers reach families and address curricular topics, the current findings require us to adjust and improve training design and ask for environmental changes that would increase the legitimacy to implement APC in schools.

The discussion urges for a change in teachers’ mind-sets so that APC may be perceived as an opportunity for acting upon disadvantaged milieus and not as a hurdle. This means that a new vision of what is to be a teacher is needed. This new vision asks for reform-minded teachers, who accept to amplify their scope of action, to interact and collaborate with other community partners.

Certainly, one needs to conduct further research in order to understand how to empower teachers in the process of elaborating or adapting, implementing and evaluating APC, identifying the means through which teachers can configure their practice and their role in a generative way.

PRODUCTIVE USE OF DIGITAL LABORATORIES FOR ELEMENTARY SCIENCE CLASSROOM: A CASE OF I-SCREAM

Seungho Maeng, Kapsu Kim, Youngseok Jhun, Donghoon Shin, Hunsik Kang, and Woosung Jung
Seoul National University of Education, Seoul, Korea

This study is to investigate how to organise science instruction modules for productive use of digital laboratory materials for elementary children. As an innovative e-learning content platform, i-Scream was selected for a focus on digital laboratory media in this study. We employed a multimedia-supported predict-observe-explain (POE) assignment task design and social constructivist teaching heuristics when developing science inquiry modules using digital laboratories. A lesson unit on liquid and gas was chosen for the module and participant teachers administered the module in their teaching. The results showed that collaborative use of POE task design and social constructivist heuristics with digital laboratories was effective for elementary children to engage with scientific inquiry practices and understand science contents and get the opportunities to articulate, justify, and debate their opinions and negotiate new and shared meanings.

Keywords: computer supported learning environment, instructional design, primary school

INTRODUCTION

A science classroom includes not only hands-on materials for scientific experiments or observations but facilities for digital media use such as science simulations, video clips for science experiment or documentary films, flash or snapshot image resources for learning science. Lots of computer-based or internet-based resources for science learning were developed and the benefits of using them have been reported for a few decades. Many science educators may agree with the idea that teaching with digital media in science classroom as an effective representation of science content, provides children with novelty and attractiveness in science, or makes children interested in science. In some cases, however, digital resources for science experiments are used to transmit and memorise science content, draw children’s attention on the contents, or only induce children’s interesting to science activities (National Research Council, 2011). Thus we may ask whether digital media use itself allows children to engage with scientific inquiry. In this study, therefore, we are focusing on how to productively use digital media on science laboratories and develop science inquiry modules with digital media-based experiments. By productive use of digital media on laboratory, we adopted Rehn et al.’s (2013) perspective in which children use digital materials as a tool to engage with specific assignment tasks for understanding of science concepts and principles.

As an innovative e-learning content platform, i-Scream (SIGONGmedia, 2008, www.i-scream.co.kr) was selected for a focusing digital laboratory media in this study. For a decade i-Scream has been predominantly employed to elementary science classrooms in Korea because i-Scream provides elementary teachers with a broad range of digital curricular contents and solutions for all school subjects (Figure 1). The quality of i-Scream would be revealed by
the winner awards from the 17th Worlddidac Awards and the 13th Japan e-Learning Awards in 2016. Extensive amounts of digital video clips, flash animation, and images for science experiments or observations in i-Scream are considered as very useful to Korean elementary teachers who need more help to prepare science classroom materials. Direct adoption of them, however, might not guarantee children’s productive use and participation in scientific inquiry practices, for the materials were aligned with focusing on procedural narration of experiments rather than children-centred inquiry activities.

### Figure 1. Front page of i-Scream

When children engage in assigned activities with digital resources they have some challenges in understanding science contents or conducting scientific inquiry practices. Many of empirical or theoretical studies about children’s science learning investigated how they learn science and what effective method or approach to science teaching and learning. Thus a science instruction module for productive use of digital materials also need to be developed according to appropriate learning theory, inquiry skills on dealing with them, and proper knowledge about science content.

For this reason, we investigated how to organise science instruction modules with digital laboratory materials provided by i-Scream in the ways of productive use and promotive science inquiry practices.

### METHOD

To design science instruction modules we employed a social constructivist teaching approach which emphasises learners’ collaborative construction of meaning by productive participation and the mediation of cultural tools between learners and the contents to be learned. About this approach we adopted Rehn et al.’s (2013) social constructivist heuristics from computer simulation study and Kearney’s (2004) multimedia-supported predict-observe-explain (POE) tasks.

It is important for a teacher to elicit learners’ ideas in social constructivist science teaching because he or she is able to promote children’s collaborative learning mediated by discursive interaction. For this purpose White and Gunstone (1992) suggested a teaching strategy called
Predict – Observe – Explain (POE). In the activities of POE model, children at first predict the result of a demonstration or experiment and discuss the reason for their prediction. Then they observe the experiment and at the last stage they explain to each other the discrepancies between their predictions and observations. Kearney (2004) adopted the POE model to technology-mediated constructivist teaching, so called multimedia-supported POE model. He used 16 POE tasks including digital video clips on science demonstrations.

According to Rehn et al. (2013), when children use science simulations in science learning, the simulation material and classroom assignment given to them and the classroom environment influence how they use the materials. Their idea was drawn from Vygotsky’s sociocultural mediated cognition and Lave and Wenger’s (1991) situated cognition. Rehn et al. also proposed six heuristics which are useful for developing assignment tasks using science simulations productively. Those are using science simulations to coordinate multiple forms of representation, to mediate discussion, to set up game-like situations and take advantage of explicit and implicit challenges, to focus on illuminating cases, to ask students to recreate or represent features of simulations, and to employ the “predict, observe, explain” method. The context of using science simulations is different from that of using digital laboratory media in this study, though, the approach to the classroom learning environment in both contexts could be similar to each other. Integrating Kearney’s (2004) model and Rhen et al.’s (2013) heuristics we designed an instruction module which had digital laboratory media supported POE sequence and social constructivist teaching sequences. Details about the instruction module are shown in the next section.

For the content of digital material in this study we chose a lesson unit, liquid and gas from Korean elementary science standards for the third grade. Before we developed science inquiry modules, we also collected descriptive data from 16 elementary teachers on their challenges in teaching this topic with i-Scream. In so doing, we sought to choose and provide relevant digital resources properly in order to solve the teachers’ challenges in teaching the topic.

Teachers’ descriptions and multimedia-supported POE tasks were the basic framework for developing and organising science inquiry modules. POE based modules were complemented by Rehn et al.’s heuristics such that the modules were to be used in social constructivist teaching. Finally the inquiry modules were administered by four participant teachers who taught the third grades. We interviewed the teachers and obtained valid evidence from their teaching and the results.

RESULTS

Teachers’ challenging points to use i-Scream

Asked about difficulties in teaching the content of the liquid and gas unit with i-Scream, elementary teachers’ answers were related to the style of content structure of i-Scream. For example, “learning goals and inquiry questions are given ahead of experiment” (Teacher A), “the way of experiment is informed along with the procedure written in the textbook” (Teacher B), “the experiment video clips in i-Scream, the procedures and results of experiment are given continuously, so that it is difficult to separate from each other” (Teacher E), or “there is not any error in the experiment and it is too much standardised so that children cannot discuss it
anymore” (Teacher G). These were due to the push-typed content structure of i-Scream and its cookbook-styled experiment structure. These challenges for teachers are barriers to improve the teachers’ pedagogical content knowledge and learners’ inquiry engagement. Teachers also said that they usually complied with the flow of i-Scream (Teacher B), they had little chance to consider variables of experiments given from i-Scream (Teacher C), they had little room for teacher-student interaction during and around the experiments of i-Scream (Teacher F), and they also felt difficult to make conceptual change or knowledge construction through the experiments of i-Scream (Teacher D). These results showed that a new way of instruction for children’s productive engagement in scientific inquiry using i-Scream.

**Designed instruction module for liquid and gas unit**

The lesson unit on liquid and gas chosen in this study consists of four sub-units such as volume of liquid, measuring its volume, space filled with gas, and movement and weight of gas. Among the learning material for the sub-unit, space filled with gas originally given from i-Scream is shown in Figure 2. It is a kind of step-by-step teaching sequence starting from introduction through inquiry question and science activities and then closing with review and assessment. At first i-Scream gives a flash animation that a boy blows a rubber ball and asks what puts into the ball. Then the sequence gives an inquiry question such as “Does gas has its space?” To solve the question, two activities are shown - one is experiment video clip with the title of “Gas occupies space?” and the other is documentary video clip with the title of “Cases of using gas occupying space in everyday life.” The sequence closes with a summary and short quiz.

![Figure 2. Original format of learning material about liquid and gas](image)

We revised this unit as an instruction module according to the teaching sequence of multimedia-supported POE task (Kearney, 2004) and social constructivist heuristics (Rehn et al., 2013). Figure 3 shows the outline of the sequence of the instruction module.
The module began with watching video-clips of experiment to introduce the procedure of experiments on the question of whether gas occupies space (Figure 4). In the video clips, a boy draws a line along the surface of water in a plastic bath, and stuck two coin tissues to the inner bottom of two plastic cups respectively. One cup has four holes at the bottom around the coin tissue, and the other cup has no hole. At this step, teachers ask children to relate everyday experiences to the situation in the video clip. Thus children are able to coordinate diverse forms of representation about the situation and talk about them with each other.
The next step of the instruction module was to show a critical scene of experiment and ask children to predict the result. On the video clip, a boy pushes a cup with four holes on the water surface, and pushes the other cup without a hole on the water surface (Figure 5). At this step, children predict the result of experiment - whether the paper of coin tissue in two cups are wet or not. Teachers prompt children’s providing their opinions if they change some conditions (i.e., variables) of the experiment. During this stage, children reveal their prior conceptions if gas has its own space or not and participate in classroom discourse. Thus the experiment is used as a mediation tool for children’s discursive interaction.

Figure 5. Predicting the result in the experiment

After the discussion, children observe the rest of the video clips in which two cups are put into the water and the surface line of the first bath is the same as before, but the second one rises up (Figure 6). Teachers help children to tell the points in which they are interested. At this step children are focusing on illuminating cases in the experiment. Children’s observations might be similar or different from their predictions.

Figure 6. Observing the illuminating cases of the experiment

Therefore, at the last step children compare what they predicted and what they observed and explain the comparison with writing or drawing of specific features of the phenomena. Constructing children’s explanation makes their thought visible about the phenomena.

Finally teachers talk about the science principle about this experiment. When the cup with holes at the bottom is pushed onto the surface of water, air in the cup goes out of the cup through the holes so that the space in the cup is filled with water. When the other cup without a hole is
pushed onto the water surface, the inner space of the cup is filled with air so that water cannot go into the cup and the water surface level goes up.

Teachers’ though about the instruction module

We interviewed participant teachers for the efficiency and validity of the instruction module. The teachers described that using the modules with digital laboratory material of *i-Scream* was much more effective for elementary children to engage with scientific inquiry practices and understand science contents compared with their prior experiences in which they used *i-Scream* along with the way as it was.

Teacher A said, “POE format of the module was effective for me to organise the class with the experiment video clips of *i-Scream*. In the module each scene of *i-Scream* could be used to give an emphasis on important points of experiment.”

Teacher B said, “As kids compared their predictions and the result of experiment, they really engaged with the activities. They were active learners.”

CONCLUSION

Science teaching with digital laboratory materials of *i-Scream* can be productively used by elementary teachers when it employs the instruction modules designed in this study. Completing POE tasks children engaged with scientific inquiry and socially constructed their own meaning about the phenomena. Teachers employed digital laboratory materials as mediation tools to establish social interaction among children. Therefore we argue that collaborative use of multimedia-supported POE task design and social constructivist heuristics with digital laboratories provide elementary children with the opportunities to articulate, justify, and debate their own and peers’ opinions and negotiate new and shared meanings.

ANALYSIS OF THE ROLE OF INTERACTIVE WHITEBOARD (IWB) FOR PROMOTING STUDENTS’ SCIENTIFIC PRACTICES IN SECONDARY SCHOOL LABWORK

Carme Grimalt-Álvaro, Víctor López and Digna Couso
Centre de Recerca per a l’Educació Científica i Matemàtica (CRECIM); Universitat Autònoma de Barcelona, Barcelona, Spain

Interactive Whiteboards (IWB) enable students not only in writing and drawing, but also inserting and dragging pictures, overwriting and storing hand-made productions. In this paper, we analyse the potential of this educational tool in a secondary school science laboratory from the perspective of promoting students’ participation in the scientific practices of inquiring, modelling and argumentation. To this end, 20 science experimental workshops have been analyzed. We describe and analyze which actions carried out with the IWB exploit the most the potential of IWB for encouraging students to think, make and communicate science.

Keywords: interactive whiteboard (IWB); scientific practice, laboratory.

INTRODUCTION AND RATIONALE

IWB: what and why?

Interactive Whiteboards (IWBs) are interactive surfaces connected to a computer that allow information to be displaying and interacted with. IWBs can be used to write on the surface, similarly to traditional blackboards, and to project text or images like traditional (non-interactive) projectors. But at the same time, IWBs can be used to drag and drop inserted text, pictures and strokes, and overwrite them with new text, new pictures or new strokes (Miller et al., 2005). In addition, IWBs allow storage of any text, picture or stroke represented on it producing a set of slides, and also reproducing a video animation showing the process of generation of these slides (Beauchamp and Parkinson, 2005).

IWBs have been massively introduced in schools because of the multiple potentialities that they offer in education, at the level of flexibility, interaction or visualization (Hennessy and London, 2013). However, using an IWB in the classroom does not necessarily imply an improvement of students’ learning, since that depends entirely on how this tool is used (Pedró, 2011). To this end, we should consider why, when and how teachers use IWBs in science education. The framework of “scientific practices” provides an interesting perspective to solve these questions.

Scientific Practices in School

Science teaching and learning, that takes place when students interact among themselves and participate in a community, can be understood as a combination of cognitive, social, and discursive practices. These practices, which can be considered analogous to those of the scientific community, are the scientific practices (Duschl and Grandy, 2012; Kelly, 2013;
Osborne, 2014). This approach is reflected in the USA Next Generation Science Standards, that define eight scientific practices to promote in the classroom: asking questions; developing and using models; planning and carrying out investigations; analyzing and interpreting data; using mathematics and computational thinking; constructing explanations; engaging in argument from evidence; and obtaining, evaluating and communicating information. In addition, Osborne (2014) proposes three interrelated spheres of scientific practice in the classroom: modelling, inquiry and argumentation. Modelling can be understood as the development, evaluation and refinement of scientific explanations about natural phenomena (Gutiérrez, 2004; Justi, 2006). Inquiry can be defined as the process that leads to design and carry out experiments, and analyze and interpret data (Windschitl, Thompson and Braaten, 2008; Minner, Levy and Century, 2010; Couso and Garrido, 2016). Argumentation can be understood as communicating the ideas and interpretations of the results to persuade others of its validity (Duschl and Osborne, 2002; Erduran and Jiménez-Aleixandre, 2007).

**Scientific Practices with IWB**

The IWB is a privileged tool in the science classroom, since it allows involving students in the development of scientific practices (modeling, inquiry, argumentation). Although there is little previous research about how this digital tool can contribute to the promotion of such practices, there are some indications of this potential. For example, Murcia, (2014), describes how showing attractive, interactive, and multi-modal visualizations can help students make explicit their prior knowledge, explore scientific ideas and generate explanations about natural phenomena. Higgins, Wall, and Smith, (2005) underline that representing abstract concepts with the IWB can help students to develop their scientific ideas, and Mercer, Hennessy, and Warwick (2010) describe how using the IWB facilitates the orchestration of the dialogue and the construction of ideas in a collective way, consistently as the dialogical process of construction of scientific meanings in the classroom, defined by Mortimer and Scott (2003). This collaborative and dialogic interaction, according to Hennessy and London (2013), may facilitate the discussion in group and the establishment of consensus on the interpretation of a phenomenon.

IWB also allows communicating and showing multimodal information and various semiotic representations (Hennessy and London, 2013; Kung Teck, 2013; Murcia, 2014), and that is, in fact, the biggest educational benefit of IWB according to many secondary school science teachers (Grimalt-Álvaro, 2016). IWB invites teachers to use a wide variety of semiotic modes (words, pictures, diagrams, graphics or mathematical formulas), which are all of them the multiple languages of science (Lemke, 1990), and also to combine and link the different levels of representation of the scientific language proposed by Johnstone (1991): macroscopic or observable, microscopic, submicroscopic or atomic and symbolic. IWB also promotes the discussion about the meaning about the different representations, and that can help teacher deal with students’ difficulties related with understanding visual representations (López and Pintó, 2017), and also support students in the active process of production and generation of their own visual representations derived from the scientific activity that takes place in the classroom (Evagorou, Erduran and Mäntylä, 2015).
Finally, IWB allows structuring teaching and learning sequences (Aflalo, Zana and Huri, 2017), so it can be used to plan and carry out processes that require a certain sequentially, like the ones involved in inquiry practices (asking questions, designing experiments, collecting data…) (Windschitl, Thompson and Braaten, 2008). In this sense, Osborne and Hennessy (2003) highlight how the affordance of the IWB for immediately displaying information can help experimentation in the classroom.

Despite all these previous signs about how IWB can contribute to students’ engagement in scientific practices, we consider that there is a lack of specific studies on this issue, and also a lack of classroom episodes that allow analysing the specific contribution of IWB to students’ scientific activity. For example, the review made by Ormanci, Cepni, Deveci, and Aydin (2015) does not address this issue. This is in contrast with the extensive existing literature on how to use other ICT tools such as video games, simulations, sensors data or mobile devices in the science classroom (Crook, Sharma, and Wilson, 2015; Linn, 2003; Pintó, Couso and Hernández, 2010; Romero and Quesada, 2014; Smetana and Bell, 2011; Webb, 2005). We believe that bringing this vision to the use of the IWB is a way to help develop the so-called Technical-Pedagogical Content Knowledge (Koehler and Mishra, 2009).

**OBJECTIVE AND METHODS**

Analysing the role of IWB in science classes can contribute to identify good practices and to disseminate them among teachers, fully exploiting IWB potential. For this reason, in this presentation we aim to study how the IWB can be used in secondary school science classrooms, and how this tool can contribute to promote students’ development of scientific practices.

**The context of study: the REVIR project**

The REVIR project (REality-VIRtuality), carried out at the Autonomous University of Barcelona, offers to students from 12 to 17 years old experimental workshops of 3-4 hours. These workshops are related to school content in physics, chemistry and biology, and they are designed, evaluated and reviewed iteratively by experts in science education, with the aim of offering educational scenarios that promote inquiry and modeling practices in a dialogic educational context. The REVIR project takes place in a ICT based laboratory, with sensors to collect data, virtual simulations, touch consoles and an IWB.

**Data collection and data analysis**

The present study is based on the work started by Bozzo, Grimalt-Álvaro and López (2015). 20 REVIR workshops of various contents (physics, chemistry and biology) were recorded, with an average participation of 25 students per workshop. Workshops were recorded using a camera focusing the IWB to register every moment in which this tool was being used (14.5 hours in total). These 14.5 recorded hours were divided into 340 independent clips, which were then categorized according to two dimensions:

- depending on the typology of actions of IWB: [A] writing and drawing over an empty background; [B] projecting information from another device; [C] dragging (and
dropping) objects, pictures and strokes; [D] overwriting and overdrawing on a previous production; [E] storing and retrieving hand-drawn productions.

- according to the phases of REVIR teaching sequence: (1) exploring phenomena and students’ previous ideas about it; (2) planning an inquiry; (3) making prediction and hypothesis; (4) gathering and analyzing data; (5) visualizing and using simulations; (6) building explanations and sharing new ideas; (7) transferring conclusions into new contexts.

Then, we created a matrix of 5 x 7 was created (see Figure 1). Each clip was coded with a combination of a letter and a number (for example [1A]). The coding process was performed independently by two researchers, to ensure a higher level of validity of the analysis. The representation of the clip sequences allowed us to define 21 different episodes, that we represented with links between clips. Each episode can be identified in more than one of the 20 recorded workshops. Then, we divided the 21 episodes in two groups. Most of episodes (16 of 21) almost only include IWB actions coded as [A] and [B], which have been represented in grey at the left side of the Figure 1. That means that these actions could have been done without using IWB (that is, only using a traditional Whiteboard or a projector). The 5 relevant episodes have been represented in red color at the right side of the Figure 1, since they exploit the real opportunities of the IWB.

![Figure 1. Representation of the 21 types of episodes coming out from the analysis and distribution of the 340 clips in the 5 x 7 matrix.](image)

The circles represent the key moments in each episode, including the beginning and the end. The dashed lines on the right are the chains that do not give one immediately one after the other, but it comes to the action "store reproductions and recover it later". They are the moments in which the teacher recovers productions (pictures, text, graphics, etc.) that the student has done a while before.
RELEVANT EPISODES

In this section, we discuss these 5 episodes, focusing on a specific example that corresponds to one of the workshops. We have included representations made ad hoc to illustrate the example, reproducing the IWB productions translated from Catalan into English.

Episode 1: Organising (and discussing) students’ previous ideas through dragging and overwriting.

Figure 2 represents a specific episode from a workshop focused on learning about energy transfer (heating and working). Students were asked to “Write a list of all the ways you think you can heat a bottle of water”, with a text projected on the screen [clip coded as 1B]. Students brainstormed for some minutes and they produced a list of “ways to heat water: sunlight, oven, microwave, etc.”, and one student wrote it on the IWB (Figure 2, left). Following, a second student classified these ideas, dragging each word on the left or on the right, based on the similarity between the different ways of heating the bottle [clip coded as 1C]. And then, a third student grouped these words, and overwrote two circles, using the ideas “hot source” and “force action” [clip coded as 1E] (Figure 2, right). Then the workshop continued with other activities, in which students learned the meaning of “heating” and “working” as the two mechanisms for transferring energy, according to Thermodynamics principles. At the end of the workshop, the teacher retrieved this slide to help students in structuring the ideas they had learned [clip coded as 6E], allowing the teacher to conclude “so, the group on the left correspond to heating mechanisms, and the group on the right correspond to working mechanisms”.

Episode 2: Planning an experimental procedure through dragging and overwriting.

In this episode students were invited to design an experimental set-up to investigate the thermoregulation of mammals (for example, how the wool helps to a sheep to maintain her temperature). Initially the teacher showed different devices which could be found in the laboratory (bottles, data loggers, computer…), and students had to drag them to build a composition [2C], and then overwrite on this composition to explain which variables would be involved in the experience [2D]. After finishing their composition, the teacher retrieves the slide to promote students making their prediction about the temperature in each bottle [3E].
Episode 3: Comparing prediction and results through storing and retrieving hand-drawn productions

In this episode, students were studying the movement of a small toy car. Before measuring this movement with a data logger, students had to make a prediction of the graphic they would obtain. Teacher provided 4 templates with coordinate axes, in which 4 different students had to overdraw their graphics [3D] (Figure 4, left). These graphic predictions were automatically stored in the IWB [3E]. After measuring the movement of the car with the data logger [4B], teacher pasted the experimental graphic in a new slide, but she also retrieved the drawings made by students (their predictions) to compare them with the experimental graphic [4E]. Finally, two students overwrote on this new slide to discuss the similarities and differences between the prediction graphic and the experimental graphic [4D] (Figure 4, right).

Episode 4: Analyzing an experimental graphic through projecting information from another device and overwriting on it

After measuring the temperature in the surface of a braking system used to brake a bicycle wheel, the teacher displays the experimental graph obtained by a student group (Figure 5, left). This graphic has been obtained connecting the IWB to an external data logger that measures temperature [4B]. With this graphic on the IWB, students had to discuss “the different steps in
the process and explain why the temperature creases or decreases”. So, different students overwrote their ideas on the graphic, identifying the different steps in the process and explaining the involved physical phenomena [4D] (Figure 5, right).

Figure 5. Left: the experimental graph obtained from an external data logger. Right: several students point out the different parts of the graphic and relate them to the involved physical phenomena.

Episode 5: Narrating a process through projecting pictures and dragging them

The last episode describes how students drag objects that are on the screen, with the aim of narrating a dynamic process, whether at the beginning of a sequence of teaching - learning to express their previous ideas [1C] or at the end, to build a model of consensus [6C]. Figure 6 exemplifies it with two moments in which one student was asked to “explain which chemical bonding are broken and which are created in a chemical reaction”. Student explained his ideas to the rest of the group by dragging the different pictures corresponding to atoms.

Figure 6. Left: representation of atoms and their links before a chemical reaction. Right: a student has dragged the atoms to explain to others what links are broken and what links are created.

DISCUSSION OF THE EPISODES AND CONCLUSIONS

One of the denominators of these five episodes analysed above is that students deal with multimodal and multilevel representations (Lemke, 1990; Johnstone, 1991). In cases in which student drag objects on the IWB (either words written by them or representations inserted by the teacher), the dragging action (coded always with [C]) becomes itself a process of “scientific communication”. Sometimes students drag to perform narrative representations, to "explain", for example, how they think that the particles move in a chemical reaction (see Figure 6), and
sometimes to communicate conceptual representations, as for example to explain, how they relate the different ways of heating the water (see Figure 2). These compositional structures proposed from semiotic studies (Kress and van Leeuwen, 1996) are particularly useful in the process of students’ modelling (Márquez, Izquierdo and Espinet, 2006).

Another common denominator of the five selected episodes is how IWB helps to create a “social space” for participatory and shared construction of knowledge, often starting from productions of the students who write or draw in the device. But unlike for traditional Blackboard, these hand-made productions (strokes, arrows, circles, drawings, words…) become automatically digital objects that can be moved on the screen by dragging them (once again, action [C]). This fact, which might seem trivial, promotes the generation of new meanings, offering a unique opportunity to foster dialogue about students’ ideas. For example, in Figure 2, we can find rich conceptual discussions among students, such as "I would drag the word "shaking" more to the right, I believe that "shaking" and "rubbing" are more similar ". In addition, the possibility to store (and retrieve later) these students’ productions (which we have coded as action [E]) is really useful for comparing students’ ideas at the beginning of a workshop with those expressed afterwards. This action can be used to promote the co-construction of models (express, review and evaluate models), such as proposed by Clement (2008) or Khan (2007).

In addition, the relationship that is established in the classroom between students and the experimental data that they obtain with external data loggers (in Figure 3 they use a distance sensor, in Figure 4 a temperature sensor) also takes a special meaning because of the IWB. IWB allow projecting a graphic from an external sensor, but that could be done with a traditional projector (action [A]). Otherwise, IWB allows overwriting on these experimental graphs (action [D]). Students can point out its parts, emphasize important elements, explain their ideas, enhancing their interpretation of the experimental results. This allows, again, generating new opportunities to promote the participation of students in the data analysis, which is one of the most relevant aspects of the inquiry practices.

Finally, another common element of the five selected episodes is that IWB breaks the traditional separation between “true” vs “in practice” information. Traditionally, the “true” and external information was represented by the information projected on the screen (those that appear in websites, in textbooks, in real pictures, in simulations, etc), and the “in practice” internal information was represented by students’ writings and drawings in the traditional blackboard. Thus, the IWB unifies these two spaces, since on the same surface students can design, manipulate and generate new information, increasing the value and authenticity of knowledge that occurs in the classroom in relation to external knowledge. This new approach can help students to view their scientific activity consistently with how the professional scientists build their knowledge (Kelly, 2013; Evagorou, Erduran and Mäntylä, 2015).

ACKNOWLEDGEMENTS

The authors would like to thank Giacomo Bozzo for their contribution in the collection of data and initial analysis, as well as the EDU2015-66643-C2-1-P: project of the Ministry of economy and competitiveness of Spain.

MULTIMEDIA LEARNING ENVIRONMENTS FOR HETEROGENEOUS LEARNING GROUPS IN CHEMISTRY EDUCATION - CONCEPTION AND EVALUATION

Thomas Baumann and Insa Melle
TU Dortmund University, Chair of chemical education, Dortmund, Germany

Since the ratification of the UN Disability Equality Convention (Deutsches Institut für Menschenrechte, 2009) in Germany, people with disabilities are legally entitled to equally participate in school life. However, this does not mean that the educational content has to be tailored individually for each student, but rather it should apply to the entire learning group according to the principles of cooperative learning. The learners are put into the position to achieve their individual goals according to their level of learning competence (Center of Applied Special Technology, 2012). In order to meet these requirements, the Universal Design for Learning (UDL) (Center of Applied Special Technology, 2012) has been developed in the United States. UDL is a framework that allows students to participate in regular classes regardless of their requirements. New technologies play a major role in the UDL. They support learning and offer more diverse approaches to teaching (Meyer, Rose, & Gordon, 2014). Based on a teaching unit about chemical reactions, which was developed in our group according to the guidelines of the UDL (Michna & Melle, 2016; Michna, Melle, & Wember, 2016), a learning software (Kerres, 2013) has been developed using new technologies. The authoring software Mediator 9.0 (MatchWare A/S, 2016) is used for the design of the learning software. In addition to free design possibilities for information presentation, the software offers the opportunity to implement interactivity. The students receive information through an expository approach (Kerres, 2013, see also the method of direct instruction, Rosenshine & Stevens, 1986) and work on exercises straight after an information unit in order to secure the knowledge. In order to meet the basic principles of the UDL, various visual and auditory tools are provided. We tested and evaluated the learning software with seventh and eighth grade students at general schools.

Keywords: chemical reaction, computer-based, learning program

INTRODUCTION

Motivation

In 2002, the Disabled Equalization Act came into effect. This law should provide all citizens with barrier-free access to all areas of public life. First of all, architectural barriers should be dismantled and information made accessible to the general public. Authorities should design their websites and offerings, as well as the graphical user interfaces they provided, in such a way that people with disabilities can use them without restriction. This includes the design of apps and other applications for mobile devices (Gesetz zur Gleichstellung von Menschen mit Behinderungen, 2002). With the ratification of the UN Convention on the Rights of Persons with Disabilities in 2009, Germany grants equal participation in school life to every student, regardless of their preconditions. In addition, a universal design is required for all areas of life to ensure everyone’s access to these areas of life (Deutsches Institut für Menschenrechte, 2009). In 2013 the school law in North-Rhine-Westphalia, our home state, was changed. Now, every student is offered a place at a general school (Ministerium für Schule und Weiterbildung...
NRW, 2013). With the amendment of the school act, the goal-oriented learning of students with and without disabilities is demanded. The enactment of these laws means that classes are increasingly heterogeneous. In order to achieve this goal, the UN Convention on the Rights of Persons with Disabilities (2009) calls for appropriate, complementary and alternative procedures, resources and materials to be used to support the learning process. The idea for such an alternative method is a multimedia, digital, individual, and universally accessible teaching unit.

**Theoretical background**

The term ‘medium’ is multifaceted and the meanings are often used synonymously. In this work, media are primarily referred to as transporters of information. In this sense, the term ‘media’ stands for books, videos, pictures or sound recordings (Kerres, 2013; Tulodziecki & Herzig, 2004). Media offer various possibilities in the teaching area as they enable indirect experience where direct experience is not possible. For example, when a chemistry teacher wants to conduct a complex experiment and they neither have the equipment nor time for the experiment in his lessons, they can show it with different types of media. Media can also be used for individualizing and differentiating students’ learning pathways, for instance, by providing a learning computer which enables students to learn at their own pace (Tulodziecki, 2003). In addition, many of the different types of media use multiple channels, in the sense of multi-channel learning, simultaneously which increases the retention performance (Paivio, 1990). As an example, Mayer and Anderson (1991) conducted two experiments in which college students watched an animation that included a verbal description given before (words-before-pictures) or during (words-with-pictures) the animation. The group which received the verbal description during the animation outperformed the other group in problem solving tasks, which confirms the theory of Paivio (1990). Consequently, computers support presenting visually based information to learners (Rieber, 1990).

The computer offers the opportunity for varied and learning-oriented lessons while taking different learning requirements into account (Tulodziecki, Herzig, & Grafe, 2010). It was surveyed that students with and without disabilities learn more efficiently with digital learning opportunities. Thus, time savings of 30 % can be achieved (Kerres, 2013; Kulik & Kulik, 1991; Tulodziecki, 2003). Various studies and meta-surveys have already been carried out on digitalized learning environments. In summary, computer-assisted learning has a slight advantage over traditional teaching (Kulik & Kulik, 1991; Tamim, Bernard, Borokhovski, Abrami, & Schmid, 2011). Hattie (2010) is of the opinion that the average effectiveness of learning with media is positive, however, it only has an average statistical effect (Cohens $d = .37$). Therefore, Hattie (2010) states that learning with media can cause positive results under specific conditions. In fact, special education schools are already using computers as prosthetic tools more frequently than regular schools. These students receive assistance through the use of computers in reading, writing and solving tasks (Mihajlovic, 2012). Moreover, students’ motivation was increased by the use of digital learning environments (Kerres, 2013). Although it is not clear whether this is due to the novelty effect or if the use of digital learning environments always causes an increase in motivation. However, an increased drop-out rate of up to 50 % could be determined when using computer-assisted learning courses as they place...
very high demands on the interest in learning. (Keegan, 2013; Lee & Choi, 2011; Moore, 2013).

To comply with the Disabled Equalization Act (2002) and the UN Convention on the Rights of Persons with Disabilities (2009), teaching units have to be universally accessible to all kinds of students. One possibility to make a software accessible for every student is offered by the Universal Design for Learning (UDL). The UDL is a framework for designing inclusive learning environments (Center of Applied Special Technology, 2012). The framework of UDL consists of instructional approaches that provide students with choices and alternatives in materials, contexts, and contents. A successful learning environment supports and challenges students in each of these areas while minimizing barriers. In turn, minimizing barriers requires flexible teaching methods and teaching materials. New Technologies and media are very suitable for providing flexible materials and are therefore of particular importance to the UDL (Center of Applied Special Technology, 2012). CAST (2012) summarizes the UDL with three overarching principles, guidelines and checkpoints (Table 1). Implementing the UDL can reduce barriers regarding methods and materials, and can also provide access to information and learning for all kind of students.

</table>

The learning unit should always be differentiated and adapted according to the present learning requirements of the students. This results in different criteria which are similar to elements of individual support (Trautmann & Wischer, 2011) and self-regulated learning (Zimmerman, 1986; Zimmerman & Martinez-Pons, 1988). The students should work on differentiated tasks (Kullmann, Lütje-Klose, & Textor, 2014) at their own learning pace (Bloom, 1968). Moreover, the learning environment should support the students during their learning process with regular feedback (Grosche & Huber, 2012; Hattie, 2010) and the students should be able to assess their learning progress by themselves. On top of that, the teaching content should be repeatable at any time and the student should have the option to skip to further content (Zimmerman, 1986).

**STUDY DESIGN AND METHOD**

A predecessor project of our group, which has already been evaluated (Michna & Melle, 2016), serves as a model for the digital learning environment that is developed in the actual project. In the predecessor project, the teacher gave an information service in form of power-point-presentations to the students. Afterwards, the students assessed how well they understood what they have heard and then chose how well they wanted to understand the section. In this way,
the students assessed their current level of learning and their learning objectives. Based on this selection, the students received differentiated tasks and information texts. In the next lesson the students conducted experiments through which the students deepened their studies from the previous lesson. For this project, we chose to make a learning software for the computer. The computer is a tool that is already used frequently at public schools and most likely available for whole classes so that all students can work on their own devices. A digital learning environment is defined as a learning software (Kerres, 2013). It can be applied to a computer, tablet, or smartphone and intends to convey teaching content. We have digitized the teaching assignments, self-assessment sheets and the differentiated tasks as well as the information texts. We deliberately did not attempt to replace the experimental part with simulation or virtual labs since they contain an additional social dimension, in contrast to the digital learning environment in which the students should learn as independently as possible.

The aim of the unit is to explain the basic concepts of chemical reactions for early chemistry lessons in general schools. In Germany, secondary school students are in grade seven or eight (13 to 14 years) when they start having chemistry as a school subject. In order to evaluate the developed digital learning environment, we formulated the following research questions.

Q1: Is the learning software suitable for increasing the level of expertise?

Q2: Do the students regard learning with a learning software as attractive?

Q3: Do the students use the learning software and its functions adequately?

In this project, an evaluation study (Bortz & Döring, 1995) is carried out in which the effectiveness of the designed learning environment is examined in the field. To determine the content knowledge we used a multiple-choice test (Michna & Melle, 2016, 24 items, Cronbach’s \( \alpha = .795 \)) in a pre-post-follow-up-design. One week before the intervention, the pre-knowledge test as well as the Culture-Fair-Test 20 (CFT 20, Weiß, 1998) for the determination of cognitive abilities are used. In addition to that, we determined the academic self-concept in the subjects of chemistry and mathematics with the DISK grid (Rost, Sparfeldt, & Schilling, 2007). The first part of the intervention is scheduled for ninety minutes. Meanwhile, laptops were recording the activities on the screens of six specially chosen learners. The specially chosen learners are determined with the CFT 20: Based on the results of the CFT 20 three different groups of different levels of cognitive ability (low, middle, high) are formed. Two students per group, hence, a total of six students per class, are chosen for the recording laptops. It was not possible to install a recording program on all laptops. One of the reasons was the lack of permission to install external programs, for example the recording program or the learning software, on the school-laptops. Therefore, we had to put the learning software on USB-drives and provided six additional laptops with the recording program. The user can start the program from the USB-drive without any problems by himself. In addition, the students’ attitude towards the learning software is measured with an attitude test (30 items, 5-point-Likert-scale, Cronbach’s \( \alpha = .908 \)). In the following lesson, the experimental phase takes place and is scheduled for forty-five minutes. In this lesson, no research tools will be used. The second part of the learning software also takes ninety minutes. After this lesson, we conducted the attitude test (students’ attitude towards the leaning software) again to document the motivational effect of the learning software. This should clarify the question of the novelty
effect. One week later, the post-knowledge test and three weeks later the follow-up knowledge test are conducted to determine the long-term knowledge. Additionally, we developed an interview guide to question the teachers about their thoughts on the learning software since their opinion as experts is of utmost importance. A coding manual to analyse the screen recordings and to evaluate the intervention is currently in development.

**Teaching Unit**

We used an authoring software to create the learning software. It is called Mediator 9.0 (MatchWare A/S, 2016) and offers the same opportunities as Microsoft Word or PowerPoint when creating the program interface. However, this software makes it possible to implement interactivity for the user. As a teaching method we choose the method of exposition (Kerres, 2013). The method of exposition is primarily a presentation method which focusses the presentation of the educational content. The learner is regulated through learning paths and material structures provided by the learning environment. It offers the opportunity to convey knowledge systematically. Especially, students with weaker learning abilities should benefit from the structuring elements. In addition, various studies have shown that this targeted regulation of the learning process affects the learning success positively (Hattie, 2010; Helmke, 2017).

The digital learning environment was conceived according to a topic-centered process, whereby not all elements have been considered as we did not implement the tests after each topic and the project at the end of the session. The topic-centered process is a framework for creating digital learning environments. After the presentation of the content of a topic follows the activation of the learner through an exercise. To assess the learning progress, tests can be used and the unit can be completed with a project (Figure 1) (Kerres, 2013).

![Figure 6. Topic-centered process. (Kerres, 2013)](image)

The learning software was divided into part 1 and part 2. Between these two parts, the experimental phase takes place. For this experimental lesson, we did not change the working materials for the students from the predecessor project. The method of exposition results in a linear linking of the individual subject areas as a software structure (Kerres, 2013; Petko, 2014). Figure 7 gives an overview of the software structure and the teaching unit is presented. It shows that the student must complete a subject area with its information input, the self-assessment and the processing of the tasks before the next topic can be addressed. Since the topic areas
build upon each other, they should not be freely selectable at the beginning. In the first part the topics “Chemical reaction”, “Reaction equation” and “Physical process” are covered while the second part is about the topics of “Oxidation”, “Constancy of mass” and “Sub-microscopic level”. After completing a topic, the learner is free to repeat a finished topic at any time.

Figure 7. Overview of the software structure and teaching unit.

The following points can characterize the learning software. We tried to keep the texts as simple as possible to make reading easier. Therefore, we tried to follow the easy-to-read rules (Inclusion Europe, 2009). Each section of the text is linked to an audio file and the presented information is supported by pictures. There are various differentiated tasks throughout the learning path which become more difficult depending on the desired learning objective. For example, there are multiple-choice, fill-in and drag & drop tasks. In all tasks, the students receive direct feedback through a correct or false message or, similar to a traditional teaching unit, are provided with a sample solution to correct their response.

FIRST RESULTS

As the study has not been completed up to now, the following results are only preliminary. The learning software was tested in three public general schools in Germany (\(N = 61\)). In two of the three schools a whole class participated, whereas in the third class only six students participated in the study. Overall, two students with emotional-social disorder and six students with learning disorder participated in the investigation. In addition, a student with hearing problems and a student for whom the diagnosis of emotional-social disorder has been cancelled recently took part in the examination. For the study, 39 grade seven and eight students were tested throughout the whole investigation through the knowledge test. The content knowledge of chemical reactions was significantly increased from \(M_{pre} = .27\) to \(M_{post} = .46\) (see also Table 2). Grade
seven students had less previous knowledge than grade eight students. However, both showed a significant increase regarding the content knowledge. Eight students with special needs could be evaluated. These were also able to increase their expertise significantly, however, not as much as the students without special needs.

The students evaluated the attractiveness of the learning software as positive with $M_{fb1} = 1.83$ for the first part and $M_{fb2} = 1.85$ for the second part on the 5-point-Likert-scale, ranging from 1 as positive to 5 as negative (see also Table 3). There was no significant difference between the students’ attitudes towards the first lesson and the second lesson. This applies to students with and without disabilities.

* 5-point Likert scale I totally agree (1) to I totally disagree (5), fb = feedback

The third research question still needs to be answered through the analysis of the screen videos in detail. However, so far we were able to measure the time spent by the students with the learning software for the respective two-hour course. We found out that the students required about $M_{\text{part I}} = 59.33$ min ($n = 18, SD = 10.05$ min) for the first part and $M_{\text{part II}} = 46.78$ min ($n = 18, SD = 9.801$ min) for the second part.

**DISCUSSION AND CONCLUSION**

The first two research questions can be answered positively. Moreover, the results from the study suggest that the digital learning unit is suitable for learning about chemical reactions. It
fits for learners with and without disabilities. The attitude test confirms that the students perceive studying with the learning program as attractive and would like to use it more often for learning. In fact, we observed that the students using the learning software were very focused and could not be distracted easily which, in turn, led to a very calm atmosphere in the classroom. The students rated the learning unit including two lessons of using the computer as positive. The attitude effect for this teaching unit could not be confirmed. However, this result should be interpreted with caution as this unit only runs over two 90-minute units, interrupted by an experimental phase. In order to capture a constant positive attitude of the students towards digitized teaching units, which has been designed according to the principles of the UDL, the teaching unit would have to be extended and tested more often. Whether the learning software and the UDL work properly cannot be said yet because the third research question still needs to be answered. The students needed about $M_{part \, I} \approx 60$ minutes to complete the first part and about $M_{part \, II} \approx 47$ minutes to finish the second part instead of the given 90 minutes. Michna's previous project showed that the students tended to be unable to completely process the materials at the end of the sessions. These two results indicate that students work faster using the digital learning environment than the traditional pen and paper-based unit. Hence, concurrent with (Kulik & Kulik, 1991) a time saving could be confirmed. This results must also be interpreted with caution, as the sample size is still relatively small.

OUTLOOK

Currently, we develop the coding manual for the screen recordings. The results will show to what extent the learning software is useful to students with and without disabilities and if elements of the UDL are properly used. In addition, we try to identify the specific elements of our learning software that particularly support learning. Therefore, we conducted an eye-tracking study (Böing, 2017) in a single-case-study.

ACKNOWLEDGEMENT

I want to thank my research group at TU Dortmund for their support with my Ph.D.-project and the participating students and teachers.

AN EVALUATION OF GREEK EDUCATIONAL ANDROID APPS FOR PRESCHOOLERS

Michail Kalogiannakis and Stamatios Papadakis
Department of Preschool Education, Faculty of Education, University of Crete, Greece

Seven years since the introduction of the first tablet (2010 - Apple iPad), the use of applications for these devices has increased rapidly and is one of the most hotly-debated topics in the fields of education and child development. However, the increase in popularity of mobile applications does not bring a corresponding increase in the quality of applications as there are contradictory data regarding the appropriateness of the self-proclaimed educational applications for preschoolers. The purpose of this study is to examine whether the self-proclaimed educational applications for Greek preschoolers have been designed in accordance with developmentally appropriate practices to contribute to their own cognitive development. In order to achieve this aim, we use the REVEAC rating scale. The study results are in agreement with international studies which highlight the low educational value of the self-proclaimed educational applications. Of considerable concern is the discrepancy between the score of an application from the users and its actual educational value.

Keywords: preschool children, mobile educational applications (apps), evaluation

INTRODUCTION

The smart mobile devices compared with other digital devices are the most popular among young children (Livingstone, 2016). International research indicates that these devices can be used as an educational tool (Papadakis, Kalogiannakis, & Zaranis, 2016a; 2016b), supporting under proper conditions, certain aspects of teaching and learning of preschoolers (Kyriakides, Meletiou-Mavrotheris, & Prodromou, 2016; Neumann & Neumann, 2017). However, children's ability to participate in rich and dynamic learning environments within and outside the school environment (Kucirkova, 2016) is closely linked to the quality of mobile applications (Kucirkova, 2016; Neumann & Neumann, 2017).

Thus, there has been an explosive increase in the number of self-proclaimed educational apps which are available for free or for a fee in the two popular online stores (Google Play and App Store) (Nadworny, 2017) and aim mostly at the age group below 10 years (Papadakis & Kalogiannakis, 2017a). However, using smart mobile devices and their accompanying apps, inside and outside the school environment, is not a panacea (Fabian & MacLean, 2014). As stated by Guernsey, Levine, Chiong, & Severns (2012), in the early days of the "Wild West" of apps (p. 9) most apps for preschoolers which were advertised as educational, had very little educational value (Kucirkova, 2016). After reviewing the relevant literature, a key issue emerged regarding the quality of the self-proclaimed educational applications (Neumann & Neumann, 2017). Children's experiences with smart mobile devices, as well as their ability to take part in rich, engaging and dynamic learning environments (Kucirkova, 2014a; 2014b; 2015), are closely linked to the quality of these apps (Neumann & Neumann, 2017; Sandvik, Smørdal, & Østerud, 2012; Verenikina & Kervin, 2011).

For instance, as Verenikina & Kervin (2011) state, several apps are marketed as having
educational value for very young children, but, in fact at best, provide few if any educational benefits. Vaala, Ly, & Levine (2015) comment that the vast majority of apps do not meet the standard education requirements for the children of today and tomorrow. In most educational apps, the educational content is based only on the format of closed type questions such as multiple-choice questions with only one possible answer. Most apps are not created with an open-type design which allows children to create their own content or explore something without their response being considered erroneous. Thus, children may theoretically be engaged with educational apps, but as they are not age or developmentally appropriate, children simply waste their time with apps which do not give them the opportunity to design, create and to express themselves (Bers & Resnick, 2015).

One of the key issues that have emerged from a review of the literature is the low quality of the self-proclaimed educational apps (Neumann & Neumann, 2017).

The purpose of this study was to examine whether self-proclaimed educational apps for Greek preschoolers have been designed in accordance with developmentally appropriate standards to contribute to the social, emotional and cognitive development of children in formal and informal learning environments. The study results were discouraging. The majority of the apps aimed to teach children the basics about numbers and letters. Overall, they were drill-and-practice-style, based on a low level of thinking skills, thereby promoting rote learning, and were unable to contribute to a deeper conceptual understanding of certain concepts.

METHOD

This research examines whether the self-proclaimed educational android apps for Greek preschoolers have been designed in accordance with developmentally appropriate practices to contribute to their own cognitive development within and outside the school environment.

Sample selection criteria

During the selection phase, the researchers considered the international literature (Chau, 2014; Goodwin & Highfield, 2012; Handal, El-Khoury, Campbell, & Cavanagh, 2013; Richards, Stebbins, & Moellering, 2013; Shuler, 2012; Watlington, 2011) to produce comparable results with similar international studies in educational apps with English content. The following criteria were used to select the sample: the apps had to:

- Belong to the educational category for preschoolers.
- Be available for free, trial or freemium version.
- Be compatible with the Android operating system. The apps did not need to run on the latest edition of the operating system, which during the period of the study was the Android 7.0 Nougat.
- Be available in Google's app store during the selection phase (December 2016).
- Contain Greek content.
- Be capable of being installed in both smartphones and tablets (this feature was not a necessary condition).
The Android operating system (Google) was selected instead of the competitive iOS (Apple), because, according to official figures, Android is the most popular operating system for smart mobile devices in the world, with a usage rate of 87.6% for the second quarter of 2016, and this increasing trend is likely to continue (International Data Corporation, 2016). In Greece, similarly, Android has become the most popular mobile operating system (Vodafone, 2016), and there are several smart mobile devices available on the market at all price ranges, as opposed to devices using competing operating systems.

In the aforementioned studies, the mean average number of applications per study ranged between 19 and 240. In the present study, initially, there was no limit on the number of apps that could be selected for evaluation. But, a thorough search on the Google Play store with the combined criteria (Category: “Education” or “Family” and “Age 5 and below” and content: “Greek”) gave rise to a selection of approximately 60 apps. Ultimately 40 apps were evaluated. The main reason 20 apps were excluded from the analysis was that the researchers observed that several of these were identical, as they had the same design, plot, and goals and differed mainly in their appearance using different colour themes. Many apps offer the same content with just a slightly different audio visual presentation (Notari, Hielscher, & King, 2016). Also, several apps by a Greek research institute were excluded as the researchers considered that the low quality of these apps, might significantly alter the assessment results.

The assessment tool

A standardized questionnaire, the Rubric for the EValuation of Educational Apps for preschool Children (REVEAC) (Papadakis, Kalogiannakis, & Zaranis, 2017), was used as an assessment tool. The scale takes into account all aspects of an app (pedagogy, design, and functionality) as well as the peculiarities of the technological mean to which it refers. The REVEAC scale differs from others in the literature in that it not only focuses on pedagogical or technical characteristics of an app, or even a single company's products, but also considers the multidimensional aspects of an educational app, as well as the peculiarities of the technological device. The rubric is not only designed to assess the educational value of an app, but also to evaluate several additional features, such as, the amount of information provided to the parents during, and on completion of the app, the configuration options of the app, the degree to which an app can affect a preschooler’s cognitive progress, etc. It also considers the existence of advertisements which may disrupt the user's attention, as well as the promotion of electronic transactions (in-app purchases). In summary, the REVEAC assesses the educational apps in the following four domains: educational content, design features, functionality and technical characteristics. The researchers analysed the sample using the following procedure:

1. They visited the Google Play store and downloaded the sample apps.
2. They “locked” each app installation by disabling the apps’ automatic updates. The necessary third-party app, Adobe AIR, was installed.
3. They recorded the app's star rating and user reviews.
4. They dealt (played) with each application until the completion of its content.
5. They evaluated each app using the assessment tool.
RESULTS

Apps categorization

In line with international studies (Noorhidawati, Ghalebandi, & Siti Hajar, 2015), the researchers classified the apps into three categories: gaming mobile apps, interactive e-storybooks and creating mobile apps (apps which aim to develop the creativity and imagination of a young child). The analysis showed that only 5% of the sample was in e-storybook form. The apps simply reproduced stories in e-format and did not use the most appropriate opportunities offered by modern communication and information technologies, not having interactive features. Although the use of interactive technology in e-book applications is not a panacea, however, the problem with these applications -independent of how the audio-visual features are used- is the absence of clearly-defined educational goals.

The remaining 95% of the apps was in edutainment game type, i.e. apps which combine entertainment activities to achieve their educational goals. Almost all apps dedicated to drill-and-practice-type activities. The questions were presented to the children mainly in the form of selected-response or closed-ended questions; typically, in the form of multiple-choice. The correct answer led to the next question of the same type. At best, the apps tended to evaluate the knowledge of the users rather than trying to teach new ones (Hirsh-Pasek et al., 2015). The apps based on low level of thinking skills and they did nothing more than promote mechanical learning, a memorization technique which is based on repetition (Goodwin, 2013). There were no apps which aimed to develop a learning environment in which children are motivated and able to learn (Noorhidawati et al., 2015; Zaranis, Kalogiannakis, & Papadakis, 2013). Some applications offered the possibility of coloring predefined shapes, but these in no way, can be considered as apps which aimed at the development of children's creativity through play and learning.

Apps score

The researchers used the results of the REVEAC scale to evaluate whether the apps have been designed in line with child development principles and practices so as to stimulate children's overall cognitive, emotional, physical and social development. The overall sample had an average score of 27.18 with a standard deviation of 2.60 ($M = 27.18, SD = 2.60$) in which 18 and 72 corresponded to the minimum and maximum score. Both total average score of apps, as well as the score of the apps in various areas of the rubric. The mean total score, as well as the mean scores for each of the subscales (design, educational content, functionality, technical characteristics), highlight the low quality of self-proclaimed educational apps. Of the 60 apps evaluated only two apps scored higher than the average rubric score, but they had below-average scores in areas such as error correction/feedback provision and learning provision (see Figure 1).

It was then investigated whether the evaluation of each app by its users as reflected in the Google’s star rating system is in line with the app rate as recorded by the evaluation rubric. The rate of an app in Google’s Play store ranges from 1 to 5. The conversion of the rubric score on the five-point scale revealed a huge discrepancy between the objective (rubric) and subjective (users) score of each app (see Figure 2).
In addition, the researchers attempted to investigate whether an app's score according to Google's rating system is associated with the number of users who rated the application. The number of users who rated the apps was not constant per application but instead presented a great variability. For instance, an app was highly rated by a single user only with 5 stars (rubric score: 2) while another app was rated by 175 users with an average of 4.1 stars (rubric score: 1.5). Figure 3 presents the association between rubric score, users’ score and the number of users, in 22 randomly selected apps.
RESEARCH LIMITATIONS - EXTENSIONS

Undoubtedly the field of mobile educational applications for preschool children is chaotic and unregulated (Papadakis & Kalogiannakis, 2017b). Although the most rapidly growing segment of the app market is dominated by two digital marketplaces (Apple iOS App Store and Google Android Play Store) the volume of apps in both stores is huge and still growing. Each of these two digital stores contain more than 100,000 applications which are advertised as educational or suitable for young children (Apple, 2016; Olmstead & Atkinson, 2015). Additionally, the mobile market for children is full of other companies that manufacture specialized devices for children such as the LeapFrog, popular mobile platforms such as the Nintendo DS, as well as other well-known game consoles such as the Microsoft’s Xbox Kinect and the Nintendo’s Wii (Chau, 2014). Each of these platforms has its own digital library including, games, applications etc.

In this study, which is part of a larger research project, it was impossible to take into consideration the different types of devices and their respective applications. The present research has several limitations.

The evaluation of the apps was performed according to the criteria of the REVEAC scale (Papadakis et al., 2017; 2018). No children participated in the research, thus, the generalizability of the study findings is limited by the nature of the setting. The assessment of the design and content of an application can only be completed through direct observation and recording of the actual experiences of children when dealing with the intended application (Chau, 2014; Noorhidawati et al., 2015). For example, studies suggest that children perform better with small touchscreens (3.5-inch screen size) rather than large (10.1-inch screen size) (Vatavu, Cramariuc, & Schipor, 2015). Moreover, the researchers –as adults- responded to various app gestures. But, it is not certain that a child could respond with the same ease in the visual and motor coordination that each app required.

A broader study is required that will examine whether there is a “gap app” between the free and paid. In other words, are the paid applications so radically different in the assessment points...
from the free apps or are they simply enriched versions of the free apps, without offering kids a meaningful experience, as is the case with trial applications. For example, the paid apps don’t include advertisements, a characteristic that was found to be a negative factor in several applications.

Also, it would be useful for research purposes to conduct a combined study between the free and paid apps for Android and iOS devices (cheap vs. expensive devices). The results of such research are critical for countries like Greece, which are affected by the economic crisis and where even middle-class people have turned to free apps and the plethora of cheap Android devices.

In addition, it would be useful for further studies to investigate whether an educational app which is available from both digital stores (iTunes and Google Play) differs qualitatively in the individual rubric axes and ultimately in its true educational value.

**DISCUSSION**

The result of this study showed that almost all the sample apps were based on behavioural theory and were simple drill and practice apps. The apps based their teaching on transmission models that encourage the rote learning of knowledge, without being interested in promoting a deeper conceptual understanding of emerging concepts and complex processes (Hirsh-Pasek et al., 2015). As is known, the more an educational software supports constructivist activities, the more likely it is to have a positive effect on the learning process (Kalogiannakis & Papadakis, 2017a; 2017b; Kucirkova, Messer, Sheehy, & Panadero, 2014). Most included applications focused on basic skills, such as number and letter recognition. This coincides with the results of research done by other scientists indicating the limited variability in the content of the apps with regard to a targeted age group (Chau, 2014; Vaala et al., 2015). Thus, we can say that the space of educational Android apps for Greek preschoolers is qualitatively “shallow”, with a severe shortage of educational content which is consistent with the developmental needs of this age group. All applications were accompanied by a poor description of their content, their development teams, as well as their evaluation process. Finally, they were unable to play a key role in the education of young children, as they fail to promote multiple aspects of their cognitive and social development. These results are consistent with other studies which highlight the discrepancy between the number of self-proclaimed educational apps and their low educational value (Chau, 2014; Dua & Meacham, 2016; Falloon, 2013; Goodwin & Highfield, 2012; Hirsh-Pasek et al., 2015; Vaala et al., 2015; Schuler, 2012; Watlington, 2011). Although frameworks and evaluation rubrics have proposed specific design features that may promote learning, the currently available “educational” apps rarely align with these suggestions, nor is there a unified definition of educational quality (Blackwell, Lauricella, & Wartella, 2016 p. 66).

However, in Greece, the impressively small number of ‘educational’ apps for preschoolers was unexpected. It can also be considered a negative factor that in Greece there are no public or private institutions as there are in the United States such as PBS Kids (www.pbskids.org), the Sesame Workshop (www.sesameworkshop.org), Common Sense Media (www.commonsensemedia.org), Resources for Early Learning...
There was no correlation between objective (rubric) and subjective app scores (Google's star rating system). We also found a mismatch between the objective score of an application and the subjective user comments, which is consistent with previous studies (Bentrop, 2014; Hirsh-Pasek et al., 2015; Stoyanov et al., 2015). In all cases, the applications seem to be overvalued in terms of their real educational value. Another issue worth mentioning is the discrepancy observed between the user comments and ratings. In Google's online store, there were few comments-reviews made by Greek language users who had downloaded the apps, and they were comparatively much fewer than the English language apps had. Overall, analyzing users’ feedback (comments - reviews) we considered that most adults who downloaded an app had a positive or very positive attitude towards the app. This finding raises concerns about the internal evaluation system used by parents and other adults who download an app. It seems that the adults are influenced in their judgment by the ‘superficial’ characteristics of an app (sound, colours) and are not able to evaluate the quality of the educational content of the app. The most successful, best-selling learning app might not be the most useful from a pedagogical perspective (Notari et al., 2016).

Of particular concern is if a user’s judgement is affected by other users’ posts or the number of stars an app has. The above assumption is a weighty matter if we consider that both evaluation methods mentioned above are very subjective. Any user who has downloaded an application can comment or rate the app. As Notari et al (2016) state most of apps classifications and reviews are a bit fuzzy and often imply a specific use-case of an app, which might be used quite differently as well. Finally, an additional element of concern, resulting from our research in both Google's online store and the websites of applications is the absence of information regarding policy on the scope of collection and the potential uses of the personal data.

CONCLUSION - PERSPECTIVES

It is a fact that we cannot isolate children from technology, but we can ensure that they are not harmed in any meaningful way (Ebbeck, Yim, Chan, & Goh, 2016; Papadakis, 2016; Parette, Quesenberry, & Blum, 2010). In the 21st century, children are growing up in media-rich homes with touchscreens and digital devices and are frequent users of these media (Guernsey, 2016; Lauricella, Wartella, & Rideout, 2015; Wartella, 2015). Similarly, the constantly evolving market of mobile applications offers parents new digital products for the education of young children (Judge, Floyd, & Jeffs, 2015). In connection with the debate about children’s exposure to digital media, all those involved in educational technology have agreed that the real question that had to be asked is not how much time it is appropriate for children to "consume", but what to "consume". With the rapid proliferation of mobile devices and applications the concerns about app content become even more topical and complicated (Guernsey, 2012).

The present study found that the sample apps in no way justify their title as educational, as they do not meet the developmental needs of the target age group. Thus, the present results are in line with other studies in supporting that special attention must be paid to the design and content
of “educational” mobile apps, if we wish the numerous advantages of smart mobile devices to translate into productive learning (Falloon, 2013). Additionally, the present study is in accordance with a number of research studies (Guernsey et al., 2012; Kucirkova, 2014a; Tian, Nagappan, Lo, & Hassan, 2015; Vaala et al., 2015) which highlight the need for a reliable and effective framework for monitoring and evaluating mobile content through which parents and teachers can download apps with real educational value for preschoolers.

In conclusion, the real question is not whether technology belongs in early childhood education, but rather, how we can leverage the efficiency of digital tools to best serve young learners (Shapiro, 2014). In this context, researchers, educators, mobile developers, and designers must ensure that the applications aimed at young children have a solid theoretical basis and follow high-quality standards so as to contribute efficiently to the progress of young children’s development.

DIGITAL NARRATIVES IN HEALTH EDUCATION:
REFLECTION IN LEARNING

Maria Augusta Palácio¹ and Miriam Struchiner²
¹Regional University of Cariri, Ceará, Brazil
² Federal University of Rio de Janeiro, Rio de Janeiro, Brazil

There is a debate, in Health professions education, about the need to stimulate students to integrate theory and practice, to act professionally, and to reflect about the role of these experiences. Therefore, there is interest in pedagogical methods that foster greater student reflective participation. Digital storytelling integrates digital technology using different media languages. The objective of this study was to analyze digital storytelling (blogs) authored by a group of 15 first year Medical students about their experiences in the course Primary Health Care. The framework adopted to study reflection as an educational strategy considers the relation between reflection and learning based on a "deep" or a "superficial" approach to learning. In general, all students' blogs presented both descriptive and reflective posts/narratives. However, narratives with a deep learning approach prevailed in the present study. Digital storytelling is an important strategy for promoting in-depth learning, which is focused on the student and his/her experience.

Keywords: digital storytelling, reflective learning, health education

INTRODUCTION

There has been a growing debate, in Health professions education, about the need to stimulate students to integrate theory and practice, to act professionally, and to reflect about the role of these experiences in their education, since early stages of the course (Mann, Gordon & McLeod, 2009). Reflection on learning should be encouraged as an important resource for vocational training (Schön, 2000). Therefore, there has been a growing interest in pedagogical methods that foster greater student reflective participation (Gomes et al., 2010).

Sandars (2009) states that there is increasing emphasis on the importance of reflection in undergraduate, postgraduate, and continuing medical education. ‘The word ‘reflection’ is widely used in a variety of different contexts, from physics to education, but all remain true to its Latin origins: ‘to bend’ or ‘to turn back’ (Sandars, 2009, p.685). In other words, reflection is a process in which thoughts are ‘turned back’ so that they can be interpreted or analyzed (Sandars, 2009). Reflection plays a role in academic and non-academic learning, self-development, critical review, considering our own processes of mental functioning, decision-making, emancipation, and empowerment (Moon, 2005).

In recent years, many strategies have been introduced to stimulate reflection on learning; one of these is digital storytelling. According to Bruner (1991, 1996), storytelling refers to a way of thinking and of organizing our experience, and, therefore, it is a resource in the process of education (Bruner, 1991, 1996). Digital storytelling integrates digital technology and its advancements in media convergence with the millenarian experience of storytelling (Boase, 2013). It encompasses the use of different media languages (text, image, video, audio etc.) in the production and dissemination of narratives based on personal observations and experiences'
representations (Robin, 2005; 2008). It consists of a teaching and learning strategy that involves teachers and students in narrative activities that foster interaction, motivation, and creativity, helping them to reflect on the educational process (Robin, 2008).

Primary Health Care (PHC) is the first level of care offered by the Brazilian health service (Unified Health System - SUS). PHC focus on community problems based on the view that health is influenced by social, economic, and cultural factors and that health meaning cannot be limited to absence of disease (STARFIELD, 2002). Different authors discuss the relevance of training in PHC. According to Bravo et al. (2014), the experience of a medical student in PHC for a longer period of time, on a continuous and regular basis, allows understanding that it is possible to solve more than 80% of a population at this care level.

PHC training is still based on the hegemonic model of biomedical attention, which strengthened the professional's specialization. Teaching is fragmented and focused on massive content transmission. Although experiences for transforming this model have been adopted, they are still considered punctual and restricted to changes in isolated segments of the curriculum (MARINS, 2007). Thus, there are few advances that favor a transversal approach to PHC training at courses in the Health area.

For Carácio et al. (2014), there should be an integration of health education with the needs of the PHC scenario. Furthermore, the training of health professionals needs to provide students with the ability to autonomously conduct their lifelong learning process, critical reasoning, and decision making.

In this perspective, the objective of this study was to analyze digital storytelling authored by a group of first-year Medical students, as they were experiencing their first professional training in Primary Health Care in a poor community.

**METHODOLOGY, SUBJECTS, AND PROCEDURES**

The framework adopted to study reflection as an educational strategy considers the relation between reflection and learning based on a "deep" or a "superficial" approach to learning (Moon, 2001).

> A deep approach is where the intention of the learner is to understand the meaning of the material. She is willing to integrate it into her existing body of previous ideas, and understandings, reconsidering and altering her understandings if necessary. The new ideas are ‘filed’ carefully and integrated. In contrast, a surface approach to learning is where a learner is concerned to memorize the material for what it is, not trying to understand it in relation to previous ideas or other areas of understanding. It is as if the new ideas need to be retained for the moment, but not ‘filed’ for any lasting purpose (MOON, 2001, p.5).

Deep learning, as opposed to superficial learning, involves a critical analysis of new ideas and experiences, linking them to already known concepts and principles, which results in content understanding and knowledge building. This is understood as a reflective behavior, as students reach beyond literal descriptions of events and reflect on their practices (Boase, 2013).

We conducted a case study with first-year Medical students (n = 18) and their Primary Health
Care (PHC) professor in a Brazilian public university. This course involved students’ first contact with patients who are public health service users. In this regard, they are supposed to deal with a range of factors such as basic and clinical sciences knowledge integration, sociocultural differences and values, communication and affective issues, among others. The course professor used to work with student portfolio and agreed to introduce the use of digital storytelling in her course.

During one semester, as part of their learning activities, students constructed digital storytelling about their PHC learning experiences. For producing and disseminating their narratives, students created and published their own blogs, using a blog application in a virtual learning environment “Vivências: experiences in illness and treatment” (http://ltc.ead.nutes.ufrj.br/vivencias) (Figures 1, 2). They were supposed to post at least once a week and were free to choose the media languages to express themselves.

![Figure 1. Blogs in VLE “Vivências: experiences in illness and treatment”](image1)

![Figure 2. Example of a student’s digital storytelling published in his blog.](image2)
Students’ blogs were analysed based on the characteristics of each posted narrative according to their superficial and deep learning approaches. In the first case, narratives are only descriptive, without relating to previous knowledge, and in the deep approach, there is a more thorough reflection in addition to the description of the basic technical events (Moon, 2001). By the end of the semester, three students were withdrawn from the study because they did not sign the Informed Consent Form. Thus, we worked with data from 15 students, labelled as Med1, Med2 ... Med18, to preserve anonymity (Table 1).

RESULTS AND DISCUSSION

Table 2 shows the characterization of the types of approaches related to the identified reflection on the students’ blogs. Narratives were classified as “superficial approach” and “deep approach”. Although not aimed at quantitative analysis, presenting the data in this way helps providing one dimension about students’ use of blogs as reflective learning spaces.

In general, all students' blogs presented both descriptive and reflective posts/narratives. Therefore, results confirm Moon's (2001) proposition that these two approaches are poles of a continuum and that both of them may occur in one student's narratives. However, narratives with a deep learning approach prevailed in the present study.

In digital storytelling that was characterized as superficial, students presented learning content description with basic technical information about health conditions, without making relations with all possible contributing factors for the problematic situation; they also did not explore the reflective possibilities provided by those experiences. They described situations regarding participation in activities in the Family Clinic, such as medical visits and home visits, describing diseases and their treatments.
Text and film reviews were also presented in some digital storytelling. But, in general, they were merely illustrative and superficial since they did not relate their impressions with the practice they were experiencing in PHC training, as the objective of this graduation stage.

In these cases, although students have narrated their experience, they have missed the opportunity to explore and to make conjectures about their observations, to relate them to previous ideas, and to build new knowledge. Examples of narratives with a superficial approach are:

"[...]. The first patient we visited was Mrs. M. do C., a lady who has lived in bed for a long time and reports having pain due to edema in her legs, which do not let her sleep well. [...] Mrs. M. takes medication for hypertension and her blood pressure was measured, but it was very low, 65/40 mmHg [...] "(Med17).

"The first patient went to the clinic to do her postpartum follow-up. She was fine and the delivery had taken place very well. The doctor examined and directed her to return after three weeks. [...] It was an excellent experience "(Med7).

"Hi, everyone! The Moment of Health today is an excellent option for those who want to know more about the health area in international settings, as well as to compare it with our system. My colleagues and I watched the movie "SICKO", directed by Michael Moore and we found the aspects he treated very interesting. [...] "(Med10).

On the other hand, narratives with a deep approach presented both description and reflections about the experience. As shown in Table 2, most of the digital storytelling presented a deep approach, indicating that there was description and reflection of the experience.

Reflections, in general, were related to different aspects of PHC learning, to the principles of the Health System in practice, to knowledge about the patient/user of the service, and to the community in which it is inserted, as well as issues that permeate the construction of identity of the health professional to act in this scenario. These narratives revealed that students were able to reach beyond the limits of technical descriptions, understanding the reasons for this formation and the established relationship between theory and practice in health teaching. The following are examples of deep approach narratives:

"I realized that the role of the doctor goes beyond simply treating the disease, that its function is also to ensure the well-being of his patients in all aspects, sharing information, offering support, welcoming, dialoguing, listening to feelings and pain, and offering a hug "(Med8).

"Even though I have heard some contrary opinions and changed my vision a bit, real and practical contact with the reality of a community and the routine of health promoters was crucial to the construction and solidification of a completely new mentality" (Med9).

"[...] I hope to be able to learn more about primary health care, a subject not much addressed during college. Learn more about what can and cannot be done during basic health procedures, such as measuring blood pressure, blood glucose and doing simple auscultation. I believe that in our training, and also throughout our lives, we have been constantly educated to think according to the hospital-centered model. [...] Often, illness could have been resolved
with prior health promotion guidance, or even by a general professional, without the need to occupy secondary and tertiary sectors... (Med18).

“[...] There is a need for very good logistics and administration to serve a society that is social, marginalized, multiracial and extremely deficient, often in various public policies [...]” (Med16).

Students’ digital storytelling presented by the end of the semester reveal students’ experiences in PHC and their learning about medical practice, PHC relevance for community health, and SUS principles, - “SUS so distant in discourses, became much closer in reality when I participated and observed how much this work depends on the involvement of a diversity of professionals, understanding its principles in theory and practice” (Med8) - and the diversity present in a community such as “Morro Dona Marta”. For Med1: “[...] This experience was very enriching for me, not only meeting the expectations I had when I arrived but overcoming them in the emotional aspect of the doctor-patient relationship.”

The deep approach is related to the students’ intentions to understand contents meaningfully and to discuss aspects of the experienced practices with the natural complexity and multifactor facets of the phenomena (Moon, 2001), as observed in the students' narratives. In this case, there is a differential in relation to the superficial approach, limited to event descriptions.

According to Sandars (2009, p.692) “a deeper reflection includes a ‘stepping back’ from events and actions with evidence of challenge, and possibly change, to existing beliefs and perspectives. This deeper level is equivalent to when ‘transformative learning’ takes place”.

An additional question about students’ reflection is the learning from experiences of patients/health service users, as observed in these results. In this case, narrative medicine emerges with this potential to allow knowledge to be produced not only by disease diagnosis but from a deep understanding of the experience of illness and their context. People do not tell only about their symptoms, but also about aspects of life that can give answers about their current situation (Charon, 2004). Therefore, the narrative is promoted in health professional education for their motivational, reflexive, and critical character.

The interest in discussing these data based on a framework that focuses on the relevance of reflection in learning, as it relates to the concepts of superficial and deep approach, is anchored in the potential of digital storytelling as a reflective space for learning. Digital storytelling is an important strategy for promoting in-depth learning, which is focused on the student and his / her experience (Boase, 2013).

PREPARING SCIENCE AND MATH TEACHERS TO TEACH DISCIPLINE LITERACY USING MOBILE TECHNOLOGIES

Rita Hagevi and Irina Falls
1University of North Carolina at Pembroke, Pembroke, NC, United States of America

This mixed methods study describes the use of Japanese Lesson Study as a professional development (PD) model aimed at aiding science and math teachers in ways to use discipline literacy in middle level (ages 13-15) classrooms using mobile technologies (iPads). The purpose was to create a blended learning environment for teachers in four rural high needs schools in order to not only improve students’ literacy but to also to change teachers’ knowledge and practices. Five science and six math teachers and 500 students participated in two middle schools in a rural high poverty county in the southeastern United States. We investigated teachers’ knowledge, practices, and reflections before and throughout the year-long PD. Additionally we collected pre and post survey data as well as semi-structured interviews at the end of the PD that were individually conducted, digitally recorded, transcribed and analyzed using the constant comparative method (Glaser & Strauss, 1967). We collected state end-of-grade (EOG) assessment data for literacy (Grades 7 and 8) to measure student achievement. The results demonstrated that the collaborative nature of Japanese Lesson Study with a focus on student achievement was effective in significantly changing teachers’ knowledge and practices in using discipline literacy and in using technology. Teachers mainly adopted technology to improve their efficiency and effectiveness as well as to improve their instruction. Student achievement in literacy improved slightly as compared to teachers that were not a part of the PD. Consequently, this type of PD may continue to support teachers who are now more knowledgeable and confident in teaching discipline literacy in science and math using mobile devices and in so continue to improve students’ discipline literacy skills.

Keywords: discipline literacy, mobile technologies, Japanese lesson Study

INTRODUCTION

The ELA Common Core State Standards require that students “systematically acquire knowledge in literature and other disciplines through reading, writing, speaking, and listening” (Common Core State Standards Initiative, 2014). According to the section on “Standards for Literacy in History/Social Studies, Science and Technical Subjects,” in order to be college and career ready, students in grades 6-12 are expected to be proficient in reading complex informational text independently in a variety of content areas. Most of the required reading in college and workforce training programs are informational in structure and contain challenging content (Common Core State Standards for Literacy in All Subjects, 2014). By viewing math, science, social studies, and literacy in a much broader fashion, “we can help students to avoid the narrow image of each ‘subject,’ helping with each small step to reach the Common Core goal of being truly ‘career and college ready’ upon graduation from high school” (Murrow, 2011). As Irwin, Meltzer, Dean, and Mickler (2010) observed, "… [L]iteracy is essential for success in almost every area of life. Literacy is far more than the ability to read and write basic text. Rather, literacy is the ability to read, speak, listen, and think in order to learn, communicate, and make meaning of increasingly complex print and online texts. Literacy and
content learning are deeply intertwined" (p. 2). Strengthening teachers’ knowledge and pedagogical skills to teach literacy in middle school improves students’ ability to learn, communicate, and make meaning of increasingly complex print and online texts in all disciplines. However, in the southeastern region of the U.S., there is an increased high school dropout rate and a low percentage of enrollments in post-secondary education. It is critical that teachers’ professional knowledge include an understanding of the ways students not only think about content, but communicate it to others as well. One way to increase student motivation and interest in learning is to use new technologies. Mobile technology has changed not only the way teachers work with information and assessment in schools, but also the way they interact with their environments and situations (Franklin et al., 2007). Mobile technologies have been used by teachers as personal management device as well as an instructional tool (Falls & Hagevik, 2013; Hagevik, Falls, & Higgins, 2014). Together with the emergence of apps and tablet technologies in the P-12 classroom, teachers can integrate mobile technologies into disciplinary literacy instruction. Teachers in this project were trained and coached on how to navigate the multitude of apps, as well as how to create disciplinary literacy app-based lessons. The coaching and mentoring of teachers in this project involved an online learning community and a teaching practicum called Explorations from the New Teachers Center (NTC), a resource called AppEd Review created by Cherner, Dix, and Lee (2014) and the use of Japanese Lesson Study to engage in recursive cycles around disciplinary literacy and Common Core strategies.

This partnership among a major University and two public school systems focused on providing supplemental support for beginning teachers and their mentors in partnering school districts. Drawing upon faculty expertise in teaching and learning in math and science, mobile technologies, standards-based instruction at the middle level, lesson study, and instructional change, as well as principles and models of teacher induction and retention, the project guided 15 Language Arts teachers and 11 math and science teachers in disciplinary literacy using the Japanese Lesson Study. The College of Arts and Sciences (Science Education) along with the School of Education worked collaboratively on every aspect of the project with school system personnel, two project directors, two lesson study coaches and the New Teacher Center staff and resources.

THE PROFESSIONAL DEVELOPMENT MODEL

Most teacher professional development efforts lack continuity and capability to produce effective change in teacher practice and student learning (Loucks-Horsley, et al. 1998). After examining the findings of The Third International Mathematics and Science Study (TIMSS), Stigler and Hiebert (1999) concluded that "American teachers aren’t incompetent, but the methods they use are severely limited, and American teaching has no system in place for getting better. It is teaching, not teachers, that must be changed" (p. 10). For professional development to lead to substantial teaching changes and improvements in student learning, it needs to (1) address all aspects of the teaching triangle and their interactions in context, (2) be implemented in a highly aligned manner and (3) include time for teachers to collaborate during the change process (Center for Technology in Learning, SRI International, 2009). To accomplish high quality professional development as described above, this project used the Lesson Study Model.
Lesson Study is a form of interactive, continuous professional development that is led by a collaborative group of teachers who engage in the recursive cycles shown in the figure below (Lesson Study Cycle, Lewis & Hurd, 2011, p. 2).

The features of the Lesson Study strategy are perfectly aligned with the evidence-based characteristics of effective professional learning that: (a) are intensive, ongoing, and connected to practice; (b) focused on student learning and addressing the teaching of specific curriculum content; (c) aligned with school and district improvement priorities and goals; (d) building strong working relationships among teachers; and (e) engaging teachers in social constructivism and reflection, essential to professional growth (Darling-Hammond, et al., 2009). The rationale for adopting Lesson Study as the professional development model resides within the theoretical framework of learning through social constructivism, which states that: a) knowledge is constructed through social interaction and shared with peers; b) knowledge acquisition is designed to organize one’s experiences; and c) knowledge is the result of active mental processing by the individual in a social environment when they are confronted with dilemmas (Fleury, 1998; Cobb & Yackel, 1996; Prawat, 1996; Gergen, 1995; Vygotsky, 1978). Therefore, teachers should be encouraged to reflect on their experiences, to create understanding, to evaluate their understanding, and to explain their understanding to others (Rock & Wilson, 2005). As seen in the Figure 1 below, as teachers work through the Lesson Study process, there are multiple opportunities for them to reflect, analyze, create action steps, evaluate, and share their understandings with other teachers.

![Lesson Study Cycle](image-url)

**Figure 1: Lesson Study Cycle as described by Lewis & Hurd, 2011, p. 2**
Utilizing Technology to Enhance Teaching and Learning

Technology is an essential component for teaching students 21st Century skills. The State Literacy Plan states that “English Language Development and Information and Technology Essential Standards are integrated into all content areas. It is the responsibility of all teachers to ensure they deliver the appropriate services and standards to all students, including English language learners, students with disabilities and academically/intellectually gifted students. Likewise, 21st Century skills and themes are embedded in all content areas rather than being a stand-alone curriculum” (The State Literacy Plan, 2012, p.9). The same source states that one of the 21st Century goals for students is to “apply[ing] information, communication and technology (ICT) and digital literacy (the use of computers, audio, video and other media) in all content areas for a variety of purposes” (The State Literacy Plan, 2012, p.18).

In teacher education, there is evidence suggesting that student teachers’ performance and self-efficacy can be improved using technology (Kopcha, & Alger, 2011). Ubiquitous handheld computing offers countless potential uses in field investigations (Soloway, et al., 1999; Franklin, et al., 2007; Bennett & Cunningham, 2009). Mobile technology has changed not only the way teachers work with information and assessment in schools, but also the way they interact with their environments and situations (Franklin et al., 2007). Mobile technologies can greatly assist in supporting teacher resilience by serving both as personal management devices and instructional tools for regular or exceptional needs children in the classroom. (Falls & Hagevik, 2013; Hagevik, Falls, & Higgins, 2014). The Technological, Pedagogical Content Knowledge (TPACK) framework (Koehler & Mishra, 2009), together with the emergence of apps and tablet technologies in the P-12 classroom are forcing teachers to integrate digital technologies into literacy instruction. However, it happens too often that teachers are being given technology devices and told to use them without any specific guidelines or recommendations for organizing and evaluating the ever-growing number of educational apps.

Currently there are over 20,000 educational apps available, and the sheer amount of choices can be overwhelming. As teachers explore the possibilities of integrating mobile devices in the classroom and in their professional organization and growth, it is important to examine how the various apps can help teachers meet curriculum goals and foster literacy development in their students (Hutchison, et al., 2012). Chernier, Dix, and Lee (2014) have created a framework that provides teachers and professional development facilitators with a much-needed resource to support their choice of educational apps and ways to create inquiry-based app-based lessons. Along with mentoring by project directors, experienced teachers, the New Teacher Center, University faculty, and Lesson Study coaches, teachers are guided through analyzing and assessing their own practice as they created disciplinary literacy app-based lessons for their students. Therefore the research questions to be answered by this project were: How can app-based lessons be used in the classroom to support discipline literacy in a blended learning environment for content teachers?

THE PARTICIPANTS

Four high needs rural middle schools from two school districts participated in this research project. The average percentage of students on free and reduced lunch in these schools was
87%. Out of the total of 26 participants in the project, 15 teachers were English Language Arts and Social Studies teachers, and 11 were Math (6) and Science teachers (5). Both groups had a mixture of beginning (years one to three) and experienced teachers with the highest level of teaching experience being 38 years of teaching. Twelve of the 26 teachers in the project owned iPads previously. iPad experience was reported as beginning to intermediate by the teachers. Forty percent of these teachers said that they had ever used an iPad or tablet in their classrooms. The participants overwhelmingly in the beginning of the project stated that they had never heard of nor participated in a lesson study. In addition, the teachers reported that they had little experience with disciplinary literacy. Each participant was provided with an iPad for use during the study and the teachers in one county upon their request were provided with a class set of iPads to share and use in their classrooms. In addition each teacher was provided a VGA adapter to use for projection on the Smart Board. For their participation in this grant-funded project, teachers were given a stipend, materials, conference travel support, enrollment in the New Teacher Center Explorations and Community program, and each teacher was given a year-long subscription to AppEd review. Results from two schools in one school system in which the 11 Math and Science teachers worked are reported in this research study.

The present study aimed to examine the use of Lesson Study and mobile technology to support the use of discipline literacy in science and math classrooms in order to change teachers’ knowledge and practices with the ultimate goal of improving students’ literacy achievement scores. There is a paucity of research which links teacher PD to knowledge and practices and to student achievement (Guskey & Yoon, 2009; Hill et al., 2013). Rural under resourced high-poverty school districts face many challenges such as children in poverty, difficulty in retaining high-quality teachers and geographic isolation from other programs (Goodpaster et al., 2009). The research question addressed in this study was do math and science teachers’ knowledge and practices about the use of technology and discipline literacy change and do their students’ literacy scores improve as a result?

METHODS

This is a mixed methods (Creswell & Plano Clark, 2011), one-year study of five science and six math teachers and 500 students at Junior and Dogwood (pseudonyms) middle schools in a rural, high-poverty school district in a southeastern state in the United States. The student population at Junior was 539 in 6 – 8\textsuperscript{th} grades and at Dogwood was 921 in K-8\textsuperscript{th} grades. All of the math and science teachers in these two schools taught the 7\textsuperscript{th} and 8\textsuperscript{th} grades (students ages 12-14 years old) and were involved in the professional development (PD). The sixth grade teachers at these schools did not participate in the PD. Approximately half of the students at Junior were African American while half of the students at Dogwood were American Indian. Of the six teachers at Dogwood, three were science and three were math teachers and of the five teachers that were at Junior, two were science and three were math teachers. Two of the teachers at Dogwood were in their first three years of teaching and three of the teachers at Junior were considered beginning teachers. The years of teaching experience ranged from one year to sixteen years of experience. Teachers participated an average of 150 hours in the PD over the one year period. Four of the teachers were male with one being African American and the other three Caucasian. Seven of the teachers were female with two being African American,
two American Indian, and three Caucasian. Teachers reported their technology use as being intermediate at the beginning of the study and their knowledge of lesson study and discipline literacy as being little to none. We collected survey data before and after the study to determine the teachers’ knowledge and practices, we collected monthly reflections by the teacher participants on technology use and implementation, we collected artifacts and video during the lesson study cycle as well as teacher reflections, we observed the teachers teaching in the beginning and end of the project, and we interviewed the teachers at the end of the year. Data was collected and analyzed by two researchers involved in the project. We used paired t tests to analyze the survey data and a qualitative software program to analyze the textual data from the teachers who participated in the study. Teacher interviews were recorded, transcribed and analyzed for emerging themes around the research questions using a constant comparative method (Glaser & Strauss, 1967). Transcripts of the teacher interviews were member checked before analysis. We did this in a parallel manner and then compared the results. Inter rater reliability was determined to be 95%. The end of Grade student data was supplied to the researchers by the school districts for analysis of reading level. These scores are determined using standardized tests designed by the Department of Public Instruction in that state and issued by the teachers in which these school districts in which these schools reside. Students’ scores are then compared with other students in that state.

RESULTS

The participant survey was given pre/post and used a paired samples t test to compare teachers’ initial and final perceived beliefs on preparedness, knowledge and implementation of technology, lesson study and discipline literacy strategies. There was a significant difference in the scores from the pretest (M=9.68, SD =2.82) and final scores (M=24, SD =3.55), t(10)= -15.437, p<.0. These results were confirmed by the teachers’ interviews in which they reflected that “The lesson study was a great tool to see which students were getting the information and which were not. It also allowed me to see students’ interactions at critical times in the lesson and how they responded to those times” and “The card sort told me a lot about how students organize their thinking, students struggle in working with groups” and “Students work really well when they graphic organizers, clearly stating the learning target, and being more aware of student engagement.”

Teachers gained knowledge and believed that they were prepared to teach discipline literacy using technology in their science and math classrooms after the year-long professional development project. Teachers reported using the iPads provided for them and their classrooms and a variety of apps for many purposes in their classrooms with 50% for educational resources and instruction and planning, 20% for personal use and training, 20% for classroom management and organization, and 10% for behavior management. Of the instructional use the iPads were mainly used for skills-based and content-based applications and not as frequently for creation-based activities.

A paired samples t test indicated that the participating teachers’ perceived knowledge about disciplinary literacy was significantly higher at the end of the project than it was at the beginning, t (18) = -14, p =.0000, d =3.03. The difference is statistically significant with a large effect size as seen in Table 1.
Table 1. Disciplinary Literacy descriptive statistics

<table>

</tr>
<tr>
<td>15.37</td>
<td>32.05</td>
<td>3.467</td>
<td>4.938</td>
</tr>
</tbody>
</table>

Table 1 shows that the cumulative post survey score of knowledge and preparedness more than doubled as compared to the pre-survey score although there is more variability in the post scores. These results were corroborated by the content of the reflections and the interviews. For example one of the math teachers reflected, “Being willing to add writing into math in new and different ways, opens more avenues of expression for your students. They may be able to explain a concept in words now and really use the vocabulary of math.” A science teacher wrote that, “My students have learned to use rubrics to help guide their instruction and give a guideline to stay on topic with their writing. In general I would issue a prompt and I would end up with writings so bad that I would just stop reading because the writing got so ridiculous. Now they have better understanding of what is expected.” All teachers, unanimously praised the value of having time to collaborate with colleagues to share their experiences and because we provided substitutes for meeting times and time to meet each month to share experiences and strategies related to the implementation of disciplinary literacy. For example, the math and science teachers remarked about the Lesson Study cycle that:

“We were able to delve deeper into the nuance of our lesson planning.”

“There was a lot of observed collegiality, reflection, and positive relationships amongst the teacher participants.”

“Lesson study will positively affect student learning because of all the thoughtful planning, collaboration, reflection and intensive focus on student learning that teachers are sharing.”

“I learned to examine and reflect on what happened in the classroom, especially student behaviors. I was not used to do this.”

“We had a better view on what we were going to teach, how we are going to teach it, and who is going to teach it.”

“We were able to take a deeper look at what would actually be happening in the classroom each day. We created the questions, worksheets, and organized the implementation of strategies.”

From the interview and survey data it was found that the math and the science teachers found that engaging in Lesson Study helped them not only to implement and deeply reflect upon and study their lessons but also to be able to better understand how to plan for individual student needs.

Student achievement in literacy when comparing the EOG scores of these same students from the previous year to the year in which the PD was implemented showed no significant increase though from the 7th to the 8th scores (56.7% weighted mean to 53.0% and 55.1% weighted mean
to 53.7%). Compared to the 6th grade students EOG literacy scores (55.4% weighted mean to 46.9%), even though there was a decrease in all scores, there was less of a decrease in the 7th and 8th grade scores (-2.5% average) than the 6th grade scores (-8.6%) from year to year. Teachers reflected that most likely there would be more of a difference in the students’ literacy scores the following year after they had more time to implement the discipline literacy strategies that they had learned.

DISCUSSION AND CONCLUSIONS

In our study, we found that teachers’ knowledge about teaching and confidence in using discipline literacy and technology was significantly changed as a result of a PD that used Japanese lesson study. Although no significant gains in students’ literacy scores were found, other studies have clearly demonstrated that there is a direct link between the teachers’ involvement in lesson study method of professional development and the achievements of their students (Barrett et al., 2013). Perhaps with more time using these practices the student achievement scores would change (Blanchard et al., 2016). Teachers did gain significant knowledge and practice using mobile technologies in their classrooms and the teachers used them for a variety of purposes. Teachers’ commented on students’ increased interest and excitement when using the devices. This affective response by students has been noted by other researchers as well (Liu et al., 2011). Finally the participant teachers expressed great interest in continuing to use lesson study in their practice and in their schools. 100% of the teachers in the PD agreed to continue with the project the next school year. Teachers cited the collaborative and positive learning environment created as well as the support from their colleagues. The focus on student achievement was the main reason given by the teachers for the success of the lesson study PD, even though the teachers did admit that completing a cycle of lesson study was time consuming and hard work. These teachers were encouraged and motivated though teaching in challenging circumstances where high teacher turnover rates (48% as compared to 24% statewide) continue to plague these schools.

Results indicated that the formation of teams within and across schools to work collaboratively on planning, teaching, and reflecting, a focus on observing student learning behaviors, and an emphasis on disciplinary literacy with multiple ways to acquire knowledge and skills and to implement them immediately in the classroom were cited as important strengths of the project. These results agree with others in that effective PD is a) intensive, ongoing, and connected to practice; b) focused on student learning and specific curricular content; c) aligned with school and district priorities, d) focused on building strong relationships; and e) involves collaboration and reflection (Darling-Hammond et al., 2009, Stewart & Brendefur, 2005). What was unique about this project was that these teachers were able to experience high quality PD and to use technology resources effectively in low performing, geographically isolated and rural, and under resourced schools with perceived effectiveness. With continued research, Japanese Lesson Study as a PD model for discipline literacy in these schools holds much promise in improving students’ literacy achievements.

WHERE DO REPRESENTATIONS AND DRIVERS FOR SOLVING PHYSICS PROBLEMS COME FROM? AN ANALYSIS OF FOUR EXPERIMENTS

Agostinho Serrano, Robson Trevisan, Graciela Meggiolaro, Juliana Anjos, Savana de Freitas and Luis Paulo Moreira
Lutheran University of Brazil, Canoas, Brazil

Using computers to enhance our cognitive abilities is now an established fact. In classroom, science educators often use simulations to teach physics, among other subjects. This paper aims to discuss four experiments in which students create representations and drivers to solve different physics problems and those representations and drivers originate from different kinds of mediations (psychophysical, social, cultural and hypercultural). Cognitive Networks mediation theory was used as theoretical referential and the methodology employed in all studies is a qualitative analysis of the speech and depictive gesture used by students when solving physics problems. Our results indicate that often the hypercultural mediation is not the preferred source of representations and drivers and not necessarily the best cognitive tool that helps learning physics.

Keywords: cognitive networks mediation theory. computer simulations. gesture analysis.

INTRODUCTION

The use of computers for teaching is now widespread in the field of science education. Apart from the fascination and novelty that bringing a computer simulation – for example – to the classroom can bring to the students, how exactly can computers help learning? How they do – and in fact there are several reports that bring evidence to this – increase our skills in problem-solving? This paper aims to discuss how simulations and modelling activities compare to other cognitive tools to help learning. Our framework departs essentially from the point of origin: when given a problem to solve, after using a computer activity that supposedly would help learning how to solve such activity, do students use representations that came from the computer activity to solve the problem? Or they rather use representations that were used by a teacher previously, or from the physical environment itself? Or from books? To address this question, we built four experimental case studies in different levels of schooling – always using physics as subject – and used the Cognitive Networks Mediation Theory to analyse the results.

Campello de Souza and Roazzi (2012) attempt to describe, in their Cognitive Networks Mediation Theory - CNMT, the growth of the cognitive ability that occurs due to contact with external mechanisms. The TMC is a contextualist and constructivist theory, founded and related to different schools of thought, represented by the following authors: Jean Piaget, Gérard Vergnaud, Lev Semenovich Vygotsky and Robert Sternberg. An important challenge for the theory is to "[...] provide a coherent theoretical synthesis of psychological and structural theories that are generally seen as separate or even in conflict with one another in order to produce a unified model" (Souza et al., 2012). It is considered an important application of TMC its understanding of individual or collective changes, associated with the introduction of technologies as tools external to the thinking of individuals.
The TMC considers that mental activities performed with the help of external tools would "free" memory for other activities. An example that currently affects many people, related to "memory liberation" through external tools, is that many years ago, several numbers of phones were stored in memory. Thus, the TMC presents the Mediation and the Extrapersonal Processing of Information as mechanisms that aid in the cognitive processing. From this main idea, the author constructs a set of concepts, within his proposed theoretical framework, of which we are called the "external mechanisms of mediation" and the "internal mechanisms of mediation", seeking to bring a unique perspective on what is refers to the so-called external cognition (the brain).

"The process by which humans depend on external structures in order to complement the information processing done by their brains (extrapersonal cognition) is named by the theory Mediation" (Souza et al., 2012).

This mediation is composed and can be written through the following components:

*Object*: the physical item, abstract concept, problem, situation, and/or relation about which the individual is trying to construct knowledge.

*Internal Processing*: the physiological brain activity (synaptic, neural and endocrine) that performs the individual basic logical operations.

*Internal Mechanisms*: mental structure that manages algorithms, codes and data that allow the connection, interaction and integration between internal brain processing and the extrapersonal processing done by the structures in the environment, working both as a "hardware driver" and as a "protocol of network". Internal mental mechanisms are essentially active mental representations, which contain operational invariants - as theorized by Vergnaud (1981) - adding concepts, schemes and skills that act as true device *drivers*.

*External Mechanisms*: They can be of several types and capacities, ranging from simple physical objects (fingers, stones) to individual and group, with complex social activities, symbolic systems and tools / artifacts.

In this sense, external processing is used through interaction with environment structures to increase information processing capacity. For example, when a computer is used to process information, or even perform a more complex calculation, it is using an external mediation mechanism. For this, it is necessary to construct some internal mechanisms that allow to manipulate this computer and to understand not only its processing, but also the information that it is offering.

The fundamental structure of Cognitive Mediation consists of the individual set of internal mechanisms, which makes it possible to connect external structures as auxiliary information processing devices. According to Souza (2004, p. 65), "[t] he elements [extrapersonal] can only effectively be of use to an individual if he has a way of interacting effectively with them, according to necessity and adequately "with existing devices in the intrapersonal structure that allow to translate the inputs, outputs and processing between them. In summary, it is the drivers that enable mediation with environmental structures. When all these factors are taken into account, a view of human cognition arises as a sophisticated set of internal and external information processing mechanisms that together form a complex organized system.
According to CNMT, learning occurs when the student after mediation with some external element (psychophysical, social, cultural or hipercultural), develops representations and drivers that originate in the aforementioned mediation. CNMT considers the drivers as "virtual machines" that alone are used as new skills able to equip the learner with the ability to solve new situations that previously were not able to solve autonomously.

As already discussed, according to the ideas of TMC, the human brain is limited and unable to process all the information set forth. Therefore, the external processing from the interaction (mediation) with the environment is used daily giving the cognitive structure an additional processing capacity. At TMC, Souza (2004) discusses the four possible forms of mediation. These forms will be presented below in Table 1.

**Table 1. The evolution of the cognitive mediation types.**

Therefore, within this perspective, which mediations are used by students to actually construct drivers and representations that are helpful to solve physics problems? Is the hypercultural mediation always the better one?

**METHODOLOGY**

Study 1 and 2 was made each with 2 Physics teaching undergraduating students. Study 3 was made with two economically disadvantaged elementary school students. Study 4 was performed with a total of 14 engineering students. All the studies used the same interview protocol, that we called report aloud, a modification of the think aloud protocol (Van-Someren, Barnard & Sandberg, 1994); basically instead of interviewing the subject while performing the given task, the interview was made right after finishing the task. The interviews were all video recorded and analyzed by transcribing the discussion and the depictive gesture spontaneously produced by the students (Monaghan & Clement, 1999). All the students were different from one study to the other. Apart from the school level difference across the studies, the mediations used were also different; all studies used hypercultural tools ranging from simulations (all studies) to computer modeling activities (study 4 only). Study 3 used also psychophysical mediation in form of ludic activities (throwing balls games and playing with slings). Study 4 also used protoboards (breadboards) to build electric circuits. Study 1 used a double-slit
quantum mechanical simulation, Study 2 used a Geogebra simulation (accessible in https://www.geogebra.org/m/eHyU8ZmU), Study 3 used a Scratch simulation built by the students with the help of the teacher and Study 4 used Modellus (Teodoro, 2008) and the well-known Phet software.

RESULTS

By analyzing the interview results as well and specially the depictive gesture produced, we were able to identify the representations and drivers that were elicited by students when solving physics problems. The results shown here specifically address each form of mediation.

Psychophysical mediation

The student under investigation in this experiment, shown below, performed playful activities during the project and being asked if what she was imagining, and gesticulating was more related to the computer activity (Scratch Programming) or to ludic activities (mental images), she says to be "a bit of them all", also describing some of these play activities. Among the several performed, the student mentions the throwing of a (football) ball, demonstrating the different movements and a “towel play activity” (representing the oblique movement), as shown to the sequences of images below (Figure 1).

Figure 1. Depictive gesture of a student showing the trajectory of a ball being thrown.

I: Is it too Scratch-related or is it more related to classroom activities?

Student: I think of everything a little, because I imagine Scratch, I imagine the play activities that we did too, that we put a towel like that, and then we played the ball, and it went away, we'd play each other too.

The picture above illustrates one of the many depictive gestures analyzed in this study. Here, a student shows the trajectory of a ball when thrown in free fall under the effect of gravity. The students specifically mention both the ludic activity of throwing balls and the simulation constructed used as the origin of what she’s “seeing with her mind’s eye” (the basketball and the ‘bird’).

These activities were also reported and gesticulated similarly by other students. However, with this analysis, it is noticeable that student described above is able to construct different "drivers" from different external processing mechanisms (computer and ludic activities) and to internalize them, it reflects an integrated view where the hypercultural external processing mechanism “talks with the” socio-psychophysical external processing mechanism of the play activity, and both are used at the same time, as drivers for the understanding of the phenomena studied.
Social mediation

Following is an excerpt of the first interview of one of the students after using GeoGebra’s simulation and answering problems to construct the resulting electric field of two charges on a specific spot in space.

I: [...] When you read this question here, what did you first imagine? In the table below, there is a charge etc, what went through your head?

A1: The field lines, the image of the lines.

I: This image of the line, how is it? Where does it come from?

A1: Of the class itself, the teacher drawing them on the blackboard. teacher <name>

I: Those field lines he draws were made with black/white or colored chalk?

A1: I remember always that he used several different colors to differentiate one thing from the other

I: So when you read it for the first time what first came to your mind was the colored chalkboard of teacher <name>?

A1: yes.

According to the student's speech, there are indications that she used drives of a previous social interaction for the explanation of the concept, which corresponds to a visualization driver. When the student described the electric charge, positive or negative, she described with her hands, indicating, by means of the movement of the fingers, if the charge attracted (Figure 2) or repelled (Figure 3).

Through the analysis of the interview, we can point out, according to TMC, that this student had a social mediation, related to the teacher's class, a cultural mediation related to the teacher's drawing in the picture, and the hypercultural mediation related to the simulation of physics in the Geogebra. From these mediations, which resulted in representations and drivers adequate to a field representation was the origin of the traditional educational process, in the form of socio-cultural mediation in the classroom. Hypercultural mediation (geogebra) served as a prior organizer (Ausubel, 1978), helping it to remember subsumes already stored in its cognitive structure.
Cultural Mediation

Analyzing the student’s reasoning regarding the answers to the questions related to Young’s double-slit experiment, an explanation like what he already presented for the interferometer is verified, that is, the interpretation of the behavior for the photons and electrons emitted by the source is the same.

Student: So we imagine that it goes through a single slit, but we do not know the way, that’s where that uncertainty comes from, and when it passes, it has a wave behavior, if it has no observer, huh. If you have an observer, then you lose the, the wave property, of interference.

Thus, the student thinks of the photon and the electron as particles, interpreting them with the corpuscular behavior throughout the experimental apparatus, but, in the answer, the student draws an interference pattern, which is an undulatory phenomenon, attributing to its response the lack of information from the slit through which the electron (the same explanation is used for the photon in the double-slit experiment) passes. However, the reason for the emergence of the interference pattern is not convincing, the student can not explain what factors cause photon interference, saying: "he (interferes) with himself, I think ... I do not know why. That was not clear to me."

If an observer detects by which of the slits the electron passed, the pattern observed in the scintillating screen would change, the image of interference in the panel would be destroyed. This understanding is expressed by the student in his speech: "My imagination would say that he would pass through one of the slits. In fact we are not sure, because if you put an observer to know, then the photon will behave exactly like a particle. He loses all wave property, right?".

When the student is encouraged to explain the image formed in the screen, in case the source emits marbles (macroscopic objects), the student explains his drawing, which characterizes the marbles presenting corpuscular behavior.

After using a computer simulation in the form of a virtual dual slit laboratory, where no representation of the quantum object is displayed, the students explain the experiment using representations and drivers obtained from cultural sources, like didactic and science divulgation books like Gilmore (1995): “…Ah, I read. The teacher had actually explained this in class. And then in the book Alice in Quantumland there's a figure, cannonball, shotgun …” And that's the pattern here "(A4). That was the only student that correctly answered the question of what is to be observed in a quantum double slit experiment.

Hypercultural Mediation

14 engineering students were able, in study 4, to use all 4 kinds of tools to answer questions regarding electric circuits; pencil and paper, protoboard, Modellus simulation or a Phet circuit modeling tool.

Out of those 14 students, all instances of depictive gesture produced were analyzed of what is their source, much like the interview except reproduced above. 76 instances of depictive gesture were identified coming from the PhET modeling tool, 4 from Modellus, 34 from pencil
and paper and 35 from the protoboard (breadboard), as expressed explicitly by each student interviewed (Table 2).

Table 2. Number of (S)tatic, (D)ynamic and Total imagery reports found during the interview of the 14 students for circuit, current, DDP and resistance imagery reports related specifically to PhET, Modellus, Protoboard or Pencil & Paper usage.

It was possible to verify, throughout this research, that, due to the fact that the students worked with different tools, they acquired diverse drivers. Of these, the use of the PhET software was outstanding in the solution of the problems, with the presence of mental images and static, dynamic, microscopic and macroscopic drivers, being even outstanding in relation to the laboratory activity. In the comparison between the two software, it is possible to observe that PhET had a superiority over Modellus, also in the generation of drivers and mental representations. This surprised us, since the activities developed in Modellus had a lower degree of difficulty than those developed in PhET. Another interesting situation that we observed in these activities is that the student develops spontaneous gestures that were acquired from the use of the tools proposed within the present study. The fact that students have been subjected to various tools and specifically to PhET intervention - a modeling activity - shows a greater cognitive change in relation to the others. Due to this process, the acquisition of a larger number of hypercultural drivers with PhET software is characterized. In the light of the theoretical reference of the TMC, it was possible to observe the cognitive change and the dialogue between the different tools in the composition of the student's gestural/imagistic discourse. It was concluded that, in the theoretical and methodological perspective, the mental images were surprisingly richer, with explanations of the students, for the computational modeling, followed for the use of real experiments, pencils and paper and, finally, computational simulations.

**DISCUSSION**

The results above all show when a specific mediation is responsible for the representation and driver used by each student to solve a given problem, in different fields of physics and different levels of schooling. Elementary students often mix hypercultural drivers with psychophysical drivers that were constructed during a ludic activity, as in Study 3. Studies 1 and 2 we actually expected the hypercultural activities to empower the students with good representations and drivers, but what we saw was that those representations and drivers came from cultural mediation (study 1) or social mediation (study 2). The reason behind is that in Study 1, the software did not display any representation for the quantum object, while in study 2, the representation was there, but the students already possessed them from previous traditional classes. Only in study 4 we could obtain evidence that a hypercultural tool (modeling software) was superior to all other tools, including another hypercultural tool (simulation software).
CONCLUSION

In this paper, we carefully selected four different experiments that – each one – shows the importance of one specific kind of mediation, be them psychophysical (study 3), social (study 2), cultural (study 1) and hypercultural (study 4). The starting hypotheses we adopted was that the hypercultural mediation would prove to be the ‘superior’ one that would allow the students to construct better representations and drivers, and actually it was only a coadjuvant source in study 3, the main source in study 4 and only mildly important for the students in studies 1 and 2. Therefore, using multiple representations from multiple forms of mediation (Psychophysical, Social, Cultural and Hypercultural) will most likely prove to be more beneficial to learning processes in physics, and perhaps, for the learning of all sciences.

TEACHING CHEMISTRY 2.0
CREATING DIGITAL LEARNING ENVIRONMENTS WITH POWERPOINT & PREZI
Amitabh Banerji
University of Cologne, Institute of Chemistry Education, Cologne, Germany

The rapid technological progress and the increasing digitization of society makes it necessary that schools include ICT-enhanced education in all parts of their curriculum. To convey a digital literacy to the learners, teachers must have a positive attitude towards technology and they should be able to embed digital tools in learning phases meaningfully. To achieve this goal, the most important factor is to include an ICT-enhanced curriculum into the pre-service teacher’s education program of the universities. Following this desideratum, a “digital seminar” was implemented at the Institute of Chemistry Education of the University of Cologne in the summer term 2016. The major goal of the explorative project was to identify which benefits and barriers the students see in the interaction with the selected tools and which design aspects have to be considered for further implementations. In other words, the students had the task to develop chemistry related multimedia animations on the particle level with PowerPoint and to embed the animations into learning environments, which they designed with Prezi. A total number of 12 third-year bachelor students visited the seminar and documented their experiences in portfolios. Additionally, the students rated the seminar in an online survey at the end of the semester. All students found the development of animations with PowerPoint as well as the compilation of digital learning environments with Prezi as highly motivating and rated the tools as very useful for vivid visualization of science content. As a limiting factor, the majority of the students mentioned the excessive time, they needed to get familiar with the functionalities of the tools. The project findings helped to identify important factors to design further ICT-enhanced curricular units for science teachers’ education.

Keywords: digital science education, Prezi, computer animation

ICT-ENHANCED SCIENCE EDUCATION

It is a tremendous challenge for the upcoming generation to stay up with the technological development and digitization of our society. As a consequence, an increasing number of schools in Europe are equipping their classrooms with laptops, tablet computers, Wi-Fi connection and interactive whiteboards. Although this is a desirable step, it won’t be sufficient to convey a sustainable digital literacy to the students, since many teachers face barriers associated with ICT (Ertmer, 1999). This could be first order barrier as the lack of technological skills or second order barriers as fears or a personal denial of new technologies. Teacher trainings can help to overcome these barriers. However, the trainings should not only address the technical skills, but also must demonstrate how to incorporate technology meaningfully into learning activities (Moersch, 1995). Furthermore, teachers must learn to design own digital teaching materials (Means & Olson, 1997) to be not only a consumer but also an author of “digital education”. Especially in science classes, there are different ways to improve teaching by embedding ICT. Tang et al. showed, that dynamic computer simulations on the particle level can help students to better understand the particulate nature of matter in chemistry (Tang & Abraham, 2015). Computer animations, which are created by the learners themselves, can
even reveal misconceptions about dynamic aspects of particles (e.g. electron movement), which are typically inaccessible in static visualizations (Akaygun, 2016). Besides that, multimedia devices can offer multidimensional learning paths, which facilitates differentiation and inclusion. Based on these preliminary works, a “digital seminar” was designed and implemented into the third-year bachelor curriculum of the chemistry teachers’ education program at the University of Cologne in the summer term 2016. The project aimed to explore problems and benefits resulting from the students’ work with the digital tools as well as general factors, which are limiting or feasible to the further implementation of ICT into the pre-service teachers’ education.

Parts of the following contribution have been published by us in the German journal CHEMKON (Banerji, 2017). The aim of this article is to make our results internationally accessible and to present the recent developments in the presented project.

**STRUCTURE AND CONTENT OF THE DIGITAL SEMINAR**

The digital seminar was implemented at the University of Cologne in the B.A. study program within the module “Selected aspects of chemistry education and curriculum”. The seminar was held in the summer term 2016 as a block-lesson with three sessions (four hours each). 12 students participated in the seminar out of which 9 were female.

It was kept in mind to actively engage the students into the design of the seminar. For instance, the students could choose the topics from the chemistry curriculum, which they were supposed to implement into a digital learning environment. The students selected to the following topics: galvanic cell, periodic table of the elements and chemical bonds.

To develop the learning environments, the students were introduced to the production of animations with PowerPoint (PPT) and in the development of interactive presentations with the help of Prezi. The students had six hours for the development of the learning environments during which they worked mostly independently. The tutor (and the author of this article) was present for any kind of consultation and expert advice.

In the last phase of the seminar, the groups presented their developments and discussed them in the plenum. In a last conclusive discussion, the students reported about their experience with both the software tools. A detailed feedback was given later in a portfolio which each student submitted two weeks after the last session.

**Selection of the software tools**

To build a digital learning environment, the software tools PowerPoint and Prezi were selected since they are available free of cost¹ and can be operated easily which is a very important factor for schools. A further reason for choosing these software tools is that the seminar tutor has solid knowledge about these tools which is important for his role as a consultor and expert-advisor.

---

¹ PowerPoint is usually installed on all computer platforms of educational institutions as a standard software. Prezi offers a free education licence for people working at schools, universities etc.
Development of animations with PowerPoint

Microsoft PowerPoint is one of the most common programs to create multimedia presentations on computers. By inserting Forms and editing their properties like colour, transparency as well as their positions (using motion-paths) one can easily develop vivid animations. The developed animations can be embedded into the presentation or exported as video files. Tutorials on how to create animations with PPT can be found on the internet (e.g. Flisser, 2018).

Development of digital learning environments with Prezi

Prezi is a platform-independent software to create multimedia presentations. The main features of Prezi are vector-based graphics, a path-structure similar to a mind map, the seamless zoom functionality and a broad spectrum of supported data like picture-, videos-, pdf-, flash- and other files. The Prezi presentations can be played on a tablet computer via the App Prezi-Viewer, which allows the user to individually zoom into any part of the Prezi using the touch-features of the tablet. In educational context this feature of Prezi allows multidimensional learning pathways.

Krause et al. have developed a Prezi environment for teaching the particle concept and investigated the benefits of this approach. Also, they have found that Prezi is a powerful and motivating tool and very popular among students (Krause & Eilks, 2015) and (Krause et al., 2014). Some examples of Prezi learning-environments are accessible online for free (Krause & Eilks, 2018).

RESEARCH METHODS

For evaluation purpose, the students, who participated on the project, documented their experiences during the whole seminar in portfolios and additionally rated the seminar in an anonymous online survey containing four closed and two open questions. Both the portfolios and the survey-data were analysed inductively by content-analysis. Also, the students’ digital products were examined to identify existing misconceptions revealed from the dynamic PPT-animations. Furthermore, the explorative observations of the author (who conducted the seminar and accompanied the students over the whole project) are summarized and described in the following result-section.

RESULTS

Observations of the author

At the beginning of the seminar all of the students indicated, that they had never used any of the special animation features of PPT. This fact was challenging for the authors’ role as tutor, as he had to coach the students intensively. After the students were acquainted with the basic animation functionalities of PPT (form-tools, effects and motion-paths) they produced their first animation, which was very motivating for them; indicated by exclamations like “Wow!” or “This is so cool!” The students converted their prepared animations to video files to embed them into Prezi.

Prezi was new to most of the students and they had to create their own cost-free education-
account2 to use the software. After getting acquainted with Prezi, the students worked collaboratively to create different digital learning-environments on the topics they had chosen at the beginning. Prezi allows to work on the same presentation with multiple users, which makes it possible to develop different parts of the presentation simultaneously. This feature supported the communication among the students and fostered team-work, but also lead to technical problems (like graphical artefacts) due to high data traffic. Though, all groups could finish their Prezi environments within the assigned time.

**Analysis of the learning environments**

At this point the author wants to point out, that it is not his aim to didactically analyse the produced learning environments, but to reveal the potential of the approach to develop digital learning-environments with PowerPoint and Prezi for teaching and learning chemistry. Following this aim, the learning environments “galvanic cell” and “chemical bond” will be presented and discussed in the following section.

**Learning environment Galvanic Cell**

The digital learning environment “galvanic cell” starts with a schematic picture of a zinc-coal-battery (Figure 1, left), which the students obtained from the website www.seilnacht.com. By pressing the next-key the presentation will automatically zoom into the red frame, where the animation of the redox-reaction between zinc and manganese-oxide is shown as a video (Figure 1, right). The animation was developed by the students with PPT and fitted seamlessly into the presentation by adjusting the layout of the animation to the picture of the battery. This allows the learners to observe the structure of the battery at one hand and to observe the chemical processes at their specific locations on the other hand. This is a great example how the strengths of PowerPoint (quick and easy creation of animations) and Prezi (quick and easy creation of vivid learning environments) can be combined to gain a benefit for digital learning.

![Figure 1: Excerpt of the Prezi learning environment galvanic cell. Left: schematic representation of the inner part of a zinc-coal-battery by Seilnacht (Seilnacht, 2018). Right: PPT-animation on the particle level showing the chemical processes, which occur in the zoomed area of the red box.](https://prezi.com/prezi-for-education/)
Learning environment Chemical Bond

The digital learning environment “chemical bond” (Figure 2) deals with the formation of two covalent bonds between two hydrogen atoms and one oxygen atom giving a H$_2$O-molecule. The student-author of this animation decided to depict the atoms in Bohr’s model and to animate the circular movement of the electrons around the positive charged atom core (arrows in Figure 2). While the electron movements indicated by the red arrows are according to the scientific understanding, the green arrows in Figure 2 (right) reveal a misconception of the student. Though the Bohr’s model is restricted to atoms and is not transferable to covalent bonds, the student projects the idea of electrons circulating around a centre point to the electrons of the covalent bonds in the H$_2$O-molecule. Hence, (PPT-) animations show a potential to reveal preconceptions of students related to dynamic processes, which are difficult to access via static representations. This is an innovative method for science education research.

Figure 2: Excerpt of the Prezi learning environment chemical bond. Left: Animation of two hydrogen atoms and one oxygen atom. Right: Animation of a water molecule with two covalent bonds. Note: The arrows have been inserted in the static picture to indicate the movements of the electrons. The green arrows refer to the misconception discussed at the end of the article.

Analysis of the Portfolios

The students had the assignment to write a portfolio about the seminar regarding the development of the PPT-animations and the Prezi-environments and to give a final statement about their experience with the tools and the seminar.

All of the students stated in their portfolios, that they were not familiar with the special animation features of PPT prior to the seminar. According to the students, the most important benefit of PPT-animations lies in the possibility of adapting the animations to the needs of the learners or the textbooks, the motivating character as well as the powerful visualization. Critical statements of the student mostly referred to the extensive time, which was needed to create the animations (see Table 1).

10 out of 12 students stated in their portfolios, that they had never worked with Prezi prior to the seminar. According to the students, the most important benefit of Prezi environments lies in the high interactivity and dynamic character of the tool combined with a high motivational factor which the students see in the tool when working with children or youngsters. A few statements also referred to the possibility of creating presentations collaboratively or offering individual learning environments to the learners. Critical statements of the student mostly referred to the extensive time, which was needed to get familiar with the functionality of Prezi (see Table 2).

<table>
<thead>
<tr>
<th>Learning environment with PREZI (pro statements)</th>
<th>Learning environment with PREZI (contra statements)</th>
</tr>
</thead>
<tbody>
<tr>
<td>• I see a lot of chances to design lessons with Prezi to make them more attractive for learners.</td>
<td>• It took me a lot of time until I had a clue how to get along in the Prezi platform.</td>
</tr>
<tr>
<td>• Prezi allows me to design my lessons more dynamic and more interactive for learners.</td>
<td>• I had to get familiar with the Prezi platform and had to ask my fellows where to find simple tools like text boxes etc.</td>
</tr>
<tr>
<td>• Prezi allows multiple users to work simultaneously on one presentation, which facilitates group work.</td>
<td>• I needed some time to find out how the paths for the frames had to be arranged to get the desired path-order.</td>
</tr>
<tr>
<td>• The teacher will be able to support differentiation with Prezi, which will help him or her to offer individual learning environment for each learner.</td>
<td>• I have to conclude, that the simultaneous group-work with Prezi shows some limits, as the program seems to be overloaded quickly.</td>
</tr>
</tbody>
</table>

Results of the online survey

In the online survey, the students rated the seminar regarding to the workload, professional relevance, motivation and overall impression on a 5-level Likert scale from very low (1) to very high (5) and answered two open questions considering the strengths and weaknesses of the seminar. All 12 students completed the survey and the average ratings were: workload = 3.62, professional relevance = 4.62, motivation = 4.77, overall impression = 3.92. The most frequent answers to the strengths of the seminar were: the autonomous work with the tools, the practice-orientation and the qualified coach. The most frequent answers to the weaknesses of the seminar were: an insufficient introduction into the software tools, the negative relation between the content-quantity and the seminar-duration and missing information on the theoretical backgrounds of learning with digital tools.

CONCLUSION AND OUTLOOK

Developing animations with PPT seems to be a promising way to motivate future teachers towards “digital education”. Furthermore, we can confirm that self-made animations can be very useful to diagnose learners’ misconceptions related to dynamic aspects. Prezi is a very motivating tool for students, that “meets the ICT experience from using smartphones and tablet PCs.” (Krause et al., 2014). Additionally, we found that the integration of PPT-animations into Prezi environments enriches the possibilities for educators to design multimedia teaching
However, the special functionalities of PPT and Prezi are quite elaborate and need plenty of time to be introduced to the students. Nevertheless, this time-investment is not a limiting factor for further ICT-enhanced implementations, as the obtained “digital skills” are versatile to the students and can be applied for many further tasks.

The aim of the media seminar presented in this article was to strengthen the media-competence of the students. Following this aim, the students have been introduced to Prezi and PPT-animations to gain practical experience with digital media. The results of this project give us reason to assume that this aim was achieved to a great extent. Our assumption is strengthened by the feedback of the students in the online-questionnaire.

The suggestions for improvements from students were mainly about the missing instructions to use Prezi and the animation-functions of PowerPoint. On the other hand, they praised the independent work with the tools and the suggestions about possible usages of the digital media in chemistry lessons. The author found the time of the seminar i.e. 3 x 4 hours to be too less. Especially the initial training of the software tools and the creative work with the animations and learning environments clearly requires more time. For these things, a separate training session has to be planned in which the important criteria like the didactical aspects of learning with the animations (keyword: misconceptions), the didactical aspects for the development of the learning environments or copyright issues should be highlighted. Besides that, a conclusive discussion of the learning environments is also preferred. Here each group should present their products and discuss it in the plenum with regards to quality factors, which should be introduced at the beginning of the seminar. In this way, the students have the opportunity to reflect upon their learning progress.

In Science and Health practical sessions, the development of both technical and soft skills is essential in terms of both student learning and employability. The Irish Institute of Technology (IoT) sector places a major value on producing graduates who are ‘workplace ready’ with an emphasis on developing practical skills. It is widely recognised that assessment can influence student learning, effort and engagement. However, there is considerable scope for improvement in practical assessment practices at undergraduate level where concerns such as over-assessment, authenticity and graduate skill development are widely acknowledged (Bree, Dunne, Brereton, Gallagher, & Dallat, 2014; Hunt, Koenders, & Gynnild, 2012). The Technology Enhanced Assessment Methods (TEAM) project led by Dundalk IT, partnering with IT Sligo, Athlone IT and IT Carlow is exploring the potential offered by digital technologies to address these concerns. It aims to develop a framework for applying the principles of good assessment and feedback to practical assessment and facilitate dialogue among stakeholders about what it is we want students to learn in practical classes and how our assessment choices can facilitate this. A peer network of discipline-specific academics and students in the Science and Health field has been established. The first phase of the project identified approaches to potentially enhance assessment using digital technologies. The project was informed by a comprehensive literature review and a stakeholder needs analysis including students, staff and employers. To date 688 students across the 4 partner institutes responded to a survey examining perceptions of practical classes and digital technology in same. From this analysis, four priority areas for intervention have been identified: (i) Pre-practical preparation (videos, quizzes), (ii) Electronic laboratory notebooks and ePortfolios, (iii) Digital Feedback and (iv) Rubrics. Currently in the second phase of the project, these technologies are being piloted and evaluated across the four partner colleges.

Keywords: assessment, practical, technology.

INTRODUCTION

The scholarship of learning and teaching advises that those in a teaching role concentrate on the quality of their students’ learning and understanding while encouraging the incorporation of learner-centred practices and conceptions (Boyer, 1991; Light, Calkins, & Cox, 2009). This paper focuses on the practical environment in Science and Health – an area that, when it comes to the practical’s format and associated assessment strategies, often does not obtain the attention warranted. The practical can be described as a ‘powerful learning environment’, a term coined by Elen and colleagues (Elen, Clarebout, Léonard, & Lowyck, 2007, p.115) to
describe sessions that present opportunities for learners to construct their knowledge in a comfortable context married with targeted support from educators, to ensure activities and approaches prove effective. During an undergraduate student degree programme, science and health students do spend a significant proportion of their scheduled timetables in practical sessions. The potential for practicing and learning a diverse range of technical and soft skills exists in every practical session, for example students engage with demonstrating practical competence, academic writing skills, clinical skills, formulating hypotheses, assessment, group work, peer- and self-assessment, data analysis and interpretation (Boud & Falchikov, 2006; Bree et al., 2014; Hofstein & Lunetta, 1982, 2004; Pickford & Brown, 2006; Prades & Espinar, 2010). A primary benefit of the practical session is to allow students to obtain hands-on experience of equipment/patients/animals ensuring the development of technical skills/competencies, understandings and personal attributes, in addition to encouraging creativity and employability skills (Knight & Yorke, 2006; Verran, 2009). However, the learning potential of practical sessions is not always fulfilled. In fact, students are regularly focused solely on obtaining the correct result in the shortest time possible, and subsequently are only interested in a grade awarded/achieved (Hart, Mulhall, Berry, Loughran, & Gunstone, 2000; Hofstein & Lunetta, 2004). Students can often be starved of time for interpretation and discussion, time for mental engagement and elaboration and application of their learning (Hart et al., 2000; Hofstein & Lunetta, 1982). Indeed, many sessions are not contextualised for learners, meaning interconnections between the elements cannot be appreciated. There is a need to develop approaches to encourage learners to suggest hypotheses, ask questions and even design investigations – all processes focused on having “minds-on as well as hands-on” experiences (Gunstone, 1991 cited in Hofstein & Lunetta, 2004, p. 32).

In many cases, the format and assessment methods in practical sessions have stayed static with dated design and assessment approaches remaining cemented in curricula (e.g. the handwritten practical/lab report in the sciences). Here, we report progress on Technology Enhanced Assessment Methods (TEAM) in Science and Health Practical Settings, a 2-year Irish multi-institutional enhancement project funded by the National Forum for the Enhancement of Teaching and Learning in Higher Education (https://www.teachingandlearning.ie/). This project focuses on addressing the impact of technology on assessment in practical settings in Science and Health disciplines across four Irish Institutes of Technology.

**FORMAT OF PRACTICAL SESSIONS**

When educators are designing the format of their practical sessions, there are numerous approaches to be considered. Domin (1999) presented learning strategies, or styles, that many are familiar with in teaching practices today: expository, inquiry, discovery and problem-based (see Bennett et al., (2009) and McDonnell et al., (2007) for an overview of each encompassing their advantages and disadvantages). The most predominantly used approach, especially in the sciences, is expository. The literature has stated that this process, while useful in certain situations such as introductory practical sessions, does lack contextualisation, self-reflection and even thinking (Bennett et al., 2009; Domin, 1999; Dunne & Ryan, 2012; Hofstein & Lunetta, 2004). With this style, students follow a provided recipe-like cookbook, to achieve a pre-determined outcome – one often known to both educator and student in advance. This
approach can often remove challenges or obstacles, making this quite predictable (Pickering, 1987). Processes of inquiry provide learners with more ownership over the activity in the practical session with students able to become more involved in the design and creation of their own procedure (Domin, 1999). Hence, the choice of learning strategy being employed in a practical session can have a significant impact on the learning experience of the student, in addition to their communication and metacognitive skill development.

ASSESSMENT AND FEEDBACK IN PRACTICAL SESSIONS

“Assessment is at the heart of the learning experience” wrote Brown and Knight (1994, p.12). The choice of assessment approach employed has the potential to impact learners’ motivation, self-confidence and also affect how the learning process is viewed (Black & Wiliam, 1998; Miller, Imrie, & Cox, 1998; Prades & Espinar, 2010). Implementing formative, assessment ‘for’ learning, activities have been shown to have a more positive impact on the student learning approach to learning (McDowell, Wakelin, Montgomery, & King, 2011). Despite the recent advances in our understanding of the role and power of assessment, associated approaches in practical sessions have not evolved at the rate of those in the classroom. In many conferences in the learning and teaching field, ‘formative assessment’ is often the most mentioned phrase, and educators are re-moulding classrooms to develop learning and empower their learners. However, this motivation does not always extend to practical sessions, where in many cases summative practical reports remain dominant in science, with students fixated on the quantity of reports, rather than their quality. In clinical skills sessions, the Objective Structured Clinical Examination (OSCE) is the primary form of assessment and while this approach is very well aligned to the practical, there remains scope for complementary, and digital, aspects to be introduced for its improvement (an OSCE represents a hand-on performance-based exam, whereby students are assessed on their level of competency with certain practical skills in an applied setting. It is “concerned with what students can do rather than with what they know” - see Harden (1988, p. 19)). Considering and implementing new elements of assessment is an aspect practical session educators must engage with in order to empower and develop the skills of their learners, realising the learning potential of the practical – something described as yet to be realised by Roth (1994).

Fundamental to a successful assessment strategy is the provision of feedback by educators, followed by uptake by learners. Feedback was previously described as the “single most powerful moderator to enhance student activity” (Hattie, 2003, p.8). The supportive and constructive comments and advice provided to learners on their work are all aimed at improving their subsequent body of work (Sadler, 2010). How learners sustainably engage with, interpret and integrate feedback has become a research area of its own accord, with a dialogue on all aspects of learning being recommended (Bloxham & Campbell, 2010; Bree et al., 2014; Carless, Salter, Yang, & Lam, 2011; Carnell, 2007; Carnell & Lodge, 2002; Merry & Orsmond, 2011; Nicol, 2010; Orsmond, Merry, & Reiling, 2002; Price, Handle, Millar, & O’Donovan, 2010; Winstone, Nash, Parker, & Rowntree, 2017; Y1Feedback, 2016). Hence, developing approaches to improve feedback engagement and uptake in the practical environment is an area justifiably requiring significant attention.
The Irish National Forum for the Enhancement of Teaching and Learning in Higher Education recently published a ‘roadmap’ for enhancement in a digital world (The National Forum for the Enhancement of Teaching and Learning in Higher Education, 2015). The document reports that in order to enrich and support vibrant learning strategies, digital capacity development must be utilised more, and be embraced by educators – a strategy recommended by the EU Commission (2011). Building and improving digital literacy and capacity can support and enrich learning strategies as well as engage learners. Technology Enhanced Assessment Methods (TEAM) in Science and Health Practical Settings is a multi-institutional enhancement project that aims to evaluate the impact of technology on assessment in practical settings in Science and Health disciplines across four Irish Institutes of Technology (Dundalk Institute of Technology, Athlone Institute of Technology, Institute of Technology Carlow and Institute of Technology Sligo) (See Figure 1 for Project partner overview). The project comprises of three stages (See Figure 2).

**Figure 1. TEAM Project Partners.** An overview of the project partners and their representative institute. Heads of School/Faculty, Head of Teaching and Learning in addition to Academic Leads are involved. There is also an external advisor to the project, Dr. Michael Seery.
Figure 2. The three phases of the TEAM project. An overview of the three phases of the TEAM project. See http://www.teamshp.ie for further information.

TECHNOLOGY ENHANCED ASSESSMENT METHODS (TEAM)

This project, in combination with an extensive literature review, engaged with multiple stakeholders (primarily undergraduate students, staff and employers) to evaluate perceptions of practical sessions and to evaluate the potential of digital approaches being introduced. To date, 688 Science students across the four partner institutes responded to a survey examining perceptions of practical classes and digital technology in same. From the analysis, students valued hands-on practical sessions and were positive about assessment. It was noted that while currently, there was a lack of interaction with digital technologies in practical sessions, students had very positive attitudes towards their introduction.

From this analysis, combined with staff and employer engagement, four priority areas for intervention were identified (see Figure 3): (i) Pre-practical preparation (videos, quizzes), (ii) Electronic laboratory notebooks (ELNs) and ePortfolios, (iii) Digital Feedback and (iv) Rubrics within virtual learning environments.
Within each priority area, potential technology approaches were identified and ‘technology champion’ staff identified. Communications to academic staff teaching practical module components in the relevant schools/faculties in each Institute were circulated. Interested staff were invited to set up a technology based assessment pilot with their students. In total, fifty academic staff responded, reflecting a significant interest in running pilots. Training was provided before pilots commenced. The majority of these pilots have now been completed, allowing almost 1,500 students to experience a technology across 45 programmes (see Figure 4). The technologies encompassed ‘Socrative’ app quizzes, ‘LabArchives’ electronic lab notebooks, Microsoft’s ‘OneNote’, ‘Turnitin’, graphic tablet- and audio-based feedback, amongst others. Ethical approval was obtained and the pilots were then evaluated, with both staff and student groups, using online surveys and focus groups. The data is currently being analysed. To date, the TEAM project has had an extended reach in the four partnering Institutes, as shown in Figure 4, in addition having an impact nationally (Figure 5).

Interestingly, despite the pilots representing the four technology themes identified (see Figure 3), there is a common theme embedded across each of them – Feedback. Sally Brown (2007, p.1) described feedback as the “oil that lubricates the cogs of learning”. Merry, Reiling and Orsmond (2005) describe feedback as a tool to enhance reflection and understanding, ultimately improving learning. Hence, the provision of feedback being embedded in each of the thematic areas represents a vital aspect of the project with regard to student learning in the practical environment.
Figure 4. TEAM Pilot numbers. An overview of the distribution of the pilots and the reach of the project.

Figure 5. National Impact of the TEAM project.

Figure 6. The integration and presence of feedback provision and distribution approaches amongst the TEAM project’s technology themes.
CONCLUSION

In summary, the practical needs to be revitalised. The introduction of learner-centred activities, varying the selected learning styles and in particular introducing appropriate technology-based assessment strategies can assist in empowering learners with metacognitive, practical, clinical and soft skills that can last a lifetime, versus the duration of a practical module. The immediate aims of the TEAM project are to complete and disseminate data from the pilot evaluations, in addition to extending the peer network further nationally via a series of workshops with other institutions. A focus is also on identifying sustainable approaches for integration of the recommended technology-based assessment methods into curricula and to continue the recruitment of new academic staff and student partners to the project and the community of practice. For further information, please see the TEAM project website (http://www.teamshp.ie).

ACKNOWLEDGEMENT

The authors would like to thank the stakeholders, namely the student partners, staff and employers, who kindly participated in the survey/analysis in phase one of the project. In addition, we would like to acknowledge funding and support from the (Irish) National Forum for the Enhancement of Teaching and Learning in Higher Education (https://www.teachingandlearning.ie/) for this project.

REFERENCES

We present data from the initial questionnaire of a EU funded project. An online 42-questionnaire was developed which probed a convenience sample of teachers for their background, use of apps, usefulness of apps and in which subject in the STEM constellation, apps were used through frequency indicators and perceptions of usefulness indicators. 81% of teachers were both female and primary teachers. There was a wide variety of scientific education between the cohort in spite of this homogeneity and 25% of the cohort peaking at higher-level high school biology. Examining the use of technology showed how providing apps and online apps for learning were needed. The 42-question x 52-case dataset was analysed.

The teacher cohort was split between those who found the use of apps in teaching specific content areas either not-applicable - rating of ‘6’; or used the frequency label - ‘almost never’ and those who did find apps for various topics useful to varying degrees. Non-metric multidimensional scaling, MDS, was applied to the transposed data matrix. Nearly all the teachers belong to one large cluster, effectively a spectrum with teachers who increasingly used apps or thought them useful at one end and the teachers who increasingly thought the use of apps in teaching problematic or irrelevant.

**INTRODUCTION**

The use of digital learning environments and Flash games or simulations in learning science has received much attention in the research literature (Peterson & Carrico, 2015). Many are quite sophisticated environments (Stylianidou, Boohan, & Ogborn, 2004) where the user is enveloped in an alternative world and often engages with a virtual or alternative reality. These digital learning environments may be best suited to single-user per computer situations, however changing the standpoint of practicing teachers can be difficult to bring about. Thus, we note a conflict between catering for the needs of the child - *i.e.*, learning and catering for the needs of the teacher - *i.e.*, change of practice – very often the teacher is as unwilling to change their practice as the child is to learn!

This work reports an attempt to incorporate digital learning into the whole-class setting. Dendrinos (Bien) notes that teachers seldom use computers available in schools. Often, such attempts are anecdotally reported to consist of single outdated computers in a poor state of repair with multiple user groups struggling to access information or at the other extreme, dedicated computer rooms are provided but these require a level of support that is often lacking (INTO & CESI, 2007).

Once the games were developed in both projects, they were used in conjunction with experimental hands-on activities which helped to contextualise the digital learning component (Sharma et al., 1999). It is important to note that the games do not replace school science hands-on activities but complement them (Clark, 1993; Tolstik, 2001). Furthermore it is the
Strand 4

instructional method that is critical to effective learning rather than merely the provision of a digital learning component, hence the importance of making teachers comfortable with digital learning (Saloman et al., 1977; Hagler et al., 1987; Clark, 1983, 1994; Niemeic et al., 1987; Belmore, 1983; Welsh and Null, 1991).

This in TEALEAF work builds on an earlier European Union funded Comenius project: SOPHIA where Flash™-based apps were explored for science learning including ‘ecology’ and focusing on the methodology of dialogic learning associated with ICT (McCloughlin, 2011; McCloughlin, Gash, & O’Reilly, 2008, 2009; McCloughlin, O’Reilly, & Gash, 2009). This present work concerns is a problem refinement within the EU funded Erasmus Plus project: TEALEAF concerning learning about biodiversity through educational 'serious games' whether as stand alone apps, online games, or games as projects within coding environments. The TEALEAF project has three 'strands' as its methodology:

i) To determine what existing resources are ‘out there’ and determine their suitability;

ii) To upskill serving teachers in game coding using a freely available system such as Scratch™;

iii) To work collaboratively in national groups to design a professionally produced game.

Figure 1. Scratch™ interface displaying the 'Blue Dog' in Ioannina game on plant biodiversity
https://scratch.mit.edu/projects/2261311

The problem refinement concerns whether the world-important concept of biodiversity is given sufficient treatment from an educational technology perspective evidenced by teachers' use of apps which factor-in some aspect of biodiversity. In this work, three broad hypotheses were tested:

1) Teachers will think that apps are useful in general, but less so for biodiversity
2) Teachers will not think that there are sufficient resources, including time, for their needs
3) Teachers will think of apps as an occasional use only
Although serious games are generally considered to increase various skills - using the term in its broadest sense - there is a lack of evidence for such a claim, which poses a potential threat to serious games. Disciplined studies of gaming are few (Squire, Giovanetto, & Devane, 2005), educators "actually know relatively little about the consequences of game play on the cognition of those who play them". What is known is that games, simulated environments and virtual reality/systems, among other forms of gameplay, allow learners to experience situations that are impossible in the real world for reasons of safety, cost, and time (Corti, 2006; Squire & Steinkuehler, 2005) and in the primary school all three are particularly pertinent. The three factors of safety, cost, and time are not however mutually exclusive. Analyses have been conducted over the years, consistently showing that games promote learning (van Eck, 2006). At the same time, it seems difficult to draw any firm conclusions from studies on computer and video games due to conflicting outcomes (Mitchell & Savill-Smith, 2004). Within the context of learning through computer applications, we enter the realm of Information and Communications Technological Pedagogical Content Knowledge - ICT-TPCK. Very often the components of this type of technological pedagogical content knowledge - TPK or "TPACK"(Mishra & Koehler, 2006) presents unique challenges in a primary school classroom where competing resources and lack of confidence both in the science content AND the competency is using digital learning are too disparate to synthesize, since synthesis requires components that coalesce at some point. In this project, we suggest that simple but serious online computer games assist teachers synthesize their ICT-TPCK concerning apps and biodiversity.

**METHODOLOGY**

The theoretical framework within which these projects were implemented was the constructivist paradigm, and for the Irish team, the constructivist emphases were:

1. Emphasis on dialogue – social construction – as a means of constructing shared meaning. On closer examination, we see that the methodologies can involve dialogue as a key component and this is an important vehicle for most, if not all, the methodologies.

2. Emphasis on teachers’ self-examination of practice and values, and the effects of engaging with the lessons having to deal with a possible alternative mode of practice.

We take constructivism to mean that "knowledge is modelled as a construction made in response to experienced discrepancies between ongoing experience and past knowledge". Pupils' own activities and thoughts are central in the construction of knowledge, and teachers play important roles in helping children differentiate their initial understandings of phenomena they understand partially.

The Irish – primary – National Curriculum (NCCA, 1999) – but not the secondary syllabus (NCCA, 2015) – involves at least some of the following methodologies, which have their origin in the work of Piaget and Vygotsky and updated by the cognitive acceleration model (Adey, Robertson, & Venville, 2002; Adey & Shayer, 1994) the key components of which are listed following:
Concrete preparation: Students require a basic experience in unfamiliar objects and events so that novelty does not detract them from the learning experience.

Socratic irony: When the teacher feigns not knowing the answer to a problem or question in a dialogue

Utilising prior knowledge: Tools to determine what students know already

Cognitive conflict: Generating and sustaining episodes where the students experience ‘dissonance’ when their experience – and interpretation – does not match their observation or the teacher’s explanation

Social construction: Allowing the students to have the opportunity to discuss the practical/results in small groups

Meta-cognition: Allowing the students to have a role in deciding the structure of a lesson and thinking about their own thinking

Bridging the lesson between the classroom and everyday life

An online 42-question questionnaire was developed which probed a convenience sample of teachers for their background, use of apps, usefulness of apps and in which subject in the STEM constellation, apps were used through frequency indicators and perceptions of usefulness indicators. Respondents could decide if certain questions were not applicable, and non-responses were treated as 'not applicable'. The questionnaire is available from: http://bit.ly/1JEC9eB.

RESULTS

Non-metric multidimensional scaling, MDS, also known as principal co-ordinates analysis, PCA, was applied to the transposed data matrix using the ASCAL protocol in SPSS Statistics v21.0, which uses the Takane-Young-de Leeuw S-stress – formula #1, and a plot was made of the emerging dimensions. Jaworska and Chupetloska-Anastasova (2009) reviewed the possibility of using MDS in a range of psychological domains. They do, however, view MDS as an 'exploratory data analysis technique' but point out its key features, namely that MDS can 'handle nominal or ordinal data, and does not require multivariate normality’. de Leeuw (2000) in a metareview of the literature using MDS, claims that "MDS, as a set of data analysis techniques, clearly originates in psychology", and as such the early history starts with Carl Stumpf around 1880 (de Leeuw & Heiser, 1980). The most common approach to determine the elements and the underlying configuration is an iterative process, commonly referred to as the Sheppard-Kruskal algorithm. A simplified view of the MDS algorithm is as follows (Borgatti, 1997; Cízek, Härde, & Weron, 2005; UNESCO, n.d.), but see Fahrmeir and Hamerle (1984): The statistic allows any measure of similarity to be examined, MDS can use any distance matrix and as a result, the analysis focuses on the cases (the teachers): no information is provided about the contribution of individual questions answered (Fielding, 2007). Since the data are non-metric, they are interpreted as ‘distance-like,’ but not actual distance.

The aim of the MDS is to transform such data into a set of genuine Euclidean distances. The outcome consists of an arrangement of points in a small number of dimensions, usually two,
and located in such a way that the distances between the points relate as closely as possible to the dissimilarities between the objects. In non-metric MDS, only the rank order of entries in the data matrix (not the actual dissimilarities) is assumed to contain the significant information. Hence, the distances of the final configuration should as far as possible be in the same rank order as the original data. The purpose of the non-metric MDS algorithm is to find a configuration of points whose distances reflect as closely as possible the rank order of the data. The resultant plot is produced in Figure 2.

Figure 2. Scatterplot of calculated dimensions from MDS of the teachers’ responses

Apart from the outliers on the left hand side, nearly all the teachers belong to one large cluster. The blue arrow represents how the teachers increasingly used apps or thought them useful; and the red arrow represents how the teachers increasingly thought the use of apps in teaching problematic or irrelevant.

The final approach to the data, and by way of summarising the data was to plot the data as a theoretical morphospace (Johnson, 2008; Kendall, 1984; McGhee, 2006) based on the original idea by Sewell Wilson in the early 20th century. Here, the theoretical morphospace was based on the average country answers for each question indicating an overall ‘frequency’ of response. As with MDS, the dimensions are not required to be fully defined referencing the actual data, however, in the TEALEAF data this does happen to be the case. Thus we have not calculated intermediate eigenvalues as in principal components. The resulting Figure 3. is not an eigenform but rather a three-dimensional curve of the data for the whole population (Hofbauer & Sigmund, 1998).
Figure 3. The TEALEAF theoretical morphospace – Country axis: 1 = Czech Rep., 2 = France, 3 = Ireland, 4 = Slovenia, 5 = Spain.

The graph is best considered from the right hand side which begins with country 1, i.e., the Czech Republic. The data appears as the foothills of a mountain resembling the data of France with a deep valley following – Ireland – to rise to low mountains – Slovenia and Spain. France and Ireland appear to stand out and for different reasons. Both had a high representation of primary teachers, but France had representation from preschool teachers also, and when one examines how they answered, the most obvious difference is that biodiversity is taught more directly than in Ireland, and there is less reluctance to engage with the use of apps to teach specific topics such as biodiversity.

CONCLUSION

Midway through the second decade of the 21st century ‘traditional’ didactics appear to still hold sway with ICT viewed as an 'add-on', little wonder teachers feel overloaded with the 'extra' workload. The results also indicate that biology, and biodiversity in particular, is poorly served by the use of digital technology in the classroom, the majority of teachers felt that apps were irrelevant to teaching concepts relating to the environment, ecosystems, and biodiversity. If this indeed the case, then investment in schools in digital technology has been a fundamental waste, since of anything a child learns, her relationship with the environment and life around him is fundamental. Lack of understanding of this ‘primitive’ will condemn much of the planet to adverse climatic phenomena including a significant mega-extinction unless all the resources at a teacher’s disposal are put to full use to allay ignorance of the environment and active in environmental and biodiversity education.

DESIGN WORKSHOP OF DIGITAL CONTENTS FOR SUPPORTING HEARING-IMPAIRED PEOPLE IN SCIENCE MUSEUMS

Ryohei Egusa$^{1,2}$, Fusako Kusunoki$^3$ and Shigenori Inagaki$^2$

$^1$Research Fellow of Japan Society for the Promotion of Science, Tokyo, Japan
$^2$Kobe University, Kobe, Japan
$^3$Tama Art University, Hachioji, Japan

We held a design workshop for supporting hearing-impaired people to learn in science museums. In this workshop, we helped participants to produce digital contents as teaching materials. At the workshop, the National Museum of Nature and Science in Tokyo, Tama Art University, and the Tokyo Metropolitan K Junior-High School for the Deaf collaborated and worked on the materials. The design workshop was held from October 5, 2015 to January 14, 2016. In this report, we describe the production process of the digital materials. The purpose of the report was to explore the characteristics of the valued digital materials about a “herbarium specimen” and “butterflies and moths.” The materials were well received by curators and students at the Tokyo Metropolitan K Junior-High School for the Deaf. After the pilot, a follow-up survey was conducted, interviewing the members of the group that produced valued digital materials about the “herbarium specimen” and “butterflies and moths.” From the interviews, two characteristics of the materials were revealed: how to secure scientific explanations for hearing-impaired people, and how to provide them with a high quality learning experience.

Keywords: science museums, design workshop, hearing-impaired people

INTRODUCTION

Recently, scientific and technological issues have gained increased attention. Improving scientific literacy and attracting the public into science has accordingly become more important (Stocklmayer, Gore, & Bryant, 2001). Science museums play important roles as informal learning institutions of science and technology in regional communities (Gilbert & Stocklmayer, 2012). When presenting the exhibits, exhibit creators select collections held by each museum hall or cultural property held by other museums; it is necessary to consider explanations and arrangements that will aid visitors’ understanding of the exhibits (Dean, 2002).

Hearing-impaired have difficulty hearing. An appropriate means to secure such information in museums is needed to resolve this problem. However, Japanese science museums seem to lack sufficient consideration for the hearing impaired with their displays and provisions of learning programs (Egusa et al., 2016b). The Convention on the Rights of Persons with Disabilities recognizes the rights of people with disabilities in education, and stipulates that educational systems and lifelong learning must be guaranteed with freedom from discrimination and equality of opportunity (United Nations General Assembly, 2006). Science museums arguably need to provide content appropriate for hearing-impaired people to ensure they have those learning opportunities.

In this study, we aimed to consider ways to improve information accessibility for people with
hearing impairments at science museums by using digital contents. Therefore, we held a design workshop to support the learning of hearing-impaired people in science museums, and helped participants to produce digital contents as teaching materials (Egusa et al., 2016a). At the workshop, the National Museum of Nature and Science in Tokyo, Tama Art University, and the Tokyo Metropolitan K Junior-High School for the Deaf collaborated and worked on the materials. Students at Tama Art University produced digital materials as the designers. In this report, we describe the production process of the digital materials that were well received by curators and students at the junior-high school for the deaf. The purpose of the report was to explore the characteristics of the valuable digital materials.

WORKSHOP SUMMARY

Purpose

Through the workshop, we aimed to consider ways to improve information accessibility for people with hearing impairments at science museums by using digital contents. Therefore, we explore the characteristics of the digital materials that were made at the workshop.

Participant

Participants were 19 students from Tama Art University as designers, five curators from the National Museum of Nature and Science in Tokyo, and 11 students from the Tokyo Metropolitan K Junior-High School for the Deaf as evaluators.

Period

Design Workshop had held from October 5, 2015 to January 14, 2016.

Method

The design workshop took place in the following manner. First of all, the 19 third-year students from Tama Art University and four staff members from the National Museum of Nature and Science decided on the content themes, deciding on eight: “mosses, mushrooms, and lichen,” “herbarium specimen,” “microscope,” “animal horns,” “butterflies and moths,” “evolution of plants,” “meteorite and space science,” and “Hayabusa.”

Next, the students from Tama Art University split up into eight groups consisting of one to four people each. Each group chose one theme they thought was interesting and developed content for it. The content development took approximately two months between October and December. The nature of the content was discussed by the university students and curators when needed. Museum curators provided guidance on areas requiring expertise during the process.

After all of the content was completed, the 11 students from Tokyo Metropolitan K Junior High School for the Deaf tried it out. The testing took place in the following manner. First, the 11 students split up into three groups of three to four people. Each group was assigned a school staff member versed in sign language to provide support when necessary.

Following this, each group was given explanations of the eight different sets of content that had been developed. Every time a content explanation ended, each student would evaluate that
set of content. Evaluations were conducted using questionnaires. The questionnaire had four sections: “the content explanations were fun”; “the content explanations were easy to understand”; “I wanted to find out more about the subject”; and “I was interested in the related exhibit.” Each evaluation section had a seven-stage Likert scale ranging from “I completely agree” to “I do not agree at all.” The workshop at the National Museum of Nature and Science took place on January 14.

After the pilot, a follow-up survey was administered, interviewing the members of the group that produced the valued digital materials about the “herbarium specimen” and “butterflies and moths.” The group that created the “herbarium specimen” consisted of two designers. The content for the “herbarium specimen” used a plant specimen to explain how to make pressed flower specimens and their advantages as specimens. The group that created the “butterflies and moths” content consisted of two designers. The content for “butterflies and moths” explained the commonalities and differences between various butterflies and moths. During the interview, we researched how to change ideas about methods of providing scientific explanations to hearing-impaired people and the participants’ material design through the workshop. Semi-structured interviews were held with the participants. The interviews lasted approximately 20 minutes. The interviews were held on October 4, 2016.

**CASE STUDY**

**Herbarium specimen**

Table 1 shows the results of the evaluations made by hearing-impaired children when they tested the “herbarium specimen” theme. Medians and modes have been calculated for each section. With the fourth scale in the range taken as the neutral value, the hearing-impaired children gave positive evaluations in all four sections (“the content explanations were fun”; “the content explanations were easy to understand”; “I wanted to find out more about the subject”; and “I was interested in the related exhibit”).

Figure 1 shows the explanation given for “herbarium specimen.” The content consisted of explanatory images, real pressed flower specimens, and specimen sketches made using tablet PCs and Adobe Flash. The tablet PCs were equipped with explanatory images and explained how to make pressed flower specimens and their advantages as specimens. Figure 2 shows a section of an explanatory image. It shows a scene where a pressed flower specimen has been put in water and is returning to its original state, with *ruby*-annotated subtitles (*ruby* are annotative glosses that can be placed above Chinese characters when writing languages to illustrate the pronunciation) saying “Amazing! It was in 3D!”
Table 2 shows a transcript of outcomes obtained from interviews. First of all, the interviewees were asked how the pressed flower specimens from the museum had been explained. It was found that important parts of the explanation about the pressed flower specimens were done orally, leading them to look into methods that would support learning among people with hearing impairments by explaining pressed flower specimens with images. They included subtitles with the images, deciding on the exact details of subtitle size, period of display, and timing based on subtitles for television news and the advice from teachers at high schools for the deaf. They felt that in the testing period with actual hearing-impaired junior high school students that the students’ interest was captured more by the experimental images than explanations of the content. They came to the opinion that it was important to use the experimental images effectively to properly attract the interest of the hearing-impaired students when giving them explanations of the pressed flower specimens.

Table 2. Transcript of interview: design process of materials about “herbarium specimen”

<table>
<thead>
<tr>
<th>Planning phase:</th>
</tr>
</thead>
<tbody>
<tr>
<td>I: Could you tell me the different stages you went through when creating the explanatory images?</td>
</tr>
<tr>
<td>D1: First of all, I discovered from a survey at the museum which bits at the pressed flower specimen exhibit were hard to get across. Then, two of us planned the image flow. We looked at pre-existing sign language news and things like that to create a plan and content with a focus on making the information easily conveyable. Then I listened to actual teachers from schools for the deaf who gave me advice about timing of the subtitles and font size and all that, then after it had all been re-examined I checked all the content over once again and then went to the museum for the filming of the experiment. I covered everything again, checked the content, then the two of us reexamined the content, and then before we actually let the children from the school for the deaf see it we showed it to the museum people once more. They had some further advice, so we increased the subtitles a little bit and improved it and then we finally showed it to the students.</td>
</tr>
<tr>
<td>I: Great, thanks. In that first phase, it was examined in terms of being targeted toward people with hearing impairments, then in the next step you made yourself aware of any mistakes in the content and corrected it.</td>
</tr>
<tr>
<td>(Omitted)</td>
</tr>
<tr>
<td>I: Did you receive any other advice from the teachers at the school for the deaf other than the advice about the font size?</td>
</tr>
<tr>
<td>(Omitted)</td>
</tr>
<tr>
<td>D2: Oh yeah, I think (they gave some advice about) timing.</td>
</tr>
<tr>
<td>I: When you say timing, in specific terms what do you mean?</td>
</tr>
<tr>
<td>D1: Speed of speech.</td>
</tr>
<tr>
<td>D2: So, the words come out at as slowly to the eye as speech is actually spoken.</td>
</tr>
<tr>
<td>I: Oh, if it goes too quickly they won’t be able to read it.</td>
</tr>
<tr>
<td>D1: Yes, that’s right. We were told that the amount of time the text is there is incredibly important.</td>
</tr>
<tr>
<td>(Omitted)</td>
</tr>
</tbody>
</table>
D2: We looked at sign language news when we were making the subtitles, but only in terms of text font size, the shape of the font, how far the text was separated; but in doing so we personally made a mistake in that actually it would appear that the sensation and time seeing the text was more important than those elements.

Examining the prototype phase:
I: Please tell me what is difficult from the point of view of design for hearing-impaired people on the basis of your experience. Which bits of the scientific content and the pressed flower specimens were difficult to convey to people with hearing impairments?
D1: All of the important information (during the explanations heard at the time of the museum survey) were being explained orally. So I (a non-deaf person) took up the idea of what exactly was a pressed flower specimen and mulled that over, and then turned my thoughts to how it could be conveyed to people who can’t hear sounds made orally…

(omitted)

D1: Ah, for this content, rather than the science, it was the bit of the image where the pressed flower specimen is dipped into water and turns 3D that really flowed in the exhibit, and it was only this bit that really excited [the students], leaving me with the idea that maybe it could be used effectively.

Note. I: Interviewer, D1: Designer 1 (female), D2: Designer 2 (female)

Butterflies and moths

Table 3 shows the results of the evaluations of the hearing-impaired students when they tried out the “butterflies and moths” theme. Medians and modes have been calculated for each section. With the fourth scale in the range taken as the neutral value, the hearing-impaired children gave positive evaluations in all four sections (“the content explanations were fun”; “the content explanations were easy to understand”; “I wanted to find out more about the subject”; and “I was interested in the related exhibit”).

Figure 3 shows the makeup of the materials in the “butterflies and moths” theme. This consists of a tablet PC, soft toys in the forms of a butterfly and a moth, and a glass case containing specimens. Figure 4 shows the tablet PC-implemented quiz games. The group aimed to engage hearing-impaired viewer in learning how to distinguish butterflies and moths through quizzes. The tablet PC development environment was HTML5. Soft toys equipped with the characteristics of butterflies and moths (e.g., antennae, wings, frenulum of moths) showed the differences between them.

Table 4 shows a transcript of outcomes obtained from the interviews. First, they observed the conditions of the exhibitions at the National Museum of Nature and Science in Tokyo in order to find problems and to get ideas. They found that the existing exhibitions and explanations about a butterflies and moths are boring for children. In particular, the specimens were too small and untouchable, which was a problem. Therefore, they had the ideas of creating a quiz game that would attract viewers and finding tangible soft toys that would help students to review what they have learned. The group intended to add the materials to the existing exhibits.
in order to provide hearing-impaired people with information using textual information and tactile objects. The group then produced a prototype and examined it. They asked an expert in deaf education for guidance. Using her advice, they found that their method of providing textual information had serious problems. They then tried to improve the readability of their quiz game considering the length of the sentence, typeface and size of letters, and ruby.

<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>I: At the beginning, what were you consulting about? For example, what did you make or what were your principles or...</td>
<td></td>
</tr>
<tr>
<td>D3: At first, I observed the existing exhibits and explanations. I first noticed that the children took a large interest in butterflies and moths. However, they seemed to feel that the existing materials were boring even after half of the explanations, so we considered ways to attract viewers until the end. And we got the idea of the program as follows. First, we prepared a game in order to attract hearing-impaired viewers. Next, we made them touch tactile object in order to learn effectively. Is that right?</td>
<td></td>
</tr>
<tr>
<td>D4: (nodding) We considered what is needed or what is important at the museum. Soft toys might look strange compared to what the other groups made. But I was sure that adding a tactile object to existing exhibitions would create a good experience for hearing-impaired viewers…</td>
<td></td>
</tr>
<tr>
<td>(Omitted)</td>
<td></td>
</tr>
<tr>
<td>D3: (Soft toys are) different from the size of specimens, so we worried about the point of scientific adequacy. However, specimens are untouchable because they are rare and fragile… and they are too small for the students to notice characteristics of butterflies and moths. We emphasized their touchable nature and the ease of noticing characteristics. We then decided to make soft toys.</td>
<td></td>
</tr>
<tr>
<td>Examining prototype phase:</td>
<td></td>

CONCLUSIONS AND FUTURE WORK

The results revealed the characteristics of the materials about “herbarium specimen” and “butterflies and moths.” The notable characteristic of “herbarium specimen” was that it made information accessible for those with hearing impairment by way of subtitled images. Based on the members of “herbarium specimen” group own surveys, they created learning about flower pressed specimens for people with hearing impairments by using interesting-looking images and attached subtitles. They enlisted the cooperation of various experts when creating the subtitles to work out a subtitle design that would convey information in an easily understandable way without any loss of meaning. This led to high evaluations from the hearing-impaired junior high school students.

The “butterflies and moths” themes had two notable characteristics. One is the way they provided hearing-impaired people with scientific explanations. The designers used a digital quiz game to provide textual information appropriate for those with hearing impairments. In addition, they prepared tactile materials instead of untouchable specimens. The second characteristic is the way the designers provided those with hearing impairments with a high quality learning experience. Combining visual information, tactile information, interactive guidance by quizzes, and specimens effectively constituted their program about learning butterflies and moths. This type of interactive content design used in an integrated visual and tactile way created content that was highly rated by hearing-impaired junior high school students.

Future work should examine the design process of the other groups and present the considerable effort being done to accumulate digital materials appropriate for learning by hearing-impaired people at science museums.

USING COMPUTER ANIMATIONS FOR TEACHING AND LEARNING CHEMISTRY

Butsari Phenglengdi
Faculty of Education Chiang Mai University, Chiang Mai, Thailand

Chemistry is a difficult subject to understand because most of the concepts are abstract involving atoms, molecules and ions—none of which are visible to the naked eye. Therefore, using computer animations to help explain the molecular level can help students achieve a better understanding. Many kinds of computer animations have been produced by educators for teaching chemistry at the molecular level. Many research studies have shown that using computer animations helped students to better develop mental models compared to using pictures or diagrams. On the other hand, using computer animations can create other misconceptions because of how the molecular level is depicted in the animation such as the colour, shape or behaviour of atoms, molecules or ions. Therefore, computer animations must be designed and presented with great care in order to encourage students to focus on the intended learning points.

Keywords: computer animations, molecular level, teaching and learning chemistry

THE THREE THINKING-LEVEL MODEL OF CHEMISTRY

The potential usefulness of computer animations is but a part of the puzzle that is chemistry teaching. Johnstone (1991) explored the reason why science topics are so hard to understand. He developed a paradigmatic three thinking-level model of chemistry, depicted in a triangle (Johnstone, 1991) (Figure 1). Each side of the triangle represents a different aspect of the chemical problem: (1) macroscopic or observable; (2) submicroscopic or molecular; (3) symbolic or equations. Students must synthesize these different levels. These three levels, then, frame the broader analysis of how animations can play a part in the learning experience, and a brief description is provided below of each level.

The macroscopic (referred to here as the observable or laboratory level) involves the things that we can observe or sense from the eyes, ears, smell or touch. Classroom experiments will often engage the senses: students can observe salt; they can see salt with their naked eyes; they can explain salt at this level (it is crystalline, solid and white).

Even though students may do classroom experiments which engage the senses, it may nevertheless be very difficult to explain the particles of salt at the molecular level because the particles are invisible, and therefore abstract. The submicroscopic (referred to here as the molecular level) is another prong of the Johnstone model. The molecular level involves things that we cannot see, such as atoms, ions or molecules. Students taught using a traditional teaching approach—one involving primarily lab work and application of formulas—have to construct or imagine their own mental models of atoms, ions, or molecules. Many students have misconceptions at the molecular level because the level is dynamic, not static, and is invisible, and thus hard to imagine and to understand. Indeed, student misconceptions in the molecular level are common. Fortunately, many kinds of models and visual representations have been produced and developed to help students understand the molecular level.
The final prong of the Johnstone triangle is the symbolic level. We use the equations or formulas to represent phenomena at the observable level, and particles at the molecular level. For example, the chemical formula Na⁺(aq) and Cl⁻(aq) can represent dissolving sodium chloride in water, or the aqueous substance solution if followed by “(aq)”. This level generates many misconceptions due to confusion over what is being conveyed. For example, does HCl indicate aqueous hydrochloric acid solution (no HCl molecules exist in this solution), or the HCl molecule? (Phenglengdi, 2015). This part is still invisible for students, so teachers have to approach the topic carefully to allow linking of the three levels. This three thinking-level model has been one of the most powerful and productive ideas in chemical education for the past 25 years (Gilbert & Treagust, 2009).

Figure 1. The three thinking-level model (Johnstone, 1991)

**STUDENTS STRUGGLE TO UNDERSTAND CHEMISTRY BECAUSE OF ITS ABSTRACTNESS**

Students struggle to understand and learn chemistry occur at all levels of education (Berg, 2012). Many research studies demonstrate that students in different ages have misconceptions at the molecular level and in different topics in chemistry (Yakmaci –Guzel, 2013; Stojanovska, Soptrajanov & Petrusevski, 2012; Smith & Nakhleh, 2011). The difficulty of teaching and learning chemistry is that the underlying concepts centre on the abstract areas or at the molecular level (Tasker & Dalton, 2008). One of the main reasons students find many chemistry concepts difficult is the high level of abstraction of these concepts, and the teachers often do not have the necessary resources to make them more concrete through laboratory demonstration and experimentation (Njoku & Eze-Odurukwe, 2015).

Typically, chemical teachers utilize laboratory experiments and chemical equations as pedagogical tools. But when students do a laboratory, they cannot see things happening in abstract areas. For example, in the redox reaction, when copper metal was placed into the silver nitrate solution, students could use the naked eyes to observe that the copper metal was corroded and the solution was changed from colorless to be blue. Nevertheless, students still could not see how the copper atom loses an electron and how the silver ion gains an electron in the redox reaction.
A VARIETY OF STUDENT MISCONCEPTIONS IN CHEMISTRY HAVE BEEN DOCUMENTED

A variety of researchers have noted particular student misconceptions in chemistry. Phenglengdi (2015) explored misconceptions at the molecular level of high school students in year 10 and 11. Drawing tests and semi-structured interviews were administered. The results indicated that students have misconceptions in the various topics. For example, misconceptions existed for the redox reaction, dissolving sodium chloride in water and the arrangement of water molecule in solid state, liquid state and gas state. Figure 2 and Figure 3 below show students’ drawing of the arrangement of dissolving sodium chloride in water.

Figure 2. Misconception, Na+ and Cl- ions as paired together

Figure 3. Misconception, Na+ and Cl- ions are not separated from each other in dissolved sodium chloride

Other researchers have similarly noted a variety of common student misconceptions. Stojanovska, Petruševski and Šoptrajanov (2014) investigated misconceptions of secondary and high school students in the Republic of Macedonia. The multiples choice concept tests and semi-structured interview were used to collect the data. The results showed that students have misconceptions at the molecular level in many areas. For example, (1) students believe that the particles of substances enlarge during heating that substance (2) carbon, hydrogen and oxygen atoms from ethanol will disappear when ethanol is ignited and (3) particles of a substance are shrinking during heating of the substance. Kelly, Barrera and Mohamed (2010) used drawing and explanations tests to exam students’ understanding of the nature of molecular level. The results showed that students have misconceptions with the definition of an aqueous solution and with the nature of ionic compounds. For example, students believe that in water, NaCl ion pairs do not break apart. In addition, many students were confused and struggling at the molecular level of substance if in the classroom the teachers taught only at the symbolic and observable levels.
ANIMATIONS CAN PLAY AN IMPORTANT ROLE IN THE CHEMISTRY CLASSROOM

Many different animations and simulations have been produced and developed. Examples include, VisChem (Tasker, Bucat, Chia, & Sleet, 1996). eChem (Wu, Krajcik & Soloway, 2001), Chemdiscovery (Agapova, Jones, Ushakov, Ratcliffe & Maria, 2002), ChemSense (Kozma & Russell, 2005), SMV:Chem (Russell & Kozma, 2005), and PhET (Moore, Chamberlain, Parson & Perkins, 2014). Not only are animation tools available, but teachers seem interested in using such tools. By way of example, Boz and Boz (2008) collected data from twenty-two prospective chemistry teachers exploring instructionally strategies, and computer animations, visual representations, and drawings were common instructional choices. Indeed, teachers have increasingly been using computer animations in classrooms to help students better understand in abstract areas, or at the dynamic molecular level.

In chemistry education, a chemical model or computer animation can be used to link students’ understanding of observable events with the molecular level (Phenglengdi, 2015). The use of computer animations has been strongly supported and encouraged as an innovative, constructivist and students-centered alternative to the traditional learning approaches in many countries (Tasker & Dalton, 2008; Phenglengdi, 2015).

Animations as a part of an overall instructional design have been shown to be effective. For example, Ikwuka and Samuel (2017) compared performance between a group teaching with animation and a group teaching without animation. The results showed that students taught using computer animation chemistry instruction (CACI) performed better than students taught using conventional methods (CM). The results might be explained because the CACI provided aural and visual representations in experiments but, in addition, added the molecular concepts. Moreover, the fun and entertainment value in using computer animation may also partially explain the better results. The finding implies that there is need (at the very least a desirability) for chemistry teachers to use CACI in teaching chemistry.

Njoku and Eze-Odurukwe (2015) incorporated a Computer Animation Instructional Programme (CAIP) for a subsample of students showing widespread learning difficulties. The topic was Nuclear Chemistry (NC), and the students were in the twelfth grade. During stage one, traditional instruction methods were used and data were collected using a 30-item short-answer essay test called Nuclear Chemistry Learning Difficulties Diagnostic Test (NCLDDT). Results were analyzed to target problem areas and categorized in a list of “learning difficulties” with factors such as “inability to label parts of the atom,” or “inability to calculate number of protons, neutrons and electrons from nuclear equations.” After using the CAIP, the result was a 52% reduction in the number of difficult nuclear chemistry concepts (from 25 to 12). The researchers noted that the animations appear to have made the abstract concepts more concrete, thus enabling students better to visualize the nuclear particles and to understand their interactions and transformations.
POTENTIAL DRAWBACKS/CAUTIONARY COMMENTS

Not every animation is necessary an effective animation. For chemistry animations to be an effective component of teaching and learning chemistry, Wu and Shah (2004) suggested five principles for designing chemistry visualization tools: (1) providing multiple representations and descriptions, (2) making linked referential connections visible, (3) presenting the dynamic and interactive nature of chemistry, (4) promoting the transformation between 2D and 3D, and (5) reducing cognitive load by making information explicit and integrating information for students. Teachers often find errors in the images and animation sequences and therefore do not want to use the animations in the classroom (Burke & Greenbowe, 1996). The time it takes to use an animation can also be a drawback. These drawbacks may be the reason that many teachers still prefer to teach students with more traditional approaches.

Using animations also assumes a classroom properly equipped, and in places like developing countries that cannot necessarily be assumed. But a classroom that is properly equipped can lead not only to increased student understanding of the concepts, but to additional instructional strategies for teaching difficult and abstract concepts.

In several animation studies, researchers have found that when students were shown animations and then attempted to draw or explain their new understanding, alternative perceptions persisted (Kelly & Akaygun, 2016; Kelly, 2014). Smith and Villarreal (2015) collected data from two introductory, college level, general chemistry courses numbering over 100 students each. Each experiment had two parts, the first involved particle position during a melting-freezing cycle, and the second positive position during a dissolving-solvent evaporation cycle. The concepts were discussed in class, and then a test provided. After the test, students were shown PhET animations of states of matter, and re-tested. The authors noted that misconceptions persisted, commenting in part that the results highlighted the need for careful guidance during the use of animations and illustrations. Therefore at least some further research will be needed to tease out details of why animations would appear to succeed in some contexts, but not in others.

AN EXAMPLE OF THE LESSON PLAN

To make this discussion more concrete, a sample lesson plan incorporating animations is provided below. The lesson plan was developed by the author and used in Thai high school settings with some success (the topic of which will be presented in a further publication).

**Topic: solid water**

**Observable level**

The students in class will be divided into groups of 4-5 students. Solid water will be prepared for each group. The teacher will ask students to observe the characteristics of solid water, and discuss what they could see with each other (Figure 4). Students will be asked to think about the arrangement of the particles in the solid water at the molecular level, supported with teacher-guided questions. Below is a sample of the teacher-guided questions:

**Teacher:** Solid water is hard and colorless. Have you ever seen particles of solid water before?
If you can see the particles, what do you think about the arrangement of the particles of solid water?

After that, students will be asked to draw the arrangement of the particles of solid water to assess their prior knowledge whether they understand at the molecular level or not.

**Figure 4. Water in the solid state (Ice)**

**Molecular level**

After students observe the solid water, they will draw the arrangement of the particles in the solid using either a pen or pencil on paper. The teacher will continue to engage students by asking questions to help them think at the molecular level. Below is an example of a question that the teacher will use:

*Teacher:* Can you imagine the arrangement of solid water at the molecular level? If you zoom down to the solid water at the molecular level, what can you see? Draw the particle from your imagination on the paper.

After students draw the arrangement at the molecular level of solid water, students then will use their drawings on solid water to discuss and exchange ideas with peers in their own group.

Next, the teacher will present an animation depicting solid water to students through an overhead projector (Figure 5) (Tasker, 2010). During the presentation of the animation, the teacher will be providing general guidance at various key points, such as:

*Teacher:* Oxygen is red, and hydrogen is white (The color is not actually representative, though, of the actual color of the particles). The particles in a solid are tightly packed in an ordered fashion. You can see that the particles can vibrate in a fixed position. Normally we cannot see this phenomenon with the naked eyes.

**Figure 5. The arrangement at the particle of solid water from VisChem animation**
After viewing the animation of the particles of solid water, the class will proceed to reflect on their current understanding compared to their original understanding. The teacher will ask students to draw the particles of solid water to compare with the previous drawings they made before viewing the animation.

**Symbolic level**

Next, the teacher will explain about the different levels of chemistry. The teacher will talk about the observable level where students could see solid water, and then compare those observations to the particles of solid water at the molecular level as depicted in the animation. Finally, the teacher will discuss and link the formula of solid water at the symbolic level to observable level and molecular level (Figure 6).

![Diagram linking between three levels of thinking](image)

**Figure 6. Diagram linking between three levels of thinking**

The teacher will ask students various questions with new situations to help them think at a deeper level about what they had observed. For example, the teacher will ask questions such as the following:

*Teacher:* If the temperature is increased for solid water, what happens to the particles of solid water?

**SUMMARY**

Computers and technology have come to play a role not only in everyday life but also in the classrooms. Computer animations have been analysed in a variety of classroom contexts and shown to be a potentially effective chemistry teaching tool. Although computer models can help students to develop thinking in the molecular level, and to link the molecular level to phenomena at the observable level, the use of computer models still needs to be investigated to develop best practices for the classroom.
ACKNOWLEDGEMENT

I give warm and sincere thanks to ChiangMai University, Thailand to support the budget for attending the ESERA conference in August, 2017, in Ireland.

THE BRIEF HISTORY OF INDEX NUMBER (EXPONENTIAL GROWTH) IN SCIENCE AND MATHEMATICS CLASS

Minoru Ito
Tokyo University of Science, Shinjuku, Tokyo, Japan

I prepare and introduce a brief history of index number (exponential growth) using Prezi animation for young students within cooperative learning. This material makes them understand exponential growth around them in everyday life. Exponential (or proportional) growth happens when we repeatedly increase a quantity by the same proportion using an index number. It is in school mathematics and science and may be hidden in the curriculum materials of many subjects. When a number grows exponentially, the bigger it gets the faster it grows, and after only a handful of repetitions the number can reach a mind-boggling size (Bellos, A. 2014). We try to show how index numbers apply to game, music, art, and of course, science and technology. For example, I introduce it in these materials - the game of Tower of Hanoi, the pattern of harmony and rhythm in music, the structure of picture and sculpture, the nature of universe including from the micro world, such as molecular, atomic and quantum to macro world, such as the size of planets, the galaxies and black holes to the edge of the observable universe, ex. Powers of Ten (Eames, 1977). I encourage enjoyment of these materials not only in science and mathematics classes but also with ordinary people in university neighbours. I want to demonstrate that mathematics and science are fun and encourage students to feel and think about our nature using index numbers (exponential growth).

Keywords: comprehension of science text, computer supported learning environments, concept and context

INTRODUCTION

Currently, more and more attention has been paid to introducing student centered lessons, which promote students’ independent and voluntary activities, rather than reviewing the contents or materials from lectures.

The Central Council for Education in Japan (2014) also pointed out the importance of independent and cooperative learning, that is ‘active learning’ and the necessity for establishing learning supporting methods. This is because the process of learning by which improving the quality of education and deepening students’ understanding has been considered more crucial rather than the contents of education or the quantity of knowledge for primary or secondary level education (Ministry of Education, Culture, Sports, Science and Technology, MEXT, 2014).

MEXT (2008) also mentioned the importance of multilateral interaction among students for domestic mathematics and science education practices. However, according to Kubo’s empirical survey (2013), 33 percent of the teachers do not believe communication is an important factor for mathematics and science lessons in primary and secondary education. Moreover, the investigation of mathematics and science lessons shows students have engaged in communication only when they were asked a question by a teacher. At the same time, he argued that, while most teachers have an ideal image of lectures with students participating to find a solution, they fail to advocate student participation due to the lack of instruction skills.
The cause of this failure can be attributed to the lack of a simple and continuous model for lectures and research aimed at focusing on students’ interactions in the field of mathematics and science education. Sharan (2002) argued that the introduction of learning activities with students’ multilateral communication is the first step to move from teacher-centered lessons to student-centered lessons.

**COOPERATIVE LEARNING STRUCTURE USING PREZI ANIMATION**

This research focuses on lessons utilizing cooperative learning structures to instruct students considering their multilateral interactions using Prezi animation. Cooperative learning is a teaching method which utilizes group or pair activities among students. Empirical research conducted in a domestic primary and secondary level educational field (Kiyomiya, 2010). It revealed that cooperative learning has positive effects on students’ educational results, personal relationship, or self-respect (Johnson & Johnson, 1990).

However, the research method of these studies is analyzing teaching materials based on only one lesson. Jacobs (2002) argued that cooperative learning can be effective through repeated activities using its methods regularly and frequently. Nail (1990) also mentioned that learning method should not be changed at one time, so that the outcome of cooperative learning can be seen gradually. These studies are important indications in terms of continuous activities for lessons using Prezi animation.

From above, in this research, introducing tutorials focusing on students’ multilateral interaction for mathematics and science education, class planning with cooperative learning methods which can be practiced continuously and frequently during mathematics and science lessons at a secondary school will be proposed. In addition, the process by which students’ belief in cooperation changes will be analyzed through long-term practices of cooperative learning using Prezi animation.

When regarded as an educational tutorial method utilizing students’ group activities, cooperative learning can be a part of group learning. However, group learning does not always mean cooperative learning (JASCE; Japan Association for the Study of Cooperation in Education 2014). Kagan (2009) defined cooperative learning as an activity which satisfies four requirements, these are, “existing inequitable cooperation (positive bilateral dependence),” “clarifying individual responsibility,” “ensuring equal opportunities for participation” and “considering simultaneity of activity.”

For example, at the beginning of this mathematics class, I introduce the following material for interactive communication between students. I show these 5 following cards. These five cards uniquely represent the numbers 1 to 31. I will find out these students’ birthday easily in a moment. If the student’s birthday is the 15th, therefore 15 appears on cards A, B, C and D.

The number 15 in base two is 1111.
Then, I will ask the student’s birth-month as follow?

If the student was born in November, therefore 11 appears on cards A, B and D. The number 11 in base two is 1011. No two numbers have the same appearance on the cards because no numbers have the same representation in base two. If another student says, my birthday number appears on cards only C. In a moment, I will say 4.

After my instruction, I let my students form pairs in a class and give them a birthday game card activity as follows:

When they play the happy birthday number game, they are very positive showing bilateral dependence and clarifying individual responsibility, ensuring equal opportunities for participation and considering simultaneity of activity during the class activity. When regarded as an educational tutorial method utilizing students’ group activities and cooperative learning it can be a part of group learning.
These five cards uniquely represent the numbers from 1 to 31.

Table 1. Cards A, B,C,D &E

Then, I introduce the history of the binary system which the I Ching (陰陽易経 Chinese old philosophy) is one of the oldest books in the world, it probably dates back to 8th century B.C. It represents an ancient Chinese philosophy which now encompasses a psychology that has been translated to English, the Book of Changes (1951), by Richard Wilhelm with a foreword by psychoanalyst Carl Gustav Jung (1875-1961). The hexagram - six horizontal segments (with the solid segments being the Yang (陽) and the broken segments the Yin (陰) - is its archetypal structure. Mathematician, scientist and philosopher Gottfried Wilhelm Leibniz (1646-1716) first wrote about the binary system in his paper De Progressione Dyadica, 1679. From 1697 to 1702 he corresponded with Pere Joachim Bouvet, a Jesuit missionary in China. It was through Bouvet that Leibniz learned that I Ching (陰陽易経) hexagrams were connected to his binary number system.

Therefore, after my explanation of binary number system, I will give the following question, to groups of five or six students in mathematics class and allow discussion in a group for five minutes:
Can you imagine? Please consider as a group, what happens to a sheet of paper as you can fold it, forever. Each fold doubles the thickness. Since the paper is about 0.05 mm thick, the thickness after each fold is as follows;

0.05, 0.10, 0.20, 0.40, 0.80, 1.60, 3.20, 6.40, ... Ordinary though doubling is, when we apply the procedure repeatedly, please you can imagine the results after 100 times folds the paper. How thick the paper is? Please find out as follows during 5 minutes group discussion.

Possible answers:

1. human (1.8m); 2. school house (10m); 3. The Big Ben (96.3m); 4. Mt. Ben Nevis (1344m);
5. Space Station (400km); 6. Moon (4600km); 7. Sun (150,000,000km); 8. more

The answer is 8, more which about $10^{24}$ km thickness after all.

Then I show the model of a terrestrial globe of size 13cm diameter in front of my desk. I ask them if the earth was this size, how big would the moon and the sun be. Please discuss your imagination and share your ideas within your group. The students within a group discuss the size of the moon and the sun. Then I show Table 3 as follows:

**Table 3: The Size of the Earth, the Moon, and the Sun**

<table>
<thead>
<tr>
<th>Size</th>
<th>Diameter (km)</th>
<th>1,000km → 1cm</th>
<th>Looks like</th>
<th>Distance from the Earth</th>
</tr>
</thead>
<tbody>
<tr>
<td>The Earth</td>
<td>12,756</td>
<td>≈ 13.0 cm</td>
<td>Baseball size</td>
<td>0 km</td>
</tr>
<tr>
<td>The Moon</td>
<td>3,476</td>
<td>≈ 3.5 cm</td>
<td>Ping Pong ball</td>
<td>380,000km ≈ 3.8m</td>
</tr>
<tr>
<td>The Sun</td>
<td>1,391,400</td>
<td>1,391.4cm ≈ 14m</td>
<td>8 Floors Building</td>
<td>14,960,000 km ≈ 1.5km</td>
</tr>
</tbody>
</table>

Finally I ask the students to please write or draw the Earth accurately.

I give them five minutes to discuss and share their ideas in a group. During their group discussion, I try to encourage their discussion. After their group discussion, I will show the circle made using the drawing compass of 13cm diameter and 0.4mm line like right hand side.

Immediately, some of my students say that the earth is not a circle because of 8,000 meter mountains and more than 10,000 meters deep seas around the world.

Another student also says that the earth is not exactly circle but an ellipse because the difference in the earth diameter between the vertical and horizontal measurements are 22 km. Then, the earth is not like the circle. There are many ideas about the shape of the earth in my mathematics class.

After all their discussion, I will ask, if the size of the earth is like Table 3 as 1000 kilometer(km) make small to 1 centimeter(cm). Then 100 km is 1mm as like small scale, so 0.4 millimeter(mm)
circle line is equal to 40 km actual size. The earth is not exactly circular however the circle of
drawing compass 13cm diameter is represented as 12,756 km, so 0.4 mm line of the drawing
circle is expressed 40 km of the real world. If the difference between 8000 m (8km) mountains
and 10000 m (10km) deep seas is total 18 km. Also, the difference between the vertical and
horizontal earth diameter are 22 km. Totally the surface of the earth can be within 40 km
represented 0.4 mm line of drawing of the earth. Therefore, the error of the drawing of the earth
is within an approximate value. The importance of science is explaining the real world using
the geometry of mathematics. Science can always explain the phenomena of nature under the
limited condition of approximate value. Science education should be useful for making students
understand our nature and phenomena around the world and universe using mathematics.
However, also it is important to let students know that science is not almighty, science always
can demonstrate and prove natural laws under the limited conditions.

Then, I introduce following story from ‘Alex Through the Looking Glass; how life reflects
numbers, and numbers reflect life’ written by Bellos (2014).

Imagine a bottle containing bacteria whose numbers double every minute. At 11am the bottle
has one bacterium in it and hour later, at noon, the bottle is full. Working backwards, the bottle
must be half full at 11:59am, a quarter full at 11:58am, and so on. ‘If you were an average
bacterium in that bottle,’ At 11:55am the bottle looks pretty empty - it is only 1/32 or about 3%
full, leaving 97% free for expansion. Would the bacteria realize that they were only five
minutes from capacity? Bartlett’s bottle is a cautionary tale about the Earth. If a population is
growing exponentially, it will run out of space much sooner than it thinks. (Bellos, A. 2014,
p.137)

Then I will introduce the Prezi animation.

**COOPERATIVE LESSON PLAN USING PREZI ANIMATION**

Wilson (2013) pointed out that the design of the learning environment and the control of class
room during (students’ learning) activities are the most crucial matters for teacher (instructor)
to plan an instruction to transfer energy and actions to students’ side. This study will design a
model of mathematics and science classes incorporating the basic structures of cooperative
learning using Prezi animation. Requirements for the planning are firstly that the tools
themselves must be simple and can be used repeatedly and secondly that the tools can be
introduced to lessons for many students. In these lessons, students are guided by to simple
tools. In addition, both the teacher and students can gradually be accustomed to the
environment for cooperative learning because of repeated practices. As cooperative learning
tools will be introduced to lessons for many students, the control of class room during
(students’ learning) activities can be comparatively easy since lecturers can still facilitate the
class partly while respecting students’ multilateral interactions and frustration can be limited
for most teachers and students.

I prepare and introduce a brief history of index number (exponential growth) for secondary
school students applying cooperative learning tools using Prezi animation. This material makes
them understand exponential growth around them in everyday life. Exponential (or
proportional) growth happens when we repeatedly increase a quantity the same proportion
using index number in school mathematics and science which is hidden many subjects’ materials in curriculum. When a number grows exponentially, the bigger it gets the faster it grows, and after only handful of repetitions the number can reach a mind-boggling size (Bellos, 2014). I show them how index number apply game, music, art, and of course, science and technology. Then, I give them a chance to talk and share their experiences and ideas through their entertainment activities in everyday life. Using Prezi animation, I also present and introduce the game of Tower of Hanoi, students can play excitingly talking with another student in cooperative leaning groups. I also give them a music so that students explore the pattern of harmony and rhythm in music in their cooperative learning groups. I sometimes show them the structure of Gaudi’s architecture works and Michelangelo’s sculpture. I show them a film of Powers of Ten (Eames, 1977) to understand the nature of universe including from micro world, such as molecular, atom and quantum to macro world, such as size of planets to galaxy until black hole and the edge of the observable universe using index number (exponential growth) using Prezi animation. After the video, students share and talk their images and understandings of nature and universe actively in their cooperative learning groups.

**CONCLUSION AND DISCUSSION**

This study enhances students’ knowledge of mathematics and science using Prezi animation with cooperative learning group. The result of this study reveals the following points. Students can easy understand the meaning of index number (exponential growth) using Prezi animation for young students with cooperative learning groups. When a number grows exponentially, the bigger it gets the faster it grows, and after only a handful of repetitions the number can reach a mind-boggling size.

There are two causes for this positive change. Firstly, ‘time management and its instruction’ and ‘instructing the value of cooperative activities’ are effective when introducing cooperative learning tools. Secondly, there had been some confusion and frustration because cooperative learning structures were introduced to lessons for many students. Students’ knowledge of mathematics and science using index number (exponential growth) can be improved immediately after the introduction and sustained, enhanced gradually, or changed to positive after an initially negative reaction.

There are still two main limitations in this study. Firstly, the result can also be attributed to participants’ individual nature. Secondly, positive change of students’ knowledge of mathematics and science using index number (exponential growth) can be affected by communication during classroom activities. To investigate these influences, cooperative learning groups have to be conducted in different seasons or for other grades of students, such as different age or gender group.

This research shows the effectiveness of Prezi animation in mathematics and science classroom applying cooperative learning group approach. However, more complicated cooperative learning program such as interaction between groups, having debate during activities, self-appraisals among students must be analysed.

Moreover, practices and investigations of cooperative learning with another Prezi animation will contribute to future development of mathematics and science education. In addition, while
this research focuses on the field of mathematics and science education, it must be meaningful.

ACKNOWLEDGEMENT

The authors would like to express their special gratitude to Mr. Tomohiko Shima for his instructive comments throughout the study, and to Mr. Masato Andou for his critical review comments on an earlier version of the manuscript. Also, my graduate students wish to acknowledge insightful comments and advice from my colleagues in our institute, Graduate School of Science Education, Tokyo University of Science.

STRAND 5: INTRODUCTION

TEACHING LEARNING SEQUENCES AND INNOVATIVE INTERVENTIONS FOR TEACHING AND LEARNING SCIENCE

This chapter of the e-proceedings brings together seven papers presented at ESERA 2017 conference. These studies focus on the design of teaching and learning sequences as well as on innovative interventions reporting on empirical studies of the classroom implementation of specific teaching and learning materials. A study that falls under this strand involves the collection of empirical research data during the implementation of innovative interventions in classroom settings so as to evaluate their potential to promote their targeted learning objectives and to identify possible ways to further refine them. In other words, the innovations are evidence based. Besides the studies could be related to a series of other relevant issues, such as the intricacies involved in attempts to adopt and transform teaching materials so as to meet the constraints of a specific learning environment.

Within this context the strand involves two subgroups. In the first group three studies include several units structured and developed as teaching learning sequence (TLS). Work concerning teaching learning sequences (TLS) involves the interweaving of design, development and application of a sequence in classroom environments in a cyclic evolutionary process enlightened by rich research data. TLS studies share several features. First the work is interventionist, seeking to develop useful and viable products in response to emerging problematic situations and needs. Second, it aims to contribute to the development of educational theory embedded in specific contexts in normal classrooms. Third, the work is iterative, in that both product and design are tested and revised in several cycles starting from a general but not fixed conception of the problem at study. These features also constitute open issues that continue to be studied and debated by researchers. The TLS by Malgieri, Onorato and De Ambrosio was developed out of several trials and refinements and provides useful insights into students understanding of rolling friction after teaching based on combining hands on and video based experiments. The study by Lauman and Heusler concerns learning about paramagnetism and diamagnetism and is based also on multiple representations of the concepts. This TLS follows also the iterative development process which continuous after two years of experimentation. The third TLS by Soulis, Psillos and Petridou has been also iteratively developed and involves a combination of hands on and modeling software aiming at conceptual understanding of students in the area of optics, their epistemological awareness and correlations between them.

The second subgroup includes four studies which are based on the design and validation of specific innovative units at different levels of science education. The paper by Franco-Mariscal España-Ramos and Blanco-López focuses on context-based learning and presents the results of a study in which two tasks involving play (TIPs) and based on daily-life contexts were used to teach the names and symbols of chemical elements. The study by Lupión-Cobos, Blanco-López and López-Castilla includes a teaching unit on oxidation phenomena which was based on a sequence of activities designed to improve students’ ability to develop explanations and arguments based on scientific evidence and to encourage healthy lifestyle habits that are
supported by scientific research. Another paper by Loretn, Mueller and Weisse concerns a research and development project for secondary school level, which included the development of instruments for various aspects of Order-of-magnitude reasoning (OMR), as well as learning activities. The intervention is based on worked examples as a scaffold to learn OMR, with a strong anchoring on teaching practice. Finally, another paper in this strand by Goździk focuses on presenting several units and their implementation in the context of the ERIS project which proposes innovative ways of teaching STEM by exploitation of research results in schools. This project is EU funded and is aiming to increase the interest of pupils in lower and upper secondary schools in STEM, and the choice of a scientific career.

THREE YEAR RESULTS FROM A MIXED EXPERIMENTAL AND COMPUTER-BASED TEACHING-LEARNING SEQUENCE ON ROLLING MOTION

Massimiliano Malgieri¹, Pasquale Onorato² and Anna De Ambrosis¹

¹Department of Physics, University of Pavia, Pavia, Italy
²Department of Physics, University of Trento, Povo (TN), Italy

In the last three years we worked on a teaching-learning sequence based on a combination of tabletop experiments, video analyzed experiments and computer simulations, meant to improve students’ understanding of rolling motion. The central thread of the sequence consists in clarifying step by step the role played by friction forces in different cases of rolling motion; in other words, the role of friction is used as a scaffolding idea to organize students’ knowledge of phenomena connected with rolling motion. The open source software Tracker is used to analyze video recorded experiments, and the free software Algodoo is adopted to create an interactive physics simulation environment. In the last two years the TLS has been tested at both the Universities of Pavia and Trento, new data have been collected and refinements have been made to the progression of activities. The final post-test has been expanded with open response/explanation items, with the aim of investigating the quality of students’ scientific argumentation as measured through the instruments of Knowledge Integration theory. In this work we intend to a) summarize the sequence in its current form, and report its results at both Pavia and Trento which display a consolidated trend of promoting students’ understanding, as measured through standard pre/post-test multiple choice items; b) discuss results from the present year student sample concerning knowledge integration in answers to open response items; c) discuss results of a test item asking students to rate the importance of the different methods used (tabletop and video analyzed experiments, computer simulations, mathematical proofs and qualitative explanations) in stimulating their understanding; d) report on students’ retention of the concepts studied as measured by a delayed post-test, given to students about three-four months after the end of the sequence.

Keywords: rolling motion, video analysis, simulations

INTRODUCTION

Rolling motion is a difficult physics topic for both high school and undergraduate students. Difficulties reported in the literature concern both kinematic (e.g. the direction and magnitude of the velocities of points on the rim of a rolling object in different frames of reference) and dynamic aspects (e.g. role of friction in rolling motion at constant speed or accelerated, or the difference between pure rolling and rolling with slipping).

Many researchers have investigated common student difficulties in approaching rotational and rolling motion (Rimoldini et al., 2005; Mashood et al., 2012; Lopez, 2003), indicating that these problems are independent of students’ background. Other researchers in the same time tried to explain the main characteristics and crucial details of rolling motion (Claessens, 2017; Cross, 2015a; Cross, 2015b, de Souza et al., 2017, Lopez, 2003; Oliveira, 2011; Phommarach et al., 2012; Pinto et al., 2001, Shaw, 1979).
In order to overcome these difficulties, we designed a teaching-learning sequence (TLS) which alternates simple tabletop experiments, video-based experiments analyzed using the open source software Tracker and simulations, designed by students themselves, using the free software Algodoo, following a series of guiding questions. Schematically, the sequence proceeds through the following steps:

a) the pure rolling condition and the kinematics of rolling motion in different frames of reference;

b) the role of friction in rolling motion at constant speed;

c) the role of friction in leading an initially sliding object to roll;

d) rolling on an inclined plane and the threshold value of friction for maintaining pure rolling motion;

e) direction of the friction force for rolling motion accelerated by a torque, or a force at variable distance from the center of mass;

f) collision of rolling objects and the role of friction in preventing the conservation of linear momentum and total mechanical energy.

In the last three years the sequence has been tested at both the Universities of Pavia and Trento, in all cases with undergraduates who had previously studied rolling motion in introductory physics courses. While the overall structure of the sequence has not been altered from the previously presented version (Malgieri et al., 2015; De Ambrosis et al., 2015), there have been improvements in the materials used, consisting for example in a more extensive use of slow motion videos at 120 and 240 fps to provide a more detailed Tracker analysis of the investigated phenomena.

Our study is aimed at answering, based on three-year data, the following general research question: does a teaching learning sequence on rolling motion based on multiple teaching strategies and ICT tools provide significant educational advantages? We will also address, based on preliminary data, the following more focused research question: can such a teaching learning sequence help meet objectives of knowledge integration and long-time concept retention?

**THE ACTIVITIES**

A series of experiments, based on video analysis is used to highlight key concepts and to motivate students exploring interesting cases. As discussed above and reported in Figure 1, the resulting TLS alternates different activities. The simple table-top experiments are mainly focussed on the introduction of sliding friction using a spring balance. The video-based experiments concern both the kinematics of rolling motion and the collision between rolling balls (enhanced with slow motion techniques available on smartphones). The videos were analyzed using the open source software Tracker which allows us to study the same phenomenon in different reference frames and investigate the motions both of the centre of mass and of the point on the rim. Simulations were designed by students themselves, using the free software Algodoo and allowed them to modify the dynamical parameters as friction coefficients and elasticity in collisions.
Figure 1. Examples of activities: tabletop experiment about the friction force, Tracker video analysis of a rolling motion, Algodoo Simulation.

Interactive simulations, which can be modified on the fly by the students to model different physical situations, contribute to stimulate autonomous investigation in inquiry activities.

The activities aim at addressing key points such as:

A. distinguishing between the velocities of different points on a rigid rolling body with respect to the centre of the body or ground;

B. understanding the role of friction (kinetic friction) in the transition from sliding to rotational motion;

C. recognizing that a body rolling without slipping across a horizontal floor is not slowed down by friction;

D. realizing that a torque is not necessary to maintain rotation;

E. understanding the role of friction force for a body rolling along an inclined plane;

F. evaluating the friction force;

G. studying the rolling motion of a disk pulled by a force applied at an arbitrary point along its radius, and recognizing that the magnitude and direction of the friction force changes with the position of the point where the pulling force is applied;

H. acknowledging that static friction force can play a motive role instead of considering it almost exclusively as resistive.

METHODS

The results of the sequence are currently evaluated by means of the following tools:

a) a pre-test before the beginning of the sequence, composed of multiple choice items only;
b) a post-test given at the end of the sequence, containing both multiple choice items and open response items;

c) a delayed post-test given about three months after the end of the sequence.

**Multiple choice questions of the pre-test and post-test**

Multiple choice questions of the pre-test and post-test are extracted from (or inspired to) standard conceptual inventories (Rimoldini and Singh, 2005).

After the first trial, some of the questions (initially 10 items) were eliminated, because they did not pose any special difficulty and produced trivial results; others were modified to make them clearer. As a result, we obtained a set of more focused questions.

In the current version, both the pre-test and the post-test contain six multiple choice items. In order to render the results comparable, pre- and post-test items are placed into five conceptual strands:

A. Rolling and frame of reference;
B. Threshold value of static friction force;
C. Rolling on the horizontal plane role of friction and other parameters;
D. Rolling on an incline;
E. Rolling and slipping motion: work done by the friction force.

**Post-test open response questions**

Two open response, explanation-type questions were introduced in the 2016 version of the post-test administered to the Pavia students, and just one of them in the post-test for Trento students, in order to evaluate the quality of students’ argumentative discourse. The first question required students to predict, providing an explanation, whether total mechanical energy and momentum would be conserved in a collision between a sphere, rolling on a plane with friction, and a cube initially at rest on a plane with no friction. The second was an explanation type item, requiring students to explain why a yoyo, lying on a horizontal plane and pulled horizontally through a string wound around a spindle of smaller diameter than the yoyo itself, rolls in the direction of the pulling force, rather than in the direction that would be predicted by considering the torque produced by the pulling force itself. Students’ answers to both questions were evaluated according to the principles of knowledge integration theory (Liu et al., 2011) through the general rubric reported in Table 1. The level at which an answer would be judged basically correct by a traditional dichotomous evaluation is between 2 and 3.

More details on the relevant ideas to be elicited in the answers to the two items will be given in the following sections.

Delayed post-test

In the past year a delayed post-test was performed for both Pavia and Trento three-four months after the end of the sequence. The delayed post-test was again on the same concepts tested in the pre-and post-test, and composed of four questions identical to ones of either the pre- or the post-test, and two new ones.

Post-test item on the effectiveness of different learning tools

In the current year a post-test item was added, asking students to rate on a scale from 1 to 10 the importance of each of the following methods or approaches (used in the sequence) to promote their understanding: a) tabletop experiments; b) Tracker video analyzed experiments; c) Algodoo simulations; d) mathematical arguments or proofs and e) qualitative and conceptual explanations of phenomena.

RESULTS

Multiple choice questions

The results of our teaching-learning sequence as measured by standard multiple choice items are reported in Figure 2, where we show cumulative results. Consistent educational gains are visible for all the tested areas.

The whole group consists of 65 undergraduates. During their previous studies they attended at least two courses on mechanics, a first introductory course on Newtonian mechanics, and a second one on Lagrangian and Hamiltonian mechanics. The programs of these courses include static and dynamic friction forces and their role in rolling motion.

Figure 2. Pre- and post-test results for items related to the same concepts and the corresponding Gain factor. Results, grouped by categories, for the multiple choice questions of the pre-test and post-test in the last three years. Sizes of the samples are N_{PRE}=65 for the pre-test and N_{POST}=47 for the post-test.
In Figure 2 we compare pre- and post-test results for items related to the same concepts. On the whole, in the post-test the percentage of incorrect answers was, below 25%. This result alone is an indication that the sequence created a fruitful environment for the students’ learning, enabling them to address their initial difficulties.

To analyse the students learning progress during and at the end of the instruction, we evaluated the fractional increase in percentage of correct answers, called Gain or g-factor. The normalized gain (Hake 1998), is

$$\text{Gain (g-factor)} = \frac{S_f - S_i}{100 - S_i}$$

where $S_i$ and $S_f$ are the pre- and post-test scores expressed as percentages. The value of the gain ranges from 1 (when a student gets all the problems right on the post-test that she or he missed on the pre-test) to 0 (student shows no improvement from pre- to post-test) or even negative values (student misses more questions on post-test than pre-test).

This parameter has become the standard measure for reporting scores on research-based concept inventories. Notice that the gain in our case is always larger than 0.5. (with a mean gain $\langle G \rangle = 0.70$ and a standard deviation $\sigma_G = 0.15$).

**Open response questions**

Results on knowledge integration for our students are reported in Table 2. Despite the smallness of the sample, a trend of high knowledge integration is visible especially for the first question, concerning the Sphere-cube collision reported in Figure 3.

![The question required students to predict, providing an explanation, whether total mechanical energy and momentum would be conserved in a collision between a sphere, rolling on a plane with friction, and a cube initially at rest on a plane with no friction.](image)

Figure 6 Results of the item concerning the importance of each of the methods or approaches used in the sequence in promoting students understanding

Delayed post-test

In 2016-17 a delayed post-test was performed by both Pavia and Trento students three-four months after the end of the sequence. The delayed post-test was again on the same concepts tested in the pre- and post-test, and composed of four questions identical to the ones of either the pre- or the post-test, and of two new questions.

In Figure 5 we compare pre-, post-, and delayed post-test results for items related to the same concepts. The gains with respect the pre-test confirm the effectiveness of the sequence, but also show a reduction of the gain passing from the post-test to the delayed post-test. This is quite evident for the Rolling and frame of reference item where the gain in the post test was 0.7 and the gain in the delayed post-test becomes 0.2.

Following Hake’s idea, we define a new quantity analogous to the Gain that we call Retention,

\[ R = \frac{S_{Delayed} - S_{Pre-Test}}{S_{Post-Test} - S_{Pre-Test}} = \frac{G_{Delayed}}{G_{Post-Test}} \]
CONCLUSIONS

We have presented extended results, based on three years of experimentation in two universities, of a teaching-learning sequence on rolling motion with a strong multimedia character. Based on these results, the sequence is effective in overcoming many of the difficulties students have in interpreting the phenomenon of rolling, which are known to persist even at advanced levels of University instruction. Results obtained through two different measures of educational gain, i.e. pre-post-test gain, and post-instruction Knowledge Integration analysis, consistently confirm the effectiveness of the sequence. Concerning students’ long time retention of acquired ideas, results are also encouraging although students’ difficulties in interpreting the kinematics of rolling motion in different frames of reference appear remarkably resistant to change, as students seem more likely to revert to their initial conceptions in this area than in others tested. Finally, students’ own evaluation of the different strategies used in the sequence sets the spotlight on the positive role of Algodoo simulations and, to a lesser degree, of experiments video analysed through the software Tracker.

LEARNING ABOUT PARAMAGNETISM AND DIAMAGNETISM: A TEACHING-LEARNING SEQUENCE BASED ON MULTIPLE REPRESENTATIONS

Daniel Laumann and Stefan Heusler
Institute of Physics Education, University of Münster, Münster, Germany

Magnetism is highly relevant for many technological applications and a fundamental topic of physics education. Traditional teaching-learning sequences (TLS) discuss only ferromagnetism, which can create a distorted picture about the universality of magnetic properties. In the periodic table of the elements, only three ferromagnetic elements (under standard conditions) are surrounded by a variety of paramagnetic (51) and diamagnetic (34) elements. Furthermore, all types of magnetism share the same origins of magnetic moments (electron spin: ferromagnetism and paramagnetism, macroscopic and microscopic electrical currents: electromagnetism and diamagnetism). Thus, the treatment of paramagnetism and diamagnetism could potentially improve the conceptual knowledge on ferromagnetism and electromagnetism. In this study, the development of a TLS on magnetism starting with paramagnetism and diamagnetism to proceed to ferromagnetism is presented. The TLS is based on an interplay of multiple representations (material structure, experiments, digital media content). Following a design-based research approach, the initial TLS has been implemented in two university physics education courses over two years and comprehensively evaluated. The evaluation focused the conceptual knowledge on paramagnetism and diamagnetism (pre-test, post-test and follow-up-test-questionnaire, problem-based interviews) as well as specific aspects of digital media content and the structure of the TLS. The results indicate an appropriate development of conceptual knowledge on paramagnetism and diamagnetism among the university students for the first and second design cycle of the TLS. However, the findings reveal several important modifications to improve the development of conceptual knowledge (third design cycle).

Keywords: magnetism, multiple representations, design-based research

INTRODUCTION

A wide range of technological applications with strong relevance for everyday life are based on magnetic phenomena. Furthermore, magnetism represents an important subject for current scientific research, e.g. in the fields of data storage or medical applications (Laumann & Heusler, 2016). Magnetism has also been an important part of physics curricula both in schools and universities for a long time. Hereby, traditional teaching-learning sequences (TLS) in school typically confine magnetic phenomena to ferromagnetism and electromagnetism. All materials are separated in two categories: Those that are attracted by a magnet (ferromagnetic) and those that are not (non-ferromagnetic). Even textbooks impart the concept of “magnetic” and “non-magnetic” materials (e.g. Fagenbaum, 2004). However, the magnetic properties of the elements of the periodic table indicate that the clear majority of elements are paramagnetic or diamagnetic (51 paramagnetic, 34 diamagnetic), and only three elements are ferromagnetic under standard conditions (McNaught & Wilkinson, 1997). In this sense, (almost) everything is magnetic. While ferromagnetic objects are strongly attracted to magnetic fields, both the attraction of paramagnetic and the repulsion of diamagnetic objects are much weaker. Many
applications for these two kinds of magnetism can be found, for example in magnetic resonance imaging (paramagnetism) or superconductivity (diamagnetism). Additionally, paramagnetism and ferromagnetism on the one hand, diamagnetism and electromagnetism on the other hand share (almost) the same origins. For these reasons, we argue that teaching concepts should comprise all four types of magnetism (Laumann & Heusler, 2016). Reviewing former TLS, many useful phenomenological approaches for ferromagnetism and electromagnetism (e.g. Brown & Jackson, 2007; Donoso et al., 2009) and several experiments demonstrating paramagnetism and diamagnetism can be found (e.g. Chen & Dahlberg, 2011; Laumann & Heusler, 2017). It is important to notice that paramagnetic and diamagnetic phenomena can only be demonstrated and investigated within strong external magnetic fields. For this reason, in traditional TLS, these types of magnetism could not be demonstrated in experiments. However, the development and dissemination of high energy neodymium magnets enables teachers to consider these phenomena nowadays (Hameyer & Belmans, 1996).

Nevertheless, no comprehensive educational concept that coherently combines all four types of magnetism currently exists. Moreover, empirical research determines insufficient conceptual knowledge about ferromagnetism and electromagnetism among students from elementary school (Barrow, 1987) up to the university level (Pollock, 2009). A key reason for the insufficient conceptual knowledge results from the quantum physical origin of magnetism and the rather complex mathematical formalisms (Pepper et al., 2012). Concerning conceptual knowledge about paramagnetism and diamagnetism, only one study investigated students’ difficulties in understanding general characteristics of these types of magnetism (Tanel & Erol, 2008). The study indicates insufficient knowledge of undergraduate students about the different types of magnetism and phenomenological characteristics.

The present study, following a design-based research approach, aims to develop a coherent and compatible teaching concept on university level focusing paramagnetism and diamagnetism. It is the first part of the project “Magnetismus hoch 4” (engl. “Magnetism to the power of 4”). This project aims to design a teaching concept that allows students to develop consistent and expandable understanding in magnetism from primary school over high school to university level. To enable such continuous development of conceptual knowledge, it seems reasonable to start the design of the teaching concept at university level and to reduce complexity afterwards. Due to the extent and complexity of the physical issues and mathematical formalisms, as well as general cognitive psychological implications (Mayer, 1997), multiple representations are used to make the teaching concept applicable. These representations include student experiments as well as digital media content (short film, interactive simulations), addressing different channels of the sensory memory (Clark & Paivio, 1991).

**METHOD**

Following a design-based research approach, the design of the present study can be divided in five stages: design, implementation, evaluation, analysis and redesign. The comprehensive design process involved the development of teaching content including the core ideas of the different types of magnetism and the preparation of experiments, and digital media content serving as teaching and learning materials (Laumann, 2015). Subsequently, the concept has been implemented and, foremost qualitatively, evaluated in two university physics education
courses over two years with N=47 participants (N₁=21 first design cycle, N₂=26 second design cycle). Each course consisted of three sessions focusing phenomenological descriptions (CS1), microscopic classification (CS2) as well as the two different origins of magnetic phenomena (CS3), see Figure 1. Electromagnetic phenomena were only briefly mentioned in both courses.

The evaluation included pre-test-questionnaires (N_pre=45), post-test-questionnaires (N_post=36) and follow-up-test-questionnaires (N₀=9) and N=18 individual problem-focused guided interviews (N₁₁=9 first design cycle, N₁₂=9 second design cycle) concerning the conceptual knowledge about paramagnetism and diamagnetism as well as two further questionnaires and group discussions concerning the developed digital media content and further aspects of the sessions, see Figure 1. All questionnaires contained closed-ended and open-ended questions. The sessions were videotaped and audiotaped. The group discussions and individual interviews were audiotaped and transcribed. The only existing former study including paramagnetism and diamagnetism did not use a validated or standardized test to investigate the conceptual knowledge or student understanding for these types of magnetism (Tanel & Erol, 2008). Therefore, all instruments were tested with students of comparable courses and revised before the present study. Due to the small number of students (N=47), the analysis mainly focused the open-ended questions of the questionnaires, the individual interviews and group discussions. For these data, a qualitative content analysis has been conducted. The results of the first and second design cycle reveal valuable indications to the development of conceptual knowledge and the usability and design of the digital media content being essential for the second redesign prior to the third design cycle.

Figure 1. Structure of teaching-learning sequence and investigation plan (QU: questionnaire, GD: group discussion, IV: interview).

RESULTS

All of the following results are related to the first and second design cycle in total. The study reveals a variety of results addressing the development of conceptual knowledge, implications for the improvement of digital media content and general aspects related to structure and realization of the specific sessions. The following results are related to the major topics of the three sessions CS1 to CS3 and provide a first impression about the development of conceptual knowledge among students related to a TLS focusing paramagnetism, diamagnetism and ferromagnetism. Each section will start with short subject-specific information related to the
major topic considered and, in this way, provide inside into expected concepts and knowledge about the three types of magnetism.

**Phenomenological description (CS1)**

Various phenomena can be observed for different types of magnetism. Inside an external magnetic field a diamagnetic sample is always repelled. Consequently, the magnetic field is weakened inside the sample’s volume. Typical diamagnetic substances under standard conditions (McNaught & Wilkinson, 1997) are water, (pyrolytic) graphite or copper (Lide, 2005). In contrast, a paramagnetic sample is always attracted by an external magnetic field and, therefore, strengthens the magnetic field inside the volume of the sample. Under standard conditions aluminum, molecular oxygen or sodium possess paramagnetic properties (Lide, 2005). For both types of magnetism relatively weak magnetic forces are observed. Furthermore, it is impossible for diamagnetic and paramagnetic samples to maintain magnetized without the presence of an external magnetic field. These phenomena are clearly different for ferromagnetic samples. Usually, ferromagnetic forces are rather strong and the magnetization of a ferromagnetic sample is kept (partially) remanent without presence of an external magnetic field. Concerning the direction of interaction between a ferromagnetic sample and an external magnetic field it is important to point out that only magnetically soft materials have been discussed and investigated in the relevant sessions. These substances are strongly attracted by external magnetic fields. Under standard conditions only iron, nickel and cobalt possess ferromagnetic properties (Lide, 2005).

The pre-test-questionnaire revealed that only a few students possessed a concept of paramagnetic phenomena (13 %) or diamagnetic phenomena (16 %) prior to instruction. Since 38 % of the students describe ferromagnetic phenomena appropriately, the pre-test-questionnaire supports the assumption that ferromagnetism is more frequently discussed in traditional TLS. Concerning the effectiveness of the developed TLS, the post-test-questionnaire and follow-up-test-questionnaire indicate that students develop an appropriate understanding of the phenomenological properties of the three different types of magnetism because almost every student appropriately describes the typical characteristics of ferromagnetic phenomena (92 %), paramagnetic phenomena (92 %) and diamagnetic phenomena (94 %), see Figure 2. Nevertheless, the small number of test persons in the follow-up-test (N_{fu}=9) should be considered.

The results of the questionnaire survey are supported by the findings of the problem-focused interviews. During the interviews 17 (of 18) students named an appropriate description of magnetic phenomena. Many of the students referred to a specific experiment of session 1 and mentioned that “if you take a thread pendulum, stick a sample on it and place a strong magnet slowly next to the sample, […] ferromagnetic and paramagnetic substances would be attracted, and a diamagnetic sample would be repelled.” Furthermore, 15 (of 18) students are aware of the omnipresence of magnetic phenomena. These students mention that “non-magnetic is a difficult term, since there are different types of magnetism and every substance can be assigned to one of those” and “every material is in a way diamagnetic, […] but it is so weak that we can usually neglect it.”
A common misconception among students is the assignment of ferromagnetic properties and metals (Kircher & Rohrer, 1993) or silver-colored objects (Stepans, 1994). Our interview study replicates this common misconception even among university students. “If we approach a bar magnet to a metal, we observe a magnetic attraction” is an exemplary statement of one student, but the interviews indicate that only 3 (of 18) students share comparable concepts.

The pre-test-, post-test- and follow-up-test-questionnaires revealed another interesting finding concerning the phenomenological description of ferromagnetism, paramagnetism and diamagnetism, see Figure 3. The students were requested to name substances that can be assigned to one of the three types of magnetism. The findings indicate that the students named on average approximately one ferromagnetic substance in the pre-test, compared to two substances in the post-test. Furthermore, almost no one named exemplary paramagnetic or diamagnetic substances in the pre-test, compared to approximately one paramagnetic substance and almost two diamagnetic substances in the post-test.
Microscopic classification (CS2)

Inside an external magnetic field magnetic moments of ferromagnetic matter are aligned parallel to the external field. Without an external field the magnetic moments are preserved and a remanent overall magnetization can be observed. As well for paramagnetic matter, magnetic moments are aligned parallel to an external magnetic field. However, for paramagnetism the magnetic moments are on average by orders of magnitude weaker compared to ferromagnetism. Even if the magnetic moments of paramagnetic matter are, as well, preserved without presence of an external magnetic field, the overall magnetization vanishes due to randomly aligned magnetic moments. Magnetic moments of diamagnetic matter are weaker compared to paramagnetic matter and aligned antiparallel to an external magnetic field. Without presence of an external magnetic field both single magnetic moments and consequently the overall magnetization vanish.

In addition to the macroscopic characteristics of the phenomenological description a microscopic classification related to the state of magnetic moments for the different types of magnetism was surveyed. The pre-test-, post-test- and follow-up-test-questionnaires included images displaying the alignment of ferromagnetic, paramagnetic and diamagnetic moments in an external magnetic field. The students were asked to sketch the state of the magnetic moments for each type of magnetism when the former present magnetic field disappears.

Approximately half of the participants of the study (47 %) drew in the correct alignment of ferromagnetic moments after magnetization without presence of an external magnetic field prior to the TLS. The findings indicate an even better understanding after the TLS, where almost every student enters the appropriate alignment in the post-test (94 %) and follow-up-test (100 %), see Figure 4. The drawings of the alignment of paramagnetic moments suggest that also for this type of magnetism the understanding of the microscopic state is improved by the TLS. While only approximately one quarter of the students (27 %) supplies an appropriate microscopic state description prior to the TLS, this number increases in the post-test (81 %) and follow-up-test (56 %), see Figure 4. For the third relevant type of magnetism, diamagnetism, the results indicate major difficulties prior to the TLS but also afterwards. The findings indicate that most of the students are not able to sketch an appropriate state of diamagnetic moments without presence of an external magnetic field, see Figure 4. The differences in the conceptual understanding of the microscopic state of ferromagnetic and paramagnetic matter on the one hand, and diamagnetic matter on the other hand, needs to be examined more closely in the subsequent discussion.

Also for the microscopic classification, the results of the problem-focused interviews provide interesting insights in the students’ understanding. In general, 15 (of 18) students possess appropriate concepts about the alignment of magnetic moments in external magnetic fields and magnetization curves.

However, misconceptions about the state of diamagnetic moments without presence of an external magnetic field appear. At this point, interviews help to take a closer look. The statements of the students indicate that the different states of magnetic moments without presence of an external magnetic for paramagnetism and diamagnetism are not clearly separated from each other on a microscopic level.
Figure 4. Findings for the conceptual understanding of students related to the microscopic state description for the different types of magnetism without an external magnetic field.

Origins of magnetic phenomena (CS3)

Magnetic moments can be assigned to two different origins, both related to properties of electrons. First, the electron spin causes a permanent magnetic moment. These spin-contributed magnetic moments are, in general, aligned parallel to an external magnetic field. Secondly, external magnetic fields cause (electrical) probability currents in atomic orbitals or influence the wave function of free electrons resulting in orbital-contributed magnetic moments. These magnetic moments are aligned antiparallel to an external magnetic field. Concerning the different types of magnetism, one can note that ferromagnetic and paramagnetic phenomena are assigned to spin-contributed magnetic moments, whereas diamagnetic phenomena are caused by orbital-contributed magnetic moments.

The pre-test-questionnaire revealed that only a few students are aware of the spin-contributed magnetic moments prior to the TLS (11 %) and very few know about both contributions (2 %), see Figure 5. Both subsequent test-questionnaires indicate that almost half of the students (post-test, 42 %), respectively a third of the students (follow-up-test, 33 %) can name both contributions to magnetic moments afterwards. In this sense, the TLS seems to enhance conceptual understanding related to the origins of magnetic phenomena, see Figure 5.

Every single student correctly related ferromagnetism and paramagnetism to spin-contributed magnetic moments within the problem-focused interviews. Furthermore, it should be noted, that 15 (of 18) participants indicated further explanations to underlying concepts of spin-contributed magnetic moments within the problem-focused interviews. These underlying concepts include an understanding of the electron configuration, the Pauli exclusion principle and the relation between net magnetic moment and paired electrons.

However, the findings of the interviews point to an insufficient understanding of orbital-contributed magnetic moments, as multiple terms are used to describe this origin (e.g. “orbital currents”, “eddy currents”, “orbital angular momentum”, “electron movement”, “Lenz law”, “current moments”, “Lorentz force”), but almost no further explanation can be found. This lack of understanding is reflected in the results shown in Figure 4, indicating that almost no student...
Strand 5

has been sufficiently aware of the microscopic origin of diamagnetism after the TLS. However, on a phenomenological level, a clear majority of students is able to describe and distinguish paramagnetism, diamagnetism and ferromagnetism after the TLS, see Figure 2.

![Bar chart showing percentage of appropriate origins of magnetic moments.](image)

Figure 5. Findings for the conceptual understanding of students related to the two different origins of magnetic phenomena (SP: only spin-contributed magnetic moments named, OB: only orbital-contributed magnetic moments named, BO: both contributions named).

**DISCUSSION**

The present study shows that paramagnetism and diamagnetism can be successfully included to a TLS on magnetism. The present TLS comprises three different types of magnetism to convey coherent conceptual knowledge about the nature of magnetism. Moreover, the interplay of experiments on the one hand and digital media content the other hand enables students to construct mental models based on real phenomena and visual representations instead of complex mathematical formalisms.

The empirical results indicate a (mostly) positive development of conceptual knowledge about paramagnetism and diamagnetism among university students concerning the implementation of the TLS (first and second design cycle). Above all, the students have excellent knowledge about the diverse macroscopic phenomena of the different types of magnetism and exemplary representatives after the TLS. Furthermore, the findings reveal challenges for the TLS concerning the transition from a macroscopic to a microscopic description including a specification of the status of magnetic moments with and without presence of an external magnetic field. The results indicate an adequate understanding of ferromagnetic and paramagnetic moments. However, students have huge difficulties to describe the status of diamagnetic moments without presence of an external magnetic field. A possible cause for this could be associated to a common misconception concerning magnetic moments related to a widespread model describing the behaviour of magnetic moments through elementary bar magnet. The misconception indicates that students identify elementary bar magnets representing magnetic moments with atoms or molecules (Wernig, 2001). In this sense, magnetic moments are no interpreted as a property but as an additional component of matter. Consequently, it is hard for students that are familiar to the model of elementary bar magnets.
to understand that no resulting magnetic moments exist in diamagnetic matter, even if atoms or molecules are still present.

Concerning the origins of magnetic phenomena, our findings indicate that students can name the two different origins (spin and orbital contribution), but a deeper understanding of the orbital contribution is lacking.

The results reveal important hints for the second redesign in order to increase the development of conceptual knowledge within the third design cycle. Also, future surveys within the scope of the present study should investigate whether the conceptual knowledge about ferromagnetism is positively influenced due to a common TLS on ferromagnetism, paramagnetism and diamagnetism compared to a traditional “ferromagnetism only” TLS. Furthermore, it is our aim to extend the sample within the next design cycle being able to improve the amount of quantitative data.

Finally, beside the further development of the TLS on university level, we aim to adapt the TLS for high school and middle school level, focusing phenomenological elements of the existing TLS.

THE IMPACT OF MODELLING PEDAGOGIES ON 9TH GRADE STUDENTS’ CONCEPTUAL UNDERSTANDING AND EPISTEMOLOGICAL BELIEFS ABOUT MODELS

Ioannis Soulios¹, Dimitris Psillos² and Eleni Petridou³

¹Department of Primary Education Pedagogic and Scientific Guidance of West Macedonia, Kozani, Greece
²Aristotle University of Thessaloniki, Thessaloniki, Faculty of Education, Greece
³Experimental Junior High School of Thessaloniki, Thessaloniki, Greece

This study investigates the impact of modelling pedagogies on the formation of epistemological beliefs about models and the conceptual understanding of optical phenomena. Two classes of 9th grade students (N=29) followed a model-based inquiry Teaching Learning Sequence (TLS) about optical properties of materials. Reflective metacognitive instances were embedded in critical points of modelling stages in order to enhance students’ awareness about modelling. Data analysis of students’ interviews, questionnaires and worksheets showed improvements in students’ conceptual understandings and epistemological beliefs, their interrelationships, and students’ modelling performance.

Keywords: epistemological beliefs, modelling, conceptual understanding

THEORETICAL BACKGROUND AND RATIONALE

There is strong evidence that model-based inquiry can fulfil various purposes of science education, such as: learning science, learning about science, learning how to do sciences, and addressing socio-scientific issues (Hodson, 2014). Although these aims are very clear in distinguishing between conceptual understanding (e.g. what students learn with models), epistemological beliefs (e.g. what they know about models) and modelling practices (e.g. what they will be able to do with models), research has shown that the relation between the development of epistemological beliefs about models and conceptual understanding seems to be under question (Soulios & Psillos, 2016). The results of a recent study on 9th grade students and prospective teachers showed that under the impact of reflection positive correlations between epistemological beliefs and conceptual understanding were spotted only in the case of prospective teachers (Soulios & Psillos, 2014). We argue that the relation between these perspectives has to be further clarified in order to understand the rationale and the necessity of models in inquiry-based teaching and learning.

Campbell, Oh, and Neilson (2013) examined how modelling practices, defined as modelling pedagogies, were embedded in high school physics classrooms to meet targeted student learning outcomes (e.g., conceptual understanding of scientific concepts, science practices, and the nature of models and science). These authors describe in detail the five identified modelling pedagogies as follows:

• Exploratory modelling, where students investigate the property of a pre-existing model by engaging with the model (e.g., changing parameters) and observing the effects.
Strand 5

- **Expressive modelling**, where students express their ideas to describe or explain scientific phenomena by creating new models or using existing models.

- **Experimental modelling**, where students form hypotheses and predictions from models and test them through experimenting with phenomena.

- **Evaluative modelling**, where students compare alternative models addressing the same phenomenon or problem, assess their merits and limitations, and select the most appropriate one(s) to explain the phenomenon or solve the problem.

- **Cyclic modelling**, where students are engaged in ongoing processes of developing, evaluating, and improving models to complete rather long science projects (Campbell et al., 2013, p. 7-8).

In order to examine how modelling pedagogies affect epistemological beliefs about models and modelling and conceptual understanding, science researchers have proposed as criteria for the evaluation of modelling practices the model’s representational coherence, the connection of empirical data and model during experimentation, and the ability to integrate data in order to revise, change and increase the explanatory and predictive power of the model (Cheng & Lin, 2015; Cheng & Brown, 2015; Pluta, Chinn & Duncan, 2011). Analysis of classroom modelling practices have illustrated how various components of the learning ecology, including technological tools, the teacher’s scaffolding remarks, and students’ collective activities and conversations, contribute to shifting epistemological beliefs about model and modelling (Baek & Schwarz, 2014). We assume that engaging students in various modes of modelling pedagogies by allowing them to focus on representational features and attend to the roles of mechanism and empirical evidence when constructing and revising models can help them to develop more sophisticated epistemologies about models establishing a more coherent relationship between them and conceptual understanding.

Within this context, the present study draws on the application of a research-based Teaching Learning Sequence (TLS) where 9th grade students were explicitly engaged in and reflected on modelling pedagogies related to the ray model in optics, the main research question being:

- What is the impact of modelling pedagogies embedded in a metacognitively oriented model-based inquiry in the field of optics on students’ epistemological beliefs about the nature, purposes and change of models, their conceptual understanding and the interrelationship between them?

**METHOD**

**Context of the study and participants**

For the purpose of the current study, a Teaching Learning Sequence (TLS) originally developed in the framework of a European project was revised and adapted (Soulios & Psillos, 2016; Testa & Monroy, 2016). Adaptation took place through an iterative process involving cycles of design and implementation in classroom in order to empirically adapt the revised TLS to the students’ knowledge and reasoning and contextual factors (Psillos & Kariotoglou, 2016). Using the TLS for research and development resulted in various versions of the original one. In the
adapted inquiry-based TLS basic aspects of the content were kept, while a cyclic modelling approach was functionally integrated in order to prompt students to express their ideas of how light behaves, apply the ray model using segments, angles and geometrical rules, evaluate their expressed models during experimentation, and refine their initial beliefs. Expressive, experimental and exploratory modelling activities made up for the cyclic modelling and were combined throughout the TLS. The cyclic modelling approach was implemented through three successive phases, comprising the (i) introduction, (ii) revision and (iii) expansion of the model. Additionally, in the present new version the TLS was enriched by a number of Metacognitive Instances (MI) that were embedded in critical points of modelling pedagogies, in order to enhance students’ awareness about aspects of modelling procedures. Metacognitive instances included prompts for reflection during modelling pedagogies (see Table 1). Following such prompts, the students initially participated in group dialogue and afterwards wrote their opinions on the matters under discussion individually on special worksheets.

The present TLS was structured in 6 sessions, lasted about 12 hours, and was applied to 29 9th grade students of two junior high school classes, in Greece. Physics teaching is compulsory in the Greek junior general high school and is usually taught in traditional knowledge-transmitting mode; consequently, the students of the sample were unfamiliar with modelling activities.

The TLS uses a model-based inquiry approach in which the behaviour of the chosen application, i.e. the optical fibre, is iteratively explored and modelled by means of a combination of hands-on experiments and computer simulations. During the first stage simulations part of the OptiLab learning Environment (OLE), which includes virtual labs in Geometrical and Physical Optics as well as flash simulations, a model space, and measurement tools, was used to enrich the activities of the adapted TLS (Hatzikraniotis et al., 2007). In the second stage exemplar experiments included observation of the pathway of laser beams in water jets and during refraction and total internal reflection phenomena in a water tank. Finally, during the third stage digital photos of experiments were imported into and treated in the Cabri Géomètre microworld (see Soulios & Psillos, 2016 for more details). Table 1 illustrates the present TLS including selected aspects of learning objectives, modelling activities and metacognitive instances.

Table 1. The re-designed model-based TLS including metacognitive instances

<table>
<thead>
<tr>
<th>Intended Learning objectives</th>
<th>Modelling activities during pedagogies</th>
<th>Reflective prompts during metacognitive instances</th>
</tr>
</thead>
</table>
| Stage 1 - Introduction of the model | Exploratory modelling: • Optilab simulations | Metacognitive Instance 1:  
– In what way is light represented in the simulation?  
– If you could see how reality is, would you see the same thing?  
– What features of the ray model helped you explain the phenomenon? |

Students be able to:  
• Understand how we see  
• Understand models as an abstraction of reality
Strand 5

- Understand that the medium and the observer have to be in a transparent medium
- Realize that models are limited in their nature
- Qualitative experiments with images, light sources and common objects

Metacognitive Instance 2:
- If there was too much fog in the air, could the cyclist see the coin?
- In this case, could the ray model help you predict or interpret if the cyclist will see the coin? Justify your point of view
- What light phenomena could you explain with the ray model?

Stage 2 – Revision of the model

- Understand how and by means of what materials one can guide the light along curved paths.
- Realize that more empirical evidence was needed for the light guide to be modelled.
- Understand the role of the interface between two homogeneous materials.
- Realize that models enhance their predictive capacity taking into account additional evidence
- Drawing the path of light after qualitative experiment with an optical fibre lamp

Metacognitive Instance 3:
- How did you think the light travels into a fibre optic lamp?
- According to the ray model, the light propagates rectilinearly into space. Can you explain, with the help of the ray model, how the light propagates through the optical fibres?

Experimental modelling:
- Drawing the path of light before the water jet and laser experiment

Metacognitive Instance 4:
- Based on the ray model, can you predict how the light is propagated in the jet of water?
- What conclusion do you reach for the predictive capability of the ray model?
- What else do you think you need to integrate into the ray model to better explain the “bedding” of light within a fibre optic?

- Distinguish simple different ways for deviating the light
- Realize that models enhance their interpretive capacity taking into account additional evidence
- Drawing the various paths of light after the water tank and laser experiment

Metacognitive Instance 5:
- Is the drawing you made in agreement with the observed path of light trying to achieve point c in the experiment?
- What additional data do you have, following the experiment, which should be incorporated into the ray model in order to increase its interpretive capacity?
- Could you now, with the enriched ray model, explain the “guiding” of light within a curved optical fibre?
Stage 3 – Expansion of the model

- Understand that refraction and reflection always occur simultaneously at the interface.
- Realize that a model could be upgraded integrating new elements

Expressive modelling:
- Measuring incident, reflection and refraction angles in order to state the law of reflection

Metacognitive Instance 6:
- After processing the experiment data by sending the light “from an optically thinner to a denser” medium, what are the new elements of the ray model that were added?
- With the upgraded ray model you have built so far, can you give an interpretation of how the light is propagated in the jet of water?

- Acknowledge that beyond a certain incident angle value the refraction ray moves parallel to the interface
- Realize the reliance of models on empirical data for making conclusions and developing interpretations.

- Importing digital photos into Cabri virtual environment and calculating refraction index and critical angle, recognising which factors affect its value

Metacognitive Instance 7:
- After processing the experiment data, now sending the light “from an optically denser medium to a thinner”, what are the new elements of the ray model that were added?
- With the improved ray model you've built up, can you now articulate an interpretation of how light is propagated in the water jet?
- With the improved ray model you've built up, can you interpret how the light is "guided" in optical fibres?

Instrumentation and data analysis

In order to elicit students’ epistemological beliefs about the nature, purpose and change of models, semi-structured interviews were conducted with all the students before and after the TLS:

- Nature of a model: (e.g. “What do you believe that a scientific model is?”, and “How accurately should a scientific model represent the reality?”)
- Purpose of a model: (e.g. “What could be the purpose of a scientific model?”), and “How it might be useful?”}
- Change of a model: (e.g. “Is it possible for a scientific model to change? Yes or no? Why?” and “How could this happen?”)

The interview protocols were analysed for each aspect of the models separately, in order to reveal the three levels of the students’ epistemological beliefs (1= naive, 2= intermediate, 3= sophisticated).

Conceptual understanding was also tested before and after the implementation of the TLS by means of a written questionnaire comprising seven tasks focusing on light phenomena:
- Task 1. Vision – Students had to choose among six options which depict how we see on a sunny day, and explain briefly why.
- Task 2. Vision – Students had to say whether Mr. Pantelis and his cat can see in absolute darkness, and justify their answers.

705
Strand 5

- **Task 3.** Reflection on a plane mirror – Students had to choose in which cases the observer sees the lamp in the mirror, and explain why.

- **Task 4.** Reflection on a plane mirror – Students had to choose which animals the observer can see in the mirror, and justify their answers.

- **Task 5.** Coexistence of reflection and refraction – Students had to explain what happens when light hits a still water surface.

- **Task 6.** Refraction (from air to water) – Students had to choose in which cases the spotlight from the air will hit the coin in the water and explain why this happens.

- **Task 7.** Refraction (from water to air) – Students had to choose in which cases the spotlight from the water will hit the butterfly in the air and explain why this happens.

Students’ replies in each conceptual understanding task were classified at levels from 0 to 3 based on the applicability of the ray model (0= incomplete replies and nil answer, 1= no application, 2= limited or false application, 3= correct application of the ray model).

The students’ modelling performance, based on the analysis of their individually completed worksheets, was evaluated according to two criteria: (A) representational clarity, relating to abstractness and coherence of constituent parts and communicative elements of the ray model, and (B) evidential support, referring to consistency between empirical data and the ray model.

A 3-level coding scheme was used to analyse each criterion. These criteria formed the framework of the analysis of the data of this research to highlight the way in which pupils functionally integrate into the ray model relationships, laws and theories necessary for the interpretation and prediction of the studied light phenomena (see Table 2).

RESULTS

Applying the non-parametric Wilcoxon signed-rank test, significant improvement after implementation of the TLS was identified for epistemological beliefs about nature \( Z = -3.78, p = .000 \), purpose \( Z = -3.38, p = .001 \) and change \( Z = -4.00, p = .000 \) of models, as well as for conceptual understanding, regarding Task 1 \( Z = -3.91, p = .000 \), Task 2 \( Z = -3.99, p = .000 \), Task 3 \( Z = -4.24, p = .000 \), Task 4 \( Z = -3.50, p = .000 \), Task 5 \( Z = -2.97, p = .003 \), Task 6 \( Z = -2.76, p = .006 \) and Task 7 \( Z = -2.74, p = .006 \). More than this, positive correlations between epistemological beliefs and conceptual understanding were spotted (see Table 3).

CONCLUSIONS AND IMPLICATIONS

The above results show that, under the impact of the cyclic modelling approach adopted, students developed more sophisticated epistemological beliefs about models and improved their conceptual understanding of light phenomena. Concerning the relationship between epistemological beliefs and conceptual understanding, after the TLS epistemological beliefs and conceptual understanding were found to be interrelated for all tasks except those examining refraction phenomena.

Moreover, modelling performance - as evaluated according the two criteria examined, i.e. representational clarity and evidential support - was found to be interrelated with all aspects of epistemological beliefs except those concerning representational clarity and evidential support during the expansion of model stage and epistemological beliefs about change of model. Also, positive correlations between representational clarity, evidential support and conceptual understanding were spotted for all tasks, except cases concerning tasks examining refraction phenomena and representational clarity during the introduction and the expansion of the model stages and evidential support during the expansion of the model stage. Our findings suggest that representational clarity and modelling support evaluation criteria are likely to be considered as significant influential factors for the formation of epistemological beliefs and conceptual understanding.

We suppose that the process of revising the initial model helped students identify the features of the ray model as well as its strong and weak points for dealing with light phenomena, and understand the need to evaluate and improve models in the light of new findings, especially during the experimentation stage, i.e. revision of the model stage, and that these in turn lead to the advancement of epistemological beliefs about models and facilitated their conceptual understanding about essential aspects of optics phenomena. In this regard, we may argue that the cyclic modelling approach, enriched by metacognitive instances, acted as an explicit and reflective instructional approach in order to establish a more coherent relationship between students’ science learning, learning about science, and doing science.

ACKNOWLEDGEMENT

We express our sincere thanks to the administrator and education staff of the private high school “Plato” for their contribution to this research. We also acknowledge the contribution of the science teacher of the above school, S. Blatsiou.

TEACHING STUDENTS ABOUT CHEMICAL ELEMENTS USING DAILY-LIFE CONTEXTS

Antonio Joaquín Franco-Mariscal, Enrique España-Ramos and Ángel Blanco-López
Universidad de Málaga, Didáctica de las Ciencias Experimentales, Málaga, Spain

Learning the names and symbols for chemical elements is a task that students often find dull, although it is of crucial importance for understanding chemistry. In this respect, the use of games or similar play activities could make the learning experience more enjoyable. This paper presents the results of a study in which two tasks involving play (TIPs) and based on daily-life contexts (football and the home) were used to teach the names and symbols of chemical elements. The experimental group comprised 38 year-10 students who studied this topic through a teaching unit built around the TIPs. A control group of 67 year-10 students followed a traditional teaching approach to the same topic. The effectiveness of the TIPs was assessed using three items, administered pre- and post-test, that explored students’ knowledge about metallic and non-metallic elements and their ability to identify them in their everyday environment. Following the TIP-based teaching unit, students in the experimental group gave a higher percentage of appropriate answers, with the Wilcoxon test indicating significant post-test differences for all three items. However, the Kolgomorov-Smirnov test indicated that the experimental and control groups only differed significantly at post-test in their ability to give the names and symbols of non-metals, with the experimental group performing better. Memorising the names and symbols of chemical elements is a complex task for students, and identifying their presence in everyday environments appears to be particularly difficult. However, the results suggest that the use of TIPs linked to daily-life contexts could help students with their learning of this topic.

Keywords: periodic table, educational games, daily-life contexts

INTRODUCTION

In the context of school chemistry the use of the Periodic Table presents students with a large amount of information about the chemical elements as building blocks of matter. Consequently, its study is an important part of the school curriculum (Quinn et al., 2012; NGSS, 2013; Ministry of Education, 2015). However, as this often entails memorising a long list of names and symbols with no apparent link to everyday life, students consider the task to be a dull one (Martí-Centelles and Rubio-Magnieto, 2014). In this respect, the use of teaching strategies such as educational games (Bayir, 2014; Franco-Mariscal, 2014; Tan and Chee, 2014; Lee et al., 2016) or daily-life contexts could help to enhance students’ learning (Franco-Mariscal, 2015, 2018).

Game-based learning involves using the game as a learning-support tool. The main advantages provided by the game as regards learning chemistry include the motivation induced in students (Lee et al., 2016), which is an element that allows their attention to be captured in the classroom and lead them to a context or problem of a chemical nature to be studied. The game itself enhances a dynamic in class, awakening interest in students and maintaining this interest during the game while also creating a positive competitiveness amongst them.
Another feature of educational games is that students acquire an active learning (Orlik, 2002), with the possibility of applying their new-found learning to a practical situation, thereby allowing them to reason and become self-reliant. A further advantage is the development and promotion of creativity, imagination, and spontaneous learning (Lieberman, 1977; Bruner, 1986).

From a social perspective, various authors agree that games help inter-personal relationships with classmates and to learn in a collaborative manner, thereby working on the emotions, self-control, honesty, safety, attention and concentration on the task (Torres, 2002), all of which help to create a better atmosphere in the classroom. In addition, digital literacy is also favoured if these games make use of ICT tools.

All these advantages mean that educational games are an ideal strategy for learning the basics of chemistry, such as the names and symbols of the chemical elements, in the first stages of learning.

However, it should be noted that learning the names and symbols of the chemical elements should help students to gain a deeper insight into more complex aspects related to an understanding of the Periodic Table, its use and application or its nature rather than merely being restricted to learning it.

Context-based science teaching is aimed at relating the science learned by students to their day-to-day life (Blanco, España and Rodríguez-Mora, 2012) and help them to make sense of the activities they carry out in the classroom or laboratory (De Jong, 2006a,b).

Although it is important to take the context used into consideration (Gilbert, 2006; Fensham, 2009), according to this approach science learning should be related to day-to-day life to ensure that it acquires functionality and attracts students’ interest. According to Finkelstein (2005), there is little gain from separating students’ learning from the context in which it occurs as context is intrinsic to this learning and gives it its form.

With the aim of improving the teaching of chemical elements in the secondary school context we designed a teaching unit comprising 24 one-hour sessions (Franco-Mariscal, Oliva, Blanco and España, 2016) in which educational games and other play activities had a central role. The teaching unit was developed as part of a doctoral thesis at the University of Cádiz (Cádiz, Spain) (Franco-Mariscal, 2011). A new type of educational resource, namely tasks involving play (TIPs), were included in this teaching unit. TIPs can be regarded as intermediate between play and game scenarios and may include artistic or technological creations by the student; they also allow the student to take an active role in the learning process. Many TIPs are based on daily-life contexts. An important difference between TIP and game is that these resources do not involve adaptations of traditional or mass-market games but are original games.

Many games have been developed to teach the Periodic Table (Alexander et al., 2008; Bayir, 2014; Franco-Mariscal et al., 2012; Kavak, 2012; Kurushkin and Mikhaylento, 2016; Martín-Centelles and Rubio-Magnieto, 2014; Moreno, Hincapié and Alzate, 2014) but only a few proposals have used daily-life contexts (Franco-Mariscal, 2015, 2018). The contribution of this work to the field of science education is to show two TIPs based on daily-life contexts providing an interesting approach to active learning in the chemical elements topic, in which
the building of knowledge with playful activities could merge without the need for traditional memorization.

METHODS

TIPs resources

The TIP resources on which this study is based correspond to one part of the teaching unit, which represented a classroom intervention of 3 hours. This paper presents the results of a study in which two TIPs based on daily-life contexts were used to teach the names and symbols of chemical elements. The TIPs elements were carefully chosen to seamlessly merge with the desired chemistry content creating an engaging and fun learning experience.

In the TIP called ‘national football manager’, students were randomly assigned the name of a country that was going to compete in the World Cup, and their task was to select a team of players, represented in this case by chemical elements. Using the periodic table each student had to select as many elements as possible by combining the letters that made up the name of the country they were manager of. For instance, the student participating with Germany could select the following elements as players: germanium (Ge), erbium (Er), rhenium (Re), nitrogen (N), yttrium (Y), sodium (Na), neon (Ne), radium (Ra), argon (Ar), manganese (Mn), radon (Rn) or gallium (Ga), as they can all be formed from the letters in the team name. Each different player “signed” is worth 1 point. Students were allowed to carry out this task with different national football teams. Once they had formed their team, the task became an educational game in which students competed with one another in the different stages of the tournament.

In the other TIP, called ‘identifying household objects and materials’, students had to produce a drawing of an everyday environment with which they were familiar and to indicate different objects and materials in which chemical elements are present. To help students with this task, the teacher gave them a handout they could consult. In the following session, the students described their drawing to their classmates, indicating the object or material in which different elements could be found.

Data collection and analysis

The effectiveness of this approach as a way of helping students to learn the names and symbols of chemical elements was assessed by means of three items:

a) Give the names and symbols of five metallic chemical elements.

b) Give the names and symbols of five non-metals.

c) A large proportion of the chemical elements form part of objects and materials that are present in our daily lives. Try to identify all the chemicals you know (up to a maximum of ten), along with the materials or objects in which they are present in items that you have at home. It does not matter if the elements are components of chemical compounds.

These items were administered as part of a longer questionnaire to two groups of students: an experimental group, who studied the topic of chemical elements via a teaching unit built around the two TIPs, and a control group, who followed a traditional teaching approach to the same topic. Students in the experimental group (38 year-10 students) answered the three assessment
items before taking part in the teaching unit (pre-test) and again one month after its completion (post-test). Students in the control group (67 year-10 students from three different secondary schools in Spain) responded to the same items one month after receiving the traditional teaching approach.

Students’ responses at pre-test and post-test were assessed by establishing a system of categories (appropriate, partially appropriate and inappropriate) (Franco-Mariscal, Oliva and Gil, 2016). For the ‘football manager’ task an appropriate response for both metals and non-metals was when the student could give the names and symbols of five elements; in both cases, giving four names and symbols was considered to be a partially appropriate response. For the ‘household objects’ task a list of 9 or 10 elements or materials was considered an appropriate response, while between 5 and 8 was regarded as partially appropriate.

Data were processed with the statistical software package SPSS 21.0. The Wilcoxon test was used to verify the existence of significant differences in the quantitative comparisons between pre-test and post-test in the experimental group. The Kolmogorov–Smirnov test was used to verify the existence of significant differences in the quantitative comparisons between the experimental and control groups.

Perception data were also collected for the students in this study using a questionnaire to assess the students’ learning experience (Franco-Mariscal et al., 2016), although this will not be discussed further here.

RESULTS

Figure 1 shows the portfolios for two TIP “football manager” students given the teams England and Argentina. As can be seen, these students managed to “sign” 20 players.

Figure 2 shows the work for a student that lists almost all the chemical elements that can be found at home. The strategy used by most students was to draw the various rooms in a house (living room, kitchen, bathroom, bedroom, attic) in detail in order to show the microenvironments in which the chemical elements can be found.

Table 1 lists some examples of objects or materials in the various rooms and the chemical elements they contain, either as a simple substance or chemical compound. The work is completed with other elements typically not found in a family setting, correctly located outside the house, such as scandium in the structure of a space rocket or the presence of radioactive elements such as uranium or plutonium in a nuclear power plant located in the background.

Table 2 shows the percentages of responses in each category for the experimental group at pre-test and post-test. It can be seen that implementation of the teaching unit in this group led to an increase in the proportion of appropriate responses, with significant improvements being observed for all three test items.

In Table 3, which compares the post-test results obtained in the experimental and control groups, it can be seen that the two groups only differed significantly with respect to their ability to give the names and symbols of non-metals, with the experimental group performing better.

**CONCLUSIONS**

Overall, the results suggest that memorising the names and symbols of chemical elements is a complex task for students, and identifying their presence in everyday environments appears to be particularly difficult. However, the significant difference observed between the experimental and control groups on one of the post-test assessment items suggests that the use of TIPs linked to daily-life contexts could help students with their learning of this topic. Although this result cannot be linked exclusively to the TIPs, the fact that the tasks were well received by students supports the conclusion that the game-based approach did at least make a contribution to the observed improvement in learning.

Finally, the limitations of this study should be noted. Although the differences found between the groups should be considered to be small in the two TIPs presented, other TIPs for which the differences were more marked were found in the teaching unit as a whole. This shows that the teacher should make a prior assessment of the design of the TIPs that takes into account the advantages and disadvantages of using the daily life context with the specific topic to be studied.

Another limitation is that the initial level of knowledge of the students in the control group was not assessed. Although the curriculum studied was the same for both groups, and samples of students came from very similar student populations in terms of skills and socio-economic level, the design used did not ensure categorically that the starting knowledge in the control group was similar to that of the experimental group. In this regard, future studies are required that take this variable into account.

AN INTEGRATIVE APPROACH TO OXIDATION PHENOMENA

Teresa Lupión-Cobos¹, Ángel Blanco-López¹ and Rafael López-Castilla²
¹Science Education, Faculty of Education, University of Malaga, Malaga, Spain.  
²Isaac Albéniz Secondary School, Malaga, Spain

Aware of the difficulties that secondary education students experience in developing an integrated view of oxidation phenomena we developed a teaching unit entitled ‘Do I oxidize, too’, the aim of which was to help students understand that the mechanism of oxidation is the same for all forms of matter. This paper presents the results of a pilot study conducted in 2016 with a group of 15 students aged 14 and 15 years and analyses the extent to which the teaching unit improved their understanding of the scientific ideas on which the unit was based. Students were assessed before and after the teaching unit using four open-ended tasks. In order to analyse students’ responses, we first catalogued the scientific ideas that were explicitly addressed by the teaching unit, those which students were expected to have acquired by the end of the study process. We then examined students’ responses across all four of the assessment tasks in order to determine which of the scientific ideas were present either implicitly or explicitly in their answers. The teaching unit helped students either to acquire new ideas or improve some existing ones about oxidation, insofar as they applied them for the first time or made more explicit use of them in their explanations. An example of this is their greater appreciation that living matter can be subject to oxidation. However, few students recognized that oxygen is an important agent in oxidation processes, and although some of them were able to identify certain examples of oxidation they did not link these to a chemical reaction.

Keywords: Oxidation, Integrated approach, Compulsory secondary education

INTRODUCTION

For some years now, science educators from many countries have sought ways of connecting the learning goals set out in school science curricula to students’ lives (Andrée, 2005). A key proposal in this respect is that the teaching of science needs to be structured around real-life contexts that are relevant to students’ lives (Pro & Rodriguez, 2010), thereby increasing their interest in the subject and fostering the development of their scientific competence (Cañas & Martín-Díaz, 2010). In this approach, known as context-based learning (Bennett & Holman, 2002; Bennett & Lubben, 2006; Gilbert, Bulte, & Pilot, 2011; King, 2012, Broman & Parchman, 2014), the learning sequence and the concepts that students need to learn are organized according to their utility for understanding the processes or problems inherent to a given context (King & Ritchie, 2012). This approach has much in common with science-technology-society (STS) education (Aikenhead, 2002) and other proposals for dealing with socio-scientific issues (Kolstø, 2001), since they all consider that the use of real-life contexts can help students engage with the host of different factors — scientific or technological knowledge, reasoning skills, attitudes, ethical and moral aspects, etc. — that are present in everyday situations and/or problems (Sadler & Zeidler, 2005; Kolstø, 2006). In the literature these approaches are widely associated with the development of scientific literacy (Bennett, Lubben, & Hogarth, 2006; Campbell, Lubben, & Dlamini, 2000) and they have underpinned many reforms of school science curricula.
Oxidation phenomena are present in various contexts of daily life (biological, technological, environmental, etc.). Processes of oxidation may affect not only metals like iron (a readily recognizable phenomenon) (Kikas, 2004; Franco-Mariscal, 2012) but also biological matter such as food or living beings (Crujeiras & Jiménez-Aleixandre, 2012). In the latter cases, the underlying chemical process is not immediately apparent to students (Barke, 2012; Shedu, 2015; Bellochi, King, & Ritchie, 2016). From the perspective of health and nutrition education, the study of these phenomena may be linked to the use of preservatives and help to combat the popular (but scientifically mistaken) belief that their presence in food is always harmful (Slaughter & Ting, 2010).

In the Spanish secondary education system (Ministry of Education, 2015), oxidation phenomena are studied in different subjects: in physics and chemistry using a chemical model that students can apply relatively easily to identify oxidation in inert materials and some foods, and in biology and geology using a biological model in which oxidation is a more complex process occurring at the level of cells. In our view, this way of addressing the concept (i.e. from distinct perspectives that are not linked to one another) does not facilitate an understanding among students that the mechanism of oxidation is the same for both organic and inert matter. Thus, aware of the difficulties that secondary students experience in developing an integrated view of oxidation phenomena we developed a teaching unit entitled ‘Do I oxidize, too?’ (López-Castilla & Lupión-Cobos, 2015), the aim of which was to help them understand that the mechanism of oxidation is, from the perspective of an oxygen-based definition (Valanides, Nicolaidou, & Eilks, 2003), the same for all forms of matter. More generally, we sought to develop their scientific competences through reference to real-life and relevant problems and/or situations (Blanco-López, Franco-Mariscal & España-Ramos, 2015). Although some educational research has focused on the process of corrosion exclusively in metals (Corominas, 2007; Heredia, 2011; Franco-Mariscal, 2012; Lazo et al., 2013), we are unaware of any previous reports that have taken a more integrative approach to the study of oxidation phenomena.

This paper presents the results of a pilot study conducted in 2016 with a group of students aged 14 and 15 years and analyses the extent to which the aforementioned teaching unit improved their understanding of the scientific ideas on which the unit was based.

THE TEACHING UNIT

The teaching unit ‘Do I oxidize, too?’ (López-Castilla & Lupión-Cobos, 2015) was based on a sequence of activities designed to improve students’ ability to develop explanations and arguments based on scientific evidence and to encourage healthy lifestyle habits that are supported by scientific research. Additional aims were (1) that students would recognize that we, as living beings, are material systems in which many kinds of chemical reaction (Johnson, 2000 & 2002) (such as oxidation) also take place, (2) that through their knowledge of chemistry they would understand that, from a chemical point of view, oxidation is the same for both inert and biological matter, and (3) that they would recognize that some substances can prevent or delay oxidation.
Figure 1 shows in the form of a flow diagram the core concepts featured in the teaching unit. Oxidation was considered across the spectrum from inert matter through to the biological world, highlighting its consequences in progressive fashion: first through reference to inorganic matter, and then moving on to inert organic matter (food) and, finally, living beings.

Starting with the oxidation of metals, the students had to consider whether only this kind of substance oxidizes. Next, they analysed whether food and living beings (including humans) are also affected by oxidation, and if so, how this might be prevented. Having established that oxidation affects all kinds of matter, the teaching unit provided students with general scientific knowledge about this concept so that they could integrate the two broad domains considered at the outset, that is, the inorganic and the biological.

This framework meant that the content of the teaching unit was organized into four sections. The purpose of the first was to identify students existing ideas and knowledge about the notion of oxidation, specifically as regards the oxidation of iron.

The aim of the next section was to determine the nature of the oxidizing agent in everyday processes and to clarify whether this agent can affect other material systems; here, students also analysed the consequences of this phenomenon in food and examined ways of preventing it through the use of certain additives.

The third section focused on cellular respiration as an oxidative process and considered its purpose and consequences. Finally, a formal definition of the concept of oxidation was
established, thereby enabling students to assimilate the idea of a single mechanism.

In designing the sequence of tasks for the teaching unit we took into account the various stages of the teaching/learning process: focus and clarification of existing ideas, building knowledge on the topic, applying this knowledge, synthesis and recap, and assessment. However, given the way in which the content of the unit was organized (Figure 1), there was not a one-to-one correspondence between sections of the teaching unit and stages of the teaching/learning process, since the content of each section cut across more than one of these stages.

We attempted to ensure that the tasks were varied, and many of them could be carried out independently by students. The tutor nonetheless played an important role, whether as moderator in brainstorming sessions and debates, or by explaining key concepts and helping students to form their own conclusions. Figure 2 shows an example of one of the tasks used in the teaching unit.

Task 1.1. Below are some images of different processes. In which do you think oxidation occurs?

<table>
<thead>
<tr>

Task 1.2. Of the above examples, choose one in which you think oxidation occurs and another in which you think it doesn’t. In each case, explain your reasoning.

Figure 2. Task included in the teaching unit ‘Do I oxidize, too?’ with the aim of identifying students’ existing ideas about oxidation (López-Castilla & Lupión-Cobos, 2015).
METHOD

This was a case study (Yin, 2003) using qualitative and interpretive methodology. The sample comprised 15 year-9 students (age 14-15 years) from a secondary school in Malaga, Spain. The aforementioned teaching unit (‘Do I oxidize, too?’) was implemented as part of the compulsory science subject Physics and Chemistry and consisted of eight one-hour classes.

Students were assessed before and after the teaching unit (pre-test/post-test) using four open-ended tasks that required them to offer evidence-based explanations of certain facts and phenomena related to oxidation. In the first task, students were shown images of various inert and biological material systems affected by a certain degree of deterioration or ageing and were asked to indicate what they had in common.

The second task considered the use of a protective barrier against oxidation of a metal. In the third task, students explored the nature of antioxidants and their effect on health by means of an advertising slogan. The aim of the fourth task was to see whether students attributed different properties to an antioxidant depending on its origin (natural or artificial).

For the analysis of students’ responses, we first catalogued the scientific ideas that were explicitly addressed by the teaching unit, those which students were expected to have acquired by the end of the study process (Table 1). We then examined students’ responses across all four of the assessment tasks in order to determine which of the scientific ideas were present either implicitly or explicitly in their answers. In order to validate this analysis, each member of the research team analysed independently a representative percentage of students’ answers, chosen at random. The level of agreement in categorization among the three researchers was above 85%. Any initial disagreements over categorization were resolved by consensus.

RESULTS

Table 1 shows the results obtained in the pre-test and post-test assessments.

The analysis of results (Table 1) reveals four scenarios:

A. Ideas that only appear at post-test. Students seem to have assimilated the idea that an isolated material cannot spontaneously oxidize alone, since the oxidation process requires the presence of another substance (Idea 1) that may come from the air (Idea 3) or water (Idea 4); a few students equated this other agent with oxygen (Ideas 5 & 12).

B. Ideas that appear more often at post-test: the concept of a barrier (Idea 2, explicitly present in 93.3% of post-test responses vs. 46.7% at pre-test) and its mechanism of action (Idea 16); the possibility of oxidizing biological matter (Idea 10) and living matter (Idea 11); halting cell ageing (Idea 13); and, albeit only implicitly, the utility of antioxidants (Idea 14, 66.7% at post-test vs. 46.7% at pre-test). At the end of the teaching unit a third of students had some idea regarding the presence of natural antioxidants (Idea 15). Although oxidation was implicitly associated with deterioration or change in the appearance of a material, and 40% of students were able to recognize certain examples of oxidation (Idea 17), none of them referred (not even implicitly) to the underlying chemical transformation (Idea 9).
Table 1. Percentage of students at pre-test and post-test whose answers indicated the explicit (EXP) or implicit (IMP) acquisition of each of the ideas about oxidation.

</tr>
</tbody>
</table>

C. Ideas that appear less often at post-test. The proportion of students who implicitly understood that oxidation in air can be a slow process (Idea 7) decreased slightly by the end of the teaching unit.

D. Ideas that do not appear either before or after the teaching unit. This was the case of water as an oxidizing agent and its mechanism of action (Ideas 6 & 8). Neither were the students able to incorporate the concept of a chemical reaction into their explanations of oxidation phenomena (Idea 9), although some of them (especially after the teaching unit) were able to associate these phenomena with deterioration or change in the appearance of a material.

CONCLUSIONS AND IMPLICATIONS

The results show that the teaching unit helped students either to acquire new ideas or improve some existing ones about oxidation, insofar as they applied them for the first time or made more explicit use of them in their explanations. To some extent it also reinforced the chemical model of oxidation, especially from an empirical perspective: students used this model to explain phenomena they observed in daily life and associated them with a transformation of matter (Crujeiras & Jiménez-Aleixandre, 2012), although they did not specifically identify this with a chemical reaction.

This model was also transposed to the biological context, even though, in terms of the phenomena involved, students did not see the similarities between the two processes. The underlying biological (cellular) model remained unclear, although students did recognize that biological matter could also oxidize.
We are aware that these results and conclusions should be treated with caution given the small number of students involved, and also that the teaching unit needs to be refined and improved so as to achieve further gains in students’ understanding of oxidation phenomena. Ideally the two models should be integrated into a single higher-level model that considers electron transfer as the common mechanism underlying the oxidation of any kind of matter or material (Valanides, Nicolaidou, & Eilks, 2003).

ORDER-OF-MAGNITUDE REASONING AS PART OF SCIENCE LITERACY: AN INTERVENTION STUDY

Cedric Loretan¹, Andreas Mueller¹ and Laura Weiss²
¹Sciences Faculty and IUFE, Geneva University, Geneva, Switzerland
²IUFE, Geneva University, Geneva, Switzerland

The Order-of-magnitude reasoning (OMR) has the objective to seek for solutions to quantitative problems, which might be imprecise, but have the correct order of magnitude (expressed as a power of 10, e.g. age of the universe ~10^{10} yrs). OMR might help to get estimates, which are otherwise hard to obtain by precise calculations, or to check the plausibility of a claim or a result. OMR is well known and has an important role in science (“Fermi questions”) and, furthermore, we consider it as an important component of general and scientific literacy, e.g. for checking the plausibility of news and internet sources. In a research and development project for secondary school level, we developed instruments for various aspects of OMR, as well as learning activities and sequences. The intervention is based on worked examples (WE) as a scaffold to learn OMR, with a strong anchoring in teaching practice (existing study plan, etc.). Test characteristics of the instruments are reported (e.g. basic mathematical OMR skills (BS), scales etc., with Cronbach’s α in the interval ≈ [0.6-0.8]). Moreover, the framework and qualitative and quantitative results from a pilot study as well as from empirical comparisons of a treatment and control group (TG/CG) are presented. Comparing TG and CG (with/without worked examples, but with the same lesson plan, duration of intervention, content, and teacher) various positive effects were found. Based on these findings, perspectives for research and teaching practice are discussed.

Keywords: Order-of-Magnitude Reasoning, Science Education, Worked Examples.

INTRODUCTION

Mathematics was and still is an essential tool for scientific work, since its historical rise with Galileo to the present times. Feynman: “[…] it is impossible to explain honestly the beauties of the laws of nature in a way that people can feel, without their having some deep understanding of mathematics” (Feynman 1985, pp. 39-40). True founding link for modern science, as Kant wrote it: "I maintain that in any particular theory of nature, there is science properly so called that as far as mathematics is concerned; ... the theory of nature will only contain true science to the extent that mathematics can be applied to it" (Kant, 1786, p.11), it always aroused a pronounced interest among the scientists themselves (see, for example, Wigner, 1960). However, there is little research and practical application of this founding link in science education.

A way for developing this link is order-of-magnitude reasoning (OMR). OMR uses mathematical tools to seek or to estimate solutions that might be imprecise but give a good idea of the importance of the studied situation. It requires people (e.g. school pupils) to adopt a critical and reflective attitude towards quantitative claims and results, in some cases linked to socially highly relevant questions and problems. A first step to solve such problems is to look for an approximate solution obtained by relatively simple calculations. This kind of approach (so called “Fermi questions”) has an important place in science (Weinstein & Adam, 2008). In
an educational context, OMR tasks have an important potential for a double empowerment of pupils: first, pupils use a powerful tool – mathematics – but its simplified use permits to master many difficulties; second, they find interesting and sometimes surprising results they have been able to discover by themselves. This enables them to overcome a common attitude, i.e. simply “believing” their teacher’s words, textbooks or other sources without thinking: pupils gain access to evidence using their own reasoning. This and further objectives based on OMR are important components of scientific and numerical literacy (see Swiss HARMOS Sciences (CDIP, 2011b), or “Project 2061: Science for all Americans” of the American Association for the Advancement of Science (AAAS, 1989)).

OMR AT SCHOOL

What about OMR in study plans? At an international level, the concept of OMR appears in various projects as for instance "Adult Literacy and Life Skills Survey" (OECD, 2011) and "Statement of Beliefs" (NCTM, USA). The latter states: "Computational skills and number concepts are essential components of the mathematics curriculum, and a knowledge of estimation and mental computation are more important than ever".

However, these prescriptions do not seem to have a great effect in science education and the teaching of OMR is often neglected. Thus, OMR activities are not frequent in classroom. An example of OMR skill that was and still is neglected is the ability to estimate. This is a skill area that was only superficially dealt in the mathematics programs of the eighties (Reys, Rybolt, Bestgen & Wyatt, 1982; Carpenter, Coburn, Reys, & Wilson, 1976) and more than two decades later, there is little change (Siegler & Booth, 2005; Jones et al, 2012. Today in textbooks, there are only a few concrete teaching sequences on this subject. As a result, pupils have difficulties with problems that do not require an exact answer or for which they do not have an algorithm leading to an indisputable solution.

In addition, others serious obstacles stand in the way of developing OMR at school. We mention three main types. A first group of obstacles is conceptual: difficulties in understanding the idea of approximation and order of magnitude, inadequate representation of large and small numbers, particularly when comparing very small and very large sizes (Delgado et al., 2007; Delgado, 2009; Tretter, et al., 2006; Hawking, 1978; Jones & al., 2007). A second group of obstacles deals with technical skills such as the use of the appropriate units, the use of powers of 10, the use of proportionality (linearity and quotient). The third type occurs with the combination of conceptual and technical prerequisites within a given learning content, creating high cognitive load (Van Merriënboer & Sweller, 2005; Sweller, Ayres, & Kalyuga, 2011). Learning OMR is thus complex and teaching it must take into account these obstacles.

HOW TO TEACH OMR AT SCHOOL

To support complex learning while avoiding cognitive overload, one well studied and promising approach is that of using “worked examples” (WE) (Atkinson, Derry, Renkl & Wortham, 2000; Gauthier & Jobin, 2009; see also Hattie, 2009 for a meta-analytic synthesis). WE are learning tasks based on a model solution, being defined as "a step-by-step demonstration of how to perform a task or how to solve a problem" (Clark, Nguyen & Sweller,
The aim of WE is to make learners to understand the rationale and work on the different stages of resolution, giving them growing autonomy. Gauthier and Jobin (2009) list the benefits of WE. First, WE increase self-confidence by understanding the basic principle of resolution procedures. Secondly, WE give sense to the procedures. Thirdly, the use of WE allow identifying the similarities and differences between several examples. Fourthly, with WE pupils anticipate the next resolution step, then confirm their prediction by referring to the targeted example.

The effectiveness of WE has been established in many studies, particularly those related to the reduction of cognitive load (Sweller, 2006) with a significant effect size ranging from Cohen d = 0.62 in secondary education to Cohen d = 0.73 at the beginning of the university (Crissman, 2006). Meta-analyses give a value of Cohen d = 0.55 for learning in general without distinction of discipline, to a Cohen d = 0.7 in science education (Crissman, 2006; Hattie, 2009).

In our research, we study the feasibility of learning OMR through the use of WE in science education.

**STUDY FRAMEWORK, METHOD AND MATERIAL**

For this research, we built a teaching sequence that uses WE to foster scientific literacy and mathematical background. The topics covered are Astronomy, Biology and the History of Earth. These three topics are very convenient to work with large and small orders of magnitude while developing a scientific literacy.

A questionnaire (OMR instrument) was also developed. The latter is divided in 6 subscales, testing pupils’ topical Scientific Literacy and OMR skills like Basic Numerical skills, the use of Spatial and Temporal Scales, the understanding of Units and the Visual Estimation of sizes (Table 1.).

The target level is secondary level’s pupils (end of secondary I / first year of secondary II, ages 14-16, where the topic of OMR are well connected to the curriculum).

The schedule of the research was the following:

(i) A pilot study was run on a first sample (secondary I, ages 14-15, treatment / control group (TG/CG): N=16 / 15) in order to test the feasibility of the approach (OMR & WE, with a traditional test about the sequence content developed by the teacher);

(ii) To validate the OMR instrument, we carried out an item / test analysis followed by an exploratory factor analysis (secondary I and secondary II, ages 14-16, N=120).

(iii) The second study is an experimental, repeated measures design (using the teaching sequence + the OMR instrument) carried out with secondary II pupils, ages 15-16, TG / CG: N = 29 / 30. Results of the latter were analysed by ANCOVA.

The teaching sequence lasted 5 weeks, with an identical instructional design for both samples: TG and CG only differed in whether WE was used or not, with the lesson plan, duration, content, and teacher being the same in both groups.

RESULTS

(i) In the pilot study, performance on a conventional test developed by the teacher (Table 2.) shows a positive effect in favour of TG ($t(29) = 2.19; p = 0.037$, Cohen $d = 0.8$, large effect (Borenstein, 2009).

(ii) Validation of the OMR instrument by classical item / test analysis shows acceptable to satisfactory characteristics (see e.g. Table 3 for internal consistencies) of the 6 subscales of the questionnaire.

To analyze the possibility of regrouping some subscales, we carried out an exploratory factor analysis (Muthén & Muthén, 2012). It yielded three principal factors: the first can be seen as a technical and conceptual factor BSTU based on BS, SSc, TSc and U, the second is a knowledge factor corresponding to the subscale SL and the third containing the subscale VE relates to the perceptual level.

(iii) For the second study, the OMR instrument was used as pre- and post-test for both groups. Table 4. shows the Test Group (TG) and the Control Group (CG) results in the pre- and post-test for the three factors mentioned above. There are no significant differences between results of both groups for all factors in pre-test (p > 0.05), but significant differences in post-test (p < 0.05). Table 5. presents the ANCOVA results for the same three factors and shows positive effect size for the group variable for each factor.

DISCUSSION

The result of the pilot study showed promising results with respect to the effectiveness of using WE for learning OMR (p = 0.037, Cohen d = 0.8). The developed and validated questionnaire for various aspects of OMR (i.e. Basic Numerical skills, Spatial and Temporal scales, Units (BSTU), Visual Estimation (VE), and elements of Scientific Literacy was used for the second study. This second study confirmed the results of the pilot study: independently of the initial level of pupils and their results for the three factors (BSTU, VE, CS) at the pre-test, the test group succeeds better for BSTU, as well as for VE and CS ($\eta^2 = 0.18$, 0.08 and 0.09), corresponding to large and medium effects size respectively (Cohen, 1988).

It is interesting to note that for the factor BSTU, Table 4, also shows that the effect size is bigger for the initial level than for the group. This indicates that whatever the method used, high performing pupils remain high performing and vice versa. There is also a bigger effect size for the initial level in VE. This result is consistent, because if the skills are initially high, they remain so… or that it is what every teacher expects!

These findings are encouraging for the use of worked examples for the teaching and learning of OMR. We are now exploring the reproducibility of these outcomes and the transferability of OMR between domains.

RESEARCH AND EDUCATION COOPERATION EXAMPLE:
EDUCATIONAL PACKAGES OF ERIS PROJECT

Agata Goździk
Institute of Geophysics, Polish Academy of Sciences, Warsaw, Poland

One very promising model of learning designs is the model of Research and Education Cooperation activities. The ERIS project proposes exploitation of research results in school practice. ERIS is EU funded project (ERASMUS+) aiming to increase the interest of pupils in lower and upper secondary schools in science, and the choice of a scientific career. Thanks to the development, pilot implementation and dissemination of educational packages and methodological materials, research results will be exploited in the education systems of at least 3 European countries: Poland, Romania and France. ERIS packages are dedicated to various topics, e.g.: glaciers, earthquakes, geomagnetism, meteorology in the Arctic, UV radiation, etc. They use freely available research databases or results published online, which may be analyzed by pupils with the help of instructions prepared by scientists. The packages include materials for teachers to work with pupils during classes or extracurricular activities. They contain worksheets for pupils and guidance for teachers. 30 packages were tested in schools in Poland, Romania and France. The results of evaluation studies are presented and discussed. Teachers found packages interesting and useful for school practice. They found the tasks for pupils rather difficult, as it was a challenge for pupils to apply a new approach, which wasn’t taught at schools before. Pupils could not solve tasks in a schematic ways, which they often use when solving typical school exercises, and it might have caused difficulties. However, challenging tasks are developing interest and engagement. ERIS packages and proposed teaching approach may be considered as an efficient way of increasing pupils’ interest in science and scientific topics.

Keywords: scientific interest, measurement, secondary school

INTRODUCTION

One very promising model of learning designs is the model of Research and Education Cooperation activities (REC). According to De Haan & Huck (2008) REC stands for a cooperation between at least one research partner (e.g., public or private science or technology research institutes, museums, individual researchers) and at least one educational partner (e.g., schools, individual teachers, pupils or students, teacher education, school authorities). Research and Education Cooperation improves the teaching quality by applying up to date didactic approaches and they raise motivation, performance and ownership of the students in a significant way. To work alongside with the schools may help to attract talented and motivated students (De Haan & Huck, 2008).

According to the recent Report of the European Commission (2015) on Science Education for Responsible Citizenship in conducting the process of science education it is vital to promote a culture of scientific thinking and inspire citizens to use evidence-based reasoning for decision making, and to ensure citizens have the confidence, knowledge and skills to participate actively in an increasingly complex scientific and technological world. These objectives of science education could be met among others with the use of educational materials based on scientific
databases and observations, as a didactic tool going beyond school routine, and contributing to Research and Education Cooperation.

Currently, researchers conducting projects, financed from public funds, especially within European Commission’s programmes, are obliged to disseminate their results and publish them in open access standards (European Commission, 2016). This creates opportunity to increase the attractiveness of science education through the introduction of real scientific results into school practice. To increase pupils' interest in mathematics and natural sciences one should make them aware of the practical importance of science and embed it in the everyday life. Hence, it is important that students in their work use the actual results of tests and measurements.

Even if data are made freely available by professional monitoring institutions, education communities need specific database in relation with pedagogic and didactic aspects: access to the data, illustrate case studies, and select data of interest. Therefore, educational materials based on scientific research results should include not only presentations, videos and descriptions, but should also be based on the latest scientific findings and use analysis of actual measurements and observations. This approach allows students to realize that science has its reference to the practice. However, it requires diligent preparation of good quality, comprehensive teaching materials and educational resources.

**ERIS PROJECT**

One of the current educational initiatives proposing innovative way of teaching STEM by exploitation of research results in schools is ERIS. It is an EU funded project (ERASMUS+) aiming to increase the interest of pupils in lower and upper secondary schools in STEM, and the choice of a scientific career. Thanks to the development, pilot implementation and dissemination of educational packages, research results will be exploited in the education systems of at least 3 countries: Poland, Romania and France.

The ERIS project is conducted by three institutions: Institute of Geophysics, Polish Academy of Sciences (Poland, leader of the consortium), University of Bucharest (Romania), and Universite de Versailles Saint-Quentin (France). Each consortium partner prepared 10 educational packages in national language and in English and tested them in schools in their countries.

ERIS project is divided into 2 parts: testing phase and dissemination phase. In the testing phase teaching materials in the form of 30 packages in national languages (French, Polish and Romanian) and in English for pupils from lower and upper secondary schools were prepared. National packages were tested in schools in each partner country. Packages in English were tested in partner countries and also outside. We invited European teachers for testing and participating in webinars with scientists. Basing on the results of evaluation studies, packages were adapted to the needs of end-users: teachers and pupils.

In the dissemination phase all interested schools in partner countries, as well as in whole Europe, will have the opportunity to take part in the project for free. They will use prepared packages during their lessons and take part in the webcasts of online lessons conducted by
scientist in national languages and in English. Such virtual meetings with scientists will give a closer look at the specificity of scientific work, the measurements and research in the field of mathematics and science. These webinars may also be an inspiration for students and encourage them to continue an independent exploration of science. Moreover, a guide for teachers on the effective exploitation of research results in school with examples of good practice in this area is being prepared.

In addition, in the dissemination phase workshops for teachers are planned, which will increase the level of use of project’s products among schools that have not participated in the testing phase. The success of these activities will be proved by the use of the product in at least 350 schools across Europe.

Furthermore, the project will contribute to the growth of pupils' ability to search for reliable sources of knowledge, which is important in today's world overloaded with information. Usage of modern technologies and forms of communication (e.g. teleconferencing system that allows pupils to participate in international broadcasts) also positively affects the increase of interest in STEM. Participation in the project will allow schools to exchange experiences and establish Pan-European cooperation. Participation in online lessons and usage of educational resources in English contribute to the increase of students’ language skills and expand specialized vocabulary in STEM. It may be very useful for future students of STEM studies, which are crucial for knowledge-based economy of Europe. In the long term, the project will also help to increase the understanding of the language of science and scientific messages.

EDUCATIONAL PACKAGES

In the ERIS project 30 educational packages in English and in three national languages (French, Polish, Romanian) were prepared. National packages were tested in schools in Poland, Romania and France. Each topic was elaborated separately for lower and upper secondary schools. Each package uses different database or set of measurements available online. Each consortium partner selected 5 topics to be presented within educational packages. Each topic was prepared in the form of two separate packages: one for lower and one for upper secondary schools. Each package contains theoretical background and introduction to the topic in the form of presentation, some multimedia and graphics. Additionally, scientists prepared introductory videos with explanations on the topic, which may be broadcasted at the classroom or serve as a preparatory kit for teachers, who are not familiar with the research topic. Practical aspects of conducted research was also presented by scientists – authors of the materials. The important part of each package consists of worksheets with tasks for students, which they may solve, calculate and fill in basing on introduction and available datasets with some necessary guidance from teachers or scientists.

Packages prepared by the Institute of Geophysics PAS

Seismological package “Physics of earthquakes,” developed by seismologist Dr. Łukasz Rudziński, allows to learn about seismology, its observations and measurements. It uses interactive seismological Platform for Anthropogenic Seismicity Research (https://tcs.ah-epos.eu/), which enables to see and analyse real seismic signals recorded by seismic networks.
At least several earthquakes occur every day. Usually the source of tremor is rock movement, but not only. Earthquakes can also be associated with volcanism and even can be triggered or induced by human activity. All of them are continuously monitored by very sensible devices called seismometers. Some of them are dedicated to record local and very small tremors which are not felt by human, while another observe strong earthquakes occurred on the other part of the Earth. Seismometers record seismic waves which are next analyzed by seismologists using sophisticated software and knowledge of Earth structures. Investigation of waves enables scientists to indicate time and location of source as well as strength of quakes and its mechanisms. Further studies describe seismic hazard on specific areas. All this information is essential to understand how earthquakes happen and may help in future in earthquakes’ forecasting.

The package on **ultraviolet radiation**, developed by Dr. Agnieszka Czerwińska and Jakub Guzikowski, informs, what UV radiation is and what factors influence natural radiation from the Sun. It presents threats and benefits, that UV radiation brings to our health, and how can we assess the danger to our skin phototype from current sun radiation. It uses some portals with meteorological data, as well as Institute’s measurements of ozone concentration (http://ozon.igf.edu.pl/). It presents also very useful practical information on how to use sunscreens effectively and how to assess the danger to our skin phototype from current sun radiation. Thanks to the package, which contains also exercises to activate students, one can learn how to use public sources about danger from natural UV radiation. Students may learn what “UV Index” is and how to check its current value (weather forecasts, meteorological data bases, hand-held meters). Furthermore, students learn about skin phototypes classification and its connection with UV Index. They learn also about positive influence of the UV radiation on human’s health, such as a vitamin D3 synthesis and phototherapy. The package allows to gain practical knowledge which can be used in everyday life.

Thanks to the package **“Earth’s magnetic field,”** developed by Paweł Czubak, students are able to answer questions regarding the influence of geomagnetism on life on Earth. Students learn what the Earth’s magnetic field is, define its sources, where the magnetic poles are and discover what actually tourist compass shows and under what conditions it shows falwed measurements. Students get acquainted with the term “magnetic declination” and learn how to calculate declination in a given year on the basis of available data from geomagnetic observatories. Calculations are based, among others, on data from INTERMAGNET, an organization of geomagnetic observatories around the world. Students learn also how to find the maximum and minimum value of the magnetic declination of the day; determine the declination for the date and for certain place; determine the difference between the declination determined from measurements and declination derived from calculator declination.

The educational package **“Glaciers,”** developed by Dr. Jerzy Giżejewski, aims to increase knowledge of the glaciers, beyond standard school textbooks. The package consists of a general part – the introduction of substantive information on glaciers and practical part with worksheets – to be filled in by pupils. General part contains description of glaciers, geographical conditions of their occurrence, presentation of the basic types of glaciers, erosion, transport and accumulation and basic glacial morphology forms. Moreover, it focuses on mass balance of
Strand 5

glaciers and glacial karst, glacier motion, calving, surge, glacial erosion, accumulation and fluvioglacial forms. Practical part of the package includes tasks related to the presentations to be performed by the students. Each exercise allows students to become familiar with the methods of monitoring of various glacial processes and the way of their use. For filling in the worksheets students use sets of measuring data, attached to tasks or obtainable in public free databases e.g. measurements from Hans glacier on Svalbard and data from www.eklima.met.no.

The package “Meteorological measurements in the Arctic,” developed by Dr. Tomasz Wawrzyniak, aims to acquaint pupils with the measurements carried out in the meteorological site next to the Polish Polar Station Hornsund on Spitsbergen, and compare them to the current weather in their hometown. The tasks use meteorological databases available online (e.g. http://hornsund.igf.edu.pl/pogoda) and contains additionally some mathematical puzzles.

Packages prepared by the University of Bucharest

The packages “Elementary particles and fundamental forces,” developed by Dr. Bogdan Popovici separately for lower and upper secondary schools, focus on notions about the Standard Model of elementary particles and the way it is investigated today in research laboratories. By means of lectures, films and applications scientist presents concepts about particles classifications, conservation laws, particles trajectories and particles decays. The exercises accompanying the lectures are inspired and use resources developed by the educational program International Masterclasses http://physicsmasterclasses.org/, which use data from real experiments and visualization tools made available by researchers in the field. The educational materials present current study on the elementary structure of nature, refined after more than a century of modern researches, which is the following: the matter is made up of two classes of particles, leptons and hadrons which interact with each other by means of four fundamental forces: strong force, electromagnetic force, weak force and gravitational force (except the leptons which don’t “feel” the strong force, but only the other three). This set of basic elements and their compounds, which together form the so called Standard Model of elementary particles, allows one to explain the wide range of phenomena we experience from the sub-microscopic scale to the astronomical one and the scale of the evolution of the Universe.

The package “Wind and waves,” developed by Dr. Mircea Zus and Dr. Roxana Zus, proposes to investigate the relation between the direction and speed of the wind and wave formation. We review concepts related to wind characteristics with an emphasis on the most relevant factors for the generation of waves. A detailed characterization of wind waves adapted to the level of study (lower or upper secondary schools) is provided. In the upper secondary school, students study notions on mechanical oscillations, allowing a more detailed investigation of wind waves features. Using free online data available on several forecast websites, the lower and upper secondary students will have to make predictions and as a subsequent step, compare their prediction with real data, on the formation and characteristics of the wind waves, such as the wave height in relation with the wind properties, the propagation direction of the wave front taking into account besides the wind, also the specific geographical characteristics, marine currents etc. For a start, the wind waves’ formation on the Romanian Black Sea Coast is
analysed. Fluid mechanics is an important part of our daily life, bringing contributions in most of the STEM domains. The students need to practically understand the physics behind these complex phenomena.

The package “Sharing data – chasing earthquakes,” developed by Dr. Dragos Tataru, makes use of the interest that earthquakes and seismology raise among children at all ages to teach a range of basic science concepts. Moreover, using real-time data available online instead of static information out of a textbook helps to engage students in STEM subjects. That is why a specific tool for accessing Romanian earthquake data has been developed and is freely available. Additionally, 15 recording locations are in schools, consisting in educational seismographs sending real time event base data to the centralizing application. It is a great opportunity for children to use not only real data but local data in their activities. To analyse data students have to understand records, to pick waves time arrival, to locate epicenter, to estimate amplitude. They use specific software dedicated to educational purposes.

By using the package “Weather – a game between pressure and temperature,” developed by Dr. Vasile Bercu, students become familiar with concepts of meteorology and weather, but also with different databases containing meteorological information. The data manipulation allows them to check different relations between pressure and temperature. Moreover, using simple materials, available to everyone, they are able to build instruments for measuring temperature and pressure.

The package “Digital maps and geographical coordinates,” proposed by Dr. Mircea Bulinski, is combining geography, mathematics, physics and technology integrated into a social and cultural context. Students investigate the geometry of geographical coordinates and how to use the related digital maps to get various type of geographical and socio-cultural information. Concepts related to “Coordinate Reference System” (2D and 3D) and to geographic coordinates (latitude, longitude and height) are reviewed within the package. A theoretical algorithm for measuring distances around the globe is provided (adapted to the level of study – lower or upper secondary schools) and a practical and fun method for measuring latitude and longitude. Also the relations between positions (and distances) on the surface of the globe and a 2D map is discussed related to “conversion systems”, in the context of modern technologies that use GPS tracking systems. Some practical applications as: usage of map for location of various places of interest, using information from databases accessible via the Internet to calculate distances and surfaces, finding important administrative or cultural information are included in the package.

**Packages prepared by Universite de Versailles Saint-Quentin**

The package “Climate,” developed by Dr. Slimane Bekki and Dr. Alain Sarkissian, aims at helping students to understand the concept of climate. The general public is familiar with the notion of weather conditions, commonly known as “weather”, and weather forecasting on a few days scale. The weather is characterized by several atmospheric parameters of which the best known are the temperature, the wind and the precipitations. The weather can vary greatly from one day to another or from one place to another, even if the two places are close enough. We say that weather is very heterogeneous temporally and spatially. The climate represents
meteorological weather but averaged over long periods, typically at least 10 years. The climate is much less heterogeneous than weather, temporally and spatially. On average, we can see several typical climatic zones, strongly dependent on the sunshine: tropical climates to polar climates and temperate climates to medium latitudes. Meteorological observations and models show that the climate has warmed up over the last 5 decades.

The package “Lidar,” developed by Dr. Phillippet Keckhut, presents the Light Detection and Ranging (LIDAR) instrument to measure the parameters needed to understand physics and chemistry in the atmosphere. Students get familiar with two important parts in the operation of the Lidar, measuring the distance and measuring the density of what is being measured. The Lidar makes it possible to measure many things in the atmosphere of the Earth but also of other planets: the ozone, the temperature, the dust, the clouds etc. It emits towards the sky a radius Green (or blue, or red or invisible to the eye) and we look at the amount of light that is diffused through the atmosphere. In this way, several properties are deduced at each altitude, following a measurement principle that is described in this package.

The package “Venus,” developed by a group of researchers (Dr. Mustapha Meftah, Dr. Slimane Bekki and Dr. Alain Sarkissian), helps to understand some operational parts of a space experiment on real example. It uses SODISM, a kind of camera onboard the satellite Picard in orbit around the Earth, which regularly takes photos of the Sun to study its atmosphere. Picard is a French satellite dedicated to Solar studies. The package uses images from SODISM, obtained during the transit of Venus (passage of Venus in front of the Sun for an observer on Earth) to explore the peculiarity of the space experiments.

The package “Mimosa,” developed by Dr. Alain Hauchecorne and Dr. Alain Sarkissian, allows to understand and predict the dynamics of the wind, vortex and the transport of air masses in the polar stratosphere (high altitude, 12-25 km) by using MIMOSA maps. MIMOSA is a model that follows the movement (dynamics) of the air masses in the stratosphere to study its evolution. Since these air masses do not mix with the air masses from below or above, MIMOSA can follow the evolution of these air masses over several days. In the Arctic, in winter (polar night) the stratosphere in addition to not being able to mix vertically, will be caught in a vortex, the polar vortex that will prevent it from mixing with neighboring air masses to create a polar vortex. The package helps to understand the behavior of this vortex.

The package “Polar lows,” developed by Dr. Chantal Claud and Dr. Maxence Rojo, helps to understand polar lows with the use of satellite images. During winter, small cyclones – typically 200 to 600 km in diameter – develop in subarctic regions over areas free of sea ice. The most intense cyclones are called polar lows. These severe storms usually form when polar air is transported over maritime areas. This cold and dry air destabilises the lowest layers of the atmosphere when it arrives over relatively warm waters, creating a polar low. Short-term forecasting of polar lows remains challenging, because they develop very rapidly, in areas with very few observations. The understanding of the formation of polar lows has been substantially improved with the advent of satellite observations. Climate change may potentially affect where and when polar lows will occur in the future.

Romanian, French and English versions of packages will be uploaded to the website by the end of April 2018.

**METHODODOLOGY OF EVALUATION OF THE PACKAGES**

**Testing of packages**

For each package online lessons were conducted, which supplemented the materials prepared by scientists in advance. During webinars scientists were presenting the materials, videos, animations. Instructions on how to use research databases were also delivered. After lessons teachers and pupils were encouraged to work additionally with worksheets prepared for each package.

National packages were tested in lower and upper secondary schools in partners’ countries. Subsequently, English versions of packages were prepared and freely proposed to European secondary schools (not only in partners’ countries). Each package was tested by at least 5 groups of students.

**Evaluation of packages**

In order to assess usefulness of packages in school practice, teachers, who tested them with their pupils were requested to fill in two separate surveys. The data was collected with the use of CAWI Surveys. CAWI (Computer Assisted Web Interviews) research technique is an interview in which participants fill in an online questionnaire or survey received via the Internet (Sharp, Rogers, & Preece, 2002), and is very popular and commonly used method of evaluation.

For each package online lessons were conducted by scientists, who prepared educational materials for packages. After lessons teachers and pupils were encouraged to work additionally with worksheets prepared for each package. Subsequently, they could have filled in the survey dedicated to the materials in the package. This survey contained some statistical questions (type of school, age of pupils, subject taught by a teacher, who participated in testing), four content questions (about importance of the topic, transparency of materials, sufficient explanations and level of difficulty), and two fields for suggestions.

In this paper results from surveys conducted after testing Polish packages in secondary schools in Poland is presented. 20 STEM teachers participated in the testing phase. Each teacher could evaluate up to 5 packages. 32 answers were obtained.

**Evaluation of impact of the project**

The second step of the evaluation was dedicated to the assessment of the general impact of proposed materials and methods on pupils’ skills and interests. This survey was conducted by each partner institution after finishing of testing packages in national languages in Poland, Romania and France. Teachers were requested to assess how many students developed the ability to apply research methods in solving problems in the field of mathematics and natural sciences, and number of students, who developed skills of analytical and synthetic thinking. Moreover, they were also assessing the number of students, whose interest in scientific topics
increased. The results of surveys conducted in all 3 countries are presented in the section Results.

RESULTS

Evaluation of Polish packages

The results are based on 32 surveys obtained from teachers from secondary schools in Poland, who tested ERIS packages in Polish (Figure 1). Teachers declared that packages contain important educational materials (definitely yes: 81%, rather yes: 19%). They assessed the materials included in the packages as clear and transparent (definitely clear: 59%, rather clear: 41%). They also found explanations and instructions for the tasks sufficient (definitely sufficient: 59%, rather sufficient: 41%). Teachers assessed materials included in the packages as generally difficult (very difficult: 3%, rather difficult: 56%, rather easy: 41%).

![Figure 1. Results of evaluation of packages (Total = 32 answers).](image)

Evaluation of impact of the project

The results are based on 44 surveys obtained from teachers from secondary schools in Poland (18 surveys), Romania (23 surveys) and France (3 surveys), who tested ERIS packages in their national languages. Teachers worked with 44 groups of students. Total number of students who tested the packages was 1054 (356 students from Poland, 631 students from Romania and 67 students from France).

The results from the surveys show that the impact of the project on students’ skills and interest in scientific topics is significant. Teachers declared that for 70% of their students, who tested the packages, they observed an increase of the ability to apply research methods in solving problems in the field of mathematics and natural sciences. They assessed that 70% of their students developed skills of analytical and synthetic thinking, with a slight difference between upper and lower secondary schools (result for lower secondary school students is 71%, for upper secondary school students, 69%). Moreover, teachers observed a significant increase in students’ interest in scientific topics. They declared that for 72% of their students interest increased. Some differences between younger and older students were observed. Students from
lower secondary schools became more interested than those from upper secondary schools (73% compared to 70%). Detailed results are presented in Table 1.

**DISCUSSION AND CONCLUSIONS**

The results of the evaluation show that teachers generally assessed the packages positively. In some cases more detailed explanations would be appreciated, but for most users materials were complete and sufficiently descriptive. After the evaluation scientists were requested to update their materials, especially worksheets for students and instructions to tasks. They discussed their materials with methodological expert. Moreover, detailed scenarios of lessons proposed for each topic were prepared by the methodological adviser in the project and will be disseminated in the last part of the project duration.

Most teachers found materials rather difficult or difficult (59% of answers). Authors of materials expected that tasks for students might be found difficult. However, the scientific materials and using research databases are demanding and should be something extraordinary and challenging for students. To boost creativity and analytical and synthetic thinking, it is necessary to propose tasks, which are more demanding than normal textbooks’ tasks. Calculations were probably not difficult for pupils in terms of their mathematical skills. However, it was a challenge for pupils to apply a new approach, which wasn’t taught at schools.
before. Pupils could not solve tasks in a schematic ways, which they often use when solving typical school exercises, and it might have caused difficulties.

ACKNOWLEDGEMENT

ERIS project has received funding from the European Union’s ERASMUS + programme under grant agreement No. 2015-1-PL01-KA201-016622. The content of the document is the sole responsibility of the author and authors of the educational packages and it does not represent the opinion of the European Commission, and the Commission is not responsible for any use that might be made of information contained.

The author of the paper would like to thank to the authors of educational materials for descriptions of packages used in the paper and originally prepared by: Jerzy Giżejewski, Łukasz Rudziński, Agnieszka Czerwińska, Jakub Guzikowski, Tomasz Wawrzyniak, and Paweł Czubak from the Institute of Geophysics, PAS, Poland; Bogdan Popovici, Mircea Zus, Roxana Zus, Vasile Bercu, Dragos Tataru and Mircea Bulinski from University of Bucharest, Romania; Slimane Bekki, Philippe Keckhut, Mustapha Meftah, Alain Sarkissian, Alain Hauchecorne, Chantal Claud and Maxence Rojo from Universite de Versailles Saint-Quentin, France.

STRAND 6: INTRODUCTION

NATURE OF SCIENCE: HISTORY, PHILOSOPHY AND SOCIOLOGY OF SCIENCE

It is widely accepted that scientific literacy includes not only a sound understanding of the central scientific concepts and practices, but also an adequate understanding of Nature of Science (NOS). Students should develop an understanding of the characteristics of scientific knowledge and scientific endeavor as well as of ethical issues related to science. As the submissions to this strand show, science educators all over the world seem to agree that such understanding is important for students on a path toward scientific careers, as well as for every other student, as part of their scientific competence for citizenship.

In ESERA 2017 the strand had a record number of presentations. In total, Dublin City University and the University of Limerick hosted thirteen NOS sessions with 45 presentations, a NOS poster session with 7 presentations, a symposium on nature of science for social justice, and a workshop on an international collaborative investigation on students’ understanding of scientific inquiry. 17 of the studies presented have been accepted for publication in the conference proceedings. The published studies cover a wide range of research methodologies as well as of themes related to the history, philosophy and sociology of science.

One of the most important strands of research concerning NOS has been the study of students’ and teachers’ views, beliefs and conceptions of NOS. The studies published here utilised a domain or topic specific approach: Freire and Motokane mapped teachers’ views about the nature of ecology, Bertoldo and Giordan analysed university students’ conceptions of science and technology, and Hamed, Jimenez and Lederman assessed middle school students’ and preservice science teachers’ understanding about scientific inquiry. Also, most of the content analysis studies shared such a domain or topic specific approach. For example, Ferreira & Custódio analysed how NOS was discussed in undergraduate physics courses, and Bub, Rabe and Krey focused on the topic of responsibility within physics textbooks.

Several studies present new approaches for NOS instruction. Such new approaches include a reflective reviewing café following an out-of-school laboratory visit (Birkholz & Elster) and the use of a movie to discuss bioethics (Badii, Farina & Lorenzo). Some of the studies also include measurements of effectiveness. For example, Michel and Neumann studied the use of an integrated approach to teaching NOS with content knowledge about energy, and Tsybulsky studied the effect of visits to authentic university laboratories and reading adapted primary literature on students’ understanding of NOS. Two studies focus on use of history of science: Marniok and Reiners used examples from the history of chemistry, and Stefanidou, Skordoulis and Stavrou used examples from the history of physics.

As usual, the strand includes also theoretical studies. Two studies discuss NOS and science education from a specific philosophical point of view: Noronha and Gurgel showed how NOS may be related to social realist Michael Young’s idea of powerful knowledge, and Toscano discussed how Wittgenstein’s concept of human knowledge may be applied to science education. Another two studies reconceptualised NOS with respect to technology (Vázquez-
Alonso & Manassero-Mas) and citizenship (Gonzáles-García, España-Ramos, Blanco-López & Franco-Mariscal).

Finally, two studies address intercultural perspectives: Gandolfi investigated how teachers in multicultural secondary schools take intercultural aspects of modern science into account when teaching NOS, and Varkey analysed Kerala science textbooks with respect to NOS conceptions in the discourse around agriculture.

Irene Neumann and Veli-Matti Vesterinen
MAPPING TEACHERS’ EPISTEMOLOGICAL BELIEFS ABOUT ECOLOGY

Caio Freire and Marcelo Motokane
Faculty of Philosophy, Sciences and Letters of Ribeirão Preto – University of São Paulo, Ribeirão Preto, Brazil

As suggested by the literature, there are several tools to identify epistemological views about the science as a whole. However, few focused on the mapping of field-dependent beliefs or views about specific scientific areas, such as the ecology, which has received less attention from researchers. Thus, this study aimed to assess teachers’ epistemological beliefs about professional ecology and school ecology. We designed two questionnaires with Likert five-point scale and carried out a cross-sectional online survey, using non-probabilistic convenience sampling. The sample size was 80 teachers. The factor analysis and the internal consistency analysis (Cronbach’s alpha) allowed to evaluate the validity and reliability of our questionnaires, which is performed only in a qualitative/subjective way by most researchers. In addition, the cluster analysis allowed to map which groups of teachers showed more accurate and sophisticated epistemological views and which presented naïve views. Therefore, the statistical techniques contributed offering more objective criteria for interpretation of the results. We can conclude that many teachers have limited views on some dimensions of the epistemology of ecology. Thus, these efforts can help collect data able to guide more contextualised and effective actions in teachers’ education (pre-service and in-service teacher training) focused on ecology teaching.

Keywords: epistemology of ecology; teacher training; validation of questionnaires

INTRODUCTION

The scientific knowledge is often guided in classroom by an epistemology that enhances naïve views on professional science. The scientific knowledge is presented as a finished product and there is no opportunity to learn about doing science and its construction process (Cachapuz et al., 2005). Thus, the literature has insisted on the distance between doing science and science teaching, highlighting the need to connect these two practices, and consequently, the relevance of epistemological studies in science education. Following this trend, there is a strong tradition of researches dedicated to the development of instruments (questionnaires, interviews) to assess the epistemological beliefs that teachers and students bring to bear in making sense of science (Sandoval, 2005).

Several questionnaires have become references for analysis of epistemological beliefs: INPECIP (“Inventario of Creencias Pedagógicas y Científicas de Profesores”) (Porlán, 1989), VOSTS (Views on Science-Technology-Society) (Aikenhead & Ryan, 1992), VNOS (Views of Nature of Science) (Lederman & O’Malley, 1990). Most of these questionnaires are related to general views on science, and do not assess beliefs about specific disciplines (such as biology, ecology). However, the nature of scientific knowledge production may vary among scientific disciplines, resulting in domain-dependent epistemological commitments (Kuhn et al., 2000). Therefore, it emphasises the importance of designing tools able to map more specific epistemological beliefs within the different scientific disciplines.
Insufficient reflection on the nature of ecology has been identified as an important obstacle to its development in school curriculum. Little attention has been given to philosophical and epistemological questions about the ecology (compared to physics, chemistry or biology), which could be related to three main reasons: i) to be a relatively young science, ii) to have a very wide variety of subfields (study objects and theoretical and methodological perspectives), and iii) to have less researchers engaged in the community of philosophers of science (Wilson, 2009).

Ecology is one of the most recent areas of biology and its establishment as an autonomous professional science began only in the early twentieth century. In 1960, after the environmental crisis, ecology reached the public arena, becoming a slogan, a guide to rethink the relationship between the human society and the environment. The sudden appropriation of ecological concepts to interpret social, political and economic phenomena distorted several epistemological features of this science. For this reason, ecology started to be confused with everything that concerns the environment, incorporating very different knowledge (Mcintosh, 1986).

This confusion also seems to be related to the difficulty in recognizing the ecology as a science able to produce knowledge in a manner similar to other sciences. In other words, there is a difficulty in recognizing that ecology surpassed the methods used by the naturalists, who were concerned only with descriptive and qualitative (broad and detailed) observations of nature and its components. It is important to understand that the ecology diversified its research methods and that these methods are committed to the same epistemic practices and analytical approaches that are easily recognizable in other professional sciences, such as: performing experiments (not just field observations); isolating and quantifying variables; treating data statistically (and with the help of computational tools); constructing models (including mathematical models) and making predictions about phenomena; elaborating theories and generalizations in order to identify more complex patterns in nature (rather than doing case studies similar to those performed by the naturalists).

It means understanding that ecology is not a "philosophy", and cannot be reduced to a holistic and preservationist perspective of nature – the perspective that all living and non-living components of an environment or system interact and that this whole set of components and interactions must be contemplated, studied and preserved in its totality to maintain the equilibrium of this system. Instead, ecology is a professional field of research, and so it needs to make use of these previously mentioned analytical approaches, even if these approaches have certain particularities / specificities (Cannon, 1978; Holling, 1998; Coudun & Gégout, 2006; Wilson, 2009; Martins & Coutinho, 2010; Spiegelberger et al., 2012).

The intention to briefly discuss these epistemological aspects of the ecology is to enrich the reflection on the distance that can exist between the “doing science” and the “science teaching” within this specific discipline, emphasising several important features of the ecology that should not have attention only from historians and philosophers of science. Is the community of biology / ecology teachers aware of these characteristics?

Thus, this study aimed to assess teachers’ epistemological beliefs about professional ecology and school ecology.
METHODOLOGY

We designed two questionnaires with Likert five-point scale: questionnaire 1. “Views on Nature of Ecology (VNE)”, containing nine questions/items to map beliefs about how professional ecologists produce knowledge; and questionnaire 2. “Views on Ecology Teaching (VET)”, containing nine items to map beliefs about how students produce knowledge in ecology classes. We carried out a cross-sectional online survey, using non-probabilistic convenience sampling. The sample size was 80 teachers (who have a degree in biology, and work in state schools of primary or secondary education in the State of São Paulo, Brazil).

The first step was to evaluate the validity and reliability of the questionnaires by factor analysis and internal consistency analysis (Cronbach's alpha). The central premise of factor analysis is that the scores (observed variables) obtained from a questionnaire are derived from some factors (latent variables). Factors are linear combinations of the original variables, being formed to explain the correlations among these variables. So, this technique allows to reduce the number of variables, grouping them into some factors that continue explaining much of the data variance.

The sampling adequacy for factor analysis was evaluated by the Kaiser-Meyer-Olkin index (KMO) and Bartlett’s sphericity test. The extraction of factors was performed by the method of Principal Components Analysis (PCA), and the number of extracted factors was defined by the scree plot and parallel analysis criteria. The extracted factors were rotated orthogonally using the Varimax method, and were named (by the researcher) according to the common meanings of the original variables (questionnaire’s items) grouped. Finally, the Cronbach’s alpha coefficient was calculated for each extracted factor to estimate the internal consistency or reliability of the questionnaires (Hair Jr. et al., 2009).

The second step of the analysis was to map which groups of teachers showed more accurate and sophisticated epistemological views and which showed naïve views. We used the cluster analysis to distinguish these groups. Using the participants’ factorial scores (in each dimension characterised by the factor analysis), we calculated the Euclidean distance among all teachers, and applied the hierarchical method of Ward to divide them into four groups (maximizing homogeneity within each group and heterogeneity among different groups) (Hair Jr. et al., 2009). The cluster analysis generates graphs showing the teachers’ performance (position) in each extracted factor and indicates which teachers belong to which groups.

The content of all items in both questionnaires (Appendix) denotes visions about the ecology that have already been historically overcome (in other words, all items express limited or naïve visions about the ecology). For example, the items in the questionnaire 1 argue that the ecology is an area characterized exclusively by holistic, descriptive and qualitative methodological approaches (based on case studies), and therefore that this area does not have the same epistemological commitments of other sciences (such as the search for quantifications, models, theories, generalizations). These limited views place the ecology much closer to the “natural history” than others currently practiced sciences, and perceive the ecology more as a “philosophy for environmental preservation” than a professional science itself. In relation to the questionnaire 2, the items also defend naïve beliefs, such as: overestimation of the importance of field work and non-formal spaces in ecology teaching; and defence of a
fragmented and linearized ecology curriculum, which is in the opposite direction to the more recent curricular proposals.

Therefore, teachers who disagree with all items of the questionnaires are those who show more current and sophisticated understandings of the epistemology of ecology. The Likert scale levels ("Strongly Agree", "Agree", "Undecided", "Disagree", and “Strongly Disagree”) were respectively converted to the numerical scores: “5.0”, “4.0”, “3.0”, “2.0” and “1.0”. The teachers who disagree with the items are those who have low scores for these items (for each original variable), and consequently low scores on the factorial scores obtained for each factor (new variable) extracted after the factor analysis.

All statistical analyses were performed using RStudio software version 0.99.902 (R Core Team, 2016).

RESULTS

The Kaiser-Meyer-Olkin index (0.71 for questionnaire 1 and 0.60 for questionnaire 2) and the Bartlett's sphericity test (significant at the 0.00 level for both questionnaires) indicated that the correlation among the variables was sufficiently strong for a factor analysis. The scree-plot test and the parallel analysis suggested a two-factor solution for both questionnaires, accounting for 55.1% of the variance in the questionnaire 1 and 47.1% in the questionnaire 2. The factorial solution of the questionnaire 1 showed that the items (questions) 8, 1, 11, 6 and 9 are more related to the first extracted factor, while the items 7, 10, 13 and 12 to the second factor. In relation to the questionnaire 2, the first factor helps to explain the strong correlation among the items 11, 8, 15 and 7, while the second factor groups the items 5, 4, 14, 20 and 3 (Appendix).

The first factor of the questionnaire 1 (VNE) is related to goals of the professional ecology – for example: if the purpose of the ecologists is just to describe the nature in a holistic way or to manage the environment. And the second factor is related to methodology of the ecology – for example: if the ecologists work like other scientists, doing experiments, formulating theories and mathematical models. The first factor of the questionnaire 2 (VET) is about the obstacles to teaching ecology – for example: the many biological levels addressed by the ecology, and the need for many prior concepts to understand ecology. And the second factor is about the goals and approaches of teaching – for example: the goal of changing students' habits towards the environment, with approaches that overestimate the fieldwork and the socio-environmental issues in ecology classes. Thus, the factors of the questionnaire 1 were named: “Factor 1. Goals of the Professional Ecology” and “Factor 2. Methodology of the Professional Ecology”. Factors of the questionnaire 2 were called: “Factor 1. Epistemic Obstacles to Ecology Teaching” and “Factor 2. Goals and Approaches of Ecology Teaching”.

All factors showed reasonable Cronbach's alpha coefficients (factors 1 and 2 of the first questionnaire: 0.76 and 0.78, respectively; factors 1 and 2 of the second questionnaire: 0.62 and 0.64, respectively).

The following graphs (Figures 1 and 2) show the groups formed after the cluster analysis. The first graph divides the teachers into four clusters according to the similarity / dissimilarity among their performances in the two factors (dimensions) of the questionnaire 1, while the
second graph distinguishes the teachers according to the performance obtained in the questionnaire 2.

The group 1 of the first questionnaire (VNE) is composed of teachers who disagree that the ecology is intended to carry out studies similar to those performed by the natural history at the beginning of the last century (factor 1 – horizontal axis). They also tend to disagree with the idea of: (i) the lack of previous goals, hypotheses and theories in ecology research; ii) the impossibility of formulating mathematical models and generalizations to explain ecological phenomena; and iii) the impossibility of designing experiments in ecology studies (factor 2 – vertical axis). Thus, these participants seem to have a more accurate perception of the activity of professional ecologists (Figure 1).

On the other hand, teachers of the group 4 (questionnaire VNE) tend to agree that the goal of the professional ecology is the environmental preservation (the active management of the environment), and the establishment of a holistic and qualitative "look" over the world (factor 1). They also believe that the complexity of the ecological phenomena does not allow realization of experiments and construction of theories, mathematical models, generalizations (factor 2) (Figure 1). This perception (ecology is only able to describe and explain what is recorded at the specific time and place of the research and needs to analyse the whole environment) is a belief that brings the ecology closer to the holistic culture of the naturalists than to the analytical culture of most other sciences. In addition, it is a mistake to understand the ecologist not as the professional who studies the environment but as the one who manages the environment. So, the group 4 showed epistemological conceptions about the professional ecology marked by a strongly "naturalistic / environmentalist" image of this science.

Therefore, group 1 showed the lowest scores, which reflect the most sophisticated epistemological beliefs about the two dimensions (factors) of each construct investigated (professional ecology and school ecology), while group 4 showed the most naïve beliefs. Groups 2 and 3 presented limited (inaccurate) views in only one of the dimensions (factor 1 or factor 2) of each construct.

In relation to the second questionnaire (VET), we observed that teachers of the group 4 tend to agree that ecology teaching depends on many prerequisites, such as prior accumulation of biological knowledge (factor 1 – horizontal axis). This is a position that denotes a more traditional view of teaching, which leads to a more fragmented and linearized curriculum. In addition, these participants argue more strongly that strictly scientific issues do not address the purposes of an ecology class, and that classroom activities should prioritize work with socio-environmental issues and qualitative data (factor 2 – vertical axis). On the other hand, the group 1, according to its position in the graph of questionnaire “VET” (Figure 2) (position with the lowest scores on the two axes/factors), showed more sophisticated epistemological beliefs about ecology teaching. The groups 2 and 3 presented partially naïve beliefs (naïve conceptions in only one of the axes).
DISCUSSION

Most teachers showed a good understanding of some aspects of the professional ecology, but some confusion about other features of this field. Most participants recognise that the work of professional ecologists is not active management of environment and their goals are not only to describe nature (as naturalists did), in a holistic and qualitative way, which constitutes an appropriate view. On the other hand, they believe that complexity of ecological phenomena does not allow to perform experiments and formulate theories, mathematical models and generalizations, which represents a limited (outdated) view on ecology.

Thus, according to the teachers, ecology is not only a philosophy to change our vision of the world and our relationship with nature, but at the same time, ecology is not able to be “scientific” as other sciences (is not able to use an analytical perspective closer to the “other sciences”, for example a perspective focused on experimental and statistical methods). Ecology is placed “in the middle” – in a “dispute” between two cultures: a holistic/naturalistic perspective focused on broader and exploratory approaches, and an analytical perspective.
(closer to the “hard sciences”) focused on experimental and quantitative methods, mathematical/statistical models, generalizations and theories.

Teachers have difficulties to evaluate if ecological studies should emphasise the mechanistic-reductionist tradition of physiology or if the complexity and interconnectedness of the ecological phenomena require a holistic approach, incompatible with laboratories and mathematical models, for example. This “dispute” seems to reflect the history of ecology. Ecology was first described by American plant ecologists as a branch or even as synonym of plant physiology. On the other hand, animal ecologists described the ecology as the “new natural history”. Thus, ecology seems to bring a dispute prior to its origin: the dispute between naturalists and experimentalists (physiologists) of the XIX century (Holling, 1998).

Many teachers showed naïve epistemological views about the school ecology. They defend a linear and fragmented curriculum, which suggests a more traditional view of teaching. More current views support that ecology can be used not as a climax (ending point), but as a “starting point” (integrating axis) of the whole biology curriculum. In addition, teachers expressed naïve beliefs by arguing that: i) learning of ecology can be evaluated by how students interact with the environment (if they have sustainable habits or not); ii) socio-environmental issues are more important than strictly scientific issues in ecology teaching, and that the classes should prioritise working with qualitative data; iii) ecology teaching is meaningful only when carried out in non-formal educational environments. These points suggest that there is a conflation of ecology teaching and environmental education in the teachers’ views.

It is important to point out that the students’ habits towards sustainability should not be interpreted as indicators of ecology learning. First because the ecology classes are not restricted to the relationship “man-nature”, and second because the human behaviour is influenced by several socio-cultural variables not associated with the school knowledge.

Teachers also need to understand the importance of working with scientific issues, quantitative data and mathematical language in ecology classes. It is important to discuss in classroom not only that ecology closer to the students’ daily life, but an ecology that is closer to the professional ecology; it is important for students not only to think about how to solve environmental problems around them, but to learn how to do an inquiry to solve scientific questions, testing scientific hypotheses, collecting and analysing data, constructing models and generalizations about several ecological phenomena, even those that are not so close to the particular context of their lives. It is necessary to bring students closer to typical skills of doing science in ecology, helping them to better understand the epistemology of this area.

Finally, teachers need to understand that field work and non-formal educational spaces are not guarantees of learning. Meaningful learning experiences are not determined by the places where they occur, but by the teacher’s performance and his didactic and epistemological purposes. The lack of resources for field work with the students cannot be used as an “excuse” not to teach quality ecology.
CONCLUSION

We can conclude that many teachers have limited views on some dimensions of the epistemology of ecology. As discussed in the introduction, limited views on ecology may constitute an obstacle to the teaching of this discipline. We need to reflect on the confused views revealed by some groups of teachers, and investigate if they understand ecology as a discipline really focused on preparing students to solve scientific problems through ecological thinking, or if they understand this discipline as "environmental education".

We emphasize that the construction of new tools for epistemological research in educational context is extremely important, and there are few studies in the area that perform a statistical validation of these tools (using, for example, the factorial analysis and internal consistency analysis). As suggested by literature, there are many instruments available for mapping views about science as a whole, but few are focused on the characterization of field-dependent epistemological beliefs.

Thus, our study is important because it allows us to map more specific epistemological beliefs, within an area that has received less attention from researchers – the ecology –, analysing not only the epistemology of the professional ecology, but also of the school ecology. These efforts can help to collect data able to guide more contextualised and effective actions in teachers education (pre-service and in-service teacher training) focused on ecology teaching. It is fundamental to increase the dialogue between epistemological studies and teacher training, and to assess the quality of our country's higher education in this training process. We need to question how our training programs (pre-service and in-service) can contribute to develop most sophisticated teachers’ epistemological beliefs about the various areas of science.

We point out to the need for both future research using other instruments and covering other scientific disciplines, and studies using our questionnaires in other contexts. The first possibility would extend and enrich the discussion about domain-dependent epistemologies, while the second is fundamental to improve and refine the validation of our instruments, offering more data about the potential of these tools.

The next stage of this study is “to assess whether some teachers with different epistemological beliefs (from different groups according to the cluster analysis) have different practices in the classroom to teach ecology”. Thus, the statistical techniques adopted here contributed offering more objective criteria to choose teachers for this next stage, since these participants will be defined from the four groups generated by cluster analysis.

ACKNOWLEDGEMENT

We would like to thank the Esera’s committee, the Postgraduate Program in Comparative Biology of the Faculty of Philosophy, Sciences and Letters of Ribeirão Preto, the research group LINCE (Language and Science Teaching), and the National Council for Scientific and Technological Development (CNPq) for financial support.

REFERENCES

APPENDIX

Questionnaire 1. “Views on Nature of Ecology (VNE)”

Mark the letter that best expresses your opinion for each statement. Avoid mark "undecided". SA - strongly agree; A - agree; U - undecided; D - disagree; SD - strongly disagree.

8. The ecological studies require the joint analysis of all variables related to living things and their environments to understand the nature in its totality / entirety.

1. The ecology requires working with concrete and practical actions of management and conservation (environmental preservation).

11. The ecological results are descriptions or explanations of what is recorded in the specific study area at the time of investigation, reflecting case studies on local realities.

6. Faced with the complexity of its study objects, the work in ecology is broad and explanatory.
9. Ecological data are qualitative data (such as responses to "what/where/when/how/why"-type questions).

7. The setting of goals and assumptions (previous hypotheses, theories, premises) for the ecological research is impossible before field observations.

10. It is impossible to formulate mathematical equations/models for ecological phenomena, considering their complexity.

13. It is impossible to carry out experiments in ecology, considering the interconnectedness and interdependence of ecological systems.

12. It is impossible to formulate generalizations in ecology, since the phenomena depend on many local environmental characteristics (particular conditions).

Questionnaire 2. “Views on Ecology Teaching (VET)”

Mark the letter that best expresses your opinion for each statement. Avoid mark "undecided". SA - strongly agree; A - agree; U - undecided; D - disagree; SD - strongly disagree.

11. Inquiry or problem-solving activities require a prior accumulation of scientific concepts.

8. The ecology teaching is most meaningful when organised respecting the levels of biological organization and addressing the contents separately and from lower to higher levels (organism → population → community → ecosystem → biosphere). For example, concepts related to ecology of organisms should be taught before studying contents of population ecology.

15. The ecology class has lower potential (when compared to other biological disciplines) to teach skills such as "constructing predictions, establishing generalizations".

7. Ecology is effectively taught after students have already acquired a wide repertoire of concepts (prior knowledge) from other biological disciplines.

5. The ecology learning is evaluated as the student's ability to express an opinion on socio-environmental problems.

4. The ecology learning is evaluated as the adoption of more sustainable habits/attitudes towards the environment.

14. The ecology teaching is focused on qualitative answers ("what/where/how/why"-type questions).

20. Field work (for example, visits to some biomes or ecosystems) is essential to ecology teaching.

3. Strictly scientific issues (and not social or socio-environmental issues) are more distant from educational goals focused on development of critical citizens.
STATISTICAL ANALYSIS OF STUDENTS' UNDERSTANDING OF SCIENCE AND TECHNOLOGY IN THE UNIVERSITY OF SÃO PAULO

Raquel Roberta Bertoldo¹ and Marcelo Giordan²

¹Interunit Program of Post-graduation in Science Teaching – University of São Paulo, São Paulo, Brazil
²University of São Paulo, São Paulo, Brazil

This work presents the quantitative stage of research on the analysis of the understanding of science and technology of the incoming students in the Biological Sciences, Physics, Mathematics, Pedagogy and Chemistry courses of the University of São Paulo. We used the statistical technique of Principal Component Analysis on a total of 29 statements that express conceptions of science. The results showed the formation of 10 components that contain between 1 and 6 variables. The grouping also showed that each group (component) has specific characteristics, such as the scientific method or the benefits of science and technology, for example. Three of these groups showed reliability at calculating Cronbach’s alpha and can be tested as indicator of the conception of science and technology.

Keywords: conceptions of science and technology; pre-service teacher; principal component analysis

INTRODUCTION

Analyzing the students’ conceptions of Science and Technology (S&T) in the pre-service teacher is very important, once we can better know the profile of the incoming students at the university, and plan formative actions to develop enlightened conceptions. Therefore, this is important because, as teachers, these incoming students will act in the future in the formation of their students’ conceptions.

We chose to use the term "enlightened conceptions" in order of referring to conceptions that indicate a knowledge of the nature of science, especially regarding its relation with society. Adorno and Horkheimer (1947), in the book 'The dialectic of enlightenment', present some reflections on the relation between man and nature, proposing the demystification of explanations of phenomena to achieve the enlightenment. Dialectics consists on the fact that the enlightenment becomes held hostage by self-enlightenment “[…] the myths which fell victim to the Enlightenment were themselves its products.” (idem, p.5). Thus, from the moment that the science (which originated from myths) becomes the only truth and the scientist gains the status of the holder of knowledge, this science becomes a product.

This way, the enlightenment that would bring the desired liberty is now replaced by estrangement, in which the individual has a false sense of freedom and knowledge, despite being aware that what is presented to him goes through a selection to keep the order. The actual knowledge that reaches the individual, mostly by media, is filtered by the cultural industry that comes with the discourse of bringing the knowledge to the interested ones.

However, the productions are made to serve the need of the public, in order to keep the consumer estranged, unknowingly, conditioned to interests of the dominant's class. According
to Adorno and Horkheimer (1947), for a dominated class, what is seen as a moment of leisure and search for information, is nothing more than the extension of work. The mechanization of industries acquired so much power that “determines so thoroughly the fabrication of entertainment commodities off-duty worker can experience nothing but after-images of the work process itself” (idem, p.109). So that the cultural product to offer pleasure, it should not require intellectual effort from the viewer and it must be in accordance with their habits, their daily life. The product that comes to the consumers is an extension of their life in the factory, that is, one must keep the existing estrangement in the mechanization of labor so that it shields the knowledge that would lead to the emancipation of the dominated class. In this way, the information and programs at large that are accessed by the public (dominated class) should offer pleasure to the viewer, that is, productions that would make the consumer think in a critical perspective or recognize their alienation would not maintain the control that the cultural industry exerts, besides the pleasure that comforts the viewer in his present situation, the language must be simple so as not to require intellectual effort.

When considering such fundamentals, we can discuss how we understand the main theme of this work: the conceptions of science and technology of students. Of the sociocultural theory, we consider that these conceptions are formed by the individual in their social relations. We emphasize in this way that besides the school, the media is an important role in this formation because it is through it the users are informed about happenings that involve knowledge of the S & T area. Moreover, as a form of entertainment, there are several programs of fiction that increase (or create) stereotypes of scientists and transmit an image of standardized science as neutral, objective, with superior knowledge and follow the interests of society.

However, it must be considered that society is structured by classes that are formed from the domination of capital, which in turn controls the processes and the investments that involve the development of scientific and technological knowledge and the media products consumed by the population. That is, in learning about science and technology, the individual has access to materials loaded with ideologies that serve the interests of the dominant class.

Since those conceptions are formed in this historically and socially delimited system, when analyze them considering only processes involving the scientific method and the science internal operation (usually learn in formal scientific education) is insufficient, because analyze the formation of conceptions in a partial way, disregarding informal teaching and social relations formed outside of school. Analyzing from the perspective of Critical Theory requires a position that seeks to identify if the student has enlightened visions so as to recognize the dialectic involved in his formative process of "enlightenment."

In this context, we highlighted the importance of the pre-service teacher to present enlightened conceptions about the nature of science. For this, we present in this work the previous data of our research that aims to investigate the conceptions of students who will work as teachers in science education.

**METODOLOGY**

We conducted a research with students of the Biological Sciences, Physics, Mathematics, Pedagogy and Chemistry courses of the first period at the University of São Paulo - Butantã
campus. We will present here the first stage of our research, which corresponds to the application of a survey on conceptions of S&T and digital literacy, as well as questions about economic and cultural factors. The number of participants who answered the survey was 221, of which 51 were students of Biological Sciences; 35 of Physics; 51 of Mathematics; 37 of Pedagogy and 47 of Chemistry.

The survey was constructed with questions adapted from other evaluation instruments used nationally and internationally, thus contributing to the validation of data. In the survey, there were 45 questions (from a multiple choice or Likert scale) and 297 variables.

In this paper, we are presenting the data of a question of the survey, referring to the theme "visions of sciences", being this question composed of 29 variables. The students should rate the affirmative on a scale of agreement from 1 to 4, where 1 is for "totally disagree" and 4 for "strongly agree".

The statistical treatment used was Principal Component Analysis (PCA). This technique consists in verifying patterns of correlation between the variables and grouping them together, and each group of variables corresponds to one factor (DANCEY; REIDY, 2013). Therefore, each component corresponds to a new variable and thus reduces the number of evaluated variables, according to the pattern of responses and the degree of correlation between them.

According to Maroco (2014, p. 441), using this technique it is possible to summarize the multiple correlated variables - and to some extent, redundant - in independent combinations that represent most of the information and can be used as indexes or indicators of the original variables.

In this paper we present only the components build up, discussing qualitatively their main subjects. Meanwhile, we highlight that we will a two-goal strategy: Cluster's Analysis, which relates to the creation of groups based on their answer's proximity and for the creation of new variables that, from Likert variables with four-point can be calculated quantitative composite variables, raising the chance of parametric tests. To build a composite variable it is needed to verify the reliability between the variables that compose it, estimated by the Cronbach's Alpha, it being an "estimation of the internal consistency from the variance from the items and totals of the test by subject" (MAROCO; GARCIA-MARQUES, 2006, free translate). To sum up, the Cronbach's Alpha measures the reliability of a questionnaire from its internal consistency and variance between the answers. The alpha value may range from 0 to 1, and if this value gets closer to 1, the greater the reliability of the survey. In addition, because this work involves human beings, we can accept values from 0.6.

To define the minimum correlation values so that the variables belong to the component, Dancey and Reidy (2013) have been suggested that the minimum load varies from 0.3 to 0.5. Thus, usually, items with a load greater than 0.4 are used. Because of this, we have been employing this minimal load to our analysis. The authors also advise that to perform the analysis of factors one requires at least 100 cases and that the number of participants is at least five times greater than the number of variables. In this way, it is worth noting that this type of analysis can be applied to our research. The grouping technique was performed using the SPSS program (Statistical Package for the Social Sciences), version 24.
RESULTS AND DISCUSSION

The greater the load of the variable, the greater the proximity and the contribution for the factor, i.e., a factor can contain several variables that contribute to a greater or lesser intensity. Here, the factor analysis reduced the 29 variables to 10 components, that holds a total of variance explained the variance of roughly 63.0%. On Table 1 we show the variance relative to each component.

It is important to highlight that the components were formed through mathematical relationships between variables. When using this data for an analysis in the field of social sciences, it is up to the researcher to establish, in a qualitative analysis, what would be the "common factor" between them, allowing the grouping and thus to name these factors. The data treatment indicated the formation of 10 components. We present each factor separately with the variables, their loads and some considerations, as follow.

Component 01: New technologies will make work more interesting (0.778); Science and technology make our lives healthier, easier and more comfortable (0.726); Due to science and technology, there will be better opportunities for future generations (0.724); Science and technology will help eradicate poverty and hunger in the world (0.625); Computers and industrial automation will create more jobs than eliminating them (0.603); The benefits of science are greater than the negative effects that it may have (0.464). Taking a brief analysis of the components, we noticed that component 01 is composed of 6 variables and, in general, show the benefits of S&T, with positive perspectives on its development. It also shows development traits and its direct impact on society, especially regarding development for comfort and the belief of better job opportunities, highlighting that in the most part the benefits from the scientific development are greater than the negative effects.

Component 02: We can always trust on what scientists say (0.823); Scientists are always neutral and objective (0.789); Scientists follow the scientific method that always leads them to the correct answers (0.761); Whether a new technology offers benefits, it should be used even
if its consequences are unknown (0.460); Science and technology can solve almost every problem (0.438). Component 02 is composed of 5 variables, those present the greatest load, deal with the scientific method and the others consider possible implications of such statements. On this component, variables that are responsible for the science internal operation are correlated, its neutrality and trust in the scientific method. Moreover, with a lesser degree of correlation, it can be seen the impact of this trust on society.

Component 03: Science and technology are increasing the distance between rich and poor countries (0.743); Because of their knowledge, scientists have powers that make them dangerous (0.583); Technological advances are destroying the environment (0.549); High-impact technological applications can generate disasters in the environment (0.426). The component 03, by contrast to the previous ones, contains statements with negative views on the development of S&T in relation to the environment and social inequality. Highlighting the damages of the scientific and technological development on the social inequality and in the environment, and also the figure of the scientist as "dangerous" because of his knowledge.

Component 04: Science and technology have great importance for society (0.687); Science and technology will find cures for diseases such as AIDS, cancer, etc. (0.564); A country needs science and technology to its developing (0.438). The component is composed by variables that address the importance and necessity of the development of science and technology for the society, placing a reliance on research that would bring direct benefits, such as curing diseases that victimize thousands of people today.

Component 05: The government must follow the guidelines of the scientists (0.705); A scientific breakthrough in itself is neither "good" or "bad", what matters is how it is used (0.584); If a new technology offers benefits, it should be used even if its consequences are unknown (0.447). On this component, the main subject presents a pragmatic conception of science that would agree with a possible neutrality of science, putting it as a superior knowledge and that must be followed independently of its consequences. This component also expresses content that involves ethics and control of scientific research.

Component 06: It is necessary for scientists to expose publicly the risks of scientific development (0.701); The population must be heard in the great decisions about the directions of science and technology (0.483); Most people are able to understand scientific knowledge if it is well explained (0.465). This component deals with public participation in S & T directions, the need to the popularization of the science and technology issues in non-specialized language, i.e., scientific dissemination, As further matter, to add participation of the people mainly in controversial decisions that have direct implications in society.

Component 07: Scientists are responsible for their misusing of their findings (0.859); Because of their knowledge, scientists have powers that make them dangerous (0.467); Our society depends too much on Science and not enough on religious faith (0.447). Component 07 contains statements about the knowledge that makes the scientist "dangerous" and responsible for misusing this knowledge. The statement about religion also is related to this thought, proposing that the religious knowledge is also considered.

Component 08: Scientists should have ample freedom to do the research they want (0.714);
Authorities must legally compel the scientists to follow ethical standards (-0.641). This component presents a negative load, meaning that the variables are negatively correlated, i.e., in the opposite way. The eighth component which regards ethics in science as a common theme, but the affirmations present opposing opinions.

*Component 09*: Scientific theories develop and change constantly (0.699).

*Component 10*: Scientific research is not essential for the development of the industry (0.869).

The components 9 and 10 were composed of only one variable that did not present correlation up 0.4 with the others.

The Principal Component Analysis (PCA) is an important tool to check how a large number of variables can be grouped according to the response pattern of the interviewees. In our research, we used PCA to perform the Cluster's Analysis, which separate individuals into groups according to the responses. This group classification is used as the basis for choosing the cases that participated in the second stage of the research, which corresponds to a focus group interview. On the other hand, for the multivariate statistical analysis, the PCA was used so that, from ordinal variables Likert with four points (small scale to be treated as quantitative), we could construct quantitative composite variables. These variables are more interesting from a statistical point of view due to its flexibility to perform a greater number of tests, such as multiple linear regression.

To the establishment of the composites variables, it was necessary to verify if there was reliability between the variables that compose each of the components extracted in the analysis. This is done by determining the Cronbach's Alpha (for components with more than two variables) or by calculating the split-half coefficient (when there are two variables in the component). The type of the calculation used and results for each component are presented in Table 2.

</table>
It was possible to verify that only the first three components had reliability up to (or near) 0.6. It is characteristic of the PCA that the components with a greater percentage of variance explained have more reliability. One of the factors that may have contributed to the low value of Cronbach's alpha in the majority components is the homogeneity of the sample (college undergraduates in science and approximate ages), that is, the answers generally have a tendency to present little variance. Considering that we intend, at the end of our study, to verify the stability of such components as indicators of conceptions of science and technology, we chose to use in our future analyzes only the first 3 composites that present important individual consistency, can be treated as quantitative (from the construction of composites) and represent important topics:

a) Science, technology and society: benefits;

b) Credulity, neutrality and internal operation of science;

c) Problems caused by S & T development.

For testing the relationships of these indicators with sociocultural data, i.e. reading habits, conceptions of science classes, social class, interests and others, we can propose a statistical model that explains the formation of the conceptions of science and technology, verifying what are the main factors may influence them. However, this relationship is not linear, it must be understood considering the structure in which society is organized, the aspects that involve the cultural industry and how the scientific production is realized. These discussions foment the continuation of this research that intends to analyze the conceptions of science and technology from a Critical Theory' perspective.

CONSIDERATIONS

The analysis of factors is very important for the reduction of variables number from their correlations. The data treatment indicated the formation of 10 components trough from 29 variables. These factors have particularities that characterize them. We also point out that what was discussed here, corresponds to only one technique, which groups the variables according to the correlation of the responses, it means, the same tendency in the classifications, but without analyzing the correlation intensity (agreement or disagreement of each affirmative). We emphasize that this is a preliminary study and in the future, we intend to select variables for the realization of the PCA in order to reduce them to a smaller number of components, higher Cronbach's alpha value and a greater percentage of explained variance, making the component the best candidate the indicator.

Another point to be highlighted is that the of the technique is a very important to be used preliminarily to other studies, such as the formation of clusters and the transformation of a Likert scale of few points in the construction of a quantitative composite variable. We emphasize technical relevance in the area of science education, highlight that multivariate statistics still need to be better explored in the area.

SCIENTIFIC INQUIRY VIEWS IN SPANISH MIDDLE SCHOOL STUDENTS AND PRE SERVICE SCIENCE TEACHERS: A COMPARISON

Soraya Hamed¹, Juan Jimenez² and Norman G. Lederman²
¹University of Seville, Seville, Spain
²Illinois Institute of Technology, Chicago, Illinois

The aim of this study is to analyse and compare future science teachers’ and middle school students’ views of scientific inquiry. A total of 159 middle school students and 100 future science teachers from Spain participated in the study. The Views about Scientific Inquiry [VASI] (Lederman et al., 2014) was used to assess participants’ scientific inquiry views. The instrument covered various aspects of scientific inquiry which are “Scientific Investigations All Begin With a Question”, “There Is No Single Set or Sequence of Steps Followed in All Investigations”, “Inquiry Procedures Are Guided by the Question Asked”, “All Scientists Performing the Same Procedures May Not Get the Same Results”, “Inquiry Procedures Can Influence Results”, “Research Conclusions Must Be Consistent With the Data”, “Scientific Data Are Not the Same as Scientific Evidence Collected” and “Explanations Are Developed From a Combination of Collected Data and What Is Already Known”. The baseline data will provide, on the one hand, information on what students learn about inquiry in elementary school, as well as their beginning knowledge as they enter secondary school and, on the other hand, information on what future science teachers know about inquiry when they begin science method course in the Primary Education Degree.

Keywords: scientific inquiry; assessment; knowledge of inquiry

INTRODUCTION

Scientific literacy extends beyond knowing the scientific concepts and methods of scientific inquiry. One goal of scientific education has been to try for years to help people gain a functional understanding of the body of scientific knowledge for their needs, interests and abilities (AAAS, 1993; Millar, 2004; Lederman, Lederman & Antik, 2013).

Scientific inquiry (SI) has been a perennial focus of science education for the past century and it generally refers to the combination of general science process skills with traditional science content, creativity, and critical thinking to develop scientific knowledge (Lederman, 2007).

Some authors indicated that the knowledge of scientific inquiry, no matter how developed, is not enough to guarantee that these concepts are necessarily manifested in the classroom practice (Lederman, 2007, Bartos and Lederman, 2014). According to Schwartz et al. (2004) SI is related to the specific aspects of the process of development of scientific knowledge, including the conventions for the acceptance and utility of scientific knowledge. Scientific Inquiry in Science Teaching is evidenced directly into pedagogical proposals that adopt research as models of teaching and learning. Quoting National Research Council (NRC, 2000) and The Next Generation Science Standards (NGSS Lead states, 2013), Crawford asserts that teaching sciences as inquiry:
[... ] involves engaging students in using critical thinking skills, which includes asking questions, designing and carrying out investigations, interpreting data as evidence, creating arguments, building models, and communicating findings in the pursuit of deepening their understanding by using logic and evidence about the natural world (Crawford, 2014, n/p).

Current science education reform documents emphasize the importance of students developing the abilities adequately to do inquiry as well as have informed visions about Scientific Inquiry (American Association for the Advancement of Science [AAAS], 1993; National Research Council [NRC], 2011). But, students in general believe in a distorted and reductionist view of scientific inquiry that is due to different reasons (school context, the media, so on) (Lederman, Lederman & Antik, 2013). On the other hand, students and future teachers should be able to understand how scientists do their work and how scientific knowledge is developed, critiqued, and eventually accepted by the scientific community. This process is scientific inquiry. The content standards for Science as Inquiry advocate the merit of students developing (a) the abilities necessary to do inquiry and (b) understandings about scientific inquiry (NRC, 2000). Thus, participants need to be able to not only “do” inquiry, but also “know” about inquiry. Although conducting inquiry, or the process skills of science, is important, students can often do inquiry without knowing how and why scientists go about their work. The efficacy of such implicit approaches to developing understandings of SI, and for that matter Nature of Science (NOS), have been called into question by a growing body of research (e.g., Abd-El-Khalick & Lederman, 2000; Akerson et al., 2000; Lederman et. al., 2013; Lederman & Lederman, 2004; Schwartz et al., 2002; Schwartz et al., 2004). Therefore, it is important to identify and explicitly teach the aspects of scientific inquiry that can serve, in the end, to develop informed views of inquiry.

In Spain, Scientific inquiry has been introduced in the classroom and in the curriculum through different programs in teacher training and in-service teachers. However, there are no evidences whether, in fact, the students achieve an adequate understanding of the scientific inquiry. Furthermore, little research has been done on Understandings of Scientific Inquiry in teachers. One of the fundamental reasons for this lack of research is the lack of adequate, valid, and reliable instruments focusing in understanding scientific inquiry. For example, Lederman et al. (2014) provide a valid and reliable instrument (the Views About Scientific Inquiry [VASI], questionnaire) derived from the Views of Scientific Inquiry [VOSI] questionnaire (Schwartz, Lederman, & Lederman, 2008) and. this instrument, focus on understanding about inquiry and students’ actions while engaged in inquiry activities. Hence, the aim of the study was to analyse and compare future teachers and seventh grade students’ understandings of SI in Spain using an open-ended instrument, Views about Scientific Inquiry [VASI], (Lederman et al., 2014).

METHODS

Seventh grade students from three public middle schools (n = 159 in Andalusia were selected to participate in this study. Two schools from Seville and the other from Granada, Spain. The Spanish educational system divided the educational levels into primary and secondary education. For Spain, middle school corresponds to the last years of primary school and the first years of secondary school.
In addition, a sample of 100 pre-service teachers from the Faculty of Educational Sciences of the University of Seville were selected to participate in this study. The pre-service teachers belong to the cohort just before entering to practicum at schools. They received several science content courses and teaching methods in science in the previous three years. College students who apply to become a science teacher in Spain after passing a coursework which included science method courses and other disciplinary courses where the aspects of scientific inquiry are not taught explicitly. All participants were chosen based on socioeconomic status and their representativeness of Spain. In general, they come and serve young people from an unfavorable and favorable economic, social context. Furthermore, both samples have similar gender average representation.

The VASI Questionnaire (Lederman et al., 2014) was utilized to establish a baseline of Spanish learners’ knowledge about SI. The questionnaire is a valid and reliable instrument composed by seven open ended questions targeting the knowledge of eight aspects of Scientific Inquiry. Validity for the instrument is reported as 100%, and reliability using the inter-rater agreement method is reported as over 90% in each question. Both values are adequate according to the nature of the instruments and international conventions for open ended questionnaires. For the goal of this research, the VASI questionnaire was translated into Spanish and then back translated into English for validity purposes. The aspects analysed were (Lederman et al, 2014): (1) Scientific investigations all begin with a question; but do not necessarily test a hypothesis; (2) There is no single set and sequence of steps followed in all scientific investigations; (3) Inquiry procedures are guided by the question asked; (4) All scientists performing the same procedures may not get the same results; (5) Inquiry procedures can influence the results; (6) Research conclusions must be consistent with the data collected; (7) Scientific data are not the same as scientific evidence and (8) Explanations are developed from a combination of collected data and what is already known.

Most of the students, both seventh grade and pre-service teachers, had no difficulties in answering the VASI questionnaire. All students presented no difficulty in reading, understanding, and answering the VASI questions during a period of 60 minutes. After that, two researchers participated in the coding and scoring process. Each researcher analysed each answer in each questionnaire independently and scored each response as naïve (N), mixed (M), and informative (I). Blank responses were coded as non-response (NA) according to the level of understanding that the participant show in their answers. Then, scores were compared between the two researchers and disagreements were discussed. The expected reliability for the inter-rater coding agreement for each aspect for the VASI study was 80% because we were measuring cognitive outcomes and also by typical international convention. In this case, the first value for the overall reliability was 81.17%. After discussing the differences, new reliability values were computed achieving overall reliability of 94%. Finally, as part of the research protocol 20% of students in each sample were interviewed. For the interviews, students were selected according to the overall score that they got when they answered the VASI questionnaire and, also, according to the level of unclear answers in the questionnaire. After the interviews, the questionnaires were scored again, however, no significant changes were observed.
This paper is part of the group of research studies coordinated by Professors Norman Lederman and Judith Lederman. This group is developing international research that is using the VASI questionnaire to evaluate the understandings about scientific inquiry among elementary school and high school students in different countries. The results presented in the present study refer to data collected in Spain plus more data collected from pre-service teachers.

RESULTS

In general, most of the seventh grade Spanish students and pre-service teachers show mostly naïve or mixed knowledge of the aspects of Scientific Inquiry (Figures 1, 2 and 3). In other words, a Naïve view shows a low level of understanding of scientific inquiry aspects, wrong answers, or answers showing misconceptions related to the aspects. On the other hand, a mixed answer shows unclear or incomplete answers that make difficult to score them as informed or naïve. In most of these cases, interview protocol was used to get clarification from the participants after answering the questionnaire during the interview process. The seventh-grade students showed the most naïve views respect to the scientific inquiry in “no single method” (83.6 %), “data different to evidence” (78 %), and “explanations are developed from data and previous knowledge” (73.6 %). The most informed aspects for the seventh-grade students were “conclusions consistent with data collected” (37.7 %), and “procedures guided by the question” (32.1 %). In the last case, informed views were under of 50 % of the students. That means, only few students were able to provide an informed view for those aspects. On the other hand, for the pre-service teachers, the most naïve scientific inquiry aspects were “not a single method” (70 %), “explanations are developed from data and previous knowledge” (42 %), and “conclusions consistent with data collected” (38 %). On the other hand, the most informed views were “same procedures, different result” (74 %), “procedures are guided by the question” (54 %), and “scientific investigation all begin with a question” (54 %). In the case of the pre-service teachers, three aspects showed mixed views. That means, the answers were not clear enough evidencing a lack of clarity in their answers. These scientific inquiry aspects were “data differs from evidence” (78 %), “the procedures influence the results” (72 %), and “explanations are developed from data and previous knowledge” (54 %).

Details of findings

Below we present the detail for each aspect of scientific inquiry.

1. Scientific investigations all begin with a question and do not necessarily test a hypothesis

Related to Begin with a Question. Most 7th grade students (65.4 %) show a naïve view about the importance of the questions to begin a scientific investigation and only 12.6 % of students show an informed view to this aspect. Some students mentioned that the questions are not important because scientific research can begin with the observation of a phenomenon, problem, experimentation or even testing. 17.6 % have a mixed view about this aspect and 4.4 % of students did not answer the question. On the other hand, 30 % of the future science teachers do not mention that the questions are an important aspect to begin an investigation.
(naïve view), 14 % expressed a mixed answer about this issue and 54 % have an informed view for this aspect.

2. There is no single set or sequence of steps followed in all investigations

No Single Method: 83.6 % of students think that there is just a single scientific method and only 15.7 % expressed a mixed response about it. No student expressed that scientists can use more than one method to do science. It seems that students have a reductionist view about the scientific method. Only 0.6 % did not answer the question. In the same way, most future teachers (70 %) have a naïve view about this issue, they do not explain the existence of more than one method to do science. Furthermore, 18 % have a mixed response and only 12 % have an informed view.

3. Inquiry procedures are guided by the questions asked

Procedure guided by Question: Only 32.1 % of the students show an informed view related with procedures are guided by the question asked. On the other hand, 54.1 % of the students have a naïve idea about the procedures are designed to answer a question and 8.8 % students showed mixed idea. Only 5 % did not answer this question. 54 % of future teachers have an informed response about this aspect, 32 % have a naïve idea and only 14 % express a mixed answer.

4. Inquiry procedures can influence results

Procedure influence the Results: Only 16.4 % of the students think that in from to the same procedures, the researchers can interpret the conclusions differently and get different results because of subjectivity and previous knowledge. On the other hand, 68.6 % of the students think that when the scientists do the same, they have to get the same results. 11.3 % of the students have a mixed view for this aspect and only 3.8 % did not answer. On the other hand, 74 % of the future teachers have an informed view about this aspect, 14 % gave a naïve response and 12 % a mixed answer.

5. Procedures guided by the question asked

Related with the importance of scientific question to guide the procedures in a scientific investigation, only 32.1 % of the seventh-grade students answered correctly the question related with the tires. 54.1 % of the students have a naïve idea about the procedures are designed to answer a question and 8.8 % of the students showed mixed idea. In that group, students were able to identify the correct procedure, but they could not justify it. In the case of the pre-service science teachers, the results show that 54 % of the pre-service teachers have an informed view respect to this aspect and 32 % showed a naïve view about the importance of the question guiding the procedures in a scientific investigation. It is important to notice that 14 % showed a mixed view related with the aspect.
Figure 1. Percentages of students and knowledge by aspects of Scientific Inquiry

Figure 2. Percentages of science future teachers and knowledge by aspects of Scientific Inquiry
Figure 3. Comparison of percentages obtained from students and science teachers by aspects of Scientific Inquiry

6. Research conclusions must be consistent with the data collected

Conclusions consistent with Data: Only 37.7 % of the students present an informed answer to this question. However, more than 47.8 % still show a naïve answer. Also, 10.7 % show a mixed answer and 3.8 % did not answer the question. This could show little ability of students to critically interpret tables and graphics. Similarly, 50 % of the future teachers show an informed view, 38 % a naïve view, 10 % a mixed response. Only 2 % did not answer.

7. Scientific data are not the same as scientific evidence

Data differs from Evidence: Most of the seventh-grade students (78 %) are not able to explain the difference between data and evidence. Showing that, for most of them, data and evidence is the same. 17 % have problems to define one or another term. Only one student (0.6 %) explains correctly the difference between the two terms, and 4.4 % did not answer the question. In the same line, 78 % of the future teachers show a mixed view, and 12 % showed a naïve response. Only 4 % of the pre-service teachers have an informed view. In other words, only 4
% are able to define and differentiate data and evidence as different terms. Finally, 6 % did not answer the question.

8. Explanations are developed from a combination of collected data and what is already known

Explanations developed from Data and existing Knowledge

None of the seventh-grade students was able to provide an informed answer for this question. Again, more than half of the students show a naïve answer for this aspect (73.6 %) and 23.3 % showed a mixed answer for this aspect. Furthermore, only 3.1 % did not answer the question. Similar to the category Conclusions consistent with data collected, students seem to have difficulties interpreting the information in charts as well as having a naïve conception of it. On the other hand, 54 % of the future teachers have a mixed view, 42 % have a naïve response, and 4 % did not answer. In this case, seventh-grade students and pre-service teachers show important deficiencies providing logic explanations using data provided in the question and using their previous knowledge to generate those explanations.

CONCLUSIONS

In general, Spanish students show a naïve view, over 50 %, for all aspects of scientific inquiry. In the same way, we see that the future teachers show mostly mixed and naïve ideas. When the views are informed they are barely above 50 %. One of the reasons for this result is the lack of an adequate understanding of students and future science teachers about science and scientific inquiry (Lederman, Lederman & Antik, 2013).

The results emphasize, mostly, the view that there is a single scientific method and the difficulty distinguishing between data and evidence by the students and teachers. Students in our educational system seem able to use scientific reasoning, but they are unable to understand the phenomena that affect them in their day to day lives. Another reason that may explain these results is related to teaching methods and content. The lack of SI as relevant to science curricular content, lack of adequate understanding of the aims and objectives to facilitate their inclusion in science lectures, resistance against reforms and educational innovations, lack of an explicit and reflexive teaching of scientific inquiry, lack of effective teaching approaches to teaching scientific inquiry, and performing scientific inquiry reflective activities (exploration, analysis, debate, discussion, argument, so on).

On the other hand, informed views of “conclusions consistent with data collected” corresponding to 37.7 % (60 students) and 50 % (25 future teachers) can be explained because they learn how to create and interpret data tables in science and mathematics classes. Another aspect with a high percentage of informed answers was procedure guided by question 32.1 % and 50 %. This could be explained because students and future teachers have to work in laboratories and take decision related with strict protocols during experiments. Additionally, in the case of future teachers, they attended science subjects in their pre-university stage.
IMPLICATIONS

Teachers: Considering the importance of “understanding” scientific inquiry as part of scientific literacy, teachers must implement teaching strategies that promote not only “doing” inquiry, but also “understanding” scientific inquiry. Nowadays, inquiry is considered an important part of the curriculum and it must be taught as another content in the science curriculum. Many science educators recommend to address understanding scientific inquiry using an explicit/reflexive approach in the classroom. In other words, science teachers must be able to teach or incorporate the aspects of scientific inquiry in order that the students can recognize how the scientific knowledge is produce and how this knowledge is translated into our daily life.

Teacher educators: Academic programs for pre-service teachers and professional development programs for in-service teachers must consider incorporating the teaching and learning of the aspects of scientific inquiry. In the same way, those programs have to consider several ways how to translate the knowledge and understanding of scientific inquiry aspects into the classrooms. Focused activities can promote the understanding of the aspects of scientific inquiry, however, teachers need to know them in order to teach them. The only mention of those aspects in the curriculum will not necessarily mean that the teachers will automatically teach them to the students. first, teachers need to know them and understand.

Researchers: Given the results, that the understanding of scientific inquiry aspects are pretty similar between seventh grade students and pre-service teachers, researchers can now look at other curricular and pedagogical approaches to reinforce the explicit teaching of these aspects. Also, focused professional development for in-service teachers based on how to address the scientific inquiry aspects can be developed to promote the understanding of SI. Researchers can design effective programs and check their effectivity. Besides, intervention studies can be applied in pre-service teacher programs or school classrooms.

Policy makers: The incorporation of "understanding" of scientific inquiry is still an issue related to educational policies. Curriculums around the world incorporate or include "inquiry" as part of science curriculum. However, it is not clear if the definition of "inquiry" is adequate or those curriculums are referring to "doing" inquiry, "understanding" inquiry, or "inquiry" as a pedagogical approach. The lack of clarity or a clear definition in the curriculum documents also promote the confusion about what inquiry is or its importance related to the objective of teaching science at schools. Policy makers should be able to identify and clarify why understanding scientific inquiry is important for the citizens and why scientific inquiry should be promoted in the classrooms in order to create policies that allow to promote not only the development of process skills, but also, do and understanding scientific inquiry.

REFLECTIONS ON THE NATURE OF SCIENCE IN UNDERGRADUATE PHYSICS COURSES IN BRAZIL: BRIEF PORTRAYAL OF CURRENT CONFIGURATIONS

Gabriela Ferreira¹ and José Custódio²

¹Universidade Federal do Paraná, Pontal do Paraná, Brazil
²Universidade Federal de Santa Catarina, Florianópolis, Brazil

In this work our purpose was to map the offer of disciplines with discussions on the nature of sciences and scientific work in undergraduate physics courses (UPC) in Brazil, providing an analysis based on legislation and directives regulating the offer of courses, searching the intentions to propose debates on the nature of sciences. To that end, we attempt a brief sketch of current configurations for 138 UPC courses relative to the offer of 375 disciplines with discussions concerning subject matter. From the results we conclude that despite what is indicated in guiding and legislative documents for this kind of discussion, the scheduled time for disciplines addressing the subject is still very low (4.5% of the total scheduled time in courses).

Keywords: training of physics teachers, nature of sciences, undergraduate physics courses

INTRODUCTION

In science education, there is a concern for and defense, by lecturers and researchers, of a teaching that allows understanding of the nature of sciences (NoS) and of the principles of scientific research, taking into consideration essential aspects such as the purpose of scientific work, the nature of scientific knowledge and the idea that science is social endeavor, valuing thus the perception of sciences as a human activity, permeated and conditioned by ethical, economic, political and cultural values (Martins, 1990; Salinas De Sandoval; Colombo De Cudmani, 1993; Matthews, 1995; Driver et al., 1996; Gil-Pérez et al., 2001; Duarte, 2004; El-Hani, 2006; Martins, 2007; Pereira; Martins, 2011).

In that sense, emergent themes in philosophy, history and epistemology of the sciences contribute to build a more rich and evaluative image of science, so long as these discussions are adequately appropriated by science teachers in training and exercising (Matthews, 1994). The guiding and legislative documents on training of teachers in Brazil mention the need to work on questions concerning gnoseology and epistemology of knowledge. Although brief, this indication motivates including reflections of this kind in courses, converging with indications by researches in the field of science teaching concerning the importance of these aspects to a more adequate understanding of the essence and origin of scientific knowledge (Brasil, 2015). In this work, our purpose is to map the offer of disciplines with discussions on the nature of sciences and of scientific work in undergraduate physics courses (UPC) in Brazil, providing an analysis based on legislation and directives regulating the offer of undergraduate courses in physics, as well an analysis based on the theoretical frame.
METHODOLOGY

We develop a documentary research in the Pedagogical Course Projects (PCP) and Curricular Matrices (CM) of undergraduate physics courses in public institutions of higher education in Brazil. This phase of the investigation occurred in the periods from October 2015 to October 2016 and it covers a sample of 138 courses, 87 institutions from a universe of 186 courses and 111 institutions, i.e., approximately 74% of the courses on offer, from approximately 78% of the institutions, in face-to-face modality.

We restrict this research only to face-to-face courses and to public institutions of higher education, eliminating courses in the distance modality and private institutions, or interdisciplinary undergraduate courses which include Physics, or other teacher training courses, for the following reasons:

- Low regularity and representativeness of courses in the distance modality and of courses offered by private institutions (only 20%).
- Broad range of training in interdisciplinary courses (offer training in more than one area) that make the analysis difficult).

After defining the universe of courses, we searched for disciplines which presented the debate about nature of science in their contents. The keywords used in this investigation, still in the pre-analysis phase, were:

- history, philosophy, epistemology and sociology of science(s) and physics and their correlates;
- nature of science(s) and scientific nature;
- scientific thought, scientific activity, scientific practice, scientific work;
- evolution of science(s)/physics, evolution of physics ideas, evolution of scientific knowledge and their correlates.

In our understanding, the presence of these keywords in the title and programs text could provide evidence of the presence of discussions about aspects of scientific activity and the nature of the sciences in these disciplines. The data were classified by: the schedule for the course on offer, year of implementation of the last version of the course’s PCP, total scheduled time of the course and scheduled time for the discipline, semester of offer or periodization of the discipline, the compulsory or optional character of the discipline, the department or centre where the discipline is offered. For classification, we use the rule of counting words by presence, frequency, co-occurrence of certain terms as well as their semantic categorization. In this paper we present only part of the results of the research under development.

RESULTS AND ANALYSIS

In the set of courses analysed, about 58% are offered in the nocturnal period, 32% in the integral or daily period (two or more periods), 9% in the vespertine period and 1% in the morning period. In these courses we find 375 disciplines with discussions concerning the subject of the nature of sciences and scientific work, 293 being compulsory disciplines (78.1%) and 82 optional or elective (21.9%). These disciplines have a weekly average of 51.7 scheduled hours, diluted in an average scheduled time for the courses of about 3121 hours. This schedule is the
minimum requirement for the fulfillment of the curriculum, that is, for completion of compulsory disciplines – including general and specific disciplines, curricular internships and practices – optional/elective disciplines and formative/complementary activities.

So, in the current scenery of undergraduate physics courses, face-to-face modality, offered by the country’s public education institutions, only 4.5% make reference to the disciplines that, among other issues proposed in their programs, also address discussions on the nature of sciences and scientific work. Furthermore, another point to mention is that the offer of these disciplines occurs with greater frequency in the final stages of the course: 17.1% are offered in the 1st and 2nd stages, 13.9% in the 3rd and 4th stages, 24.0% in the 5th and 6th stages, 37.3% from the 7th stage onward and 7.7% do not mention at what stages the disciplines are offered (great part are optional/elective).

We identify three groups or sets of disciplines, which we divide according to Tardif’s theory of Teaching Knowledge (2014a) (Figure 1). The first group consists of disciplines that deal with the nature of sciences and scientific work theme, classified as **Disciplinary Knowledge of History, Philosophy, Epistemology and Sociology of Science(s) and Physics**. The contents of these disciplines refer to the social knowledge emerging from the tradition of studies in History, Philosophy, Epistemology and Sociology of Science selected and present in university education (Tardif, 2014a). In the collected sample, this group is constituted by 272 disciplines (72.5% of the total) – of which 199 disciplines are compulsory and 73 disciplines are optional/elective –, with exclusive discussions on the nature of sciences and scientific work. These disciplines were identified through the presence of excerpts making explicit reference to the History, Philosophy, Epistemology and the Evolution of Sciences and Physics. Scheduled time for these disciplines represents 3.1% of the average scheduled time for the courses.

The second group is composed of disciplines that deal with the nature of sciences and scientific work theme, classified as **Pedagogical Knowledge**. The contents of these disciplines refer to the professional training knowledge generated by reflections on the educational practice with the intention of being incorporated into the teaching activity (Tardif, 2014a). In the collected sample, this group is constituted by 80 disciplines (21.3% of the total of the disciplines in the sample) – of which 74 disciplines are compulsory and 6 disciplines are optional/elective –, with discussions about Science and Physics teaching and learning and other didactic and methodological aspects. These disciplines were identified through the presence of excerpts making reference to the “use of history, philosophy, epistemology of sciences/physics in the teaching of sciences/physics” in their programs, and designated by “Practice of Sciences/Physics Teaching”, “Methodology of Sciences/Physics Teaching”, “Instruments for Physics Teaching”. Scheduled time for these disciplines represents 1.0% of the average scheduled time for the courses.

The third group consists of disciplines that deal with the nature of sciences and scientific work theme, classified as **Disciplinary Knowledge of Physics**. Similar to the Disciplinary Knowledge of History, Philosophy, Epistemology and Sociology of Science(s) and Physics, the contents of these disciplines refer to the social knowledge emerging from the tradition of physics studies selected and present in university education (Tardif, 2014a). In the collected sample, this group is composed of 23 disciplines (6.1% of the total of the disciplines in the
sample) – of which 20 are compulsory and 3 are optional/elective –, addressing specifically contents in physics and mention in their programs discussions about historical, philosophical and/or epistemological aspects of knowledge in physics. These disciplines were identified through the presence of excerpts making reference to concepts of physics in their names and programs. Scheduled time for these disciplines represents 0.36% of the average scheduled time for the courses.

Figure 1. Distribution of the quantitative of disciplines that deal with the nature of sciences and scientific work classified in relation to total of disciplines, classified in relation to total of disciplines, Disciplinary Knowledge of History, Philosophy, Epistemology and Sociology of Science(s) and Physics (Group 1), Pedagogical Knowledge (Group 2) and Disciplinary Knowledge of Physics (Group 3), and in relation to the compulsory or optional/elective offer.

Another element that we consider important to analyze, refers to the departments and centers that offer the disciplines with discussions concerning the subject of the nature of sciences and scientific work (Figure 2). Considering the totality of the disciplines, prevail the offer by the Physics Departments (32%) and the Specialized Training Centers (15%). In a smaller percentage the offer is made by the Interdisciplinary Departments and Centers (7%), for example Departments of Natural Sciences, Exact and Technology, Departments of Social Sciences and Humanities (6%), Departments and Centers of Education, Teaching and Pedagogical Practice (5%) and Basic Training Centers (3%). Unfortunately, a significant portion of the disciplines (33%) do not explicitly present information about the department or centers responsible for their offer.

An analysis can also be performed on each of the groups. With respect to the first group – disciplines with exclusive discussions on the nature of sciences and scientific work – even as in the general scenario, most of them are offered by the Physics Departments (35%), followed by the Specialized Training Centers (11%), Departments of Social Sciences and Humanities (8%), Interdisciplinary Departments and Centers (7%), Departments and Centers of Education, Teaching and Pedagogical Practice (4%) and Basic Training Centers (3%).

Regarding the second group – disciplines with discussions in the area of science/physics teaching –, most of them are offered by the Specialized Training Centers (30%), followed by the Departments of Physics (21%), Departments and Centers of Education, Teaching and
Strand 6

Pedagogical Practice (9%) and Interdisciplinary Departments and Centers (8%). This group does not present disciplines associated to the Departments of Social Sciences and Humanities and Basic Training Centers.

Regarding to the third group, of disciplines that specifically deal with Physics contents and also discuss discussions about historical, philosophical and epistemological aspects of Physical knowledge, most of them are offered by the Departments of Physics (30%), followed by Basic Training Centers (9%) and Specialized Training Centers (9%). This group does not present disciplines associated to the Interdisciplinary Departments and Centers, Departments of Social Sciences and Humanities and Departments and Centers of Education, Teaching and Pedagogical Practice.

![Figure 2. Departments and centers that offer the disciplines with discussions concerning the nature of sciences and scientific work classified in relation to total of disciplines, Disciplinary Knowledge of History, Philosophy, Epistemology and Sociology of Science(s) and Physics (Group 1), Pedagogical Knowledge (Group 2) and Disciplinary Knowledge of Physics (Group 3).](image)

It should be noted that a significant portion of the disciplines of each of the groups (31%, 33% and 52% in Disciplinary Knowledge of History, Philosophy, Epistemology and Sociology of Science(s) and Physics (Group 1), Pedagogical Knowledge (Group 2) and Disciplinary Knowledge of Physics (Group 3), respectively) do not explicitly state the information about the department or center.

Finally, with this data and this classification proposal, we also identify the quantitative of the undergraduate Physics courses in public institutions of higher education in Brazil that
contemplate the debate about the nature of sciences and scientific work in disciplines belonging to each of the groups of knowledge. Our interest was to identify especially the quantitative of undergraduate courses that presents a greater diversity of disciplines with discussions concerning the subject of the nature of sciences and scientific work, this means, how many and which are the courses that offer disciplines in each of the groups of knowledge. This systematization is represented in Figure 3.

Figure 3. Schematic representation of the distribution of courses that present disciplines related to the Disciplinary Knowledge of History, Philosophy, Epistemology and Sociology of Science(s) and Physics (Group 1), Pedagogical Knowledge (Group 2) and Disciplinary Knowledge of Physics (Group 3) and their intersections, in the undergraduate physics courses in public institutions of higher education in Brazil, according to our classification proposal.

In short, this systematization shows the current scenario of how these disciplines are offered in the undergraduate physics courses. Most of the courses (65.5% that concentrate 47.4% of the total number of disciplines in our sample) present in their curricular matrices only disciplines, which deal with the subject of the nature of sciences and scientific work, referring to the Disciplinary Knowledge of History, Philosophy, Epistemology and Sociology of Science(s) and Physics (Group 1).

A slightly smaller share of the courses (22.8% that concentrate 34.6% of the total number of disciplines in our sample) present in their curricular matrices both disciplines, which deal with
the subject of the nature of sciences and scientific work, referring to Disciplinary Knowledge of History, Philosophy, Epistemology and Sociology of Science(s) and Physics (Group 1 – 17.4%), even as referring Pedagogical Knowledge (Group 2 – 17.2%), that is, which propose the discussion of the thematic subject of the nature of science associated to the debate of didactic and methodological aspects of Science/Physics Teaching.

A minor part of the courses (6.9% that concentrate 10.2% of the total number of disciplines in our sample) present in their curricular matrices both disciplines, which deal with the nature of sciences and scientific work, related to both Disciplinary Knowledge of History, Philosophy, Epistemology and Sociology of Science(s) (Group 1) and Disciplinary Knowledge of Physics (Group 3), that is, that propose some intersection of the discussion of the thematic of nature of science and scientific work associated to the study and conceptual understanding of the Physics knowledge.

Finally, an even smaller part (3.4% that concentrate 7.2% of the total number of disciplines in our sample) present in their curricular matrices, which deal with the the nature of sciences and scientific work, referring to the three groups: Disciplinary Knowledge of History, Philosophy, Epistemology and Sociology of Science(s) and Physics (Group 1), Pedagogical Knowledge (Group 2) and Disciplinary Knowledge of Physics (Group 3). This systematization is also represented in Figure 4.

Figure 4. Schematic representation of the distribution of courses that present in their curricular matrices disciplines related to the Disciplinary Knowledge of History, Philosophy, Epistemology and Sociology of Science(s) and Physics (Group 1), Pedagogical Knowledge (Group 2) and Disciplinary Knowledge of Physics (Group 3), in the undergraduate physics courses in public institutions of higher education in Brazil, according to our proposal of classification.

In the disciplines classified as Pedagogical Knowledge, there is a more effective concern with the didatization of scientific knowledge regarding the discussion of what, how, for what and for those we should teach science and physics; didactic transposition; didactic procedures and strategies, whether traditional or innovative. Thus, even if the number of disciplines classified
as Pedagogical Knowledge is representative, it still seems to us that only a small part of the scheduled time for the courses is dedicated to the disciplines which approach the nature of science and scientific work in undergraduate physics courses. According to the data presented in Figure 4 (and represented by the elements inside the lower left blue circle of Figure 3): 22.8% of the courses that concentrate 34.6% of the total number of disciplines in our sample with Disciplinary Knowledge of History, Philosophy, Epistemology and Sociology of Science(s) and Physics and Pedagogical Knowledge, 3.45% of the courses that concentrate 7.2% of the total number of disciplines in our sample with Disciplinary Knowledge of History, Philosophy, Epistemology and Sociology of Science(s) and Physics and Pedagogical Knowledge and Disciplinary Knowledge of Physics, and 0.7% of the courses that concentrates 0.3% of the total numbers of disciplines in our sample with only Pedagogical Knowledge.

In the same sense, the data show that the disciplines classified as Disciplinary Knowledge of Physics are weakly articulated with the Disciplinary Knowledge of History, Philosophy, Epistemology and Sociology of Science(s) and Physics. According to the data presented in Figure 4 (and represented by the elements inside the lower right black circle of Figure 3): 6.9% of the courses that concentrate 10.3% of the total number of disciplines in our sample with Disciplinary Knowledge of History, Philosophy, Epistemology and Sociology of Science(s) and Physics and Disciplinary Knowledge of Physics, 3.45% of the courses that concentrate 7.2% of the total number of disciplines in our sample with Disciplinary Knowledge of History, Philosophy, Epistemology and Sociology of Science(s) and Physics and Pedagogical Knowledge and Disciplinary Knowledge of Physics, and 0.7% of the courses that concentrates 0.3% of the total numbers of disciplines in our sample with only Disciplinary Knowledge of Physics.

FINAL CONSIDERATIONS

In this work we seek to strengthen our argument that discussing aspects of scientific activity is fundamental in the initial training of teachers, especially those who work in science education, bearing in mind that the epistemological conception endorsed by them defines, to a great extent, their attitudes as teachers. Positions that are permeated by inadequate conceptions result in the reproduction of models of the construction of socially accepted scientific knowledge, of a science which is empiric-inductivist, aproblematic, ahistorical, of linear growth, cumulative, inductivist, elitist, decontextualized and socially neutral (Gil-Pérez et al., 2001).

The data allow us to assert that there is another concern, however brief, in addressing the demands of legislation on the training of teachers relative to the offer of disciplines dealing with discussions on the nature of sciences. In a general way, 4.5% of the scheduled time for courses are devoted to discussions on the subject, but some disciplines are not exclusively devoted to this kind of discussion (Pedagogical Knowledge (Group 2) and Disciplinary Knowledge of Physics (Group 3)) and approach an array of subjects, also relevant for the undergraduate’s training but with diverse characteristics.

Furthermore, a part of the disciplines are optional/elective, which does not allow us to say that this discipline was a part of the student’s training, bearing in mind that disciplines of this character generally perform a role which is complementary of the main training. In obtaining
their degree in physics, students make their choices from a varied list of options, some of which deal even with current specific subjects in physics, of great interest to the undergraduates.

In that sense, relative to Disciplinary Knowledge of History, Philosophy, Epistemology and Sociology of Science(s) and Physics (Group 1), presenting discussions exclusively devoted to the subject of the nature of sciences and scientific work, only 2.3% of scheduled time in undergraduate courses in physics is reserved to compulsory disciplines on offer. Relative to Pedagogical Knowledge (Group 2) and Disciplinary Knowledge of Physics (Group 3), ranging from nature of science and scientific work among other contents, representation reduces to a mere 1.3%. These data lead us to two important considerations: there is not much space destined to discussions exclusively about the nature of sciences and scientific work theme and even less to integrating this subject with other disciplines and contents, such as the field of teaching physics. Even though the scheduled time is not that expressive, it is important to ponder how to make the debate on nature of science more effective, incorporating it in the methodological debate and the learning of physics itself (Martins, 2007; Pereira; Martins, 2011).

The weak presence of this type of discussion revealed by these data leads us to affirm that the gap of a more qualified debate on the nature of sciences and scientific work, especially in the intersection between the three knowledge type, leaves room for the epistemological beliefs of the graduates, and even of the training teachers, are more valued than the Disciplinary Knowledge of History, Philosophy, Epistemology and Sociology of Science(s) and Physics (Group 1), strengthening a naive conception about the nature of sciences, as it has been widely criticized by researchers in the field of science education and science teachers.

The data presented in this work makes evident the weak presence of the discussion about the nature of science and scientific work in undergraduate Physics courses in public institutions of higher education in Brazil. The gap of a more qualified debate, especially at the intersection between the three types of knowledge, opens space for the personal epistemological beliefs, both graduates beliefs and teacher educators beliefs, to be more valued than the Disciplinary Knowledge of History, Philosophy, Epistemology and Sociology of Science(s) and Physics itself. This gap strengthens the construction of a naive and outdated conception of the nature of science, which has been widely criticized by researchers and science teachers in the field of science education, who have proposed renewed perspectives for understanding what is meant by nature of science, origin of science, objectives of science, scientific progress, scientific development and scientific consolidation.

At first, it seems acceptable to advocate for a more expressive and diversified number of disciplines with discussions about historical, philosophical, epistemological and sociological aspects of scientific knowledge as compulsory training for future teachers. In this sense, it seems interesting to deepen the analysis around the courses that propose in their curricular matrices disciplines of the three groups of knowledge: Disciplinary Knowledge of History, Philosophy, Epistemology and Sociology of Science(s) and Physics (Group 1), with exclusive discussions on the nature of sciences and scientific work theme; Pedagogical Knowledge (Group 2), which of propose the discussion of the nature of science and scientific work associated with the didactic-methodological aspects of the area of Science/Physics Teaching;
and Disciplinary Knowledge of Physics (Group 3), which of propose the discussion of the nature of science and scientific work together with the study and conceptual understanding of the Physics knowledge. The analysis presented here, associated to a more detailed investigation of the programs of the subjects of our sample, gives us indications and points out ways to characterize the discussions about the nature of the sciences offered to the future professors in the undergraduate courses in Physics. In addition, we have diagnosed that most of the disciplines are offered by Physics Departaments and Specialized Training Centers, and, in this sense, in the next stage of this study, we intend to map the academic training of these university professors, especially those who take these disciplines in which discusses the nature of science and scientific work.

Following this research, we intend to analyze the disciplines programs with the objective of understanding their offer configurations, as well as exploring scenarios around questions such as: How can we construct with the teachers and future teachers an acceptable vision of the scientific work? What is the influence of the teachers' beliefs in building a vision about science and about scientific work?

ACKNOWLEDGEMENT

The authors would like to acknowledge the European Association for Research in Scientific Education (ESERA) for rewarding one of the authors with fellowship to attend the ESERA 2017 Conference.

REFERENCES

Science and technology are playing a crucial role in modern society: Well-being and progress are both connoted with science and technology, as are risks and danger. Therefore, it is agreed upon the need for scientific and technological literate citizens able to participate responsibly in society (Vesterinen, Manassero-Mas, & Vázquez-Alonso, 2014). As there is no mandatory technology subject in upper secondary schools in Germany, physics courses (or elsewhere science as a combined subject) have to evolve both scientific and technological literacy (Dow, 2006). The question arises how this literacy can be developed in physics lessons, how a conceptual understanding of science, technology, and their impacts on each other as well as on society and environment can be acquired. To answer this question this study focuses on two aspects of physics teaching, highly relevant for this purpose: teachers’ implicit knowledge about the interrelations of physics and technology in the context of responsibility and the socially approved knowledge about this field as represented in schoolbooks. Teachers’ knowledge is reconstructed based on a qualitative interview study with physics teachers at German high schools. Common physics textbooks for German high schools’ early and senior classes were qualitatively analysed using a reconstructive, discourse analytical approach being based on the methodology of the Documentary Method (Nohl, 2016). Here we give a short overview of the research in the field of interest and an insight in one section of the comprehensive study namely methods and preliminary findings from the textbook analysis.

Keywords: physics, technology, responsibility

PHYSICS EDUCATION IN THE ANTHROPOCENE

Technology is shaping not only our way of life, our social interactions, and our identity. It has also shaped the world as a whole. A vast technological development along with the exploitation of fossil energy sources has led to a great acceleration of a variety of socio-economic trends like urban population, economic growth, water use, fertilizer consumption and transportation (Steffen et al., 2015). These developments may “damage the system that keep Earth in the desirable Holocene state” (Rockström et al., 2009, p. 472) by exceeding so called planetary boundaries. Therefore, it is agreed upon the need for scientific and technological literate citizens able to participate in the public dialogue about science and technology (Vesterinen, Manassero-Mas, & Vázquez-Alonso, 2014).

But - as there is no mandatory technology subject in upper secondary school in Germany - how should students gain the postulated technological literacy? Should (and can) physics courses as an important element of general education foster both, scientific and technological literacy? If so, how can students acquire a conceptual understanding of the nature of science, technology and their interactions in physics classes? To address this question we study the views about these relations inherent to physics textbooks and the partly implicit knowledge of physics teachers in narrative interviews.
PHYSICS AND TECHNOLOGY

One quick look in a physics textbook suggests that technology plays a big role in physics as a school subject as many pictures show artefact that we would call technical. But how can we differentiate between physics and technology? A strict and clear distinction might not be possible, as in many cases, those fields seem to merge (Tala, 2009). Nevertheless, the following criteria (Spiegel, 1999) might help to illustrate different priorities of the enterprises. One main criterion is the goal, which is pursued. While physicists in general try to gain new knowledge about nature, technologists mainly focus on innovations namely products that satisfy someone’s need. For example, one can either try to build a windmill (which can also be done without science) or try to understand the behaviour of fluid dynamics (without thinking about its importance for technical machines). The mode of operation is a second helpful criterion. In physics, experimentation is one central working method. In the field of technology construction is considered central (Tesch, 2010). These two activities differ in their underlying goal perspective, which is - consistent with the mentioned goal perspective of the whole enterprise - gaining knowledge versus innovation of products. For example, an experimental setup for studying fluid mechanics has no purpose on its own but the objective of gaining knowledge. In contrast, a constructed windmill is functional by itself. Experimentation and construction also differ with regard to optimisation. While experimental setups are optimised for gaining knowledge, the optimisation of constructions is multi-perspective with many, possibly conflicting claims like aesthetics, cost effectiveness or durability (Tesch, 2010). The area of interest is a third distinguishing criterion. While the natural phenomenon is of interest in physics, the artefact is central in technology. This characteristic may not apply to modern physics - as the studied phenomena often are artificially prepared - like for example in a large particle collider.

As already mentioned, the distinction between physics and technology is often not sharp as there are close links between those two enterprises. There are three possible perspectives on these links. First, the relation can be understood as unidirectional. For example, new scientific knowledge is gained and this knowledge is transferred right into a useful technical device. This idealistic relation also called “technology as applied science” is surely rare but very common for example in textbooks (Gardner, 1999). One historic example for this may be the discovery of x-rays and its rapid application for medical purposes. A reversed direction of the relation between physics and technology is central to the materialist view (Gardner, 1994): New scientific knowledge can only be gained by the use of technological inventions. The already mentioned particle collider may serve as vivid example here. An interactionist viewpoint (Gardner, 1994) takes both ways in consideration as we see the interrelation between physics and technology as mutual and closely linked - which is a key element of many fields from fundamental research in genetic engineering to studies on gravitational waves. With an increased interaction and a fast acceleration of the scientific and technological development, questions arise about the responsibility for impacts these developments have.
RESPONSIBILITY

We can understand responsibility as a term that constructs relations between different points of reference (Düwell, 2006): someone is responsible for something/someone towards someone because of certain normative standards (Figure 1). Different points of reference result in different forms of responsibility – and in practice, many of the reference points remain implicit (Heidbrink, 2003). To illustrate these different points of reference, climate change may serve as a vivid example: Who is responsible for the problem of climate change and - linked with that question - who has to solve it? Assuming a causative principle, the energy suppliers or the agriculture might be the responsible ones. A democratic approach may identify the United Nations as responsible. Taking principles of justice as the underlying norm, the global north might be identified as responsible towards the global south or future generations. Considering bioethical principles, nature itself could be an authority of responsibility.

Figure 1: Concept of responsibility as a multi-perspective relation

All these variations show one aspect that is central to modern, high-tech societies: Diffusion of responsibility, which describes a mechanism of non-functional responsibility relations. This mechanism can occur on the subject or the object level of responsibility. On the subject level the diffusion of responsibility is characterised by the presence of multiple subjects. In a group of potentially responsible actors, the responsibility is split and the single subject can deny its own responsibility by attributing it to other subjects. Effectively, no one takes responsibility (Bierhoff & Rohmann, 2011). Second reason for the diffusion is the great sphere of influence that has come with technological development (Jonas, 1992). Crucial present problems like the mentioned climate change are characterised by an important time-gap between actions (like burning fossil fuels) and its effects (like global warming). This makes it difficult to attribute responsibility easily. However, the sphere of influence has not only expanded in time but also in space: affected persons or goods are not necessarily in spatial proximity. As our value system is orientated towards our direct environment, there are no effective norms (especially laws) established to govern responsibility. Because the fast progress of science and technology plays a crucial role here, it becomes more and more important to reflect on the relations between science and technology - a key element of scientific and technological literacy.
ROLE OF TEACHER KNOWLEDGE

Among others the Science-Technology-Society (STS) movement as well as approaches for socioscientific issues (SSI) have already offered a variety of possible answers to the challenge of enabling scientific and technological literacy (Vesterinen, Manassero-Mas, & Vázquez-Alonso, 2014). The role of teachers’ views in this context must not be underestimated, as their knowledge “can also be held implicitly and therefore have important implications for how technology and science education is constructed and presented” (Dow, 2006, p. 315). Studies suggest, “that science teachers may not, in fact, hold adequate understandings of the nature of science and technology and their interactions. This may be a factor in the degree to which science teachers integrate STS into science instruction […] and the quality of the STS instruction.” (Rubba & Harkness, 1993, p. 429) A common misconception is the imbalanced perception of technology as applied science without considering the mutual relations both enterprises have and a deficient differentiation between science and technology (Constantinou, Hadjilouca, & Papadouris, 2010, p. 168). Beside the interrelations between science and technology, their impact on society and environment becomes important nowadays. However especially physics teachers “often struggled to describe value-laden issues in their fields” (Sadler, Amirshokoohi, Kazempour, & Allspaw, 2006, p. 370).

ROLE OF TEXTBOOKS

Beside teachers’ (implicit) knowledge, textbooks play a crucial role as they “convey messages, explicitly and implicitly, about the nature of these fields [science and technology, FB] and their relationship” (Gardner, 1994). In contrast to studies on textbooks role in planning of and implementation in physics classes (e.g. Merzyn, 1994) we choose a knowledge-sociological approach to acknowledge textbook knowledge as the result of a social process. According to this, textbooks carry a socially negotiated and accepted kind of knowledge and represent not only for science learners and teachers an approbated understanding of the discipline. They constitute a form of discourse, which is according to Keller an attempt to stabilise an attribution of meaning and creating an obligatory knowledge system (Keller, 2011). However, compared to other forms of discourses textbooks have a prominent standing as they also carry a specific inherent knowledge about their social relevance and trustworthiness (Höhne, 2003, p. 71). For learners as well as for teachers, textbook knowledge has a special authority and is implicitly connected with other forms of knowledge and discourses.

By defining for example distinct roles and functions for individuals (e.g. scientists) and claiming argumentations as approved or false, textbooks open a specific perspective on reality. Hereby they are not only seen as an educational medium but as an important sociocultural medium that influences public dialogue and vice versa (Höhne, 2003). However, textbooks often convey an inconsistent picture: “Most texts briefly, and inadequately, discuss the nature of science in the opening chapter, and then portray science in a distorted, positivistic, and 'final form' fashion throughout the rest of the book” (Lederman, McComas, & Matthews, 1998, p. 507). Besides the representations of the interrelations between science and technology are often imbalanced: “All reflect the dominant idealist view: artefacts are presented as applications of
the laws of physics; the contribution of technology to the development of physics is downplayed or ignored” (Gardner, 1999, p. 344).

**METHOD OF TEXTBOOK ANALYSIS**

How can we reconstruct the implicit, social knowledge-structures that underly the textbooks? “From a linguistic point of view, no satisfactory answers can be gained for example by using content analysis only” (Ott, 2015, p. 254). So a more in-depth, reconstructive analysis is necessary. We decided for the Documentary Method, which provides a sophisticated methodology based on the “sociology of knowledge” by Karl Mannheim. The Documentary Method has already been used for analysing pictures, group discussions (Bohnsack, Nentwig-Gesemann & Nohl, 2013) and interviews (Nohl, 2017) in order to reconstruct frameworks of orientation, as expressions of implicit, shared structures of knowledge. Nohl recently has suggested to use the Documentary Method also for the analysis of public discourses and given a methodological justification with reference to Karl Mannheim (Nohl, 2016). Within the Documentary Method, it is differentiated between the explicit, immanent meaning of a statement and its implicit, documentary meaning. The implicit meaning, which has to be reconstructed by gaining insight in latent regularities, can be understood as a modus operandi (Nohl, 2016, p. 122). These modi operandi are usually tied to distinct communities where implicit knowledge is part of a shared, common knowledge base and thus is not explained explicitly. In the case of discourses the modus operandi is based on the competition between different ways of thinking (of different communities) and thus reflecting societal power structures too (Nohl, 2016, p. 122). Therefore, the implicit knowledge refers to a very stable and comprehensive mind-set that is crucial for understanding a discourse.

For our analysis we choose textbooks from major German educational publishers for introductory physics classes, for end of secondary education and for senior classes to cover all potential readers’ age groups. Objects of investigation are texts about science, technology and their social and ecological impacts, given often in introductory chapters, but also texts only implicitly dealing with this perspective on the discipline while explicitly focusing on subject content. The comparison and scrutiny of potential inconsistencies in conveyed viewpoints allows a better understanding of the inherent subtext.

First, we analysed the apparent content to identify a topical structure of the texts (formulating interpretation). By doing so we can gain insight in the intrinsic structures of meaning, the specific architecture of a text. The comparison with contrasting texts can already indicate a specific mind-set (Kruse, 2015, p. 477). As an intermediate step the text is analysed with regard to wording. The analysis of chosen words and groups of words is useful for the following reconstructive analysis of implicit knowledge structures.

The subsequent reconstructive analysis is mainly based on an interpretative work carried out in small interpretation groups. It focuses on how a topic is dealt with (reflecting interpretation). This takes into account for example (Kruse, 2015, pp. 550-551)

- The narrative persons: Narrative persons can be distinct individuals or groups, collectives. By using passive voice, the specification of narrative persons can be avoided.
The roles of the narrative persons: The narrative persons can be presented as powerful and active or have a rather passive role. This role can be presented as universal and stable or area-specific and variable.

The position of narrators and change of perspective: The position of narrators can be first person “I” or “We” whereby the exact meaning of “We” usually is not clarified and therefore must be interpreted. Other positions can be generalized “one” or indefinite. The narrator can also take the perspective of the narrative persons of a text.

Tropes: Tropes are rhetorical, symbolical figures like metaphors, allegories, or anthropomorphism.

Marks of reliability: These marks indicate the degree of certainty like “assuming” and “thinking” versus “knowing” and “being sure.”

Legitimisations: Legitimisations give justifications for statements (e.g. “why”, “therefore”) and can name authorities or references for this.

A comparative analysis throughout one textbook and between different textbooks then leads to different types of implicit knowledge structures.

**EXEMPLARY TEXTBOOK ANALYSIS**

Here we exemplarily discuss two introductory texts that explicitly address the elsewhere rare topic of responsibility arising from interrelations of physical and technological developments. The texts are taken from Meyer & Schmidt, 2006 (text A) and from Bredthauer et al., 2010 (text B) (Figure 2). Both editions are authored for senior classes at German high schools.

**Figure 2: Illustrative quotes from introductory chapters from german physics textbooks**

Text A (approx. 300 words) is part of a 34-paged introductory chapter “Physics – a natural science” [all quotes translated by Frederik Bub] which gives an overview over science history,
theories and methods. Text A deals with explications about physics, its relation to technology and the exceptional responsibility of scientists. Text B (approx. 600 words) precedes the first chapter and is entitled with “Why learning physics?” The passage deals with the great impacts of scientific progress and technological inventions especially on everyday life, why it is important to learn physics and how the textbook is structured.

A first brief linguistic analysis of the texts reveals several characteristics. We focus here on the attribution of responsibility by analysing the narrative persons and their role.

When giving a definition for physics and discussing its relations to technology text A names no acting subject at all. All statements are in passive voice conveying physics as a rather impersonal venture. In the paragraph about responsibility (see quote), which is based on the complex impacts that science and technology have, this changes as narrative persons are mentioned. These persons differ noticeable in their attributed activeness. First science and technology were introduced as something powerful that has complex impacts. The object of these effects is our personal and societal life. Here the narrator takes the perspective of first person plural. It is not specified who is included within this “we”. However, it creates a distinction between the active science and technology and the passive, receiving “we.” These gap is outlined further when the active and in the paragraph dominating subjects scientists were introduced. They have a special responsibility and their activities include to influence, to use authority, to conduct, to permit while the other named agents - humans, general public or animals - remain passive as no activities are attributed to them through associated verbs. Politicians or any civil-society actors were not mentioned, so decisions about scientific or technological developments were set in the sphere of scientists. This distribution of roles contrasts to the call for an informed general public given explicitly in the text.

Text B is describing the improvement of everyday live through science and technology in first person plural. In the given quote, the responsibility in the context of scientific-technological development is specified. It is described as a responsibility towards the community of all living beings and is attributed to the first person plural without further specification or limitation, which may suggest the assumption of society responsible as a whole. Beside this first person plural perspective (“we have towards…”) the statements are in a way generalising (“should always be”, “must not be”, “has to be”) and may be characterised as orders. An authority or reference for these orders is not mentioned. Significant is the reference to the community of all living beings, which suggests a bio-centric worldview with a united collective of beings. The role of the responsible citizen is to gain comprehensive knowledge. Implicitly this knowledge about physical correlations is connected with the avoiding of damages. Few experts carrying the knowledge solely is rejected as a non-desirable state.

In summary, it can be stated that the texts differ considerably in their attribution of responsibility for scientific-technological impacts: While text A emphasises the status of scientists, text B stresses the role of a society as a whole. Text A conceptualises the scientific-technological development as a venture for scientific experts and thus emphasise their responsibility. Text B in contrast has a more democratic approach and stresses the importance of a general education. Through the remarkably frequent use of plural and passive voice, both texts avoid an attribution of responsibility on an individual level. This may reflect a diffusion
of responsibility that is characteristic for the named problems as no concrete agent but only groups of agents are addressed.

CONCLUSION AND OUTLOOK

We have discussed the importance of partly implicit knowledge conveyed by both physics teachers and textbooks for the attainment of a scientific and technological literacy. Due to their high degree of acceptance teachers’ knowledge and textbooks have the potential to shape the development of students’ world-views. This world-view can correspond with the ability, the willing and thus the success in participating in the overdue great transformation towards a sustainable development. The given methodological approaches appear to be promising in gaining a better understanding of these spheres of knowledge as the presented findings demonstrate the appropriateness of reconstructive methods to analyse the inherent knowledge structures in physics textbooks. Complemented by the carried out interview survey our study can give a profound insight in the knowledge conveyed in physics classes about the nature of science, technology and their interrelations in the context of responsibility.

REFLECTIVE REVIEWING OPERATING ON
CONCEPTS OF NATURE OF SCIENCE

Julia Birkholz and Doris Elster
University of Bremen, Germany

An appropriate understanding of the nature of science (nos) and of scientific inquiry (nosi) is one of the essential tools for critical thinking about and reflection on scientific knowledge. To improve this understanding, the nos/i aspects “(un)certainty” and “purposes of scientific knowledge” as well as “scientific practices/justification” were emphasized in the “reflective reviewing café” (rc) conducted in the outreach lab “backstage science” (basci) at the university of bremen. In a long term study the impact of the rc on the understanding of nos/i was analysed in a complex mixed-methods approach via questionnaires (pre/post/follow-up) and via dialogues conducted within the rcs (32 transcripts). The quantitative results indicate that multiple participation in basci modules with rc-dialogues leads to an improvement in the nos/i aspects “development” and “scientific practices/justification”. The qualitative results show a distinguishable shift in the understanding of “(un)certainty” and “scientific practices/justification” towards deeper awareness of the structures of scientific research. The present qualitative study further investigates these reflective reviews: 12 dialogues from the transcripts are analysed via the documentary interpretation method by bohnsack. The findings show that students mostly demonstrate stable views on nos/i aspects, in one an ongoing change of view throughout the dialogue can be observed. The rc method is able to influence students’ views on nos/i in certain aspects and it might do it through forcing the students to justify their positions.

Keywords: nature of science, nature of scientific inquiry, reflective activities, outreach lab

INTRODUCTION

A critical vigilance and debate over scientific research and knowledge is of great importance for future responsible citizens (Felt, 2008). As a basis for informed decision making, privately or as public stakeholder, a sound knowledge base about the scientific information at hand as well as their relations, dependencies and constraints, is needed (Babour et al., 2008; Zeidler et al., 2011). Scientific knowledge has certain characteristics resulting from these relations, dependencies and constraints, to which research and researchers are subject. The characteristics form the nature of science (NOS) and nature of scientific inquiry (NOSI) processes.

This knowledge has to be accessible for citizens (Trench, 2008), therefore certain competencies are needed. The foundations of understanding scientific contents and surroundings should be built within science education to facilitate participation for a maximum number of future citizens.

While there is little consensus between scientists, historians and philosophers, regarding the “true” Nature of Science (Wiltsche, 2013), these philosophical questions, e.g. about the true nature of objectivity, truth or perception, are of little relevance for students and citizens. If considering relevance of a NOS/I aspect along with a general consensus and accessibility, there are certain aspects of NOS/I to focus on: e.g. the tentative nature of scientific knowledge, imaginative, theory-laden, culturally influenced nature of scientific inquiry or the justification
of scientific knowledge (Lederman et al., 2002; Schwartz et al., 2008). In this study the limitedness of knowledge certainty due to extern (e.g. research purposes and goals, indirect perception of environment) and inherent (e.g. research procedures, need for interpretation, researchers as humans) factors emphasized. Scientific results are generated through customized and well documented methods. From the start until publication, research is embedded in peer review processes and general logical skepticism from the executive researchers as well as their work group or faculty. Repeating experiments, reinterpreting results or challenging verified hypotheses have the purpose to minimize the uncertainty of results and derived knowledge. Even exhaustive testing, re-testing and challenging may not ensure complete certainty, because the underlying theories are the yet imaginable ideas, created culturally, historically as well as personally embedded, and results are interpreted on their basis.

In a long term study we investigated the influence of a supportive activity, group reflective reviewing of own conducted research (Reflective Reviewing Café) within the outreach lab “Backstage Science” (basci), on the development of “reasonable concepts of NOS/I” (RECONs). Questionnaire results and results of a content analysis on the reflective dialogues suggest a fostering effect of the Reflective Reviewing Café discussions. The goal of the present qualitative study is to append in-depth data to the nature of this identified positive influence.

HOW TO IMPROVE STUDENTS’ CONCEPTS OF NOS/I

With the tacit knowledge theory of Polanyi (1985) the knowledge of scientific skills is learned implicitly “in action”. University science students and young researchers may observe, and be instructed by, more experienced scientists and the scientific community. But students mostly do not develop RECONs through hands-on research activities. Their sources of information are lab activities during lessons, school book texts, teachers’ language and particular didactic and entertainment media (Hofstein & Mamlok-Naaman, 2007; McComas et al., 2002; Clough, 2006). From these heterogeneous sources it is unlikely to “stumble upon the formalisms, theories and practices” (Leach & Scott, 2002: 121) that characterize science.

The underlying NOS/I aspects need to be addressed explicitly, e.g. by reflection about research activities guided by questions (Khishfe & Abd-El-Khalick, 2002; Khishfe, 2008). Reflection in this context means to retrieve memories of own experiences from long term memory and to examine them in the light of the own and external views on NOS/I. Important is the superposition, a new and superordinate perspective, from which the available knowledge can be reconsidered and connected to new insights (Minnemeier, 2000). Reflective activities can have a great impact on learning, especially when performed in dialogue, because of the supportive role of interactivity (Chi & Wylie, 2014). Students might benefit from each other’s ideas, the argumentative structure of dialogues or the conversation partners adopting the superposition.

NOS/I in the outreach lab “Backstage Science”

Fostering RECON’s through reflective outlining of science characteristics first requires suitable research activities, which the sample students perform in the basci outreach lab. Following the IBSE principles (Inquiry-Based Science Education; NRC, 2000) the research
activities are designed as partly authentic scientific endeavors providing “reflectable” characteristics, e.g. leaving the development of hypotheses, experimental plans or analysis ways to students’ discretion. Three basic lab modules are developed: “Farmer seeks harvest” (sustainability, resources, ecology), “Crayfish invasion” (neobiotica, ecosystems) and “Beltway for Tenerife” (endemic plants, ecosystem-services). With content-dependent varying emphasis, the components Asking questions, Developing hypotheses, Gathering data, Analysis, Explaining data, Connecting results, Communicating results and Reflecting results are partly opened to students’ autonomous activity. This way, students may build memories of research activities with rich reflection angles.

The basic modules are developed for school classes who visit for a school day and work on a certain socially and/or economically relevant biological context (Elster et al., 2011). The students work in small groups on the same issue and present their findings in a final congress, where their results and interpretations are used to defend their conclusion and to support a (fictional) decision making. To manage this difficult task as independently as possible, the small groups are carefully tutored and the materials are didactically organized in different content-related and methodical levels of process support.

**The Reflective Reviewing Café**

Reflection upon these activities is initiated through the Reflective Reviewing Café (RC), a group-dialogue method based on the “World Café” (Brown & Isaac, 2007). In a hospitable atmosphere the students form small groups at three different tables and discuss a table guiding question. First there is time and space on the table cloth to note thoughts, ideas, questions and comments on the question. The table moderator then provides a platform for interchanges of thoughts and discussion based developments of new ideas and insights. Important findings are noted on the table cloth as well and then the groups change tables and questions. Every group may benefit from the comments and ideas of the other groups, written down at the table. As the key position the moderator is not allowed to give input or to grade statements, but to deepen the discussions and explanations of thoughts as well as to ask for examples, reasons and to (carefully) be the advocatus diaboli.

Three guiding questions on NOS/I contents regarding lab activities enable corresponding dialogues:

1. *Which scientific research methods did you apply today? And what for?*

   The students remember their lab work and notice the different kinds of methods and levels of strategies. They may discuss reasons for preferring one method over another or for applying different methods for one result. Also thoughts about the necessity of reviews and the certainty of results may be discussed.

   NOS/I aspects: Methods for increasing certainty; Reasons for uncertainty.

2. *What were the objectives for today’s scientific research and what are they in general?*

   Objectives followed through the basic module may be remembered as well as other goals scientific endeavors might have. The students can discuss possible influences, that different purposes might have on a research project or the exploitation of research results. On the other
hand, students might discuss the role of science (problem cause, solution or both) when thinking of societal or environmental problems.

NOS/I aspects: Reasons for uncertainty

3. Was your scientific research subjectively influenced and is scientific research in general?

As human beings researchers are influencing their research. Imagination and creativity, the theoretical base, resourcefulness and the cultural background may affect the research approach as well as the results and interpretation. In remembering their own work, students may reflect upon their actions (or those of classmates) as subjectively influencing the results. They also might talk about ethical problems like cheating under pressure or to win fame. Many factors affecting the certainty of knowledge may be discussed here as well as possible strategies to reduce subjective influences.

NOS/I aspects: Methods for increasing certainty, Reasons for uncertainty

STUDY DESIGN AND RESEARCH METHODS

The questions asked about the RC and its ability to support the development of RECON’s are: Does the RC improve students’ views on NOS/I? And if so, which factors are relevant?

With Khishfe & Lederman (2002) and Khishfe (2008) a supportive effect of conducting the RC, compared to the non-RC group, can be expected, at least if repeated several times. After one RC-visit there probably is no effect (Leach et al., 2003), because the adjustment of concepts needs time. As relevant factors for developing more reasonable concepts the reviewing of own concepts from a superposition (Minnameier, 2000) can be expected as well as the interaction with classmates and moderator (Chi & Wylie, 2014) as extern perspectives and sources of new ideas and concepts (Säljö, 1995).

The sample consisted of 509 students in 25 classes, eighth to tenth grade, of college-preparatory and normal high schools. The average age of participants was 15. The study was conducted as shown in Figure 1.

Figure 1. 2x2 design with 2 interventional groups (1 or 3 basic visits; RC or nonRC) and 1 control group without basic visits and RC.

The intervention group visiting the basic lab (N=310) consisted of two groups with different number of visits (1 or 3) in these groups respectively subsets with or without RC conduction. The control group neither visited the lab nor conducted reflexive activities.
The students of the intervention group answered a questionnaire before and after a lab visit as well as 12 months later (pre/post/follow up). In the control group the questionnaire was answered three times. It is based on a closed NOS Questionnaire (Kremer, 2010) and the VOSI Questionnaire (Schwartz et al., 2008): A short term intervention had no clearly significant fostering effect, while the group with three visits of the basci lab combined with the RC showed significant development in the aspects Development of scientific knowledge and Scientific practices/ justification (Birkholz & Elster, 2016).

All conducted RC-discussions on each table were recorded and transcribed. With a structuring content analysis (Mayring, 2015) the intended aspects can be distinguished. A clear determination of naïve or informed propositions prove difficult due to ambiguity and statements mostly short in reasoning. But a thematic hierarchy was found: most statements consist of slight topic shifts, because the moderator insisted in justification or asked for an example. If then the student reached for something more abstract or regarding reasons for or measures against uncertainty, her expressed RECON was rated more informed, than a statement development staying on “certain grounds”. Comparing the statement developments of the three modules, changes to more abstract or constructive topics in the aspects (Un)Certainty of scientific knowledge and in Scientific practices/ justification were found.

The pending question about how such a change might happen and what student behavior connected to this how might be observed, was investigated via the Documentary Interpretation Method (Bohnsack, 2014). Dialogues (at least two dialogue partners including moderator) from the category Scientific practices/ justification were analyzed. First the dialogue facts were sorted thematically and the statements paraphrased nonjudgmental (Formulating Interpretation). With the Reflecting Interpretation every statement was analyzed to find the motivations and functions of the statements, to fathom the implicit knowledge about “science” being used. Every interpretative step was executed in researcher tandem and with monitoring verification processes. The close proximity to the verified transcripts ensures an adequately narrow interpretative context.

RESULTS FROM FIVE CASES

In five dialogues the Justification of scientific results and resulting knowledge are the subject of discussion. All conversations were conducted in basci module 2 or 3, because in the first module students and moderators were inexperienced in conducting the RC-method and only few genuine dialogues occurred. In the following RCs the students (and moderators) attuned to the situation and fruitful discussions were the result as well as the students starting conversations and explaining their thoughts without interferences of the moderator.

Apart from one student the participants display stable views of NOS/I, regarding the certainty of scientific results and knowledge under varying conditions. Asked about the certainty of their findings, students explained: “No, well it has to be repeatable, obviously. [...] and you have to try the stuff under many different conditions [...]” (8aM3F2_116_118f), “[...] certain experiments you have to conduct very, very often for a clear result.” (9bM3F1_231f). Both speakers express certainty, that an experiments’ result is clear and certain, a fact, if the experiment is done properly. If the result is repeatable under varying conditions, it is a “clear result”. Both statements don’t take into account, that the experiment result may be “clear”, but
the implications it has on their hypotheses are not as certain and are not the same thing. One might argue, that the students rigorously think about their measured values and don’t take into account the (un)certainty of their further research work. But there are many statements starting at this point and then developing a differentiating view on results and “clearness”. Nonetheless, it is possible, that levels of RECON’s expressed in statements staying on the level of measured values are underestimated. Because of this uncertainty of fit between expressed and actual RECON, the rating refers to the statement rather than the student behind it.

One participant shows conviction of the absence of certainty: “Yes (eight times out of ten the same result means clear), but who knows. Maybe it was just a coincidence. Maybe it was just- [Girl2: Eight times by chance!] Yes. Maybe. It’s possible. You don’t know that.” (9bM3F1_244f). First the student remains on the level of measured values, when he talks about coincidences. Certainty and probability are rejected equally. But with the reference to the other student not knowing, the horizon of meaning is expanded to inferential and interpretational uncertainty. Without reasoning it is impossible to determine the students’ concept on this matter, but the mention may imply an informed or an emerging RECON on knowledge developments’ (un)certainty.

In one of the dialogues, between stable statements and without influence on the other participants, there is one expression of change: the student begins with “[…] sometimes you want a clear conclusion, that is, you count in all the results and make up your mind and then you get the conclusion, and that’s a fact. […]”. Then the student disassembles the “results” having problems with comparability and unpredictable living subjects. In the end “[…] every person has a different type of thinking […], when all the facts are counted in the same way, you may get to a different conclusion without wanting it.” (10M2F3_369-87).

This student tries to justify his statements in front of himself and the moderator. By searching examples and arguments for his case, he first finds constraints to his statement, followed by counter-examples and connections to knowledge from other disciplines.

This change within a students’ expression, explaining one problem with certainty in clear words and students’ language, has no observable effect on the other group members. The next speaker ignores the previous statement and states certainty of results again. Also in other dialogues, interaction can be observed, but the students don’t (recognizable) influence their dialogue partners. There is either dispute, which ends unsolved by stopping to talk about it, or ignorance of different views.

**DISCUSSION AND NEXT STEPS**

In the *Reflective Reviewing Café (RC)*, following a basci lab module, students are able to improve their views on NOS/I in certain aspects. The questionnaire results as well as the statement shifts found in the RC-discussions indicate a supportive effect in aspects regarding the certainty and justification of scientific results.

It was assumed, that the interaction between the students, their interchanging ideas and statements, would support the development of RECONs (Chi & Wylie, 2014; Säljö, 1995) The observations suggest otherwise: There were no dialogues found, where students influenced each other’s ideas or were convinced by another’s opinion. This, still, might be the case outside
of the analyzed conversations. Maybe a direct observation of the participating students in a follow up study would bring valuable insights.

It is possible, that the students want to avoid showing an influence of a classmate on their thoughts. Maybe the integration of new thoughts need to be processed thoroughly, changing or extending existing concepts. But maybe the students need to learn to listen to each other, as they had to learn to express their opinions on NOS/I and to interact in dialogue in the RC.

Further investigations of dialogues versus single-reflection as well as students’ experiences about them are needed, because besides the effectiveness in RECON development an appropriate method for the basci outreach lab also has to provide for a positive experience, supporting positive attitudes towards the life sciences. The social interaction as an important factor for a constructivistic environment (Urhahne et al., 2011) should be preserved unless it is a disturbing factor rather than a supportive or indifferent one.

The observed change in view occurs in monologue with the moderator as catalyst. This might show the influence of the RC forcing the students to justify their position. They have to argumentatively encounter their classmates, the moderator and, as shown by this one student, the own views. More data has to be analyzed to typecast this “changing” or “argumentative” type and to determine the influence of argument on the improvement in views of NOS/I.

At the moment the Reflective Reviewing Café is adapted for school science lessons. For this the role of moderation and guiding questions as well as students’ possibilities and competencies for reflection on action can be analyzed and investigated in the context of practicability.

ACKNOWLEDGEMENT

I would like to take this opportunity to express my deep gratitude to my colleagues and fellow researchers Barbara Wernicke, Dr. Tanja Barendziak, Marie Eschweiler and Stephanie Grünbauer for validating, discussing and reasoning about the qualitative strategies, code manifestos and guiding principles.

And many thanks to Kevin Henning and Nadine Konjevic & Deniz Yaman, who developed two of the basci modules during their master theses and worked fruitfully together with us and our research questions.

The diseases, the need for new materials and the lack of renewable resources are some of the issues that humankind has always had to deal with. Hence, science has offered some solutions to them. Although a positive connotation has been attributed to these scientific advancements, the research methods and strategies that specialists employed in order to reach the knowledge that would solve these problems have been called into question. Specifically, experimental research carried out in the field of health science uses animal experimentation for their scientific and teaching endeavours. Throughout the centuries, the stance taken towards this matter, not only by our society but also by the scientific community itself, has evolved significantly. Nowadays, for instance, the respect for life has become a guiding principle in all fields. Adopting this new perspective challenges the relationship between the notions of research, experimentation and results, all of which combined in this context have the goal of improving people’s quality of life. Therefore, we wonder whether science education itself is inseparable from the dilemmas that arise from these bioethical problems. Our presentation illustrates a way of teaching science that takes into account the bioethical problems that stem from research carried out with living subjects, taking the findings of our field work as a starting point.

Keywords: nature of science, biological experimentation, ethics in science.

INTRODUCTION

The society of the new millennium, while claiming quick solutions for its problems and a better quality of life, questions the ways that enable it to reach those comfort levels. Thus, for example, it is intended to have dermatologically tested hypoallergenic cosmetics but the use of laboratory animals for these tests is condemned. It is precisely this type of paradoxical issues that give rise to the need to build a new knowledge which considers the promotion of health, the prevention and treatment of diseases and other forms of scientific knowledge while addressing the most sensitive issues about caring for the lives of human beings, animals, plants and the environment.

In this sense, the articulation between the scientific disciplines of the biological field and Bioethics allows the integration of knowledge related to this care, with the ideas and conceptions regarding the nature of science (NOS) and the ways in which scientific knowledge is constructed.

Bioethics is a relatively new discipline dedicated to the analysis of the articulation between ethics and science and the study of human behaviour in relation to life in a broad sense, both of human beings and other forms of life and the environment in general (UNESCO, 2005, Michel Fariña & Lima, 2009). Now, how are bioethical principles articulated with the forms
of knowledge production and how could they be integrated into their teaching? What is the relationship between Bioethics and conceptions about the nature of science?

In order to answer these questions, one can resort to the narrative trend in Bioethics which proposes a deliberative method articulated with aesthetic, cultural and narrative references. This allows the establishment of reflection and critical thinking in situations of teaching, learning and research in natural and health sciences, while simultaneously constituting a new field of research. Thus, we have started a study that investigates such situations in order to describe and understand them, so as to elaborate proposals for the science classroom in a timely manner.

In summary, in this work we present the advances of a research that deals with the interrelationships between scientific research practices, the teaching of biological sciences and the bioethical issues that permeate them using film narrative as an instrument to highlight the different dilemmatic situations which cross this particular ecosystem.

THEORETICAL FRAMEWORK

Bioethics is dedicated to analysing and sharing principles for a practice that includes both the care of human life and animal and plant life, and even the environment (Jahr, 1927, UNESCO, 2005). Specifically referred to the biomedical field, it can be defined as "the systematic study of human behaviour - examined in light of moral principles and values - in the area of life sciences and health care" (Stagnaro, 2002, p.1). Its four fundamental principles are: autonomy, non-maleficence, beneficence and justice (Beauchamp and Childress (1999 [1979]).

Although it has its disciplinary roots in Philosophy (Sass, 2008, Lolas Stepke, 2008), after the contributions of Potter (1971), Bioethics has been focused for many years on principles of medical ethics related to the doctor-patient relationship. However, the international law of greater scope and dissemination in this regard, the Universal Declaration of Bioethics and Human Rights promulgated at the General Conference of UNESCO in 2005, has twenty-eight general principles which are not restricted to the biomedical field but that extend the traditional concept of Bioethics, dealing with issues such as the biosphere, the environment, the fate of the planet and future generations. Respect and care for life - in its multiple forms, taking into account the environment and future generations - then take on a new scope. On the other hand, the articles that address limited issues in the field of health, do so in a more comprehensive way and in articulation with the concept of Human Rights.

One of the chapters of Bioethics deals with research and teaching involving animals or their derivatives, which exposes issues such as animal suffering, animal rights, responsibility for the environment and the care of future generations, among others. What are the concerns regarding animal experimentation for which Bioethics could open an interdisciplinary dialogue? In the first instance, there would be man-animal relationships in different contexts of culture in general, for example, the historical development of vivisection (Atalić, 2012), historical studies on anatomy, the contexts of emergence of animal rights, as well as local and international regulations, from the guide for international biomedical research International Guiding Principles for Biomedical Research Involving Animals (Geneva, 2012), the guide for animal research for Psychology Guidelines for Ethical Conduct in the Care and Use of Nonhuman...
Animals in Research (APA, 2012) and the Regulations for the care and use of laboratory animals of the CICUAL, in Argentine territory. For this analysis we have also included the "3 R’s" principle of Russell and Burch (1959), which continues to be paradigmatic for thinking about the guarantees of respect and the rational use of animals used in teaching and research. The "3R’s" refer to the Replacement, Reduction, and Refinement: it is necessary to replace the animal with other types of models when possible, reduce the number of animals in the research projects and in the lessons, and refine the techniques and procedures of manipulation of the animals in such a way as to minimize the possible discomfort and pain that they might suffer.

On the other hand, the narrative trend within Bioethics (Hauerwas & Burrell, 1977, Gracia, 2000), as a conceptual and practical basis, includes not only the norms and principles, but also the circumstances, emotions and feelings, in a "double dimension of narrativity" (Moratalla & Feito Grande, 2014): the anthropological (as a way of being: "we are a narrative species") and the methodological (since the use of the stories allows us to live or decide better). This method of bioethical deliberation is used both in research and in teaching and learning processes. Within the narratives of this trend in Bioethics, the cinema and the audio-visual media are constituted as privileged articulators to achieve links between ideas, make explicit knowledge and previous assumptions, and promote the encounter with new themes and concepts.

In the first place, the film narrative is a system of external representation, which allows the representation of beings, objects or phenomena, either with a graphic character (on paper or audio-visual, mainly) or mental (from a process of abstraction more or less complex) (Perales, 2006). Therefore, due to its dynamic image character, it admits a didactic use which offers a field of reflection for the physical and natural sciences (Ortega, 2002). In this way, the narratives and bioethical deliberations through the cinematographic narrative are excellent bridges to analyse and rethink aspects related to experimentation with animals, as well as other topics of great interest for the teaching of sciences. The design of these bridges is fundamental for the construction of meaningful learning (Estévez Nénninger, 2002) to prevent the contents from being memorized and forgotten quickly. In this regard, Arnheim (1993, p.89) emphasizes visual learning and its importance as "the main vehicle to approach the organization of thought".

The inclusion of this type of studies in teacher education devices offers the opportunity to reflect on what can be taught (Perrenoud, 1994), considering both aspects related to didactic transposition and promoting the construction of competences in scientific-professional training. Although what is transposed refers to scientific and technical knowledge, its integration takes place in a situation of action, with particular competences of specific contents and attitudes and evaluative positions in this regard (Sánchez Vázquez, 2013). That is why the integration of bioethical categories in teaching and learning processes (such as responsibility, justice, among others), exceeds the disciplinary corpus and therefore requires a continuously reflective practice. This reflection on the practice also includes the social system (Rovaleitti, 2003) constituted by the scientific community that supports the research processes.
Science education and animal experimentation

Up to this point, the basis which have given rise to a new field of research that articulates bioethics with science didactics have been presented. Then, it is deepened in the specific aspects of this field applied to the training of science teachers.

Health Sciences (Medicine, Psychology, Pharmacy, and Biochemistry, among others) have in common their primary interest in the care and well-being of human beings, which is reflected in the research they conduct, and in the practices linked to the promotion of Health, the prevention and the treatment of diseases that they promote. Therefore, the social representation of science is usually that of a discipline that strives for an advancement in knowledge that intends to benefit humanity at large. However, as it has been pointed out, there is sometimes a lack of a critical view regarding how this knowledge is acquired (Solbes, & Traver, 2001; Solbes & Vilches, 1997).

Following Solbes & Traver (2001), Serres (1991) & Ziman (1986), we consider that the process by which any knowledge is acquired, the instruments that are employed for that purpose, and the institutions where research is conducted must all be taken into consideration when analysing the notion of scientific advancement. The relationship between all these elements emphasizes the strong bond between science and other social players and institutions (such as the State, Education, Public Health, the Industry, among others), and the impact in terms of policy that scientific work can have (shaking beliefs, swaying opinions, and shattering paradigms).

The concept of Nature of Science (NOS) refers specifically to the aspects of science education that deal directly with the development of an understanding of the nature of science itself, its methods and its complex interactions with society (Hodson, 1992). In fact, Bell & Lederman (2003) point out that NOS is relevant beyond the scientific theory, as considering this notion would promote teaching and learning processes themselves, thus shifting the focus away from the repetition of scientific facts, laws and theories alone. Learning about knowledge and the critical construction of concepts requires the socio-historical context in which they were constructed, in order to be understood in a more holistic way, together with interdisciplinary reflections from History, Philosophy, Sociology and Psychology.

In this line, how can we regard, from the NOS point of view, the use of animals or living subjects in experimentation? It is common knowledge that animals or other living organisms have been both used for research and for science education since their very beginnings. Approximately three million animals are currently used every year in scientific procedures around the world (Cardoso & Mrad, 2008). For the past decades, these practices have been reviewed by different agencies, and various regulations have come into force (UNESCO, 2005). Likewise, attempts to replace animals or their derivatives by other tissues synthesized in laboratories, have decreased the number of specimen used, although it is still considerable.

Taking into account the conditions in which scientific knowledge is produced in light of the concept of NOS, and in line with the concerns about the use of animals in scientific experimentation, we raise the following questions: Which aspects related to research, teaching and learning involve the use of living animals and animal tissues, and how has this activity
changed in the last century - both in research and in science education? What are the contributions that Bioethics can make to reflect upon this matter?

Most universities are academic institutions dedicated to the training of professionals, but they are also a space for the construction of new knowledge through the processes of scientific research, both in its basic dimension and in an applied way by solving specific problems and offering a service to society. In the case of career study programs linked to biological sciences such as those mentioned above, the use of laboratory animals for experimental tasks is commonplace. And they have also been used for research as a didactic resource for teaching in the training of health professionals. Unlike the obligatory levels of the educational system that promote scientific literacy, the university is characterized by the specificity of the contents it imparts and the practices it promotes (Figure 1). Consequently, it constitutes a privileged space for the study of the interrelationships between Bioethics, scientific research practices and science education.

![Figure 3. Research, teaching and services at university](image)

**RESEARCH QUESTIONS AND WORK PROPOSALS**

At this stage of the research we raise the following question: What are the bioethical issues that stem from the use of animals or other living subjects for teaching or experimentation? Which of these issues can be answered through films, considering they can serve as a narrative for bioethical deliberation? What are the bioethical notions linked to animal experimentation that can be analysed through a cinematographic narrative? How can these bioethical notions be linked to the Nature of Science? How can this knowledge be transferred to the current teaching and learning environment? What issues can be conveyed to our students through the analysis of fictional scenarios presented by films? What are the advantages that films offer for the transmission of concepts in science education?

In order to answer these questions, we have carried out an integral study. In this first stage of work we have designed an instrument to research the bioethical problems related to animal experimentation, based on audio-visual narratives. Our design follows the guidelines established by Rest (1979), who proposes the use of an instrument for analysing the ethical
sensibility of teaching. The instrument is based on *The Boys from Brazil* (Franklin Schaffner, 1978), which allows us to establish a bond between bioethical dilemmas and animal experimentation, as well as it explores other relevant issues such as informed consent.

The film is based on the homonym novel by Ira Levin. The fiction states that, running away from the trials against the Nazi doctors and the international condemnation of the participants and ideologists of the machinery of the Holocaust horror, the Nazi doctor Josef Mengele hides in the Paraguayan-Brazilian jungle.

Mengele, who was a fugitive in Brazil in order not to be tried for his crimes as the doctor responsible for Auschwitz concentration camp, is recreated in the film as a doctor who plans to continue with Hitler's ideology of Aryan domination. He has started a genetic and social project based on the use of Adolf Hitler's blood and skin tissues, obtained when he was still alive in the Third Reich, in order to have another Hitler in the history of humanity.

A Jewish survivor begins to investigate the escape of Mengele and learns that, in a clandestine laboratory, the doctor intends to generate ninety-four clones of the Führer. This cinematic fiction allows us to think about the issue of cloning almost twenty years before the procedure with Dolly the sheep.

In that laboratory, Mengele experiments with animals and with natives of the Brazilian jungle. The human embryos (exact genetic copies of Hitler) are transferred to indigenous women of the Brazilian jungle, who - anticipating the modality of surrogate gestation, so present in the debate on contemporary assisted human reproduction - officiate as pregnant women for nine months, without having given any kind of consent. Then, these babies are given for adoption to families in Europe and the United States, carefully chosen. In order to control not only the genotype but also the phenotype of the children, and the environmental factors, Mengele chooses ninety-four homes strategically located around the world, so that the children could grow and develop the personality of Hitler. Likewise, the plan includes the repetition of different events that had marked the life of the Führer, among them, the accidental death of the father, which occurred when Hitler was fourteen years old.

In the selected scenes, the focus is on animal experimentation, the explanation of the cloning process and experimentation with human beings without their consent.

**Methodology**

This qualitative exploratory study was carried out within several teacher training courses held during 2017 as a first approximation for the description and interpretation of the problems of the field. In general, in order to collect data, the audio-visual resource is projected in a full group session (selected episodes or complete films) and then a specially designed questionnaire is applied individually or in small groups (Figure 2). For this experience, the film *The boys from Brazil* was used.
Figure 4. Questionnaire for data gathering

The corpus of information was constituted by the responses of the participants of the activity. The writings were analysed following the Grounded Theory (Glaser and Strauss, 1967), which allows to infer concepts, theories and propositions starting directly from the data. Among the categories of analysis are:

- *The aspects of the particular situations that the students manage to capture*: descriptions of the cinematographic situations, interventions of the doctors and biologists, adjustment to the norms, processes of decision making, juridical or legal questions.

- *Explicit marks of personal positioning*: interpretations of what happened, values in relation to their moral positioning, explicit appearance of the enunciation position (“I believe”, “I think”).

RESULTS

The incipient results of this first exploratory study showed the importance of the cinematographic narrative in the visibility of bioethical problems, evidencing the sensitization of the people who participated in the training activity. In order to show the impact of the activity, some examples collected during the investigation are presented below (it should be noted that it has not been of interest for this study to establish correlations with certain characteristics of the participants, it is enough to know that science teachers have been active).

From the work done from the film *The Boys from Brazil*, the participants highlighted the intervention of the doctor / scientist, Josef Mengele, who is also a historical person recognized worldwide for his contribution in the Nazi experiments of Auschwitz. The figure of Mengele was seen as someone without limits who, according to the words collected from the questionnaires, performs "macabre experiments" and that this was done in a framework of "total impunity".

810
Another emerging aspect has been the possibility of placing human beings as part of Nature, as expressed by two of the participants (translation is ours)

— “The general impression is amazement and rejection towards evidence of human beings who marvel at scientific achievements, which were believed to be science fiction until a few years ago, accounting for human intellectual possibilities, without considering emotional, ethical and humanity aspects”.

— “There are some elements of the final dialogue which are very interesting. While the biologist fantasizes with the possibility that someone has achieved the reproduction of clones in humans, the main actor is horrified by the ethical implications of the experiments. I believe that this dichotomy arises permanently for those who in one way or another are linked to scientific activities. On the one hand, the possibility of crossing barriers that at one time seemed insurmountable. On the other, the awareness of the social, political, environmental scopes … of these advances”.

The scenes about the project of cloning in humans (mainly, with the aim of cloning Hitler) were the most commented. On the one hand, the participants expressed amazement at the representation of these cellular processes, anticipating the advances of science itself (we must remember that the film is from the year 1979). On the other hand, rejection has been the most widespread sensation. This is restricted to the ultimate purpose of the experiment and not to the modes of experimentation itself (it is striking that the experimentation with animals is omitted in their mentions about what they visualized in the cut out of the film, to focus on the effects that this experiment could have in the history of mankind). For example, they noted:

— "This fiction allows us to reflect on the human, cultural, scientific activity, and on the fact that it is not exempt from ethical issues and political and ideological positions."

— "The responsibility towards society is not present from the moment that this is hidden. The rights and obligations do not exist. The scientist has the place of the creator. In the film, life, pain and death play a secondary role against the advance of science. The means is justified by the aims."

The participants also stressed that experimental animals are seen as mere objects, inanimate, without feelings, unprotected. In this regard, it was pointed out that in some cases the damage inflicted and the possibility of replacing animals with other research models should be taken into account.

— "Humans and animals are represented as objects of investigation, that is, as if they lacked sensitivity."

— "The animals and people that are part of the research are treated as a mere set of cells that can be a treatment substrate. No bioethical precautions have been taken into account. Respect for life and the characteristics of each species must be paramount when planning, designing and implementing an investigation of any kind. In the case of human beings who offer themselves voluntarily, they should be anticipated about the possible damages that the practice to which they will be subjected may cause".

**CONCLUSIONS AND PERSPECTIVES**

From the broad field of study that makes up Science Education as a research discipline, we find that the concept of NOS is what allows to build bridges with Bioethics as a relatively new discipline, which promotes the construction of meaningful learning. In addition, this articulation between ethics and science enables the construction of competencies in scientific-professional training at the university level. Therefore, the inclusion of NOS is considered in order to be able to visualize the complex interactions with society.

The use of film narrative as an instrument of intervention and research offers a unique display of situations that can be used to interrogate bioethical issues in the teaching and learning of the biological sciences, as well as in relation to scientific experiments and research. In this opportunity it allowed to open the debate and the reflection on diverse underlying aspects of the scientific practice, transcending an initial glance (for example, on Mengele in moral terms as a good or bad person) to focus on the role of the scientist and the developed scientific activity, his responsibility to his colleagues and his time.

From the studies carried out, the following emerges:

- Dynamic representations such as television series or films allow us to work on issues related to NOS aspects through their narratives.

- The cinematographic narratives achieve the sensitization of viewers on bioethical issues in relation to the development of scientific research or the application of specific fields, such as medicine.

- The interrelations between NOS and Bioethics as an active field for research in science education need to be nourished by new theoretical and methodological contributions.

- The high availability of varied technological devices allows to enhance the possibilities offered by the film narrative and / or the series for teaching science.

Definitely, the articulation between Bioethics and the Biological Sciences offers a different view on the complexity that allows new perspectives for the analysis of social and scientific issues, which attends to human wellbeing and its quality of life, and also promotes the reflection of students and professionals facing highly dilemmatic situations.

NATURE OF SCIENCE AND SCIENCE CONTENT LEARNING – TEACHING ABOUT THE CONCEPT OF ENERGY

Hanno Michel and Irene Neumann
Leibniz-Institute for Science and Mathematics Education (IPN), Kiel, Germany

Among other arguments for including aspects of nature of science (NOS) in science education, researchers have repeatedly claimed that NOS understanding would support students’ efforts in gaining conceptual understanding (e.g. Driver et al., 1996). However, only few studies have systematically investigated this potential effect (Lederman, 2007). In the present study, an epistemologically informed teaching unit about energy, in which aspects of NOS and of the energy concept were taught in an integrated manner, was compared to a conventional teaching unit about energy that did not focus on NOS aspects. 191 students from grades 10 to 13 participated in one of the two teaching units. Students’ NOS understanding, their disciplinary content knowledge about energy (CKE), as well as their understanding of epistemological aspects of energy (EAE) were assessed before and after the respective teaching unit. While there was no difference between the groups regarding students’ CKE gain, students’ understanding of NOS and of EAE could greatly be fostered by an explicit integration of NOS and energy aspects during instruction. These results imply that for students to develop a sound understanding of science concepts including the concepts’ epistemological aspects, these aspects should be explicitly integrated and discussed in addition to the disciplinary content.

Keywords: nature of science, energy concept, epistemologically informed teaching

INTRODUCTION

In their literature-based rationale for the importance of including nature of science (NOS) in science instruction, Driver, Leach, Millar and Scott (1996) provided a so-called ‘science learning argument’, concluding that NOS understanding might foster students’ ability to interrelate scientific concepts and thus coherently adopt scientific content knowledge. Until now, however, only few studies focused on the impact of NOS understanding on students’ acquisition of science content. In fact, there seems to be a lack of systematic investigations clarifying the relations between NOS instruction and learning of science concepts (Lederman, 2007; Peters, 2012). The present study aims to address this lack of research. More precisely, we compared two teaching units addressing the concept of energy (1) through a traditional teaching approach and (2) through an epistemologically informed teaching approach, which concatenates NOS aspects and traditional disciplinary aspects of the energy concept, and which explicitly focuses on epistemological aspects of energy.

THEORETICAL BACKGROUND

Nature of Science and Science Learning

The role of NOS understanding for science learning has been subject of several investigations. For example, Tsai, Ho, Liang, and Lin (2011) reported about a positive relation between students’ NOS understanding and their self-beliefs. Similarly, NOS understanding was found to correlate with students’ interest in science (Lin, Hong, & Chen, 2013), learning strategies in
