science (Tsai, 1998), and other affective, motivational, and cognitive variables (e.g. Bell & Linn, 2000; Khishfe, 2012), all of which are believed to promote the learning of science. Thus, studies like the above may indicate an – at least indirect – relation between NOS understanding and science content learning. Far fewer studies, however, have undertaken to investigate the relation between NOS understanding and science content learning in a direct manner. For example, Peters (2012) investigated the teaching of electricity and magnetism with and without explicit metacognitive prompts focusing on particular NOS aspects. Regarding both, NOS understanding and content knowledge, students receiving such metacognitive prompts outperformed students that did not receive prompts. In a similar manner, Schwarz and White (2005) investigated the role of NOS in the teaching of genetics, and Kim and Irving (2010) studied the effect of NOS understanding on the teaching and learning of force and motion. However, in contrast to Peters’ study, the latter studies did not indicate a relation between NOS and content learning. Overall, in contrast to the broad research base on the relation between NOS understanding and learning-related factors (indicating an indirect relation between NOS understanding and science content learning), a potential direct relation is far less investigated and the so far results are somewhat ambiguous.

Regarding NOS instruction, a lot of research has focused on how ideas about NOS can be taught and how NOS instruction can be realized for students of different ages. It appears to be important to teach NOS explicitly, as opposed to just engage students in science activities and expect them to derive the underlying epistemological ideas on their own (Khishfe & Abd-El-Khalick, 2002). At the same time, even though NOS can be introduced and taught as a stand-alone topic in a decontextualized manner (see e.g. Lederman & Abd-El-Khalick, 1998), NOS should best be taught contextualized, i.e. set in a scientific context (Clough, 2006). On the one hand, science content aspects can be used to exemplify concrete manifestations of NOS aspects in everyday science, and on the other hand, NOS can help to connect different scientific disciplines or areas with each other by providing a joint framework, in order to make sense of science as a whole.

**Epistemological Aspects of Energy**

Each scientific concept consists of particular disciplinary aspects (e.g. that there are several forms of energy), but also holds epistemological aspects (e.g., the theoretical nature or explanatory power of energy). Several scholars have argued that such epistemological aspects should be addressed in science education (e.g. Driver et al., 1996; Duschl, 1990; Erduran et al., 2007). To be included in science teaching, such epistemological aspects should be simple enough for students to understand, relatively uncontroversial, and productive, i.e. supporting students in making sense of disciplinary content knowledge (Papadouris & Constantinou, 2017). If they meet these criteria, epistemological aspects of science concepts can contribute to students’ learning by promoting facility with content knowledge, helping students develop an informed epistemological stance towards science learning as a whole, and at the same time

---

1 The activities presented by Lederman and Abd-El-Khalick (1998) can be used without a science context, the authors themselves, however, recommend using them in a contextualized manner.
enhancing students’ NOS understanding (Erduran et al., 2007; Papadouris & Constantinou, 2017). As such, epistemological aspects of science concepts are closely linked to NOS, so they can serve as contextualized examples of NOS aspects that can then be discussed and taken to a more general level. At the same time, teaching NOS aspects seems to be important as a prerequisite to help students understand and to appreciate students’ understanding of epistemological aspects. According to the above reasoning, integrating NOS and science content instruction appears quite worthwhile and promising for efficient science education. With respect to the energy concept, for example, disciplinary aspects would contain that there are different forms of energy, which can be transformed from one into another, and that energy is conserved but usually degrades (Duit, 2014). Epistemological aspects of energy would include ideas about the status, purpose and value of the concept (Bächtold & Guedj, 2014) such as that it is to be applied to a broad variety of phenomena (crosscutting nature of energy), or that it is human-conceived and theoretical in nature (Papadouris & Constantinou, 2017). Papadouris and Constantinou (2011) developed a teaching unit that focuses on these epistemological aspects of energy, connecting energy aspects to aspects of NOS in a way that both concepts mutually promote each other. They qualitatively showed that the unit was promoting students’ understanding of NOS and of energy (Papadouris & Constantinou, 2014). The present study aims to substantiate these findings by providing quantitative data and by comparing students’ learning gains regarding NOS and energy to those of students in a respective control group, by addressing the following research questions: (1) How does an epistemologically informed unit about energy influence students’ gain in conceptual understanding – regarding disciplinary and epistemological aspects of the energy concept – as compared to a conventional teaching approach? (2) How does such teaching unit influence students’ NOS understanding?

METHODS

To investigate whether students’ understanding about NOS and energy would benefit from an epistemologically informed teaching unit, an intervention study was performed with 191 students from grades 10-13. The students participated in one of two teaching units, each comprising of two days with a total of five 90 minute lessons. Students in the treatment group (n = 94) received a unit, which partially followed the teaching sequence developed by Papadouris and Constantinou (2011). In this sequence, selected NOS aspects were introduced using generic NOS activities (Lederman & Abd-El-Khalick, 1998) and were then meaningfully concatenated with activities fostering students’ understanding of the energy concept. During the unit, three epistemological aspects of the energy concept were explicitly discussed and connected to aspects of NOS: (1) The energy concept can be used for approaching and explaining a broad variety of phenomena, i.e. it is crosscutting and transdisciplinary in nature; (2) the energy concept serves as a powerful framework for the unified analysis of the operation of physical systems, that is, it holds great epistemic value and explanatory power; and (3) energy – from an ontological viewpoint – is a theoretical, human-conceived construct, which has been brought up by scientists, rather than being a directly observable and measurable entity (see also Bächtold & Guedj, 2014; Papadouris & Constantinou, 2011). NOS aspects that were emphasized throughout the unit (as they are thought to support students’ learning of the
respective epistemological aspect of energy) were (1) the desired generalizability of scientific knowledge; (2) the aim of scientific theories to provide explanations and to allow for the unified analysis of natural systems and phenomena; and (3) the difference between observation and inference, the role of creativity and invention in scientific processes, and the tentativeness of scientific knowledge. Students in the control group (n = 97) received a conventional unit on energy that did not explicitly emphasize aspects of NOS or epistemological aspects of energy. Before and after the respective teaching unit, all students were administered questionnaires assessing students’ understanding of epistemological aspects of energy (EAE), their disciplinary content knowledge about energy (CKE), as well as their NOS understanding (NOS).

RESULTS

Students’ learning about energy

Figure 1 displays the results for both groups’ average scores on the CKE assessment before and after the respective teaching units. A respective ANOVA did not show a significant difference in learning gains between the groups (F(1,188) = 0.002, p > .05). Furthermore, when exploring individual items, we did not find any significant difference in students’ average gain in item score between the two groups. For both groups, there are significant learning gains regarding CKE (p < .001). The effect sizes were similar for both groups (treatment group: d = 0.78, control group: d = 0.8).

![Figure 1. Means and 95% confidence intervals for students’ understanding of disciplinary content knowledge about energy (CKE) before and after the teaching unit.](image)

Students’ understanding of EAE, as assessed before and after the respective teaching units, is shown in Figure 2. A respective ANOVA shows a significant difference in students’ average learning gain (F(1,188) = 18.39, p < .001). While students of both groups show significant learning gains (p < .001), the learning gain regarding EAE was higher for the treatment group (effect size: d = 0.74) than for the control group (d = 0.48, see Figure 2). Additionally, when exploring individual items, there seem to be differential effects for the control group on the one
hand, and the treatment group on the other with respect to the addressed epistemological aspects of energy

![Figure 2](image)

**Figure 2.** Means and 95% confidence intervals for students’ understanding of epistemological aspects of energy (EAE) before and after the teaching unit.

**Students’ learning about nature of science**

Students’ understanding of the selected NOS aspects appeared to develop similar to their EAE understanding (Figure 3). There was a significant difference in learning gains between groups ($F(1,188) = 65.74, p < .001$), with the treatment group showing a much higher learning gain ($d = 0.84$) than the control group ($d = 0.57$). While both groups showed a learning gain throughout the respective teaching unit ($p < .001$), the impact on students’ NOS learning seems to be particularly huge for those receiving explicit NOS instruction.

![Figure 3](image)

**Figure 3.** Means and 95% confidence intervals for students’ nature of science understanding (NOS) before and after the teaching unit.
DISCUSSION AND CONCLUSION

The results indicate that the epistemologically informed teaching unit on energy (treatment group) could enhance students’ acquisition of both NOS understanding and an understanding of the epistemological aspects of energy, when compared to a conventional unit on energy (control group). The small but significant learning gain regarding NOS understanding, that was found for the control group, might indicate that an adequate NOS understanding can also partly be conveyed without explicitly emphasizing NOS aspects in science instruction. This, however, seems to happen at a much slower rate as compared to when NOS aspects are explicitly addressed in the teaching unit. This is in line with the literature identifying an advance of explicit against implicit NOS instruction (e.g. Khishfe & Abd-El-Khalick, 2002).

A similar effect can be observed when analyzing the data for students’ EAE understanding. The control group shows a significant learning gain throughout the unit, despite these epistemological aspects not being explicitly addressed. Applying the energy concept to a broad variety of different phenomena and experiencing its explanatory power seems to implicitly convey ideas about the status, purpose, and value of the concept, even if these are implemented in an only implicit manner. However, this learning gain seems to not relate to all epistemological aspects to an equal amount. Thus, explicitly addressing these aspects and connecting them to aspects of NOS in general, can strongly increase the degree in which an adequate understanding of all epistemological aspects is supported.

For disciplinary content knowledge about energy, the epistemologically informed teaching unit appeared to have no additional effect on students’ learning gain, when compared to a conventional unit about energy. This finding, however, only relates to a potential short-term effect of NOS instruction on science content learning about energy in general. In the long term, NOS understanding might indeed foster students’ acquisition of conceptual understanding, e.g. through promoting students’ motivation or their ability to coherently adopt new knowledge, as well as it might have different effects on students’ learning of the various aspects of the energy concept. Such possible long-term effect however, was unfortunately not investigated in the present study and calls for further research.

Overall, the results substantiate those of Papadouris and Constantinou (2014b) and extend them by providing quantitative data. At the same time, the results of the present study provide evidence for the so-called “science-learning argument” stated by Driver, et al. (1996): There seems to be a relation between NOS understanding and science content learning, at least regarding epistemological aspects of science concepts. Thus, when science education aims to not only convey traditional disciplinary aspects of energy (e.g. knowing different forms of energy, applying the law of energy conservation etc.) but also to let students perceive the value of energy as a central theoretical framework in science, which can be applied to manifold different phenomena and problems, an epistemologically informed approach towards the concept appears to be highly supportive. In order to find out if epistemologically informed teaching is supportive for concepts other than energy as well, and which aspects of NOS are contributing to which aspects of conceptual understanding, further studies should examine other concepts central to science, identify their epistemological aspects and investigate how they can be taught to best effect. Furthermore, as the literature so far provides mixed results,
more research is needed on the potential role of NOS for learning about disciplinary aspects of science concepts. Our study provides promising results as to the effect of integrated NOS instruction on both students’ NOS and conceptual understanding about energy. Whether and how these results can be assigned to other concepts as well should be subject of further research.

THE ‘SCIENCE AS INQUIRY’ APPROACH TO NATURE OF SCIENCE TEACHING

Dina Tsybulsky
Tel Aviv University and Mofet Institute, Tel Aviv, Israel

The paper deals with two novel methods of NOS teaching in an authentic context: 1) reading Adapted Primary Literature (APL); 2) visiting of Authentic University Laboratories (AUL). Both methods are based on Schwab’s approach of ‘teaching science as inquiry’, yet involved different type of ‘authenticity’. APL grounded in indirect contact with scientists (via texts), while AUL grounded in direct contact with scientists. The paper describes the methods, studies their effect on students’ NOS understanding and compares between the two methods in terms of their effectiveness. The study uses a quasi-experimental, pre-post control design, which utilizes quantitative (Likert-type) evaluation methods. The sample comprised grade 11 biology students (n=210) from Jerusalem area (Israel). The study employed 3 research groups: 1) experimental group 1 – students who learned according to APL method; 2) experimental group 2 – students who learned according to AUL method; 3) control group – students who learned the standard biology program. The study indicates that teaching NOS in an authentic context by using science as inquiry methods is an effective approach for NOS learning. We believe that both APL and AUL methods have a high potential and can be successfully adapted for teaching various science subjects, in different cultural contexts.

Keywords: nature of science, inquiry-based teaching, teaching methods in science

INTRODUCTION

This paper focuses on teaching NOS through Schwabs’ (1962) science as inquiry approach for teaching science, which stress ‘enquiry into enquiry’ as an optimal approach to promoting inquiry learning. A variety of instructional methods have been used within this context, including integrating the teaching of history and philosophy of science (Galili 2012; Galili and Hazan 2001), discussions of socio-scientific issues (Lederman, Antink, and Bartos, 2014), as well as the discussion of contemporary cases (Allchin, Andersen, and Nielsen, 2014). All of these methods are intended to demonstrate to students the manner in which scientists interpret information and draw conclusions. At the same time, they present science as a human activity for constructing tentative but objective knowledge, i.e., a rational account of Nature (Galili 2012).

We focus on two novel ‘science as inquiry’ methods for biology teaching in high school: reading and analyzing Adapted Primary Literature (APL) and visiting an Authentic University Lab (AUL).

The APL method was developed at the Weizmann Institute of Science and was included in the Israeli biology curriculum as one of the elective topics that high-school teachers can choose to teach (Israeli Ministry of Education, 2010; Yarden, Brill, and Falk, 2001). APL refers to an educational genre specifically designed to enable the use of research articles in teaching biology in high school. The APL method has been shown to improve the students’ understanding of the nature of scientific inquiry and to raise scientific criticism regarding the researchers’ work (Baram-Tsabari and Yarden, 2005).
The AUL approach to NOS teaching was developed at the Hebrew University of Jerusalem (Tsybulskey, Dodick, and Camhi, 2017a; 2017b). This method was designed to enhance the understanding of the NOS among Israeli high-school biology students. The AUL approach focused on a four-hour visit to a university with guided learning experiences, and stressed the dialogue between students and researchers, as per Hodson and Wong (2014), who claim that students can attain a richer NOS understanding through direct contact with authentic scientists. The three-year research study at 12 Israeli schools (n=497) showed that AUL method does indeed have a positive effect on the students’ NOS understanding (Tsybulskey, Dodick, and Camhi, 2017a; 2017b).

The APL and AUL methods involve different types of ‘authenticity.’ APL is grounded in indirect contact with scientists (via texts), whereas AUL is grounded in direct contact with scientists. In order to assess and to compare the effect of the methods on students’ NOS understanding, we designed, implemented, and evaluated two versions of a biology learning unit, called Students Meet Authentic Science. Version 1 of the unit is based on the AUL method, while Version 2 is based on the APL method. We focused on the following NOS aspects: tentativeness of the scientific understanding, cooperative nature of the scientific process, methodological diversity, socio-cultural embeddedness of scientific knowledge, and aims of science. A few of these were derived from US and Israeli position papers that address science-education standards (NRC 1996, 2000; 2012; NGSS Lead States 2013; Israel Ministry of Education 2010) and others were significant features of NOS that we determined were missing from these documents. These aspects relate to science as a cognitive-epistemic system and as a social-institutional system (as per Irzik and Nola, 2014).

METHODS

Design and Implementation of the Units

The learning units that were developed are intended for high-school students (in the 11th grade) specializing in a high level of biology studies (i.e., students studying for the highest possible level, ‘5 units,’ for the Bagrut, the Israeli matriculation exams). The units are directly related to the biology curriculum in that they focus on two core issues: cell biology and ecology. Each of the units spans a total of 14 hours. Each is comprised of three stages: preparation, a visit to a lab or reading of articles, and summary. The preparation and summary phases are more or less identical in the AUL and APL models, and they include an additional practical involvement of learning science as inquiry (including both inquiry narratives and historical narratives). We kept this parallel structure to strengthen the impact of these models on the students’ understanding of the nature of science. In addition, this design enabled us to compare the two models through proper research methods, as the main and most substantial difference between them took place at the second stage, which involved either the lab visits or readings – i.e., the difference between the two methods; thus, the structure enabled comparison between the two models. We prepared a student manual that included the materials that we prepared for the project and room for the students to write in (for the stages in which they were expected to write, such as answers to questions or their own reflective analysis).
Evaluation and comparison of the APL and AUL methods

In order to evaluate and to compare the effect of APL and AUL methods on students’ NOS understanding, we conducted a one-year research study. The study used a quasi-experimental, pre-post control design, which utilized quantitative evaluation method (Likert-type pre-post questionnaire). The study employed 3 research groups: 1) experimental group 1 (n=75) – students who learned according to AUL method; 2) experimental group 2 (n= 64) – students who learned according to APL method; and 3) control group (n=71) – students who learned the standard biology program (cell biology or ecology) without science as inquiry teaching methods. All of the students signed informed consent forms to participate in this study.

Data analysis included statistical analysis of the Likert questionnaires by using non-parametric, Wilcoxon signed-rank and Sign statistical tests. To compare the effects of the teaching methods on the three participant groups, we conducted (a) pre-and post intragroup comparisons, and (b) pre-and post intergroup comparisons.

RESULTS

In Tables 1 and 2, we present findings of the intragroup comparison of Likert-like scores of the two experimental groups, calculated as poste-minus-pre-differences. Findings from the control group are not shown, as no significant differences were found.

An examination of the findings demonstrates that in Experimental Group 1 (AUL), the pre-post differences were significant in all NOS aspects, indicating that students who studied in the AUL method experienced a significant improvement in their NOS understanding. By comparison, in Experimental Group 2, significant pre-post differences were demonstrated in only two NOS aspects (the tentativeness of scientific understanding and the methodological diversity of scientific inquiry), suggesting that their NOS understanding improved only partially.

In Table 3, we present findings of the intergroup comparison of Likert-like scores, calculated as post-minus-pre-differences.

A significant difference was found between Experimental Group 1 (AUL) and the control group on all examined NOS aspects. This finding indicates that the NOS understanding of students whose study program included visits to university laboratories improved significantly compared to the NOS understanding of students who participated in the standard biology study program. In contrast, a comparison between the outcomes of Experimental Group 2 (APL) and the control group rendered a significant difference in only two NOS aspects: the tentativeness of scientific understanding and the methodological diversity of scientific inquiry. On the category of the sociocultural embeddedness of scientific knowledge, a significant difference was found on only one of the two relevant items, and no significant difference was found on either the category of the cooperative nature of the scientific process or on the aims of scientific inquiry. These findings indicate that the NOS understanding of students whose program included reading of adapted scientific articles improved only partially, in comparison to the improvement demonstrated by students who participated in the standard biology study program.

A comparison of the outcomes of experimental groups 1 and 2 found a significant difference on both items pertaining to the following four NOS aspects: the cooperative nature of science, methodological diversity, the aims of scientific inquiry, and the tentativeness of scientific understanding. On the latter category, a significant difference was found on only one of the two Likert-like items. This finding indicates that a greater shift was achieved in the NOS understanding of students who studied according to the AUL method, compared to changes in the NOS understanding of students who studied using the APL method.
To summarize, these findings indicating that students who studied according to the AUL method improved their NOS understanding both in terms of pre- and post-intervention comparisons within the group and in comparison to students who studied according to either the APL method or the standard biology program. The improvement in NOS understanding among students who studied using the APL method was only partial, as indicated both by the comparison of intragroup pre-and post-intervention results and by a comparison with the improvements gained by students who studied either according to the AUL method or according to the standard biology program.

CONCLUSIONS

Our findings indicate that in terms of inculcating the NOS aspects of the tentativeness of the scientific understanding, and methodological diversity, both the AUL and the APL methods were effective. However, regarding the inculcation of the NOS aspects of the aims of science, the cooperative nature of the scientific process and the sociocultural embeddedness of scientific knowledge, only the AUL method was fully effective. In inculcating these aspects, the effects of the APL method was only partially effective.

Moreover, a comparison the NOS understanding gained by participants in the two experimental groups suggests that the AUL, which involves students' visits to university laboratories, was a more effective teaching method than was the APL method. We suggest that the reading of scientific articles as a way to teach NOS has a more limited effect because the text does not reflect a true research sequence. Direct contact with scientists in authentic research laboratories reflects the non-linear sequence of scientific inquiry, and presents an authentic and exciting research environment that enhances NOS understanding.

Our findings support those of other studies, in which the effects of reading scientific articles as a teaching method were found to be limited (Medawar 1986; Woolnough 1989) and of studies that demonstrated the significant effect of face-to-face interaction involving an active discussion between scientists and high-school students on issues pertaining to NOS (Hodson 2012; Hodson and Wong 2014).

The current study contributes to the literature on explicit teaching of NOS as part of the teaching as inquiry approach. The current findings indicate that teaching NOS using science-as-inquiry methods is an effective approach for inculcating an understanding of the NOS. Both of the methods studied herein appear to be promising. We believe that both AUL and APL methods are useful and can successfully be adapted for teaching various biology subjects in different cultural contexts.

USING HISTORY OF CHEMISTRY TO TEACH THE NATURE OF LAWS AND THEORIES

Karl Marniok and Christiane S. Reiners
Universität zu Köln, Cologne, Germany

The nature of scientific laws and theories is an integral part of the nature of science (NOS). However, there are three prevalent misconceptions about laws and theories among both students and the common population: The idea that scientific laws are an absolute kind of knowledge, the belief that scientific theories are mere guesses or particularly uncertain knowledge lacking sufficient “proof”, and the misconception that laws and theories are hierarchically related with theories “maturing” into laws. As a consequence, some national educational standards specifically require the students to learn about the nature of laws and theories. Our research project investigates these misconceptions among pre-service teachers, and possibilities of improvement. As a part of introductory courses for students, two different approaches with varying degrees of contextualization were tried. The highly contextualized approach featured historical case studies in chemistry in order to achieve a better understanding of laws and theories, while the decontextualized approach featured the definitions of laws and theories as elements of epistemology. It also provided more room for reflection and discussions between students. The results were assessed using open questionnaires and portfolios in which the students documented their learning progress accompanying the courses. The results show that while the de-contextualized approach showed hardly any improvements at all, the highly contextualized variant is much more effective.

Keywords: nature of science, theories, laws

INTRODUCTION

Chemistry students are often confronted with different technical terms that include the words theory or law (Table 1). These words are supposed to encompass epistemological functions that are often vague to students, and even to pre-service teachers (Abd-El-Khalick et al., 1998; Lederman, Abd-El-Khalick et al., 2002). The uncertainty about the meanings of scientific laws and theories makes people prone to myths and misconceptions. Those myths may even manifest themselves in political debates, where the term theory is often being used in a derogatory, non-scientific sense, as in “only a theory” (Ben-Ari, 2005). This kind of abuse of scientific terminology illustrates the relevance of the topic, hence it is often included in national educational standards as part of the NOS topic (McComas and Olson, 1998; Waddington et al., 2007). Furthermore, knowledge about fundamental epistemological concepts of science is a contribution to scientific literacy.

The nature of scientific laws and theories is a well-researched topic in philosophy, while there is little research on the field in science education. It is often included as one of many aspects inside the NOS complex (Lederman, 1992; Lederman et al., 2002), while little research has specifically targeted this aspect of NOS. Examples include McComas (2003), who focused on biology teaching, and Tobin (2013), who focused on chemistry education. An interesting
approach by Allchin (2007) has suggested to teach science without any laws. In order to cope with the common misconceptions, however, our study aimed at a better understanding by explicitly targeting the concept of scientific laws (and theories). We used historical case studies to convey an informed image of scientific laws and theories. Our goal was for pre-service teachers to acquire a better understanding of this topic in order to be able to teach it to students. Since the exact definitions of laws and theories are open to philosophical debate, our aim was to provide simplified definitions that can be used on a school level.

THE NATURE OF SCIENTIFIC LAWS AND THEORIES

The nature of scientific laws can be discussed on various levels of philosophical complexity, and philosophical viewpoints might differ in certain details (Weinert, 1995; Swartz, 1995; Armstrong, 1983). At the school level and for chemistry teacher education, a simple definition is sufficient to convey the general idea. According to such a definition, originating from science education, scientific laws “are descriptive statements of relationships among observable phenomena” (Lederman et al., 2002, p. 500). Similarly, the definition of a scientific law in a chemistry textbook is that of “a concise verbal statement or mathematical equation that summarizes a broad variety of observations and experiences” (Brown et al., 2005). In a nutshell, laws are of descriptive nature, dealing with regularities in empirical data, but without the potential to explain the data. For example, Proust’s law (or the law of definite proportions) describes how the mass ratio is equal for a given chemical compound, but does not provide an explanation of the reasons behind that.

Scientific theories, on the other hand, are a different kind of scientific knowledge. Theories are used to explain and predict scientific facts and observations (Winther, 2015). In a historical perspective, “[t]he discovery of laws of nature is only the first stage in scientific interpretation. The second stage is the incorporation of these laws into theories. According to [John] Herschel, theories arise either upon further inductive generalization, or by creation of bold hypotheses that establish an interrelation of previously unconnected laws” (Losee, 2001). Karl Popper
Strand 6

(1934/1976) described a scientific theory as “the net which we throw out in order to catch the world—to rationalize, explain, and dominate it”. This research project uses a more precise definition, also based on NOS research:

Scientific theories are well-established, highly substantiated, internally consistent systems of explanations. Theories serve to explain large sets of seemingly unrelated observations in more than one field of investigation. [...] Theories have a major role in generating research problems and guiding future investigations. Scientific theories are often based on a set of assumptions or axioms and posit the existence of nonobservable entities. Thus, theories cannot be directly tested. Only indirect evidence can be used to support theories and establish their validity. (Lederman et al., 2002, p. 500)

As an example, the ideal gas law can be used to describe how pressure, volume, temperature and the amount of substance relate in a gas. The kinetic theory of gases provides an explanation for this behavior, drawing from models involving submicroscopic particles. Conclusively, scientific laws and theories are two separate categories of knowledge. Both are substantiated based on empirical evidence and are equally valuable to science. There is no direct, hierarchical relationship between theories and laws, as both serve different functions. Thus, a theory cannot be “transformed” into a law or vice versa (see Figure 1). It should be noted that theory as a term is also used in the humanities, such as in feminist theory, critical theory or linguistic theories. While also serving to provide a framework for research, they differ from scientific theories as they are lacking an experimental basis. This paper, however, is focused on the domain-specific nature of theories and laws in science.

Figure 1. A simple scheme showing theories and laws as non-hierarchical entities, and how they are obtained from observation and facts.

MYTHS ABOUT SCIENTIFIC LAWS AND THEORIES

There are three prevalent misconceptions about laws and theories among both students and the public. First of all, there is the idea that scientific laws are an absolute kind of knowledge and equivalent to “the truth” (Horner and Rubba, 1978; McComas, 1998). However, scientific laws are as tentative as other types of scientific knowledge. They are not “absolute” knowledge and not simply statements that are universally “true” (Cartwright, 1983; Giere, 1988; Allchin, 2007). As an example, the discovery of non-stoichiometric compounds showed that not all chemical compounds behave according to Proust’s law. Iron(II) oxide, for instance, typically
has a composition ranging between Fe$_{0.84}$O and Fe$_{0.95}$O, not one fixed ratio. Scientific laws are results of idealizations of nature. The term *ideal gas law* even suggests this itself, since there is no such thing as an ideal gas in real life.

Related is the myth of a hierarchical relationship between laws, theories and hypotheses (Horner and Rubba, 1979; McComas, 1998; Maeng and Bell, 2013). This myth pictures scientific research as a linear process starting with a hypothesis, gathering evidence leading to a theory, which is then proven, becoming a scientific law. Aside from the impossibility of “proof” in science, laws are not “mature” theories, as they serve completely different functions.

The false conception of hierarchical relationship is related to the notion of scientific theories as particularly uncertain knowledge. It is common to hear people dismiss scientific knowledge as “just a theory” (Ben-Ari, 2005), implying that scientific theories on evolution or climate change are poorly substantiated and lacking sufficient “proof”. This manifestation of common misconceptions demonstrates the actual relevance of teaching the nature of scientific laws and theories to students. Scientific theories are in fact the mightiest tools of science, offering explanations and predictions of phenomena. They are constructs based on indirect evidence, with no possibility of direct testing. It is however possible to deduce hypotheses from a theory, which can be tested empirically. Thus, scientific theories are well-supported by empirical evidence and not particularly less substantiated than scientific laws.

The origin of these three misconceptions has not yet been researched. It seems plausible that the usage of *theory* and *law* in colloquial speech is highly influential. In colloquial speech, *theory* is often used as a derogatory term for mere speculation, while a *law* carries a normative connotation. Allchin (2007) has discussed this problem with regard to scientific laws, concluding that “[w]e need to ensure that our thinking about science is not biased by meanings in cultural contexts”. The absolute idea of laws corresponds to the historical origins of the notion of “scientific laws” in theology (Zilsel, 1942). The idea of laws as principles inherent to the universe is conveyed in the distinction between *natural law* and *scientific law*, with the latter corresponding to our definition used for modern science (Weinert, 1995).

**PROJECT OVERVIEW**

The main objective of this research project was to incorporate the nature of scientific laws and theories into a university course for pre-service teachers. The rationale was that an adequate understanding of these concepts is an important precondition for teaching NOS-related content to students. Previous NOS research has shown that most students and pre-service teachers are not able to give adequate definitions of laws and theories, with many maintaining a hierarchical concept (Abd-El-Khalick et al., 1998; Lederman et al., 2002).

The research question is whether case studies are suitable means to improve student teachers’ conceptions of scientific laws and theories, since history of science is often suggested as an adequate context for teaching NOS (Matthews, 1994; Irwin, 2000; Heilbron, 2002). As a part of chemistry education courses, these conceptions were assessed and two different approaches with varying degrees of contextualization were tried (see Figure 2). The highly contextualized approach encompassed historical case studies in chemistry in order to achieve a better understanding of laws and theories. The results were assessed using open-ended questionnaires.
asking for participants’ definitions of laws and theories and their relationship, and diary-like portfolios in which the students document their learning progress accompanying the courses.

Figure 2. Overview of the project.

The pilot study was part of an introductory course in the winter term 2014/2015 involving 49 participants (only counting students who filled in both the pre-test and the post-test). Most of the student-teachers were in their 3rd semester with little previous knowledge of NOS. The course featured general topics related to science education, such as the role of experiments in chemistry classes, national educational standards and curricula, safety regulations, and the role of models in science. The nature of scientific laws and theories was addressed during three sessions covering an introduction to the nature of scientific models (Kircher, 1976), the evolution of atomic theory over history (Dalton, Thomson, Rutherford, and Bohr), and the epistemological foundations of scientific experiments (Chalmers, 1999). This pilot study was limited to “explicit and reflective decontextualized NOS instruction” (Clough, 2006), with one portfolio and two questionnaires per student documenting the pre- and post-conceptions along the course.

After the pilot study, there was another course in the summer term 2015 involving 18 participants, featuring a highly contextualized approach based on historical case studies. During six sessions in the advanced chemistry education course, the students were introduced to NOS and given historical source material on chemical discoveries. These included chemical contents relevant to school curricula, such as

- gas laws (Boyle, Gay-Lussac),
- the law of mass conservation (Lavoisier, Lomonossov),
- organic structural theory (Kekulé, van ’t Hoff), and
- inorganic structural theory (Werner).

The source texts were selected to illustrate several NOS aspects, such as tentativeness, the inferential and the social nature of science. As an example, the emergence of organic structural theory was met with some hostile reactions by elderly chemists, such as Hermann Kolbe, who defended their old-fashioned “empirical” chemistry against the “esoterical” (inferred) claims made by August Kekulé or Adolf von Baeyer. The student-teachers analyzed and discussed the inferential nature of scientific theories through Kekulé’s original articles from 1866 and 1872. Additionally, the student-teachers were periodically asked to draw a scheme of how they think
terms like “hypothesis”, “theory”, “law”, “observation” or “facts” are related. In the end, the schemes were discussed together and a non-hierarchical view was established. This context-embedded study used the same kinds of portfolios and questionnaires as described before.

METHODS

All participating student-teachers responded to two questionnaires (pre- and post-test) on the nature of science, with special focus on the nature of scientific laws and theories. The following questions were considered for analysis:

- What, in your view, is a scientific theory? Illustrate your answer with examples, preferably from chemistry.
- What, in your view, is a scientific law? Illustrate your answer with examples, preferably from chemistry.

What is the difference between theories and laws? Is there a relationship between these two terms? If so, what kind of relationship? Please explain. The questionnaire was based on the VNOS-B questionnaire (Lederman et al., 2002), breaking one question about theories and laws down into three separate items. It was then piloted with student-teachers to eliminate ambiguities. Since there are no other chemistry courses at our university dealing with philosophy of science, it appears unlikely that other factors apart from our treatment may have influenced the outcomes.

Analysis of all data was carried out through qualitative content analysis (Mayring, 2002; 2008) with a deductive category system based on definitions and misconceptions of scientific laws and theories, as described in the previous sections. The categories were connected to a scoring scheme with informed aspects yielding positive points and misconceptions giving negative points, adding up to a total score. Their definitions are based on the descriptions given in sections 4.1 and 4.2.

The categories encompassed important aspects of scientific laws and theories, including

- the function of scientific laws (score +3),
- the function of scientific theories (score +3),
- the empirical nature of scientific laws (score +1),
- the empirical foundations of scientific theories (score +1),
- the mathematical form of scientific laws (score +1),
- the inferential origin of scientific theories (score +1),
- different theories may be used for solving the same question (score +1),
- the absolute nature of scientific laws (score −1),
- the scientific theories as mere speculation (score −1), and
- the hierarchical relationship between laws and theories (score −1).
The following statement provides an example of how the scoring rubric was used: “A law is the determination of relations between at least two physical quantities. Their correlation can be observed and described by a law.” This statement scored +3 points for stating the descriptive nature of scientific laws, as well as +1 point for mentioning observation as a foundation. As it can be inferred, total scores could range between −3 and +11 points. These scores were used as an indication for the students’ progress along the courses. The portfolios were consulted as an additional source, especially for ambiguous cases.

**FINDINGS**

The findings of the pilot study show that the common misconceptions were also prevalent among all participants:

- “Laws grow out of theories; theories are proven until they become law.”
- “A theory was designed and postulated by a scientist, while a law is mathematically proven. Theories may change or improve or be untrue, but a law may not be changed by any person.”
- “A theory is a tested hypothesis. A law is a theory that has turned out to be proven by many experiments over a longer period of time.”

While students may recognize the tentative nature of scientific theories, this was mostly due to a hierarchical understanding of theories and laws, considering theories as mere guesses. The view of scientific laws as absolute, “proven” knowledge was even more common, with none of the students mentioning the tentativeness of laws. Overall, there was not one single informed view (i. e. one leading to a positive score according to our rubric) of laws and theories among all of the 49 students. Strikingly, even after the explicit instructions, only one student showed significant improvement with six students mentioning at least isolated aspects of an informed view. This led to the conclusion that the decontextualized approach can be deemed unsuitable for teaching the nature of laws and theories.

However, the highly contextualized approach proved considerably more successful. With the same misconceptions prevalent in the beginning, the analysis of case studies resulted in more informed statements, such as:

- Theories are mental constructions that explain observations at least in part. They have to be inferred indirectly and include a creative process. A law is a generalization of statements that was directly deduced. It is of descriptive character (e.g. gas law). While laws work as a generalization of observations and allow predictions, the theory provides the corresponding explanation. Several theories may exist for the same phenomenon.
- A theory explains a phenomenon, e.g. collision theory explaining the behavior of molecules in space. A law describes an observation, e.g. the gas law that describes the behavior of ideal gases during changes of state. The difference is that one explains a phenomenon while the other describes it. Both may relate to the same phenomenon.
In total, 11 out of 18 participants showed an increased score. Likewise, a better understanding was noticeable in the portfolios, as one student wrote: “While a theory seeks to explain observations (or a law), a law only describes the observations and may make predictions due to regularities. Laws are also falsifiable, which is exemplified by the law of conservation of mass in the context of mass defect.” Another student wrote: “Laws are limited to observations, while theories add the explanations of those laws.” Yet another student stated: “Hence, laws describe phenomena, while the theory is the explanation behind them. … However, theories can never be proven”. Many participants added to their portfolios that they were presented new perspectives on science. The overall feedback was positive.

CONCLUSIONS

The results reconfirm that a highly contextualized approach is an effective means of NOS instruction (Clough, 2006). This is further supported by the fact that our study failed to yield improvements using the decontextualized approach. Hence, the advanced chemistry teaching course featuring historical case studies continues at our university and further studies are conducted to investigate its success. It would be desirable to further investigate the origins of the misconceptions of scientific laws and theories. In order to counter these naive NOS views, it may prove helpful to sharply distinguish between the colloquial meanings of law and theory, and their scientific meanings. The long-term goal is to transform how the topic is taught in chemistry classes. Possible approaches are to improve learning material and school textbooks, as well as implementing (aspects of) NOS into university courses in the long term.

TEACHING LAWS, THEORIES AND MODELS IN THE CONTEXT OF NATURE OF SCIENCE THROUGH THE HISTORY OF MAXWELL’S ELECTROMAGNETIC THEORY

Constantina Stefanidou¹, Constantine Skordoulis¹, Dimitris Stavrou²
¹National and Kapodistrian University of Athens, Athens, Greece
²University of Crete, Rethymno, Greece

Nature of Science (NoS) is an objective of science education worldwide. Laws of nature, scientific theories and scientific models constitute an integral part of NoS. The study reported here formed a part of a broader enquiry into primary student teachers’ understanding of laws of nature, scientific theories, scientific models and the relationships between them. In respect of the research reported here, we investigate the extent to which primary student teachers could construct a scientifically accepted point of view regarding laws of nature, scientific theories and scientific models. Moreover, we aim to investigate primary student teachers’ learning procedures in regard of the aforementioned notions. In the empirical investigation, the so-called “teaching experiment”, a kind of interview deliberately employed as a teaching and learning situation, was used. Forty (40) third-year university students divided into groups of 3-4 students each took part in the investigation. The data were videotaped and analysed according to qualitative content analysis methods. The study illustrates that primary student teachers are able to construct satisfactory explanations of laws of nature, scientific theories and models. It also shows that the conceptual difficulties the student teachers have, originate from one or two ideas: that laws of nature and scientific laws do not differ, or that a law is a proven scientific theory. Moreover, they overstress that scientific theories are proven hypothesis, thereby leaving little room for prediction and development.

Keywords: nature of science

INTRODUCTION

In recent years, there has been an increasing interest in the systematic inclusion of the nature of science in curricula worldwide (Lederman, 2007). The rational is that, if students gain an understanding of how scientific knowledge is developed, and of how historical and philosophical contexts influence its development then they will acquire a more comprehensive view of science.

Scientific theories, laws and models lie at the core of the nature of science as such notions constitute the products of scientific investigation (Duschl, 1990, Matthews, 2007). Kuhn describes normal science as a puzzle-solving (1962/1970, 35-42), implying that while someone has a reasonable chance of solving the puzzle, his doing so will depend mainly on his own ability to develop theories, laws and models in the paradigm’s context (Bird, 2013). At the same time, these terms are met in school science, in all disciplines: physics, chemistry and biology. Extensive work has been carried out on the role of laws, theories and models in science education (McComas, 2004; Gilbert & Justi, 2002; Van Driel & Verloop, 2002).

The National Science Education Standards in United States (NRC, 1996, 2012) underline the importance of students understanding the notion of scientific theory in general and being aware of the procedures whereby scientific explanations and models are formulated and developed,
in particular. According to the *Science as Inquiry* standard, “students’ inquiries” are expected to “culminate in formulating an explanation or a model”. Moreover, “this aspect of the standard emphasizes the critical abilities of analyzing an argument by reviewing current scientific understanding, weighing the evidence, and examining the logic so as to decide which explanations and models are best” (NRC, 1996, p. 175). In *Next Generation Science Standards* the notions of scientific theories, laws and models are specified for different levels with specific targets for each. For High School students: “A scientific theory is a substantiated explanation of some aspect of the natural world, based on a body of facts that has been repeatedly confirmed through observation and experiment, and the science community validates each theory before it is accepted. If new evidence is discovered, that the theory does not accommodate the theory is generally modified in light of this new evidence” (NGSS, 2013, p. 99).

Students’ acquiring a certain degree of NoS understanding requires science teachers to be knowledgeable on corresponding issues. The literature includes numerous studies on the views of students and science teachers on NoS (Coll et al., 2005; Dagher et al., 2004; Driver et al., 1996; Justi & Gilbert, 2002; Matthews, 2007; Meyling, 1997 and van Driel & Verloop, 1999, 2002) but less on the related teaching approaches. This paper seeks to cover this gap proposing that NoS be explicitly taught in a History of Science context. Didactic sequences were designed and implemented based on the History of Science, namely the history of Maxwell’s electromagnetic (e/m) theory. Such a context aims at what Erduran and Dagher write as “building students’ understanding of how various form of scientific knowledge relate to each other and how they contribute to scientific explanation in a given scientific discipline in a specific topic” (Erduran & Dagher 2014). The teaching sequences were applied to university students in the Department of Education (Primary Education). The novelty of the work lies in the fact that an attempt was made to investigate specific difficulties relating to NoS and the corresponding learning processes.

**LITERATURE REVIEW**

**Views on Laws and Theories**

Mackay has pointed since 1971 that pupils do not have sufficient knowledge about the functions of scientific models, the role of theories in scientific research, the distinction between law and theory, and the relationship between model, theory and reality (Mackay, 1971). Scientific theories are probably the most misunderstood aspect of NoS, as they are often considered to be conjectures or very temporary explanations for natural phenomena. Such views also cause difficulties in understanding the way theories are developed and the features of theories that distinguish them from laws but also from non-scientific explanations. A typical student misconception is the view that scientific theories, through continuous control and validation, will eventually mature and become laws (Rubba & Andersen, 1978; Meyling, 1997). This view has passed into the literature as the “laws are mature theories” myth.

Regarding scientific laws, Meyling’s study (Meyling, 1997) showed a diversity in student responses which mainly relates to the distinction between ontological and epistemological dimensions of scientific law. Specifically, some students present laws as eternal, unchangeable, independent of man, referring implicitly to the ontological dimension of the laws, namely their
existence independent of human knowledge of them. In this context, they express the view that laws are inviolable rules that cannot be changed. This makes NoS understanding difficult, since the scientific laws may change in the light of new evidence or theories. The same study also reveals views regarding the epistemological aspect of scientific law, such that the laws formulated by scientists are in doubt and subject to amendment.

Regarding university students’ and teachers’ views on theories and laws, Blanco and Niaz classified them in positivists, transitional and Lakatosian. Most views were positivist which means that according to them a scientific theory has not been proved in its totality, whereas a scientific law has not only been proved, but is also universal, and furthermore, a theory tells us about more complex and explicit things (Blanco & Niaz, 1997, p. 203). Transitional responses indicated a partial understanding to the existence of competing models for explaining the experimental observations and that no knowledge is ever absolutely established. Lakatosian responses indicated that scientific progress subsumed by process involving conflicting frameworks.

Irez revealed that science teacher trainers had inadequate conceptions about NoS which appeared to be linked to uninformed views on laws and theories (Irez, 2006, p. 1113). Brickhouse et al. (2002) focused on how much student understanding of the NoS varied with content. The study suggested that student talk about the NoS differs depending on the particular scientific topic under discussion.

Dagher et al (2004) noted that students explicitly emphasize the empirical content of the theory, using terms such as “evidence” and “proof” which may undermine a fuller understanding of the nature of theories, given that their research revealed that none of the students could cope with theories as models that show how the world works. By the end of a particular course, though, students also referred indirectly to other aspects of scientific theory, such as its social and historical dimension.

**Views on Models**

According to Grosslight et al. (1991) student conceptions of models were basically consistent with a naïve realist epistemology. Most students perceived models as natural copies of reality rather than as constructed representations which can incorporate a range of theoretical perspectives.

In the same spirit is Treagust et al. whose research shows that while most students can grasp the descriptive role of models, they do not display a comparable grasp of the predictive role of models and their role in developing scientific ideas (Treagust et al., 2002, p. 357). There is indeed a tendency for students to link models with reality, with the link to the development of ideas and theories far less prominent.

Regarding university student and science teacher views on models, research shows that teachers probably do not hold coherent ontological and epistemological views on models (Justi & Gilbert, 2003, p. 1369). If so, this would support the work of Koulaidis and Ogborn in the broader field of the nature of science (Koulaidis & Ogborn, 1989, p. 1382).
Van Driel and Verloop concluded that while experienced science teachers agree on the general idea that the model is a simplified representation of reality, they have quite different views on models and modeling in science (van Driel & Verloop, 1999). Some functions of models were rarely reported: their predictive role, for instance, or their use in approaching and learning to study systems to which you have no direct access. This supports the study of Justi & Gilbert which reveals the insufficient knowledge of science teachers both of the nature of models and of how to use models in the educational process (Justi & Gilbert, 2002).

THE PURPOSE OF THE STUDY

This study aims to investigate primary student teachers’ teaching and learning procedures in relation to scientific laws, scientific theories and models. For this purpose, Maxwell’s electromagnetic theory and related historical excerpts were mainly used as didactic material. Maxwell’s electromagnetic theory, the related laws and Maxwell’s idle-wheel model, were used as didactical framework in order student teachers to develop the different forms of scientific knowledge. The study reported here formed part of a broader enquiry into primary student teachers’ understanding of laws, theories, models and the relations among them.

In respect of the research reported here, two questions were addressed:

a. To what extent are primary student teachers able to construct the scientifically accepted view about scientific theories, laws and models?

b. Which are the teaching and learning procedures of student primary teachers in regard of these notions?

c. Which are the conceptual difficulties regarding these notions?

METHODOLOGY

The empirical investigation was designed as a learning process study. In order to collect the data the so-called “teaching experiment”, a kind of interview deliberately employed as a teaching and learning situation, was used (Komorek & Duit, 2004).

The study was carried out in the University of Athens’ Department of Primary Education. The sample group consisted of 40 student teachers divided into 11 groups of 3-4 students each. They were all third-year university students who had studied a Physics course, but no course on the Epistemology of Science.

The empirical investigation consisted of three sets of interviews which lasted about 3 lesson hours each. In this particular study we refer only to the first set of interview, which was focused on the concepts of laws, scientific theories and models. The main parts of the teaching experiment phases (Komorek & Duit, 2004) were as follows:

1st Part: Scientific laws are characterized by universality, truth and empirical evidence. During this part of the interview, students were asked their opinion on law in a general speaking context (phase of expectation and explanation of expectation) and some examples of scientific laws (phase of observation). Students argued about their opinion on laws or non laws statements (phase of explanation). Just after that, students were given a scientific law, namely Faraday’s law of e/m induction, in order to decide not only whether it is a scientific law but to find the
properties that make or does not make it a law (phase of first generalization). Finally, students were asked to find more examples of laws and support their views according to the properties they “should” have, arriving in a conclusion (phase of second generalization – construction of concepts).

2nd Part: A Scientific theory is a systematic set of hypotheses constructed to explain and predict phenomena. During this part of the interview, students were asked to express their views on what a scientific theory is and to bring related examples in order to argue (phase of expectation). Then, they are given the meaning of Maxwell’s equations (not the equations themselves) and are asked whether such a set of sentences could constitute a scientific theory (phase of observation). They are expected to gradually develop some of theories’ properties, such as that it explains phenomena, it includes laws and models, etc. Regarding the development of theories, students were asked their opinion about whether a theory is developed by one scientist or it is the result of successive achievements of a community of scientists. In this phase students were provided with a numerous excerpts from Maxwell’s Treatise on Electricity and Magnetism, such as the following:

It had been noticed by many different observers that in certain cases magnetism is produced or destroyed in needles by electric discharges through them or near them, and conjectures of various kinds had been made as to the relation between magnetism and electricity, but the laws of these phenomena, and the form of these relations, remained entirely unknown till Hans Christian Oersted, at a private lecture to a few advanced students at Copenhagen, observed that a wire connecting the ends of a voltaic battery affected a magnet in its vicinity. This discovery he published in a tract entitled Experimenta Circa effectum Conflictus Electrici in Acum Magneticam, dated July 21, 1820 (Maxwell, Treatise II, par.475, pg.128).

The excerpts are expected to shed light on theories’ properties, such as that they are based on numerous experiments, evidence and previous scientific work (phase of first generalization). The texts reveal Maxwell’s thinking processes and his intention not only to describe and explain phenomena but also to predict:

In several parts of this treatise an attempt has been made to explain electromagnetic phenomena by means of mechanical action transmitted from one body to another by means of medium occupying the space between them. The undulatory theory of light also assumes the existence of a medium. We have now to shew that properties of the electromagnetic medium are identical with those of the luminiferous medium...If it should be found that the velocity of propagation of electromagnetic disturbances is the same as the velocity of light, and this not only in air, but in other transparent media, we shall have strong reasons for believing that light is an electromagnetic phenomenon, and the combination of the optical with the electrical evidence will produce a conviction of the reality of the medium similar to that which we obtain, in the case of other kinds of matter, from the combined evidence of the senses (Maxwell, Treatise II, par.781, pg.383).

Finally, students are asked to conclude about the properties of scientific theories, and extend their views in order to argue for further examples (phase of second generalization).

3rd Part: Scientific Models are representations of either a physical system or a theory that aims to simplify and explain the system. Students are asked about their opinion on scientific models, examples and their properties (phase of expectation). Then, they are given some pictures in
order to decide which of them depicts scientific models and why (phase of observation). Among them is a miniature of a car, a DNA model, an equation, a graph, a photograph, and the Maxwell’s idle-wheel model (See Picture 1).

Picture 1: Maxwell’s Idle-Wheel Model (Maxwell 1861-1862)

Students are then asked about the contribution of models in the scientific making (phase of first generalization) and specifically the role of models in theory construction (Stefanidou & Skordoulis, 2012). Finally, they are asked to conclude about model’s properties and role in scientific practice giving examples (phase of second generalization).

The first author conducted the interviews which were videotaped and transcribed. Due to the explorative character of the study, qualitative content analysis methods were used (Mayring, 2000) to analyze the data.

RESULTS

The findings of the study suggested that the majority of students are able to construct the basic aspects of scientific laws, scientific theories and models, so as to establish an adequate background in order to discuss the relations between them.

The difficulties that arose were strongly related to the following beliefs:

1. Laws of nature are identified with scientific laws.
2. Scientific laws are experimentally proven scientific theories.
3. A theory is an experimentally proven hypothesis.
4. A model is a representation of reality.

In what follows, we briefly present students’ conceptions and the learning pathways they followed to reach a scientifically and epistemologically accepted point of view.

The confusion between scientific laws and laws of nature impeded students’ understanding of the tentative character of scientific laws. Particularly, students expressed the belief that “laws are laws” and they remain the same under any circumstances. Through the examples of Newton and Einstein, students realized that Newton’s Laws are scientific laws which have been successfully applied to all non-relativistic phenomena. On the other hand, Einstein’s Laws of Special Relativity, which remain unchallenged, describe phenomena related to a wider spectrum of conditions. Regarding the field of e/m theory, students were given the case of
Ampere-Maxwell law. Particularly, Ampere had formulated a law which successfully described distance-force between current elements. Some forty years later, Maxwell introducing the idea of field, developed Ampère’s law in order to include a wider spectrum of phenomena. The so-called Ampere-Maxwell law describes that both electric currents and changing electric fields cause magnetic fields. Through discussion and certain examples, students were facilitated to conceptualize that laws formulated by scientists are the best descriptions of our knowledge and are subject to change.

The idea that “all successful theories will become laws someday” blurs the line demarcating the descriptive character of laws from the explanatory and predictive character of theories. Students were provided with Maxwell’s electromagnetic theory and the laws it encompasses. Through discussion, they concluded that theories and laws constitute different kinds of scientific knowledge.

The students’ conception of a theory, as an experimentally proven hypothesis, relates to the difficulty students have developing the idea of the predictive power of a theory. If a theory is “scientifically proven” then there is nothing more to expect from this specific theory. Students were provided with excerpts from Maxwell’s writings which show that Maxwell had not proven experimentally his hypothesis concerning the electromagnetic nature of the light: rather, he simply formed a prediction based on both experimental data and mathematics. Students gradually concluded that while scientific theories are supported by experimental evidence, in order to remain fertile, it is in their nature to leave room for further investigation and hypotheses.

The idea that models represent reality impeded students understanding of the explanatory and predictive role of a model, namely its function to represent a theory. They were provided with different models such as double helix DNA model, an equation, a model of electromagnetic wave, so as to perceive that models represent theories as well. Moreover, Maxwell’s Idle-Wheel Model facilitated students’ understanding of the role of models in theory construction.

CONCLUSIONS AND DISCUSSION

The results showed that primary student teachers can formulate a scientifically and epistemologically accepted view on such notions related to the NoS as the laws, theories and models. The findings of this study show that students’ learning processes were affected by difficulties in specific subjects which appear to interrelate and impact on all the issues under discussion.

Students’ difficulties were surpassed when the terms theory, law and model were faced in a “coordinated fashion” (Erduran & Dagher, 2014), focusing in their interrelations and in their role in scientific investigation and processes, like the developing of Maxwell’s e/m theory.

According to students’ initial view the difference between laws and theories lies in their degree of validity and not in their different functions; as a result, students believe that mature theories become laws. This belief that laws have "absolute power" and do not change then prevents an understanding of the temporary nature of scientific knowledge. When students are gradually confronted with examples of well-known laws which do not apply to the full range of values,
they are forced to accept that laws have limits on their power and to conclude that laws of science, as well as theories and models, are subject to control and can change in the light of new evidence. They thus conclude that whether there are some laws in nature which are independent of our knowledge of them or not, the laws made by the scientists are the best possible descriptions of our world and can be changed or corrected if new theoretical or experimental data occurs. After students have overcome this difficulty, they are more ready to develop the relationship between laws and theories.

The students’ view that theories are scientifically “proven” was projected when they wanted to justify the scientific character of theories and to focus on the contrast between theories and laws, which they consider as mere "cases". If students claim that the theory must necessarily be confirmed, they leave little room for further prediction through theories. This finding correlates with corresponding investigations (Meyling, 1997; Dagher et al., 2004). Through discussion and a breakdown of Maxwell’s texts, students distinguish the fact that "light is an electromagnetic wave" was a prediction of Maxwell’s e/m theory which resulted from a combination of observations and mathematical thinking. Experimental confirmation of this fact was achieved several years later. Thus, the students gradually attribute the characteristic of prediction to theory.

Finally, students had difficulty understanding models’ other functions beyond representation. This is highlighted by Grosslight et al., (1991), Meyling (1997) and Treagust et al., (2002). Maxwell’s modeling processes gradually made students conclude that models play an active role in theory construction as well as playing a representational role; they contribute to the process of theory development, since scientists’ thinking is facilitated by modeling.

**FURTHER RESEARCH**

The study indicates that there is still a good deal that needs to be investigated in depth with regard to NoS in primary and secondary education but also tertiary education. The implementation of classroom research is highly recommended. Following adaptation according to each level of education and updating based on the findings of the present research, research could provide further evidence for effectively teaching NoS elements in a broader educational context.

Particularly, it is suggested to explore the triptych laws, theories and models as a framework of understanding other aspects of the NoS; i.e., the fact that science is based on experimental data, the difference between indication and inference, or the socio-cultural context of science. As one student put it: "Finally, I understood that science is a team sport which isn’t necessarily only played in a laboratory conducting experiments. There are other factors that influence the production of scientific knowledge ... It may not be a coincidence that Faraday was poor and mathematically illiterate, while Maxwell was wealthy ".

Moreover, NoS could be regarded as a framework for understanding science itself. Understanding concepts such as the difference and the relationship between the notions of theory and law helps to create the proper conditions for particular laws and theories to become more comprehensible. As one student said: "If you do not know the whole, i.e., what is a
scientific law in general, how are you supposed to learn the parts? for example, Faraday’s law?”.

All the above give a perspective in terms of primary student teachers science curricula. What is here suggested is an epistemologically and historically contextualized module focused on NoS through the triptych laws, theories and models. The idea is that if primary student teachers gain some knowledge about these concepts and the relations between them, then they could not only construct other aspects of scientific endeavour but facilitate their conceptual approach to science as well.

NATURE OF SCIENCE AS A POWERFUL META-KNOWLEDGE

André Noronha\textsuperscript{1,2} and Ivã Gurgel\textsuperscript{2}
\textsuperscript{1}Federal Institute of São Paulo (IFSP), São Paulo, Brazil
\textsuperscript{2}University of São Paulo (USP), São Paulo, Brazil

In this work we propose a transposition of Michael Young’s concept powerful knowledge to a meta-level in order to defend the relevance of the nature of science in science education. We highlight that powerful knowledge enables those who acquire it to see beyond their everyday experience – or, their local standpoint. We argue that nature of science is a powerful meta-knowledge, since it can take science students beyond the content of specific knowledge already consolidated in the schools science curricula. To go beyond science knowledge content is to see it as a human-historical enterprise, conditioned by socio-cultural factors at its origins, but growing in time as an intersubjective-objective knowledge. We state that the relevance of ‘going beyond’ in a meta-level in science education is based on its role to resist growing tendencies of post-modern epistemic relativism and curriculum localism. In conclusion, we stress that our approach is consistent with a view of nature of science that encloses its controversial aspects, which is seen as pedagogically positive in science education nowadays.

KNOWLEDGE OF THE POWERFUL, POWERFUL KNOWLEDGE AND SOCIAL REALISM

In sociology of education, knowledge of the powerful is an important concept that relates to the work of Michael Young in the so-called new sociology of education in the 1970s. Back then, knowledge of the powerful meant the knowledge selected by the ruling classes, which by its own nature would perpetuate the structures of power in society by excluding the knowledge of the oppressed classes (Young, 1971). In the late 1980s, however, Young began to change his understanding about the role of specific knowledge in education. He moved toward the proposition of a new social theory, notoriously opposed to the ‘old new’ sociology of education, and very critical to post-modern and conservative traditions in curriculum studies and policies. He and others called it Social Realism, and at the heart of this new approach lies the concept of powerful knowledge.

Another of the key aspects of Social Realism is the recognition that there are knowledges that are objective, which transcends the historical conditions of its production. Taking into account the detailed historical and ethnographic studies that demonstrate the contested nature of intellectual debates, social realists affirm that knowledge is seldom historically stable. Unlike positivist and postmodernist scholars, social realists argue that the social nature of knowledge is an essential element for its own objectivity and not the reason makes it impossible as socio-constructivists affirm (Young, 2016). Affirming this, Young and others social realists are not denying that the production and transmission of knowledge is always entangled in complex sets of social interests and power relations.

In curriculum theory issues, social realists are very concerned with the role of specialized knowledge in curricula (Young, 2016; Maton & Moore, 2010). Young advocates for a
sociology of education that gives to powerful knowledge a central role in curriculum, opposed to many education policies associated with post-modern tendencies as well to conservative or neoconservative ideologies in education (which reclaim centered curriculum in the name of a ‘naturalized a-historical higher culture’, rather than the epistemic force, cultural-historical background and political relevance of powerful knowledge). In fact, it turns out Young’s theory is opposed to both conservative and relativist-progressive trends in education. In his words, the persistence of social inequalities in society asks for a radical shift in favor of knowledge, not the contrary – which one may misinterpret as a politically conservative approach (Young, 2010).

The structure of a curriculum based on Social Realism is constituted of powerful knowledges. According to Young, a powerful knowledge: (i) provides reliable and in a broad sense ‘testable’ explanations of ways of thinking; (ii) is the basis for suggesting realistic alternatives; (iii) enables those who acquire it to see beyond their everyday experience; (iv) is conceptual as well as based on evidence and experience; (v) is always open to challenge; (vi) is acquired in specialist educational institutions, staffed by specialists; (vii) is organized into domains with boundaries that are not arbitrary and these domains are associated with specialist communities such as subject and professional associations, and; (viii) it is often (but not always) discipline-based (Beck *apud* Young, 2013). This set of propositions provides a picture of how Young understands the concept of powerful knowledge. Nevertheless, many of these propositions do require additional clarification or specifications (see Young and Muller, 2013), and are still in development and discussion (see Guile, Lambert & Reiss, 2018).

In this work we propose a curricular argument based on Young’s concept of powerful knowledge for the presence of a specific approach of nature of science (henceforth NOS) in science education. As a powerful meta-knowledge, NOS is conceptualized in a realist way, with objectivity-intersubjectivity as one of its core stones – which does not mean deny that science has historical, social and cultural roots, as well that objectivity is historical and socially embedded (Young, 2016; Daston & Galison, 2007). This conceptualization may provide a more smooth way to define NOS in comparison to controversial (and sometimes misleading) debates in the last years (see Hodson, 2014). Another role to NOS as a powerful meta-knowledge in science education is to inspire resistance against the growing relativist tendencies in curriculum theory debates – something which is not sufficiently stressed in the ‘standard’ tenets-approach of NOS (Lederman, 2007). A powerful knowledge about the science may discourage NOS conceptions on the opposing edges – the positivist-scientism view and the post-modern epistemic relativism view. It may encourage the fruitful debates on controversies within NOS, which is commonly defended by science education researchers (Kötter & Hammann, 2017).

**RESISTING POST-MODERN RELATIVISM AND CURRICULA LOCALISM IN SCIENCE EDUCATION**

One of the driving forces behind Young’s recent work, the influence of post-modern relativism on the curricula was visible in the 1990s educational reforms worldwide (see for instance Usher and Edwards (1994), Aronowitz and Giroux (1991), Doll Jr (1993) and Pourois and Desmet (1997). In fact, Usher and Edwards (1994, p.25) argue that, although such an influence was not
uniform, it manifested itself in the appeals for interdisciplinarity and more experiential (practical) approaches – all of which apparently opposed to the 'Enlightenment tradition' of education based on disciplinary knowledge.

According to post-modern scholars, the frustration with the Enlightenment spirit and revolutionary ideals of society – both typical flags of post-modernism - lead to the abandon of the social role of the knowledge-centered curriculum. Doubts about the 'canons of knowledge' are increasingly emphasized, as Bauman (2005) stated. This has opened the way to other forms of knowledge in the curricula – those Young (2016) calls 'local knowledges', based philosophically on the contingency of truth and rationality opposed to the thesis of truth and rationality as unique, universal, and invariant (Usher & Edwards, 1994, p.27). Although some authors associated with post-modernism deny that their posture coadunate with an epistemic relativism, social realists accuse the exaggerated simplification of social constructivism and the complete reduction of knowledge to power relations (Deng, 2015). Such total reductionism reflects what Maton (apud Zavale 2013, p.484) calls 'blindness of knowledge', a logic of absolutes that opposes social constructivism (as the ‘good way’) to a straw man form of positivist-objectivist scientism (the ‘bad way’). Concerning research trends in education, there are at least two examples of epistemic relativism we wish to comment in this work briefly: Ernst Glasersfeld’s (1995) Radical Constructivism, and some branches of multiculturalism theories in education.

Constructivist trends have been quite influential in education. In fact, it was argued years ago that constructivism was the 'new paradigm' in education (Tobin, 1993, p.ix). Many different constructivist currents arose in education, and often they were uncritically associated with ideas such as emancipation and empowerment. On the other hand, Good (apud Cobern, 1990, p.3) argues that the rapid advent of constructivist currents associated with their large-scale acceptance have made them resemble a kind of 'dogmatism' in education. After its apex of influence of the 1980s and 1990s, constructivist currents began to decline slowly. Among them, Ernst Glasersfeld’s (1995) Radical Constructivism is undeniably the most controversial one. In short, radical constructivists argued that there is no objectivity and that knowledge is inescapably individual and subjective. As Matthews (1994, p.149) has pointed out, the curricular implications from Radical Constructivism would result in the exclusiveness of 'individual-subjective and experiential knowledge' – one could say ‘local knowledge’. A very common constructivist radical strategy is to indiscriminately depart from the premise that all knowledge is a human construct, historically and culturally conditioned - which, at first, is perfectly acceptable. However, from this premise the radical constructivists quickly conclude that all scientific knowledge - including its theoretical objects and real objects - are 'only' (in the pejorative sense) a 'human construct', without any secure connection to a 'supposed' independent external reality. According to Matthews (ibid., p.150), radical constructivists, as well as empiricist philosophers like Locke and Berkeley, reverse the epistemological function of experience - instead of serving as a means to knowledge, it becomes the end, or, the very object of knowledge. Thus, radical constructivists make the possibility of knowledge about the world totally lost, and embrace the epistemic relativism.
Gaining momentum in the last decades, multicultural theories in education have come to meet important demands of ethnic diversity, gender, sexuality, and religion. Post-colonial studies have indicated the direction of disruption with 'Eurocentric', 'colonial' and also 'white' and 'masculine' qualities, and have influenced curricular debates with appeals for contingencies, differences, and the identity and culture of the 'Others’ – whom voices has been suppressed. It is often argued that 'traditional' knowledge univocally reflects such qualities, becoming oppressors of cultural (local) knowledge. In a sense, multicultural theories in education owe to the post-modern skepticism of truth and certainty, since this directly attacks the ‘traditional’ knowledge taught in schools. The problematic aspect of some branches of educational multiculturalism lies in their epistemological claims. According to Levisohn and Philips (2012, p.46), it is precarious the fact that some multiculturalist currents do not distinguish knowledge from belief, claiming that there are undeniably standpoint epistemologies. These, in fact, are quite distinguished from epistemologies such as empiricism and rationalism, which are almost always mutually exclusive. According to Philips and Levisohn, the epistemic relativism of multiculturalism is explicit in its appropriation of the skepticism of post-modern authors such as Jean-François Lyotard. Far for disrespecting the local cultures and denying the clear influence that cultural, social and political aspects have on the historical development of science, Levisohn and Philips (ibid., p.62) argue that they do not necessarily offer different knowledge to different people. As they quote the philosopher of science Helen Longino, one should not think of doing a 'feminist science' for instance, but rather 'do science as a feminist'. In this sense, it would not be appropriate to argue for 'multicultural epistemologies', but rather for 'doing epistemology with multicultural sensitivity'. Multicultural theories in education do not need to embrace epistemic relativism in order to seek social justice to oppressed minorities, which is a urgent cause that aren’t ignored by social realist authors.

Radical constructivist trends, as well relativist multicultural theories in education are linked to curricular localism. Curricular localism is related to localized knowledges, based on a cultural relativism for truth, the replacement of universalism and objectivity of knowledge for perspectivism and knowledge-reduced-to-experience. Subjects like etnomathematics and indigenous science are likely to be considered as cornerstones of curriculum in educational reforms proposals (Rata, 2012). The problem is not the subjects themselves – they have a huge importance as pedagogical resources helping teachers to take into account the student’s socio-cultural background (idem) –, but to mistake them as the central element of the curriculum. Young (2016) stresses that this mistake arises from the confusion between curriculum and didactics – a controversial topic that should be addressed with more attention and less theoretical prejudice (see Young, 2018). The main problem with curricular localism is that it limits the access of ethnicised minorities and working class to the powerful knowledge, uncovering them from growing waves of oppression due to the globalization and de-centralization of capital (Rata, 2012) and the revival of pre-modernism fundamentalism (see Sim, 2011). That is the reason why powerful knowledge – as well NOS as powerful meta-knowledge, as we will argue in the next section – has also a political role in education and society as a whole, not only an epistemic one.
NATURE OF SCIENCE AS A POWERFUL META-KNOWLEDGE

Although social realists are already engaging debates defending the powerful knowledges in curricula, the case for the powerful meta-knowledge is fresh new. In fact, one can affirm that both its epistemic and political relevance often are underestimated. Our argument is based on a transposition of Young’s concept of powerful knowledge to a meta-level, that is, on the same level as the NOS debates. According to Young powerful knowledge enables those who acquire it to see beyond their local experiences, or their local standpoint. Then, we argue that powerful meta-knowledge enables those who acquire it to see beyond the powerful knowledge itself, to reach its historical roots and philosophical foundations, as well its social-cultural embedment. From a political point of view, granting access to powerful knowledge carries within a particular sense of social justice, as has been argued by Young and collaborators (2014).

To define NOS has been a hard and controversial task in the research area of science education (Hodson, 2014). Researchers struggle to give it a universal educational purpose, but full consensus seems far from accomplishment. Demands for a more strong and complex philosophical-conceptual base for NOS (Irzik & Nola, 2011, Dagher & Erduran, 2016) are confronted by contended postures appealing instead for the pedagogic relevance of systematic definitions (Lederman & Lederman, 2014). On the other hand, understanding NOS as a powerful meta-knowledge may give a more straight way of conceptualizing it and give it a more properly education purpose, at least for three reasons. First, this understanding relies on a critical realist approach to NOS, which has already been also advocated elsewhere (Aduriz-Bravo, 2007; Matthews, 2012). Second, Social Realism embraces an enhanced concept of objectivity that does not denies the social and cultural roots of knowledge but strongly states that a powerful knowledge – in the case of natural sciences – becomes progressively independent of its origins. Third, as a powerful meta-knowledge, NOS teaching takes a political role concerning social justice, going beyond its well-known epistemological relevance for science education (see Noronha, 2018).

The importance of ‘going beyond’ in Social Realism is far from being only a philosophical jargon. It is grounded in core principles of nowadays societies. In fact, as Wheelahan (2010) quotes Basil Bernstein, access to abstract theoretical knowledge – which social realists calls powerful knowledge – is a precondition for an effective democracy. Conservative approaches in education, as well relativist and instrumentalist ones tends to emphasize the utility of knowledges (wherever they are powerful or not), not the knowledges themselves. This ‘knowledge utilitarianism’ is the kernel of most ‘modernizing’ reforms in education worldwide (see Zavale, 2013; Rata, 2012) which disguises a savage meritocracy with a ‘progressive neoliberalist’ speech (Fraser, 2017). To take powerful knowledge by its intrinsic value in curriculum (not only its utility) is to defend an issue of distributional justice and fair access to it (Wheelahan, 2010).

CONCLUSION

We believe that a rapprochement between the NOS studies in science education and curriculum theories is necessary (see Noronha & Gurgel, 2016). Several educational policies are aiming to include the NOS as a subject in official curricular documents and national assessments
(McComas & Nouri 2016), which means that rapprochement represents an important (and necessary) enhance in the debate on purposes and relevance of NOS in science education (Noronha 2016). The presence of NOS-tenets-approach in standard tests has been discussed insufficiently in the science education research literature. What makes this alarming is that several authors had already pointed out to the negative effects of such tests in both teacher and student’s autonomy in the learning process. Au (2011) observed in several USA’ public schools the phenomenon called ‘teaching-to-test’, consisting of teachers teaching subjects aiming mainly high-stakes tests – dismissing any possibility of critical learning process. This ‘tests-laden’ effect is a trace of the ‘neo-taylorism’ in education according to Au, which in turn is a symptom of a major problem in education policies: the commodification of education process (see Leher (2016) and Noronha (2018)).

Despite Young’s approach ensures a form of scientific realism, we are not closing all the roads for philosophy of science in science education. It can be argued that our approach is compatible with philosophical pluralism in science education (see Noronha 2018) – a kind of pluralism averse to wittgensteinian dogmatic silence (Noronha & Gurgel 2013) as well to anything-goes epistemic relativism. On the other hand, our argument goes alongside with growing demands for inclusion of scientific controverses subjects in science education (Noronha, Bagdonas & Gurgel 2017), which is interpreted as pedagogically positive nowadays and may contribute to a more critical and engaged citizenship education (Johnson & Morris 2010). As pointed before, our transposition has limitations and is not free of criticism – the same can be said about Social Realism theory and Young’s concept of powerful knowledge. Nevertheless, it may provide a new and promising way to make NOS relevant both epistemologically and politically to science education.

ACKNOWLEDGEMENT

We are thankful to CAPES for the support to our PhD research (2014-2015).

WITTGENSTEIN, CRITERIA AND SCIENCE EDUCATION

Maurizio Toscano
Melbourne Graduate School of Education, The University of Melbourne, Australia

This paper focuses on the potential of Wittgenstein’s concept of human knowledge (as interpreted by Stanley Cavell in his seminal work: ‘The Claim of Reason’) to expand the scope of what is researchable in science education. Cavell’s reading of the ‘Investigations’ reminds us: “…every surmise and each tested conviction depend upon the same structure or background of necessities and agreements that judgments of value explicitly do”. It is the investigation of this background of necessities that is central to Wittgenstein’s philosophy and which, I argue here, should find prominence in science education research. It requires no less than the re-examination of the connection between how scientific knowledge is predicated and how it is proclaimed; that is, how criteria and values are both pre-conditions for the establishment of knowledge communities and invitations to (ongoing) membership of such communities.

Keywords: criteria, judgment, science

INTRODUCTION

This paper draws its inspiration from Stanley Cavell’s interpretation of the role played by criteria in Wittgenstein’s Investigations, namely: that Wittgenstein’s employment of criteria do not so much, or cannot do so much, as refute scepticism as respond to the threat of scepticism (Cavell, 1979). It is an analysis that rests upon the subtle positive and negative analogies he sees between Wittgenstein’s use of criteria and the ‘ordinary’ use of criteria. It leaves one with the sense that not only is the human form of life a response to the unavoidable tension between certainty and scepticism but also that this tension is whole-most our own. His reading of the text lays open the possibility for acknowledging both the moral and tragic dimensions of life. This revelation asks of us – as all the later work of Wittgenstein demands of us – to re-examine and clarify (but not necessarily explain), in situ, the practices of ordinary life.

Cavell’s insightful reading of the Investigations offers us a novel way of framing the philosophical questions concerning the ownership and dissemination of knowledge. Using a broad brush, we could render Cavell’s examination of Wittgenstein’s peculiar use of criteria as highlighting the centrality of criteria in at once establishing knowledge and determining who owns and has access to it. However, such phrasing is misleading – or rather leads us away from Wittgenstein’s nuanced conception of knowledge. Cavell better captures Wittgenstein’s sense by suggesting that the issue of knowledge generation and dissemination comes to rest in the predicative and proclamatory functions of criteria…in the face of (he would add hastily) the ever-present threat of scepticism.

This paper takes the perspective of one participating in pre-service teacher education in general science and physics: someone with a biography that includes experiences as a research scientist, as a secondary school classroom teacher and as a visual and conceptual artist. It is a perspective that draws upon a life immersed intensely in these respective language games. This paper is directed towards a re-examination of science education from this (unique, let us say personal) perspective, coupled with the demands that Wittgenstein puts upon philosophers and
non-philosophers alike. What is the objective of such a re-examination? Proselytising the very approach that makes re-examination and clarification seem necessary!

The singular advantage of Wittgenstein’s later philosophy to (science) education is the fact that it is not a philosophy of which one merely speaks or writes, but rather one that only makes sense if it is lived, experienced. From the point of view of educational philosophy, therefore, it has strong affinities with the philosophy of Dewey. I make this point both as a prelude to later examining the possible role of the lived (aesthetic) experience in science education in the spirit of Wittgenstein’s later philosophy; and to rebuke *sotto voce* those who panic about the theory-praxis divide (they are like those that mistake long shadows for chasms). This paper does not argue for the application of a philosophical position, but instead its enactment. Its aim is to promote a discourse about the means by which teacher educators, pre-service teachers, practicing science teachers and their students can actively participate in an examination of the *site* of science education (see Schatzki 2003) and its social and material reality.

**INTRODUCTION CRITERIA: ORDINARY AND WITTGENSTEINIAN**

Cavell posits that ordinary criteria are “…specifications a given person or group sets up on the basis of which (by means of, in terms of which) to judge (assess, settle) whether something has a particular status or value” (Cavell, 1979, p. 9). He identifies seven elements as functioning in the ordinary application of criteria and these are illustrated below by way of paraphrasing the following familiar example:

A science teacher uses an assessment rubric to grade students’ written reports of classroom practical work. Along one axis of the assessment rubric she employs, there appear the following phrases: has included the aim of the experiment, has listed the apparatus required, has written the method in their own words, etc. Along the other axis there appear the numerals 0 through 5. The teacher deems a student’s work satisfactory if their grade (the sum of the numerical score assigned to each criteria) is 25 or greater.

In terms of Cavell’s seven elements of ordinary criteria (see Cavell, 1979, p. 10), this becomes:

<table>
<thead>
<tr>
<th>Element</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Source of Authority</td>
<td>the teacher</td>
</tr>
<tr>
<td>2. Authority’s mode of acceptance</td>
<td>uses</td>
</tr>
<tr>
<td>3. Epistemic goal</td>
<td>to evaluate</td>
</tr>
<tr>
<td>4. Candidate object or phenomenon</td>
<td>students’ practical reports</td>
</tr>
<tr>
<td>5. Status concept</td>
<td>satisfactory</td>
</tr>
<tr>
<td>6. Epistemic means</td>
<td>has included the aim... etc.</td>
</tr>
<tr>
<td>(specification of criteria)</td>
<td></td>
</tr>
<tr>
<td>7. Degree of Satisfaction</td>
<td>grade 0 - 50</td>
</tr>
<tr>
<td>(standards or test for applying 6)</td>
<td></td>
</tr>
</tbody>
</table>
Before dealing directly with what Cavell identifies as the major disanalogies between the ordinary and Wittgensteinian application of criteria, it is worth noting that in the context of the practices and culture of the science classroom, not all these elements bear on the lived experience of the teacher or the students in equal measure. For students, and by analogy with the sensory homunculus of neuroscience, the seventh element (degree of satisfaction) would certainly represent the hand. It is what fashions, moulds, what holds and wields the tools of the craft. [To what end this obsession with quantifiable degrees of satisfaction? Why, the social construction of self!] Consequently, the quantification of the degree of satisfaction often outweighs the significance of the social criteria from which a quantitative measure of satisfaction is drawn. We could extend this investigation so as to include the perspective of the teacher, or the parents, members of the general community, education bureaucrats and so forth; looking here and there for points of agreement between these communities; searching for causes. But in searching for explanation we risk loosing sight of the question: in what is there agreement? As we shall see, for Wittgenstein these are agreements in judgment.

Cavell reminds us that in the Investigations, Wittgenstein’s departure from the ordinary use of criteria is made conspicuous by the absence of his engagement with the element described as the ‘degree of satisfaction’. Wittgenstein concerns himself only with the question of whether, in a particular instance or circumstance, the criteria do or do not apply. By restricting the question of the applicability of criteria to aye or nay, Wittgenstein in effect provides a kind of ‘test’ for meaning. According to Wittgenstein, we can say only of objects or phenomena for which there is a definitive answer one way or the other that they are meaningful in the language game: all others are “non-standard”. For example, if a student wrongly submitted her poetry composition assignment to the science teacher, the teacher would not consider this poem meaningless: for practical report criteria evidently do not apply to this poem (this is irrespective of whether or not some other set of criteria may apply). What would the teacher say of the practical report that takes the form of a poem? Do the criteria specified in the assessment rubric apply in this case? Let the teacher remind herself: has included the aims of the experiment; has listed the apparatus required, etc. So long as the student’s adherence to the criteria was as consistent as her adherence to the use of Iambic Pentameter, say, the teacher would, on Wittgenstein’s view, surely have to accept her reportage as meaningful – in fact, grant it (predicate it) the status of a practical report.

Wittgenstein’s insistence would have made the teacher in question a little uneasy and no doubt because prima facie it does not to stand up to our ordinary sense of meaningful. The teacher would know in her heart that it would not be right to call (let us say proclaim) the poetic form of reportage in the science classroom a practical report. Why should she feel uneasy: even guilty? She could excuse her decision by claiming that the lack of space on the criteria sheet did not afford the inclusion of criteria of the following kind: the practical report is in prose, the practical report is written in English, etc. Her expression of dis-ease in fact becomes generative of a social criterion itself: one might say it was borne out of the local moral order of the science classroom. Moreover, she knows that to play the language game of science-practical-report-writing, students must first learn the rules of the language game such as coping-in-the-science-classroom, being-a-good-student, etc. Her disquiet stems from the feeling that the student who
writes poetical practical reports has somehow not come to know the rules of the game. Wittgenstein’s own illustration of this phenomenon is very illuminating:

§314. Imagine that the schoolboy really did ask “and is there a table there even when I turn round, and even when no one is there to see it?” Is the teacher to reassure him – and say “of course there is!”? Perhaps the teacher will get a bit impatient, but think that the boy will grow out of asking such questions.

§315. That is to say, the teacher will feel that this is not really a legitimate question at all. And it would be just the same if the pupil cast doubt on the uniformity of nature, that is to say on the justification of inductive arguments. – The teacher would feel that this was only holding them up, that this way the pupil would only get stuck and make no progress. – And he would be right. It would be as if someone were looking for some object in a room; he opens a drawer and doesn't see it there; then he closes it again, waits, and opens it once more to see if perhaps it isn't there now, and keeps on like that. He has not learned to look for things. And in the same way this pupil has not learned how to ask questions. He has not learned the game that we are trying to teach him. (Wittgenstein, 1969, p. 40)

The preceding example of the ‘poetic practical report’ offers a clue to the directedness of criteria in Wittgenstein’s scheme. For the criteria provided by the teacher in some sense tells us – and certainly tells the students if they are made publically available [and they are always publically available!] – what a practical report is. Wittgenstein’s application of criteria is directed towards coming to know objects and phenomena, rather than an application of criteria to objects already known: or as Cavell put it “…in using ordinary or official criteria we start out with a known kind of object whereas in using Wittgensteinian criteria we end up knowing a kind of object” (Cavell, 1979, p. 16).

This should come as no surprise to the science teacher. How could students come to know of such things as ‘atoms’, ‘experimenting’, ‘learning’, ‘knowing’, etc, otherwise? In providing the criteria for atomic identity (or experimenting, learning, etc), the science teacher sets up the possibility for the existence of atoms (or experimenting, learning, etc). What is true of the invisible or conceptual is also true of the material world available to the senses. There are criteria by which the ‘scientific’ is made to materialise from the ‘non-scientific’ stuff of this world. The actions of a student who sets a beaker of water atop a gauze mat and tripod and heats it with a Bunsen burner count as experimenting in the language game of the science classroom. Yet the action of putting a kettle on the stove-top to boil does not meet the same criteria. We might say they constitute different aesthetics. In this way student come to know what experimenting is and realize that it requires a large degree situated-ness: a having-to-be-there. Interestingly, heating water in the science classroom in this manner would certainly not meet the criteria of what scientists would count as experimenting. Does this matter? Should we care? Once again, if criteria are constitutive of knowledge then the meaningfulness can only be determined by asking whether the criteria do or do not apply in a given instance.

For science teachers, the question of whether criteria do or do not apply for a particular object or phenomenon may appear to be a purely empirical one. If this is pre-supposed then the answer can then only be found in our knowledge of the criteria and our knowledge of the candidate
object or phenomena of said criteria. This bypasses the ontological status of objects as one emerging from the criteria themselves. Furthermore, if science teachers [in particular] have a strong commitment, tacit or otherwise, to a scientific realist position, then in the relationship between the object and criteria it is the object that holds the balance of power. The objectification – or put another way, the claim to objectivity – would demand a rephrasing of Wittgenstein’s question but this time in empirical terms.

In education, the claim to objectivity or certainty is something most strongly expressed in the rhetoric of science teachers and in the rhetoric and methodologies of science education researchers too. This stems in some part from the place of the object (or the material more generally) in the science classroom (Miettinen, 2006). But it also stems from the scientific programme of explanation: one that favours the grammar of causality.

Objectivity, in the discursive space of the science classroom, might be associated most readily with statements of fact and logic of the propositional calculus that accompanies it. This is contrasted with non-factual, non-propositional statements (gestures, exclamations, metaphors, etc) which are taken as expressions of the subjective ground of judgments of value. The former are prized in science for the certainty they seem to inherit from their receptiveness to the application of truth conditions. The latter are resistant to such objective analyses. What, for instance, is the logical form of ‘ah-ha’? Does this statement index a thing or a thought? Is it less true, expressed with less certainty, than the statement ‘2 + 2 = 4’?

The polarization of discourse into subjective and objective domains carries through into the practices of the science classroom. In the context of praxis, the dichotomy often enshrines itself in the distinction between what counts as genuinely scientific and what is ‘merely’ pseudo-scientific, non-scientific or purely social. In the science classroom, for instance, the only practice that is seen to embody science more than writing a practical report is the expectation that it should be written alone. To acknowledge its social construction – its origin and realization in the social – would leave open the possibility that non-material entities could undermine its objectivity. The tragedy of this state of affairs stems much less from its dissonance with the practices of the scientific community as much as from the fact that it is taken as what distinguishes the science classroom form other educational contexts. The dichotomy also extends beyond language and practices to modes of reasoning: drawing distinctions between those that are rational and irrational, cognitive and emotional, logical and illogical and so forth.

Perhaps it is the presence of the word ‘science’ in science education that makes researchers in science education so drawn to science’s siren song: with its promise of certainty in the face of scepticism, with its objectivity (recast in terms of measureable ‘objectives’), and with its worship of the mechanical splendour of causal explanations. Alternatively, it may be the values of science, not the word itself that moves the hands of science education researchers towards its instruments, its paradigms, or even its ontological commitments. But even when they acknowledge the value-ladeness of science, its social construction, its messiness and brutality; and extend their analyses of data from the science classroom to include the social and the cultural; it is easy to forget that the researchers are not those wielding the research instruments, and nor are the researchers research instruments themselves. The subject and the object of
research are unified in the people that live in the material and psychological place under investigation.

Wittgenstein’s fame as a philosopher, but more so his infamy, was largely derived from his suggestion that philosophy’s task was to “…shew [sic] the fly the way out of the fly-bottle” (Wittgenstein, 1958, §309). He saw philosophy as a kind of therapy to cure us of our “bewitchment” with language and our obsession with scientific explanations of the human form of life:

We must do away with all explanation, and description alone must take its place. And this description gets its light, that is to say its purpose, from the philosophical problems. These are, of course, not empirical problems; they are solved, rather, by looking into the workings of our language, and that in such a way as to make us recognize those workings: in despite of an urge to misunderstand them. The problems are solved, not by giving new information, but by arranging what we have always known. Philosophy is a battle against the bewitchment of our intelligence by means of language”. (Wittgenstein, 1958, §109)

By analogy, we might say that science education researchers and teacher educators must treat their own bewitchment with the causal language of science, and see their role as one of facilitating the form of therapy Wittgenstein envisioned. But this misses a large part of what Wittgenstein was positing. In “arranging what we have always known”, Wittgenstein is speaking of what we cannot help but know. What we already know, what we already share, and what we are in agreement about in our agreements about language constitute what he famously calls forms of life.

Herein we discover the basis of the final distinction Cavell draws between the ordinary and Wittgensteinian application of criteria. For Wittgenstein’s criteria the source of authority remains unwaveringly ours. According to him, we share in the generation of the very criteria that we apply in everyday judgments. There is then, as Cavell points out, an immediate consequence of this shared reality:

…every surmise and each tested conviction depend upon the same structure or background of necessities and agreements that judgments of value explicitly do…both statements of fact and judgments of value rest upon the same capacities of human nature; that, so to speak, only a creature that can judge of value can state a fact. (Cavell, 1979, p.14)

For the science teacher (pre-service or practising), the teacher educator or the science education researcher, this opens up a clearing in which we come to see for the first time the dissolution of the traditional dichotomy between the objective and subjective. The dichotomy is only possible if criteria could somehow be viewed atomically; by which the criteria we share are seen as the sum total of our individually possessed criteria. But this is impossible for the same reasons that a private language is not possible.

Cavell’s “structure or background of necessities and agreements” may well be the best articulation of what Wittgenstein intended the phrase form of life to convey. For science education researchers, acknowledging that such a background exists is an ontological
commitment to researching science education as it is lived. The commitment is ontological in so far as it takes the science classroom to be a space in which persons, practices, discourses, narratives, mythologies, histories and norms exist: thus opposing a systemic view of causal relations amongst cognitive machines (a cognitive machine is no less a machine). The latter approach serves the interests of scientific inquiry well because causal relations carry the burden of the scientific enterprise of explaining phenomena. A science of science education would usher in (perhaps already has ushered in) an industry of behaviourism whereby the degree of satisfaction of individuals stand in causal relation to criteria as responses to stimuli.

Under this representation, then, we come to access forms of life through the application of criteria in judgment. Furthermore, the criteria that are constitutive of a language game and the judgements we make in accord with these criteria are as Cavell puts it “claims to community” (Cavell, 1979, p. 22). The first act of judgment is judging whether someone belongs to your community, whether the criteria of your form of life apply at all to that parson. Here Wittgenstein’s test is just as pertinent. We can judge whether of a given person or persons the (shared criteria, rules of the language game, conventions etc) do or do not apply. Those, for whom the criteria apply, are broadly speaking, spoken for by the community and may speak on behalf of the community. They have accepted the invitation to community predicated by the shared criteria and judgements of that community: “Once you recognize a community as yours, then it does speak for you until you say it doesn’t, i.e., until you show that you do” (Cavell, 1979, p. 27). Those, for whom the criteria fail to apply, must speak for themselves. Finally, when our judgments find in people or communities no positive or negative answer to the applicability of our shared criteria then we have come to know of non-persons. With respect to the psychotic, people with severe dementia, those in a vegetative states and so on, our judgement of personhood is suspended; perhaps indefinitely.

We have seen how Wittgenstein’s peculiar application of criteria suggests a directionality whereby we come to know the objects of our criteria. Moreover, the application of criteria in judgements also serves as claims to community. Hence, judgments have a role in predicating and proclaiming what is the case (Cavell, 1979, p. 34): in making a judgment we say something about something (predicate it), and then says it out (proclaim it). For instance, a science teacher may judge a students’ actions or signing to be unscientific; that such-and-such a practice or such-and-such a use of symbols does not count as science. She may go on to express it or proclaim it in any number of ways: with a puzzled expression on her face or with silence. The issue is not one of truth or falsity but rather one of correctness, of conforming to norms on such-and-such an occasion. Whence the criteria applied in her judgement? If we ask her for her reasons will they seem reasonable to the student in question, will she find them reasonable herself? Do not the students also pass judgement on what counts as scientific? Do they not proclaim it whenever they utter something that is judged a misconception? There is no causal mechanism to be unearthed here: the space of reasoning here is a normative one. The pertinent question is about correctness, not truth or falsity: it is a moral not logical question. Agency is possible and necessary in this picture. In fact, it is a fundamental part of what it means to be human to be capable of exercising agency: to know whether criteria may be applied on a given occasion, to apply such criteria in judgment and proclaim the result. Such a
judgment (both as predication and proclamation) offers some finality, the sort of make-shift certainty that is necessary in light of the fact that we cannot know with certainty what is in the minds of others, for instance. There are two important aspects about agency in this context. Firstly, that as humans we inherit an understanding of the shape criteria should take from our forms of life. This ensures that when necessary, we can change the criteria we apply in our judgments normatively. Secondly, that the authority to change the criteria is not invested in everyone in a given form of life. Agency is only possible when persons are positioned as having certain rights, duties and obligations (Harré and Langenhove, 1998). It is important to note that even though they seem to be changed by individuals exercising personal agency, criteria remain firmly grounded our (social) form of life.

KANT’S AESTHETIC JUDGMENT

If we are to take seriously the agenda set in this paper’s introduction – that is, to proselytise the personal, therapeutic application of Wittgenstein’s later philosophy to science education – then our focus on judgements and criteria must find resonance and instantiation in the kinds of judgments enacted or experienced in the science classroom. This paper has asserted that those judgments, whatever they are, are infected by the rhetoric of the objective-subjective dichotomy. So, any attempt by teacher educators, science education researchers, etc to be true to the demands of Wittgenstein’s philosophical programme must engage with this apparent dichotomy.

There is, I propose, some hope to be found in using aesthetic judgement in the tradition of Kant (Kant, 1928) as a vehicle for addressing many of the issued canvassed in this paper. A prima facie case for the use of Kant may be made on the grounds that his thesis of aesthetic judgement is an attempt to describe what Wittgenstein would say is that which “we have always known”: the sense that the elements of our aesthetic experiences seem to have simultaneously an objective and subjective character. This is, perhaps, the least controversial, though deeply contested, parts of Kant’s theory of aesthetics (The greatest criticism is levelled at his explanation of aesthetic experiences and judgment). That Kant seeks to unify the objective (empirical judgement) with the subjective (judgment of agreeableness) into a single judgment (judgment of taste [or beauty]) reflects, perhaps, his intuition about a common normative grounding to experiences of the beautiful and the sublime. The case for application the application of an aesthetic approach to science education research also finds support in Wong’s investigation of the sublime in the science classroom (Girod and Wong, 2002).

CONCLUSION

The objective of this was to promote a Wittgensteinian approach to re-examining and clarifying the lived science classroom. It is an agenda directed as much to science education researchers as practicing science teachers, pre-service science teachers and those charged with the responsibility of training them. This paper has argued that if such a re-examination is possible two major shifts need to occur.

Firstly, it requires a shift in practice and discourse away from the dominance of quantitative measures of the degree of satisfaction of criteria in the ordinary sense and towards a
Wittgensteinian application of criteria as the means by which we come to know of objects and phenomena in the world: that is, using criteria to know what counts as something. Secondly, it requires a shift away from the dominance of a scientific approach to science education that enshrines an objective-subjective dichotomy, a strongly empiricist stance towards epistemology and ontology, and the causal grammar of explanation; and towards describing and clarifying the background necessities and agreements in judgment that constitute human forms of life.

There is cause for hope for such shifts in perspectives, and that hope may well rest in an acknowledgement of significance of the aesthetic dimension of science education.

A NEW ALTERNATIVE CONCEPTUALIZATION OF NATURE OF SCIENCE FOR SCIENCE AND TECHNOLOGY LITERACY

Ángel Vázquez-Alonso and María-Antonia Manassero-Mas
University of the Balearic Islands, Palma de Mallorca, Spain

Since years researchers agree that the Nature of Science (NoS) is a constitutive and relevant component of scientific (and technological) literacy for all citizens. This agreement contrasts with the controversy about the best curricula to genuinely represent NoS in education. The controversy focuses between the “consensus view”, whose conceptualization proposes a list of discrete ideas on NoS, and some proposals emerged from the criticisms to the consensus view for misrepresenting NoS. The critics converge in suggesting broader perspectives for NoS, which are labelled as whole science, features of science or family resemblance approach (FRA). In particular, FRA has been applied by Erduran and Dagher to propose a reconceptualization FRA to NoS (RFN), which develops heuristics involving two interactive categories (cognitive-epistemic and social-institutional). This paper assumes the criticisms to the consensus view and presents a new conceptualization of NoS, which is obviously alternative to the consensus view, and in some extent to the RFN. This conceptualization starts from Popper’s three-world model about science, where the interactions and relationships among the three worlds naturally generate and justify a set of interdisciplinary meta-knowledge that conforms NoS. Technology is a cross-cutting feature, which enlarges science to techno-science and thus re-conceptualizes NoS as Nature of Science and Technology (NoS&T). This NoS&T framework allows elaborating a holistic four-strand scheme where multiple specific topics and subtopics lead to a functional and open taxonomy that structures 3-world/NoS&T conceptualization. This conceptualization shares the criticisms to the consensus view and also many aspects of RFN; further, NoS&T provides an open taxonomy that allows depicting RFN as a particular case and avoiding some semantic problems of RFN.

Keywords: science and technology literacy; nature of science and technology; teaching and learning conceptualization

INTRODUCTION

The paper presents a conceptualization of the nature of science (NoS) for functional science and technology literacy in the service of citizens, thus for teaching and learning NoS (Allchin, Andersen, & Nielsen, 2014). The paper elaborates a broad and genuine framework for NoS, and consequently, suggests what to teach and learn on NoS.

Besides, the current integration of science and technology into the concept of techno-science (Tala, 2009) suggests enlarging with technology the classical NoS into the new label nature of science and technology (NoS&T). This feature allows addressing in a natural way both scientific and engineering practices for science and technology education as it is usually presented in recent curricula (i.e. NGSS Lead States, 2013).

The conceptualization proposed here (thereafter 3-world/NoS&T) is alternative, both to the so called “consensus view”, as the paper assumes the general criticisms raised in the literature on the view, and is also alternative to the recent Reconceptualization FRA-to-NoS (RFN
thereafter) proposed by Erduran and Dagher (2014), as the 3-world/NoS&T conceptualization chooses a different model-base and provides a wider taxonomy for NoS features than RFN.

THEORETICAL FRAMEWORK

NoS&T refers to the interdisciplinary meta-knowledge on scientific and technological knowledge and practices elaborated from multiple disciplines (history, philosophy, sociology, etc.). This demarcation depicts NoS&T as a complex (interdisciplinary contributions), dialectical (evolutionary), multifaceted (multiple analytical perspectives), controversial (argumentative nature) and contested research territory (scholars often disagree). Consequently, its teaching and learning in science and technological education becomes a difficult and innovative challenge for teachers (Millar, 2006).

Scientific and technological literacy

Scholars view two main components for scientific (and technological) literacy (STL): the traditional understanding "of" science (concepts, laws, models and theories, and processes) and the understanding "about" science (NoS&T). For most, teaching and learning NoS&T is considered a central component of STL for all citizens (not just for scientists or engineers), thus, STL is the factual context for teaching NoS&T in ST-Education (Hodson, 2008).

In the literature, teaching NoS&T has been justified across these reasons (Sjøberg, 1997): socio-economic (fosters economic and social development), cultural (enculturates people in S&T), autonomy (facilitates personal and social welfare), utility (helps personal and social decision-making), democratic (promotes public participation on social matters), and ethical (scientists’ and technicians’ responsibility for the management of techno-scientific affairs).

Some pedagogies of traditional science classrooms (i.e., rote memorization) often cause meaningless learning that alienates and disaffects students, as they do not meet students’ interests, needs, or self-image. For instance, many women feel uncomfortable when learning science, and many students reject S&T for their future careers and jobs. On the other hand, ST-Education education without NoS&T often clash with the constitutive values of science (i.e. promoting credulity instead of scepticism) that NoS&T advocates (Aikenhead, 2006). Instead, the active presence of NoS&T in science classrooms provides a sense of global coherence to the whole curricula, so that teaching NoS&T is a source of values that develops authentic STL (Duschl, Maeng, & Sezen, 2011; Erduran & Dagher, 2014). All in all, an additional relevant educational reason to teach NoS&T stems from their global meaning making to learning contents for all students in the context of STL: pedagogy and contents must be coherent with NoS&T features (Bennássar, Vázquez, Manassero, & García-Carmona, 2010).

The learning about NoS&T is often called functional STL, as it serves citizens to engage in science or to make informed decisions in their daily life (Allchin et al., 2014). Functional STL involves understanding some key features of the development and validation of S&T knowledge and practices: assumptions, gathering and interpreting data, reliability of claims, and the relationships between science, technology and society (funding, communication, institutions, policy, etc.), where environmental and socio-scientific issues are prominent centres of interest. Thus, functional STL is the context for teaching and learning NoS&T.
The consensus view

The consensus view features NoS through a list of NoS aspects, under the rationale that a short and clear list may be enough for STL aims and for facilitating teaching NoS&T issues. The Lederman’s seven are considered a conspicuous representative of this view, and include the following NoS aspects of scientific knowledge: empirical, theory-laden, inferential, creative, tentative, uncertain, and socially embedded (Lederman, 2007). McComas (2008) developed a longer list of NoS tenets (fourth column of the table in the appendix).

The lists of the consensus view have been criticized as reductionist, and thus invalid for adequately portray the NoS&T. The criticisms report confusion among the ontological, philosophical, sociological, and ethical features of science, the inaccurate depiction of the heterogeneity of scientific practices, the distortion of the historical development of science, and the ignorance or devaluation of some features, such as the role of technology, and the social, verbal and communicative aspects in the construction of knowledge (Allchin, 2011; Duschl & Grandy, 2008; Matthews, 2012; van Dijk, 2012). Thus, the critics advocate for an integral and inclusive view of NoS&T (i.e. Allchin calls “whole science”), where all features about doing science (cognitive, epistemic, and social practices, as well as material and technological contexts) are the valid contents “about” science to be taught in ST-Education.

Alternatives and criticisms to the consensus view

Through an empirical Delphi study that gathered teachers’ opinions, Osborne, Collins, Ratcliffe, Millar, and Duschl (2003) developed a list. The categories of this list (science and technology, culturally embedded, cooperative development of knowledge, creativity, analysis and interpretation of data, questioning, hypothesis and prediction, scientific method critical testing, certainty, diversity of scientific thinking, historical development) depict a new profile for NoS as they are wider than the former list proposals.

Matthews (2012) pointed out to change the denomination from NoS to features of science (FOS) and proposed a set of FOS that depict an integral and broader image of science (see details in the third column of the table in the appendix). Indeed, broadening the field does not mean setting high-level educational aims; rather, modest goals are proposed for FOS. Further, the appropriate teaching pedagogy must allow students’ elaboration, discussion and inquiry about FOS issues, rather than just learn and assess FOS. The change from NOS to FOS remains focused on the nature of scientific knowledge, though it involves a deeper concern with the processes, institutions and cultural and social contexts where the knowledge is produced.

Acevedo, Vázquez, Manassero and Acevedo (2007) empirically analysed 637 sentences of the Views on science-technology-society (VOSTS) item pool (Aikenhead & Ryan, 1992) searching the agreement of expert judges on those sentences. The criterion for agreement was set up when 2/3 of judges agreed on the sentence classification as adequate or naïve. The results showed an extensive catalogue of sentences that met the strict criterion for empirical agreement: 41 sentences reached the status of adequate ideas and 93 sentences as naïve ideas. Thus, this empirical analysis shows that experts are able to agree on a much larger set of different statements about NoS&T than a simple and reductionist consensus list.
Summing up, it seems also consensual that the consensus view is a reduced depiction of NoS&T, so that the critics advocate for a holistic and inclusive view of NoS, where all features related with doing science are candidates to be taught to students in science and technology education. The broader view of NoS&T about authentic (whole) science not only includes, but also enlarges the lists of tenets to also involve a large amount of naive conceptions, which must be worth of be taken into account in the pedagogy. Further, the controversy on the consensus view shows that any vision of NoS&T is partial and fragmentary; thus, a structuration of the field is needed not only to overcome the reductionism, but also to develop classifications that may help researchers and teachers to pinpoint their aims amid the complexity of NoS&T field.

**RECONCEPTUALIZATION FRA-TO-NOS (RFN)**

Erduran and Dagher (2014) assume a broader view of NoS&T, and apply the Irzik and Nola’s (2014) family resemblance approach model (FRA) to develop the idea that the different sciences, like the members of a family, resemble and differentiate one another in some aspects, thus, accounting for domain general and domain specific aspects of science. The RFN model reconceptualises NoS in terms of two interactive dimensions (cognitive-epistemic and social-institutional) that embrace many NoS aspects into meaningful wholes. The cognitive-epistemic dimension includes four categories: scientific practices, aims and values, methods and methodological rules, and scientific knowledge. The social-institutional dimension contains the following categories: professional activities, scientific ethos, social certification, social values, and organizational, political, and financial aspects of science, though just four of them appear later on. The RFN is a holistic view, where the specific aspects (classification, observation, experimentation, epistemological issues relevant for science education, disciplinary similarities and domain-specificity, etc.) that are assigned to the categories account for the disciplinary variations. The science eye and the heuristic rings model the RFN elements (Table 1).

All in all, RFN reconceptualization structures NoS according to a comprehensive view of scientific knowledge and practices and other family categories. This paper puts forward an alternative reconceptualization to the RFN proposal, sharing the criticisms to the consensus view to go beyond reductionist lists of tenets and the same global conception for NoS&T, and trying to improve some organisational aspects.

**THE THREE-WORLD NOS&T CONCEPTUALIZATION**

The theoretical inspiration for this new proposal is Popper’s three worlds analogy for science, which draws on Plato’s philosophy. The first world (W1) is the physical world of material objects (both natural and artificial), while the second world (W2) refers to the human thoughts, cognitions and mental states about W1. Scientists develop their mental states (W2) about W1 through human consciousness, mental activities and perceptions implemented by means of observation, classification and experimentation that generates data and positive and negative tests of ideas (Figure 1). The advanced elaboration of cognitions (W2) through personal and social tools such as communication, reasoning, argumentation, contradiction, replication, self-criticisms, peer review, etc. creates new independent and tangible products of mind about W1 (ideas, laws, models, theories, artwork, handicrafts, problems, arguments, books, papers, etc.) that conform the World 3 (W3) of created (objective) knowledge. Further, W3 and W1
feedback W2 with innovative practices (theory-inspired observations and experiments): the validated scientific and technological knowledge (W3) may suggest innovative orientations for new or replicating practices, and the data and tests results drawn from W1 may influence new practices in W2 (evolutions or revolutions) and new developments and refinements of scientific and technological knowledge (W3) through continuous and interactive processes.

In addition to the subjective mental states of scientists, W2 develops a wide array of complex interactions among scientists themselves, and between the scientific community and the whole society (social impacts). Further, the intense, permanent, and dialectic interactions between W2 and W3 imbricate both worlds so deeply, that the distinction between objective (W3) and subjective knowledge (W2) becomes rather diffuse. In fact, Hodson (2008) dismissed objectivity as a property of W3, thus calling W3 "the world of scientific and technological knowledge" (technological and scientific ideas theories, and artefacts), and W2 "the world of scientific practices" (scientists’ subjective thinking about W1). The imbrication between W2 and W3 conforms a new entity (the community of practices), which combines both knowledge and mental states, individual and collective actors, weaving a complex system on a dense network of mutual relationships and interactions between society, actors and knowledge.

An endless spiral of innovations and developments arises from the deep interactions and feedback among W1-W2-W3, through the social and organizational inner interactions among scientists, and between the techno-scientific community and the global society. When the S&T knowledge (W3), the activities in W2, the impact on W1 and society from the W2-W3 interactions within the community of practices are studied from different social disciplines.
(philosophy, sociology, history, psychology, politics, economy, etc.), a new meta-knowledge on S&T (about knowledge, mental states and actors of S&T on society) is generated. This meta-knowledge forms a new World 4 (meta-knowledge on S&T), where a new form of interdisciplinary, complex, multifaceted, critical, dialectic and controversial knowledge is continuously informed, influenced and transformed by the activities within the community of practices (Vázquez & Manassero, 2017).

ST-Education can be considered a subsystem within this community of practices. World 4 feeds back an innovative educational proposal: the inclusion of its meta-knowledge on features of the NoS&T as contents for school science curriculum. These NoS&T curriculum contents involve impacts, communication, validation, information, and analysis of scientific knowledge (see details in the table of appendix). The former elaboration the theoretical proposal of 3-world NoS&T reconceptualization accounts for the basic knowledge on NoS&T to be taught.

Summing up, the 3-World/NoS&T conceptualization develops the mutual interactions between the three worlds to display the complex, multifaceted, and controversial contents and structures that feature science and technology. In particular, the interdisciplinary meta-knowledge of World 4 created through the study of contents and structures of Worlds 1, 2, and 3 constitute the core of NoS&T for science education (Vázquez & Manassero, 2017).

A taxonomic framework for NoS&T conceptualization

The complexities of the new meta-knowledge of NoS&T, which is generated in the W4, can be summarized using a taxonomic framework elaborated by the authors from the proposal of Aikenhead and Ryan (1992). The taxonomy involves four strands (I) Definitions (Science and technology), (II) External sociology of S&T, (III) Internal sociology of S&T, and (IV) Epistemology. The nature of the strands I and IV is epistemic and cognitive, while the strands II and III gather the many facets of the social and institutional relationships of S&T that develops in seven topics (Table 1). Further, each topic flexibly splits in several open subtopics (see the first column of the appendix), which help the taxonomy to accurately accomplish its function of providing systematic, open and detailed classification for all NoS&T issues.

The proposed conceptualization based on the 3-world/NoS&T model and its elaborated VOSTS taxonomy allows demonstrating that the dimensions and categories of RFN are a special case of the former. The main coincidence is the overall global picture for the NoS conceptualization that both proposals provide. Beyond numbers, Table 1 makes fairly evident that both systems rank NoS features along broad equivalent sets; RFN puts forward two dimensions about epistemic-cognitive and social-institutional, whose correspondence to 3-world/NoS&T strands definitions-epistemology and internal-external sociology, respectively, is quite obvious. However, the epistemic and cognitive dimension of the RFN system seems more developed than the social-institutional dimension, and specially the category on scientific practices. This over-development leads to question some issues that might be better ranked as social rather than epistemic. This might be the case of some categories such as critical argumentations, evaluations and reflections on practice, and the analysis of dis / advantages and risks of scientific and technological developments. This caveats may also be extended to the consideration of organizational, political, and financial aspects of science, which are not fully developed in RFN proposal. On the contrary, the many subtopics of the 3-World/NoS&T
system, especially for social topics (see first column of the appendix) may correspond to that lack of development of many RFN categories (check first and second columns of the appendix).

Table 1. Comparison between the dimensions and categories of the RFN and the strands and topics of 3-World/NoS&T taxonomy proposed here for conceptualizing the features of the nature of science, showing the coincidences and the differences between both proposals.

Other differences between RFN and 3-world/NoS&T refer to the account and consideration for technology, as an important companion of current science, and a crucial reference to the many aspects of the external sociology of science (from environmental to energy and social welfare); while RFN gives a generic account of science-technology-society relationships, the 3-world/NoS&T provides a detailed and explicit consideration of technology. On the other hand, the RFN system present different labels for some important categories such as values (aims and values, social values and scientific ethos) and practices (scientific practices and professional practices). Needless to say that this multiplicity of labels seems excessive when it refers apparently to the same entity; further, this unnecessary multiplicity may put at risk the integral depiction of NoS and may lead to some conceptual confusion.

The 3-world/NoS&T model provides a powerful representation for conceptualising the NoS&T for ST- Education, as the dimensions and categories of NoS&T arise naturally from the interactions and relationships between the three worlds, as shown in Figure 1. Further, the 3-world/NoS&T taxonomy for classifying the NoS&T features is wide and flexible enough to easily include any new issue that may appear within its framework. In fact, all NoS issues proposed by the authors cited in this paper can be assigned to one of the subtopics of VOSTS taxonomy, as the table in the appendix shows; especially all the categories put forward by the RFN conceptualization of Erduran and Dagher (2014) correspond at least to one subtopic;
however, many subtopics of 3-world/NoS&T model lack any correspondent issue yet from other authors, what shows that the 3-world/NoS&T model is detailed enough to encompass all the previous proposals for NoS issues. Further, it is clear enough to facilitate teachers designing explicit plans for teaching any NoS&T issue, helping teachers to situate any NoS&T issue within the NoS map and the curriculum, to plan them to be taught, to understand their importance for S&T education and to develop heuristics for lessons.

**DISCUSSION AND CONCLUSIONS**

This paper presents a conceptualization of the NoS&T based on an overall global framework for science and technology education (3-World/NoS&T model and VOSTS taxonomy). Its global view is mainly alternative to the list-based consensus view. It shares the global view for NoS and many issues with the RFN reconceptualization of Erduran and Dagher (2014), though some details make it also alternative to RFN.

Both conceptualizations (3-world and RFN) stem from the criticisms to the consensus view and propose a wide set of similar specific issues for NoS&T. However, they differ in the underpinning model base: RFN is based on FRA model and heuristics while the 3-World/NoS&T proposal draws its conceptualization from the Popper’s 3-world model for science, which naturally also involves artificial nature from technology and engineering practices. The 3-world/NoS&T model provides a powerful representation for NoS, as their strands and topics arise straightforward from the elaboration of the natural interactions and relationships between the three worlds that are flexible enough to be open to new scrutiny and subsequent future change. Further, the analysis of the community of practices from external disciplines, alien to science and technology, give naturally rise to the meta-cognitive dimension that characterize NoS&T knowledge.

Both re-conceptualizations, 3-world/NoS&T and RFN, share a high degree of convergence for the field and many key features: first, their common basic holistic view for NoS and a highly coincident map of NoS features (3-world strands and RFN dimensions) and suggestions for science and technology education. However, 3-world/NoS&T strands and topics arise naturally from the powerful 3-world model, while the FRA heuristics does not fully allow making so explicit the justification of their dimensions and categories. 3-world/NoS&T conceptualization displays larger number of strands (4), topics (9), and subtopics (over 50) than RFN dimensions (2) and categories (over 20), thus, 3-world includes RFN contents as a particular case and this differential configuration raises some specific questions. On the one hand, RFN appeals to a basic common sense heuristic (Irzik and Nola’s FRA) whose limited prospective scope points out to some caveats of RFN analysis. For instance, some kind of imbalance between the RFN two dimensions (epistemic and social) might be perceived, as the social and institutional dimension seems to be developed in a lesser extent than the cognitive–epistemic system.

Further, some categories of the RFN social-institutional dimension look a bit confusing. For instance, RFN attributes a category of aims and values in science to both dimensions (epistemic and social) so that its role might appear mystified and controverted between the cognitive–epistemic and social systems, and again the category is less developed within the social system. In addition, the repetition of several categories involving values is not much justified (scientific
ethos against social values), yet the complex and cross-sectional nature of values do not help clarification. RFN puts forward some categories (i.e. scientific ethos, organizational, political, and financial aspects of science, scientific critique) that disappear in some parts of the proposal. Finally, the asignment of some RFN aspects to a specific category is also contentious, due to their apparent overlapping across several categories (i.e. peer-review might be both assigned to social certification or to professional activities).

Beyond caveats, it must be stressed again that both proposals share a holistic account for the representation of science and technology that try to overcome the reductionist visions of the consensus views, through integrating and enlarging contents, methods (teaching, learning, researching…) and the creation of dynamic and interactive developmental tools.

All in all, the prospective of the 3-World/NoS&T conceptualization involves testing its effectiveness for developing educational curriculum and programs, and especially for coping with S&T teacher education as a main target group. The theoretical rationale of the new approach must be developed for empirical validation, and the effective tests on teaching strategies through the work of policy makers, curriculum developers, researchers, science teachers, etc. Within this prospective, must be taken into account that much research (i.e. literature on teaching socio-scientific-issues, responsible research innovation and others) is insistently starting to point out that the lack of higher-order thinking abilities (critical thinking abilities, critical reflection, valid argumentation and reasoning, decision-making, solving open problems …) impedes understanding NoS&T. The detailed 3-World/NoS&T conceptualization may also contribute to systematically include and develop those abilities in education that may be critical for successful teaching and learning of NoS&T contents.

* Authors’ elaboration of the VOSTS framework (Aikenhead & Ryan, 1992). Some labels and citations are trimmed due to space limitations.
In recent decades numerous publications have highlighted the need for citizens to acquire not just knowledge of science content but also knowledge about science. In a previous Delphi study about the key aspects of scientific competence for citizenship we identified a number of aspects related to the nature of science (NOS). Our aim here was to analyse four aspects which, in the Delphi study, yielded differences of opinion among the Spanish science professionals we surveyed. These aspects of the NOS concerned the environment and sustainability, an appreciation of science, problems in science, and scientific method. A more detailed understanding of the meaning and importance of these aspects could help to identify which of them, if any, should underpin scientific competence for citizenship. To this end, we drew up a redefined list of eight aspects (one pair for each of the original four aspects) and asked a group of experts to rate (on a 5-point Likert scale) their importance and to justify their rating with any pertinent comments. Descriptive statistics were calculated for each redefined aspect and statistical tests were applied to identify any significant differences between the ratings awarded and between professional groups. Significant differences in ratings were only observed for one pair of aspects, and similarly, only one pair of aspects yielded a significant difference in the ratings awarded by different professional groups. For the other three pairs of aspects the experts did not ascribe greater importance to one or the other element. We nonetheless believe that this new analysis adds to understanding of the epistemological beliefs of experts regarding these aspects and goes some way to identifying elements of the NOS that should underpin scientific competence for citizenship.

Keywords: nature of science, scientific competence, citizenship

INTRODUCTION

An understanding of the nature of science (NOS) is now regarded as an important goal of formal science education (Alchin, Andersen, & Nielsen, 2014; Berland & Crucet, 2016; NGSS Lead States, 2013; OECD, 2013 a,b; Van Dijk, 2014). However, there is no consensus as to how the NOS should be defined or its key elements identified (Schizas, Psillos, & Stamou, 2016). Broadly speaking, the different viewpoints can be grouped under two main approaches: the ‘domain-general’ (or ‘consensus’) view (Abd-El-Khalick, 2012; Kampourakis, 2016; Lederman, Abd-El-Khalick, Bell, & Schwartz, 2002) and the ‘domain-specific’ view (Hodson & Wong, 2014). The former offers a more restrictive view of the NOS.

Lederman and colleagues, from the domain-general perspective, define the NOS in terms of the “characteristics of scientific knowledge that are necessarily derived from how the knowledge is developed” (Lederman et al., 2014: 66). In a similar vein, Bartos and Lederman consider that the NOS is exemplified by the following principles: “(1) scientific knowledge is empirically based; (2) observations and inferences are qualitatively distinct, in that the former are directly accessible to the senses while the latter is only identified through its manifestation or effects; (3) scientific theories and scientific laws are different types of knowledge; (4) the
generation of scientific knowledge requires, and is partly a product of, human imagination and creativity, from generating questions to inventing explanations; (5) scientific knowledge is theory-laden (i.e. influenced by scientists’ prior knowledge, beliefs, training, expectations, etc.); (6) scientific knowledge both affects and is affected by the society and culture in which it is embedded; and (7) scientific knowledge, while reliable and durable, changes” (Bartos & Lederman, 2014: 1153).

This perspective has been challenged by proponents of the domain-specific view such as Hodson and Wong (2014), who argue that the NOS encompasses “the characteristics of scientific inquiry, the role and status of the scientific knowledge it generates, the modelling that attends the construction of scientific theories, the social and intellectual circumstances of their development, how scientists work as a social group, the linguistic conventions for reporting, scrutinizing and validating knowledge claims and the ways in which science impacts and is impacted by the social context in which it is located” (Hodson & Wong, 2014: 2642).

The domain-general view has also been criticized by philosophers of science, notably Irzik and Nola (2011), who propose an alternative they call the ‘family resemblance approach’, in which science is conceptualized as being both a cognitive-epistemic system and a social-institutional system. The former refers to processes of inquiry, aims and values, methods and methodological rules, and scientific knowledge, while the latter includes professional activities, scientific ethos, social certification and dissemination of scientific knowledge, social values, social organizations and interactions, political power structures, and financial systems. This broader view has been used by Erduran and Dagher (2014) to characterize the NOS in the context of science education.

In general, the NOS has not been a central focus of debates about science education for citizenship. However, as the relationship between science and society has come to be considered in light of the model referred to as ‘public engagement with science’ (PES; Bauer, 2014; Michel, 2012; Ryan, 2015; Sturgis, 2014), increasing attention has been paid, including by institutions (European Commission, 2015), to this issue. Some citizen science projects have also considered the NOS as a component of scientific literacy (Price & Lee, 2013).

In a recent Delphi study (Blanco-López, España-Ramos, González-García, & Franco-Mariscal, 2015) we sought to determine empirically the degree of consensus among a panel of Spanish experts regarding which aspects of science and technology citizens needed to assimilate in order to participate effectively in the different areas of their lives. The analysis identified 40 aspects, of which 12 could be considered — in light of the aforementioned theoretical perspectives — as being related to the NOS. During that study, however, a number of disagreements arose regarding the meaning and relevance of four of these NOS-related aspects. This raised the need for a new study that would examine in greater depth the experts’ beliefs about these more controversial aspects and the importance they ascribed to them. Our aim in doing so was to shed further light on which elements of the NOS should underpin scientific competence for citizenship (Bybee, 1997; DeBoer, 2011; Fensham, 2007, 2009, 2011).
METHOD

The present study involved four stages: 1) identifying the NOS-related issues that, in the previous Delphi study, generated differences of opinion and/or definition, thereby enabling us to formulate the aspects that the experts would be asked to evaluate; 2) producing a document that would be sent to the experts, containing a description of the four aspects and a questionnaire; 3) completion of the evaluation task by the experts; and 4) analysis and discussion of results.

The four aspects which produced differences of opinion are shown in the left-hand column of Table 1: posing versus solving problems, environment and sustainability, appreciation of science, and scientific method versus scientific practice.

Table 1. Aspects of the NOS that produced controversy, and why.

</tr>
</tbody>
</table>

In light of the comments made by the experts during the Delphi study (see second column of Table 1) we decided to redefine each of these four aspects, generating a new series of eight aspects — in four pairs — that expressed views which were either different from the original description or which included new ideas in their formulation (Table 2). For example, ‘Environment and sustainability’ now comprised both the original aspect, ‘Environmentally-friendly attitudes and behaviour’, and a new aspect, ‘Responsible attitudes and values, and actions that contribute to a sustainable future’, because some experts considered that these two aspects should be evaluated independently.

We then asked a number of experts to rate (on a 5-point Likert scale) the importance of each of these eight aspects and to make any comments they regarded as pertinent to their rating or to the aspects themselves. The 22 participants belonged to the following professional groups: 4 scientists and engineers (SE), 4 researchers and/or private sector scientists (RP), 5 philosophers of science (PS), 6 science educators (ST) and 3 science communicators (SC).

The mean, mode and standard deviation were then calculated for ratings of each aspect, and we examined possible differences between: 1) the ratings awarded to each pair of aspects resulting from the four original aspects (here we used the non-parametric Wilcoxon test, due to the small group sizes), and 2) the ratings awarded to each aspect by different professional
groups (here using the non-parametric Mann-Whitney test). Effect size was also calculated whenever a significant difference was observed. Finally, we examined and compared the comments made by the various experts in order to support the overall conclusions.

RESULTS

In this section we present the results from the analysis of ratings for each of the eight aspects (Table 2) and summarise the comments made by experts.

Table 2. Rating of the eight aspects derived from the four aspects of the NOS that generated controversy.

Posing versus solving problems

Here we introduced a new aspect labelled *Ability to pose problems*, since some of the experts in the original Delphi study had commented that this was as, if not more, important than the ability to solve problems. Although the mean rating for posing problems was higher in the present study the difference was not significant.

In terms of the comments made by the experts, one of the RP justified the greater importance of the ability to pose problems as follows: “*If we are talking about the average citizen, then I think their ability to pose or formulate problems matters more than their being able to solve them. Solving problems is what specialists are for*” [RP1]. The justification given by one of the ST stressed the importance of “*[…] knowing how to formulate problems when faced with a situation that is initially unclear: the problem does not present itself, it has to be formulated in a precise way, modelling the situation, carrying out a qualitative analysis and making certain decisions so as to break it down in such a way that it can be addressed, clarifying the objective, etc. And all this must start from the body of knowledge that is available within the specific field in which the research is carried out*” [ST3].
It should be noted that this pair of aspects was the only one to produce a significant difference in ratings according to professional group, specifically between PS and ST ($Z = -2.777$, $p = .024$). The mean rating for the importance of problem-solving ability was 2.5 points higher in the former group, and this difference was associated with a large effect size ($r = .93$).

**Environment and sustainability**

The new aspect referring to responsible attitudes and actions that contribute to a sustainable future was rated as significantly more important ($Z = -2.054; p = .040$) than the original one, which alluded to environmentally-friendly attitudes and behaviour, with the effect size for this difference being moderate ($r = .44$).

The comments made in relation to these aspects revealed support for different models of development: one of the experts (RP1) called for a more general sense of collective responsibility and of solidarity with future generations, while another (RP2) argued against a static model of sustainability and in favour of making ecosystems more resilient:

“*Framed in this way* [i.e. Responsible attitudes and values, and actions that contribute to a sustainable future; authors’ note], then I think it acquires more importance than if we simply refer to environmentally-friendly attitudes and behaviour. Attitudes can then be located in a broader context of collective responsibility, not as solely individual but as something pertaining to the members of a community, a response to the problems we are already facing and which will likely pose an even greater challenge for generations to come. This attitude represents a sense of solidarity with these generations.” (RP1).

“The environment and sustainability have become fashionable issues, but it is frankly difficult to define what is sustainable and what isn’t. The world has been evolving since the dawn of time, but now you often hear this idea of sustainability, that we shouldn’t change the world as we knew it 20 or 50 years ago, which of course was nothing like the world of 500 or 1000 years ago. More than sustaining or not changing things, we should make our ecosystems more resilient so that they are able to adapt to the changes ahead, which will inevitably come. The future does not lie in a static model of sustainability, and in a survey about promoting scientific competences the environmental aspects should be similar to those considered for other scientific disciplines such as physics, chemistry or biology, or even music and the arts”. (RP2).

The experts also referred to environmental values whose acquisition would enable citizens to adopt behaviours that are less harmful to their surroundings, to make well-informed decisions and to participate in community projects aimed at achieving sustainable development.

**Appreciation of science**

Some experts in the original Delphi study stated, in relation to the aspect labelled *Appreciation of scientific results and an approach based on scientific reasoning*, that an appreciation of scientific results should be treated separately from an appreciation of scientific reasoning, since these were two distinct aspects. However, the present analysis revealed no significant differences in ratings. The comments regarding these issues revealed beliefs about the importance of scientific reasoning and procedures in relation to citizens’ ability to function adequately in everyday life. Thus, one of the experts gave a high rating to this new aspect and also posed a series of questions:
“I think it is really helpful to split this aspect in two. I believe that an appreciation of the results of science is less important than an appreciation of scientific reasoning, and that is because the kind of reasoning on which the scientific method is based is valuable in every sphere of life — which is not the case for the outcomes of science. There is a lot of science behind genetically-modified crops, in the industries that produce pesticides or petroleum or arms, in plastic surgery, and so on, but is all this compatible with a sustainable planet? Is it worth investing so many human and financial resources in these activities? Should we admire these achievements?” (RP1).

Another expert argued that citizens should be taught to think scientifically so as to prevent them from being taken in by anti-science narratives: “Certain social, political, and religious movements [...] are disseminating [...] attitudes that are not merely critical of science but openly hostile towards it. This is occurring both from positions regarded as progressive (radical ecology, new age, the rise of ‘alternative sciences’, etc.) and those considered to be reactionary (creationism, intelligent design, etc.). Citizens need to be equipped to counter these anti-science movements.” (PS3).

Scientific method versus scientific practice

Two experts in the original Delphi study (both ST) criticized the often rigid interpretation of what constitutes scientific method. One of them suggested alternative terms, such as ‘the scientific approach’, and this was used in the wording of a new aspect here. However, although the statement ‘Familiarity with the characteristic features of a scientific approach’ obtained a higher mean rating the difference with respect to the other aspect in this pair was not significant.

This lack of consensus is apparent in the numerous comments made in relation to this issue and which reveal notable differences in the experts’ epistemological beliefs about scientific research:

“The scientific method is important in the experimental sciences, but not in the pure sciences or history or law...In everyday life it teaches you to analyse situations and to try to make your own deductions.” (RP2).

“I think the three comments made in round 2 about the aspect ‘Knowledge and understanding of the scientific method’ are highly pertinent. I don’t think there is a scientific method as such (at least not in the singular; perhaps ‘methods’, in the plural), and it would be better to think in terms of the strategies or approaches used in scientific activity. Think of how often in everyday life you see expressions like ‘scientifically tested’ being used in advertising campaigns in an attempt to make people believe in the supposed value of a certain product. There are scientific ways of approaching things, but there’s no magic recipe that leads without fail to success.” (RP1).

“I think it’s important to remember that the scientific method is not exclusively experimental. Sciences such as astrophysics rely heavily on observation, not on experiment, and yet they progress in accordance with the scientific method, or perhaps we should say, in accordance with the recognized strategies of scientific activity ...” (SC3).

In their comments the experts, and especially those who gave greater weight to the aspect we labelled ‘Knowledge and understanding of the scientific method’, also made reference to
science education for citizens. In this respect it was argued that an awareness of ‘scientific methods’ enables people to understand why natural phenomena occur and the reasoning behind technology, to recognize the limits of science, and to assimilate and adapt to new ideas. This awareness was also seen as useful in everyday life: for distinguishing between rigorous and flimsy research, for constructing a logical argument with one’s peers, and for analysing situations and trying to make one’s own deductions.

**DISCUSSION AND CONCLUSIONS**

The four aspects of the NOS we analysed here were those that generated differences of opinion when a panel of Spanish experts was asked to list the aspects of science and technology which, in their view, were key competences for citizens to acquire in order to participate effectively in the different areas of their life. These aspects mainly concern the practice of science and science-technology-society relationships, in other words, they correspond to a broader view of the NOS (Erduran & Dagher, 2014; Hodson & Wong, 2014; Irzik & Nola, 2011). For instance, within the framework of the family resemblance approach, the aspect we label ‘environment and sustainability’ would come under the ‘social values’ category of the social-institutional system, while the other three aspects would correspond to the following categories of the cognitive-epistemic system: ‘processes of inquiry’ (posing vs. solving problems and scientific method vs. scientific practice), ‘methods and methodological rules’ (appreciation of science, posing vs. solving problems and scientific method vs. scientific practice) and ‘scientific knowledge’ (appreciation of science).

In three of the four pairs of the NOS aspects we considered, the experts did not ascribe greater importance to one or the other element. However, the newly defined aspects did receive high ratings from the experts surveyed. With respect to the aspect we labelled ‘scientific method versus scientific practice’, it is worth noting that our experts did not rate ‘Familiarity with the characteristic features of a scientific approach’ as being significantly more important, despite the fact that it is regarded as one of the most important issues in current discussions of the NOS.

Identifying elements of the NOS is a complex and controversial issue, and in this respect we believe the present study makes a useful contribution, despite the limited number of statistically significant results in our analysis. By expanding and redefining four controversial aspects of the NOS we achieved a more nuanced understanding of the importance ascribed to them and were able to shed new light on the epistemological beliefs of the experts surveyed (especially with respect to the aspect labelled ‘Environment and sustainability’, where the experts proposed different environmental values and considered that citizens who had taken these on board would be better able to make environmentally-responsible decisions and to act accordingly; also, regarding ‘Scientific method versus scientific practice’, it was suggested that an appreciation of this aspect could help people to understand their world and to think critically).

The study does, however, have certain limitations, notably the possible influence of the researchers themselves through the reformulation of aspects based on comments made by a panel of experts in a previous study. Further and more specific studies of the NOS are now required in order to elucidate those elements which are most crucial for citizens to acquire as part of their science education.
ACKNOWLEDGEMENT

This work is part of the ‘I+D Excelencia’ Project “Development and evaluation of scientific competences through context-based and modelling teaching approaches. Case studies.” (EDU2013-41952-P), funded by the Spanish Ministry of Economy and Finance through its 2013 research call.

NOS AND INTERCULTURAL PERSPECTIVES IN SCIENCE EDUCATION: A VIEW FROM THE CLASSROOM

Haira Gandolfi
UCL Institute of Education, London, UK

This project investigated science teachers’ practices in multicultural secondary schools, with special attention to the examples they employed in their lessons and to how they incorporated discussions about Nature of Science (NOS). This investigation was informed by intercultural perspectives about science and by debates surrounding the teaching about NOS, and aimed at answering the following research questions: How do science education practices deal with intercultural aspects of modern science? Are science teachers taking these aspects into account when teaching about NOS? This research consisted of an ethnographic investigation of science lessons in 2 multicultural secondary schools in London (UK), involving 5 science teachers and 9 classrooms (students aged 12-15). Data was collated through participant observation of these science lessons and analysed through a qualitative thematic approach. This analysis resulted in 3 codes describing teachers’ practices (Setting the scene: using an example; Connecting knowledge with socio-scientific contexts and people's lives; Talking about science and the scientific world). Preliminary results and conclusions pointed to a scenario where teachers’ choices of examples are largely disconnected from intercultural perspectives, and their teaching about NOS is usually done in the form of an implicit approach.

Keywords: intercultural science, nature of science, teachers’ practices

INTRODUCTION

The expansion of science education has stimulated several research regarding the teaching of science in multicultural contexts. In a global scenario of cultural exchanges, where a wide range of students from different backgrounds are learning about science, many of them also have to deal with their world-views in situations where modern science and their cultural traditions can conflict (Jegede & Aikenhead, 1999; Krugly-Smolska, 2013; Matthews, 2014; Sarukkai, 2014).

Some authors (e.g. Nola & Irzik, 2005), however, argue that the relationship between mainstream science and culture does not need to be antagonistic in school science settings. Here, the goals of science teaching:

should not be to indoctrinate students, but to equip them with skills to critically make their own assessments regarding modern science and historical and traditional knowledge, as well as to understand this modern science as a result of historical processes of intercultural exchanges and contributions from different people, communities and ways of seeing the world (Gandolfi, 2017, p. 78)

In other words, as argued by Matthews (1995, p. 192), “the history of science shows how dependent European science has been upon the achievements of non-European cultures”, and this type of narrative can be integrated into school science in order to bridge science and culture. This approach to the History, Philosophy and Sociology of Science (HPSS) is based on the “Global History of Science” studies (Roberts, 2009; Elshakry, 2010; Fan, 2012), which are closely connected with the field of Post/Decolonial Science. The argument behind these
studies, similar to Matthews’s citation above, is that modern Western Science is one of the most important products of exchanges between cultures and of the movement of different kinds of knowledge throughout the world along the centuries. These exchanges and movements of knowledge, practices and resources were promoted by historical and geographical encounters, such as the trade in the Silk Road, and the European colonising and imperialist projects. In this scenario, scientific development, its history and nature are thus understood under an “intercultural perspective” (Sarukkai, 2014).

There seems to be an almost intrinsic connection between this intercultural perspective to science and the teaching about Nature of Science (NOS), long advocated in Science Education. According to different authors, learning about NOS should include discussions about its epistemic (models, theories, experimentation) and social-institutional/non-epistemic (controversies, ethics, certification and negotiation of knowledge) dimensions (Driver et al., 1996; Erduran & Dagher, 2014). Going back to the intercultural perspective described previously, it can present many possibilities to the teaching of NOS, with its main potentialities residing on the fact that this whole approach is now informed by notions of collaboration, negotiation and adaptation of scientific knowledge, exploitation of and power-struggle regarding natural resources and knowledge, ethical, economical and political aspects of science, among many others.

Interestingly, another relevant feature of this approach to NOS teaching is that, according to Sarukkai (2014), it can bring a more diverse view of science to science lessons, challenging traditions in HOS that “led generations of students in non-Western societies to believe that their cultures have had no contribution to the science of the modern world” (Sarukkai, 2014, p. 1696). Hodson (1999) also argues that this model can help students to overcome some distorted views about NOS, such as the notion that science is an exclusively Western and post-Renaissance practice.

Nevertheless, recent reviews (Krugly-Smolska, 2013; Sarukkai, 2014) have shown that little attention has been paid to discussions about the type of approach to scientific narratives/examples employed to teach about NOS. In this case, the introduction of NOS has been made almost exclusively by traditional examples from cases in Western science, such as Geocentrism in Europe, and with very few connections made with a more intercultural perspective towards this Western science. That is, the potentialities of this intercultural view informed by contemporary research in the field of HPSS still lack investigation regarding its incorporation into school science.

Thus, this research investigated science teachers’ practices under this intercultural perspective, being informed by the following research questions: How do science education practices deal with intercultural aspects of modern science? Are science teachers taking these aspects into account when teaching about NOS? These practices were analysed through the lens of the following sensitising topics inspired by Barton (2000):

- **Teacher’s choice of examples** (“whose knowledge is being taught?”): historical science, contemporary science, non-Western science, local science, out-of-school knowledge, etc.
Throughout the lessons, teachers may employ examples to illustrate, contextualise or promote in-depth/critical thinking about a specific idea. These examples can be specific items or cases.

2 According to the schools; official classifications.
“Specific items” is a group of examples comprising single ideas (such as the Turtle Theory about the Earth, the geocentric model, or a graph displaying the amount of CO₂ in some countries) or material entities (such as hand warmers, glow sticks, a nerve cell, wild bananas, a picture of twin brothers or a fluorescent rabbit). Among them, the most common situation is the teacher’s option for using objects from everyday life item (glow sticks, hand warmers), with less attention dedicated to material entities or ideas coming from other scalar, historical, technological, and cultural contexts. There are, however, some lessons where the teacher opted to expand her/his repertoire of items/examples, such as teacher K’s lesson on theories of the Earth (year 9 classroom), which involved several different ideas (“specific items”) about the Earth and its location within the Universe (Chinese’s view on the flat Earth, India’s theory on the 12 pillars, the Hindu’s Turtle theory, among others).

“Cases” is a group of examples comprising situations or occurrences where something happened, is happening or is going to happen. A case can be, for instance, deciding which fuel (methanol and butan-1-ol) is better in terms energy released during combustion, as proposed by Teacher B in her lesson about sustainability (year 9 classroom), price of fuels and internal combustion engines. Or teacher A’s lesson on Inheritance (year 8 classroom), which included the discussion of the case of a child with “Eyes like my mom, ears like my dad”. Similarly, teacher P’s lesson on Lifecycle of materials (year 10 classroom), presented her students with the case of “the life of a plastic bottle”, in which they had to work on the scientific, technological and economical implications of “drinking a bottle of Coke”.

As a general note, working with cases seems to enable teachers and their students to establish a dynamic way of reasoning about scientific concepts, where different aspects informing the case can be analysed and employed to understand the context, implications, participants and science involved in the situation under study. Therefore, it seems clear that the choice of examples (specific items or cases) is also connected to how they are going to be employed by the science teachers during their lessons. In other words, how are they presenting these examples to students and what are their purposes when choosing these specific items or cases? Once again, patterns were identified during these observation sessions, indicating three ways of using an example (a specific item or a case) in a science lesson: illustrative/factual; contextualising; and in-depth/critical thinking.

The illustrative/factual approach is characterised by a superficial mention of the item/case merely as a representative of the topic being taught, without any further discussion about its specificities, contexts or implications. That is, it is an example employed solely to illustrate the topic and it can be easily replaced by any other equivalent item/case. Some examples of this approach found during the lesson are: mentioning a glow stick as an example of exothermic reaction, stating that Emma Watson's dress was made of plastic produced from crude oil, or presenting different objects from everyday life which contain magnets, as done by teacher A (year 8 classroom).

There are, however, situations where the teacher opts to establish these connections between the specific example and different contexts, types of knowledge or applications. Some notable situations are teacher B's move from the “cans of coke in the ice bucket” case to the connection of endo/exothermic concepts with photosynthesis, respiration and combustion processes (year
9 classroom), and teacher P's work from Crude Oil to relevant scientific concepts and then to the Carbon Cycle (year 10 classroom). This further development of factual examples can lead, then, to a contextualised approach, where the teacher addresses the implications and/or importance of these examples (and the scientific content related to them) to a specific context or situation, and actively thinking about this context/situation is an integral part of understanding the example.

That was the case, for instance, of teacher K’s lesson on Radioactivity (year 9 classroom), where she talked about Henry Becquerel’s research on radioactive rays, including information about the steps he took and how his experimental choices had led him to his discovery. This strategy towards the case of Becquerel’s research is clearly different from her choice, during the same lesson, of only mentioning of Ernest Rutherford as the discoverer of the alpha, beta and gamma rays, with no attention to any relevant context of discovery (thus, an illustrative approach).

A third use of examples identified during these observations was the in-depth/critical thinking, where scientific concepts and/or results were discussed simultaneously in different levels: conceptual (symbols, numerical results, theories, laws, models, among others), contextual (implications/importance of these concepts to a specific context/scenario) and critical reasoning (making distinctions, comparisons, predicting impacts, considering alternatives, thinking about reliability, making interpretations, among others).

Teacher P’s lesson on Crude Oil involved, for instance, an introduction of environmental discussions on Fossil Fuels, coupled with the case of a British airline starting to use alternative fuels. Her choice of questions involving conceptual (understanding the chemistry of combustion), contextual (impacts of combustion to the environment) and critical thinking levels (assessing the causes and consequences of the choice made by the airline) seems to have helped her to move her lesson from a very abstract reasoning in Chemistry (intermolecular forces, covalent bonds, hydrocarbons) to a socio-scientific level of work with her students.

Similarly, teacher F’s constant discussions about Drug Trials and animal testing (year 8 classroom) simultaneously fostered the learning of scientific concepts (such as types of drugs, stages of drug trials, placebo effect, double-blind test) and the critical thinking about this topic (such as alternatives to animal testing, relevance of each stage of drug trial, ethical and moral considerations, impact on peoples’ lives.). Teacher K’s lesson on the origins of the Earth (year 9 classroom), for instance, fostered discussions about models of the Earth in different cultures, such as Christian, Chinese, Indian, and students had to compare them and reflect about cultural beliefs, evidences and instrumentation in knowledge production.

In summary, the type and uses of the examples found in school science can vary and there seems to be a close connection between this choice and students' everyday life objects in the classrooms observed, with less attention to more in-depth/critical thinking approaches. In this scenario, teaching about Earth's atmosphere and Drugs seems to offer a better context to the work with large-scale examples and discussions than Endo/Exothermic reactions, at least from a more direct perspective about the scientific content. That is, while the curricular components on Earth's atmosphere and Drugs, for instance, presuppose these contextualised and critical discussions from the start, the same is not the case with Endo/Exothermic reactions.
Connecting knowledge with socio-scientific contexts and people's lives

Even though teachers often try to use their examples as a way of connecting the topic to be learned with their students' lives, the level in which this connection is made is variable. In some cases, the idea of “people's lives” is part of the lesson only under an illustrative perspective, as seen, for instance, with the examples cited earlier of the hand warmers or Emma Watson’s dress. However, this current code of analysis encompasses a different approach, where impacts of scientific research and knowledge on people's lives (and in the world as a whole) are clearly and critically addressed by the teacher, thus involving discussions about socio-scientific contexts/issues and/or applied science in terms of the topic currently being taught.

Discussions about socio-scientific contexts/issues involve the connection of a specific scientific content knowledge to societal aspects, such as politics, health, ethics, economics, social justice and environment, comprising both positive and negative relationships of science with these scenarios. Teacher P's lesson on Crude Oil, for instance, is an example of connection between a scientific topic (fossil fuels and combustion) and socio-scientific discussions (in this case, an environmental issue). While finishing her talk about combustion, she asks: “Why are we interested in products of combustion? Why are we concerned?” Students then recall the impacts of carbon emissions on the environment and issues of sustainability as well. In a similar “environmental perspective”, teacher B's experiment on energy released by different fuels, already explained in other sections, brings the discussion about fuel efficacy and choices of energy sources to her lesson about endo/exothermic reactions.

This work with tasks involving socio-scientific contexts/issues and impacts of science on people's lives was also seen during teacher F's lessons on Drugs, Drug Trials and Animal Testing. One interesting example is her use of the history of thalidomide to introduce a discussion on the importance of medical trials when developing and delivering new medicinal drugs. While contextualising this historical case, she highlighted the failure of the drug company in testing the drug with pregnant animals (the test were carried out only with regular animals) before releasing it in the market for pregnant women. The brief use of HPSS here as a way of contextualising the example provided students with a real case regarding the impacts of science on people's lives, raising ethical questions during this lesson. The teacher also employed this historical case to discuss changes in the processes of medical trials, highlighting the impact of this specific case on the history of the field. While deepening this discussion, she also mentioned other brief examples to illustrate the complexity (scientific and ethical) of the topic, with its positive and negative stances. Among them there were the (negative) case of a British hospital where volunteers suffered from severe brain swelling during a clinical trial and the (positive) case of a company having successful results in trials for replacing chemotherapy drugs by immunotherapy ones.

Teacher K’s lesson on the origins of the Earth also fostered discussions about people’s lives, mainly by introducing the concept of cultural influence on the process of knowledge production. Similarly, her lesson on Stem cells also generated debates among the students about how scientific knowledge and lay society’s values, morals and religions are still an active part of scientific research and policies.
On the other hand, even though also paying attention to the impacts of scientific knowledge on people’s lives, discussions about applied science differentiate themselves from discussions about socio-scientific contexts/issues by focusing on the benefits of scientific work to everyday life, usually in terms of development of new technologies, appliances or solving problems, such as better computers, new materials and drugs, etc. In her lesson on selective breeding, for instance, teacher F talked about how this historical technique allowed humans to domesticate dogs into pets and to create new and more resistant types of vegetables (such as carrots, bananas and mustard) and textiles.

Similarly, in the following lesson, the teacher discussed the benefits of Genetic Engineering to the production of new types of crops and to the genetic modification of cows to enable them to produce more milk. This emphasis on applied science was also seen in teacher B’s lessons about Electrolysis, where she discussed the relevance of this technique as a faster and cheaper way of producing different types of substances and materials, such as aluminium (electrolysis of aluminium oxide), sodium hydroxide, hydrogen and chlorine gas (electrolysis of brine). In her lesson on Space travel, teacher K also talked about the impact of the space programme on the development of new appliances, such as mobile phones, water filters, dried foods, etc., while teacher F emphasised the relevance of satellite technology to everyday communication and entertainment in her lesson on the Universe.

Lastly, it seems clear that discussions about socio-scientific contexts/issues and applied science are intrinsically connected with different aspects of NOS, involving not only the notions of prediction, consequence, evidence, theories and models, but also ethical, moral, economic, technological and political perspectives.

**Talking about science and the scientific world**

Talking about science and its nature is understood within this study as an important part of science teaching alongside learning a specific scientific content. However, it is worth remarking that this discussion was not always part of the science lessons observed during this research, which usually placed more emphasis on teaching scientific content (products of science) than on its production (processes of production of scientific knowledge). Here, this absence of reflections about NOS during science lessons is itself understood as one specific view about NOS: an authoritarian one, which very often approaches scientific knowledge as “ready-made”, that is, as given by objective and neutral sources of information (scientists, teachers, textbooks, among others). In other words, it is important to acknowledge that when teachers do not incorporate discussions about science and its nature into their lessons, a specific view of science as authoritarian and unquestionable, as content-driven and disconnect of general society (or only dedicated to the production of goods and appliances) is being portrayed to their students.

Nevertheless, during the observed lessons, this perspective about discussing (or not) science and its nature with students was seen more as a continuum (more or less emphasis on NOS) than a clear-cut division between “without NOS” and “with NOS”. This scenario included then different approaches towards NOS, ranging from lessons with no explicit talk about it, to lessons with some remarks (examples) involving some specific aspects of NOS, and finally to
lessons which encompassed more discussions connected to NOS than to specific scientific content. In this context of teachers’ diverse ways and levels of talk (or not) about science and its nature during their lessons, their discussions, when present, were mainly related to two different dimensions of NOS: epistemic and social-institutional/non-epistemic.

The epistemic dimension was related, in these lessons, to the nature of scientific knowledge and practices, such as models, variables, fair-testing, double-blind test. For instance, teacher B’s lesson on Activation Energy employed molecular kits to explain the process of breaking/forming bonds. Even though the teacher briefly emphasized the use of these kits as models and not as a real representation of the molecules, she did not opt for developing an explicitly discussion on the role of models and other forms of representation in Chemistry (and, more generally, in Science). In this example, the introduction of NOS aspects was then made implicitly, that is, as only a by-product of the activity, without being specifically addressed by the teacher. During the observed lessons, this approach towards NOS teaching was often seen when NOS aspects were related to its epistemic dimension. In other words, when teaching NOS involves its epistemic features (models, evidences, theories, laws), teachers usually adopt an implicit approach.

On the other hand, some explicit approaches towards NOS were sometimes seen in discussions about its epistemic dimension. In opposition to teacher B’s approach to models in Science, teacher K’s lesson on the theories of the Earth involved an explicit discussion about this epistemic dimension of NOS. This included an initial prompt where students had to write down their own definition for “model” (“what’s a scientific model?”) and share their answers with the group. Starting from these answers (“a 3D structure”, “a plan”, “a clone of something”, “a type of physical diagram”), the teacher then talked about a model being physical or mathematical (equations) and about how it is used to understand what we investigate (and sometimes cannot see) and also to make predictions about what will happen. Similarly, in her lesson about the Solar System, teacher F presented her students with the history of Copernicus’s theories about the heliocentric model and how instrumentation (namely, telescopes) was decisive for this model to be accepted at the time, mainly by stating that new instruments allow scientists to get knowledge (and evidence) for phenomena they cannot directly observe, such as the universe.

Similarly, while presenting the history of the thalidomide case to her students, teacher F also discussed aspects of testing in Science and the possibility of errors in planning an experimental design. It is also worth noting how, during this lesson, the explicit work on epistemic aspects of NOS opened up the debate to its social-institutional dimension, connecting this process of trialling with discussions about moral and ethics in research, including animal testing (a student: “what’s the difference between a human and an animal life?”), volunteering selection (a student: “why were all the volunteers white?”) and impacts on peoples’ lives (students ask about moms suing the company). This approach built up a clear picture of Science as a process of knowledge production, involving not only several (and long-term) stages of intensive research in different levels (for instance: lab testing, animal testing and human testing), but also ethical and moral dimensions from its start point.
This social-institutional dimension of NOS encompasses then aspects related to the connection between Science and society (such as ethical and cultural values, politics and economics of Science) – external level – and to social and institutional work within the scientific world (such as scientific conferences, processes of certification, sharing and accumulation of knowledge) – internal level.

Discussions about this internal level were part, for instance, of teacher F’s lesson about Inheritance, students were asked to read an abstract of a scientific paper presenting a study about humour between twins. After finishing this reading, teacher F talked not only about some relevant conceptual information from the abstract, but also about the importance of scientific reports in Science, which are mainly intended as a way of disseminating research and new knowledge (he also employed my own research and how I would share my findings from observing her lessons as another example of disseminating knowledge within the scientific community). Interestingly, this same teacher, during her lesson on Stem Cells with her year, stated that ethics and ethical debates are an intrinsic part of Science, highlighting the relevance of this aspect not only to an external relation between science and society, but also to the internal work and decision-making processes within the scientific community.

Nevertheless, discussions about the social-institutional dimension of NOS usually placed more emphasis on the relationship between Science and society (as also exemplified in the previous section) – its external level – than on the discussions about social and institutional aspects within the scientific culture – its internal level. This seems to be linked to an easiness, from the point of view of school science, to work on the borders of the scientific world (that is, in-between Science and society), not fully entering this world in order to understand its specific and complex internal ways of operating. Teacher K’s lesson on the theories of the Earth, for instance, even though explicitly addressing the concept of “scientific models”, avoided having an in-depth discussion about why scientists can develop different theories about a phenomenon (processes of certification, controversies, different theoretical standpoints, instrumentation, etc.) by only stating that “it is difficult to prove a theory”.

In summary, different approaches related to talking about science and its nature were observed during these lessons, not only in terms of which aspects of NOS were being addressed (epistemic and social-institutional dimensions), but also how these aspects were introduced into the lesson (implicitly or explicitly) and which scenarios (examples) were employed by the teacher to do so. Furthermore, as already discussed in the beginning of this section, these diverse forms of discussing NOS highlighted the “continuum” aspect of talking about science in school science, that is, how NOS can be part of a lesson in different ways and levels of depth, including here the scenarios where no explicit discussion about it was actually carried out by the teacher (the “read-made”, top-down authoritarian view of scientific knowledge).

FINAL THOUGHTS

As argued throughout this paper, an intercultural perspective towards science teaching is connected to the examples employed by the teachers and to how they connect these examples to students’ lives, to other societies and periods of knowledge production. Moreover, discussing NOS in different contexts and its relationships with domains such as Ethics and Culture is an
important way of opening up the scientific world to students, especially in our multicultural European schools. However, during this research, few examples of these intercultural practices were seen, and many of the lessons were dedicated to teaching through traditional examples, with less attention to NOS and people’s lives.

In the case of the examples employed, most of them were connected to everyday life objects (e.g.: glow sticks, fridge magnets, etc.), some with the media (e.g.: Emma Watson’s dress), and few from authentic science (e.g. the Thalidomide case). Very few examples intercultural experiences were observed (e.g.: origins of the Earth, selective breeding in China), but when they were part of the lesson, interesting connections between NOS and intercultural perspectives were made, highlighting how knowledge about NOS can foster (and be fostered by) these more diverse examples and discussions about science.

It is also important to remark that the introduction of NOS into the lessons was intrinsically connected with the amount of time and work dedicated to the discussion of examples. That is, when the teachers adopted a more contextualised or in-depth approach to these examples (items or cases), there was more space for an explicit analysis of epistemic and social-institutional (non epistemic) aspects of NOS alongside the students. This scenario, however, was not commonly seen during the lessons, as stated above, due to a large usage of an implicit approach towards NOS and an illustrative approach towards the examples employed and the relationship between science and people’s lives.

Additionally, while some topics like Stem cells or Drug trials seem to foster an intercultural and critical work, others are still more related to rote learning (such as Endo/Exothermic reactions). Thus, it became clear that the topic being taught can easily constrain teachers’ practices, especially regarding the use of diverse examples and teaching about NOS, a topic that still needs to be further investigated by this research. Furthermore, the constraints of official content-drive exams in relation to the use of intercultural examples and explicit discussions about NOS and, more importantly, the lack of materials bridging this teaching of content and of NOS aspects under an intercultural perspective can be considered the main causes behind this scenario.

Here, future impacts on the public perception of science (and on students’ interest in the field) of a school science that does not explicitly address NOS and its intercultural aspects need to be considered.

REFERENCES

This paper examines the conceptions of the nature of science (NOS) in the discourse around agriculture in science textbooks used in Kerala, a south-western state in India. Four types of discourses around agriculture, corresponding to the transitions in agriculture sector in the larger social contexts are identified. Green Revolution period presents a science imported from the west, which is the only answer to the questions on India's food self-sufficiency. In the Post-Green Revolution period, textbooks avoid serious discussions on the novel scientific understandings on the environmental costs of high input agriculture. During the neoliberal period, agricultural discourse shows an ecosystem perspective, discussing the need to exercise caution while using the technoscientific advancements. Orientation towards an interdisciplinary approach is also seen in the recent textbooks, which explicitly support organic farming movements. This reflects a deepening understanding of the importance of a science informed by science studies. However, recent textbooks also resort to an appropriation of a scientist tag to farmers- which is problematic.

Keywords: nature of science, agriculture, history of agricultural education,

INTRODUCTION

Similar to many other parts of the world, deepening understanding on soil degradation, pollution, pesticide-induced biodiversity loss and diseases, and high carbon footprint of global food regimes strengthened and expanded organic farming movements in India. The agricultural history of Kerala, a south-western state in India, is not so different. However, a unique mixture of socio-political and geographic factors made it an exemplar of an internationally acclaimed human development model (Tharamangalam, 2010). Kerala is going through a 'silent organic farming revolution' (Thottathil, 2014) now, with mass participation in an unprecedented level. Though organic farming movements are gaining momentum worldwide, mass participation of people from various fields- the government, political parties, civil society movements and organizations, conventional farmers, agricultural research stations, scientists, educational institutions, press and entertainment media, religious bodies, social networking sites, environmental activists, intellectuals, and writers- is a unique feature of Kerala's organic farming movements. As Thottathil (2014, p.149) remarks, “the world today has the opportunity to learn a lot about organic farming's global and local possibilities by watching Kerala's latest sustainable development initiative unfold.”

Since the (modern) Indian formal education system has always been textbook-centric (Advani, 2009; Kumar, 1988), the content of the textbooks can be considered as a documentation of how the formal education system in India responded to the transitions in agriculture. This paper aims to illustrate that a change in the conceptions of NOS (Urhahne, Kremer, & Mayer, 2011) is also imperative in these transitions. As schools, textbooks also exist in a political context (Purves, 1993; Johnson, 1993). Studying the historical development of ideas in textbooks...
Strand 6 presents a goldmine to the 'archaeologist of knowledge', because 'textbooks offer clues to the circumstances, hands and forces that created them' (Issit, 2004).

Here, the discourse around agriculture in 14 purposively selected Kerala school science textbooks published during 1947 to 2015 were analyzed to understand the evolution of the discourses around agriculture and how their conceptions of NOS change. Four phases during 1947-2016 have been identified (Table 1) through literature survey that marked major shifts in the agricultural sector during this period.

Table 1. Phases in Indian agriculture during 1947-2016

<table>
<thead>
<tr>
<th>Phases in agriculture</th>
<th>Characteristics</th>
<th>Periods</th>
</tr>
</thead>
<tbody>
<tr>
<td>Green Revolution (GR)</td>
<td>Promotion and celebration of technoscientific advancements</td>
<td>1947 - early 1980s</td>
</tr>
<tr>
<td>Post-Green Revolution</td>
<td>Disenchantment with science, Environmental movements</td>
<td>Began by late 1980s</td>
</tr>
<tr>
<td>Neoliberal</td>
<td>New Economic Policies, Effects of globalization</td>
<td>Began from 1990s</td>
</tr>
<tr>
<td>Organic Farming</td>
<td>Orientation towards Sustainable Development</td>
<td>Ongoing</td>
</tr>
</tbody>
</table>

These phases are typically associated with a time period and involves a simple to complex evolution in ideas with time, though a strict chronologically progressing sequence is not observed in textbooks. This could be because of the unsystematic revisions of the textbooks before, compared to their frequent revisions in recent years. These four phases gave a rubric for discourse analysis.

**TEXTBOOKS FOR ANALYSIS**

The sample textbooks (Table 2) follow the syllabus prescribed by committees appointed by the state or state education board in Kerala. They were chosen purposively from a collection of approximately 500 textbooks kept in the Textbooks Archives section in the library of State Council of Educational Research and Training (SCERT), Kerala. Filtering a sample for study from this collection followed a process of eliminating less relevant ones, after assessing whether they include topics related to agriculture in a relevant manner. The following pointers were used in this process:

- Textbooks published in other states and not used in Kerala schools.
- Textbooks published before India’s Independence from Britain in 1947.
- Textbooks on Maths and English: agriculture as a topic had rarely been included in these textbooks.
- Frequent textbook revisions had begun in 1990s. Since many ideas were found repetitive, representative samples were chosen for textbooks published after 1990’s for each decade. However, almost all the parts related to agriculture from textbooks published during 1947-1990s are included in this analysis.

All the textbooks are first published in Malayalam language. More recent textbooks are also translated into English by SCERT for use in English Medium schools. The analysis, guided by a literature survey of the prevailing socio-political environment, sought answers for the following three questions:

- What is the aim of the discourse?
- What conception of NOS is presented?
- How are farmers and their practices represented?

**DISCOURSE AROUND AGRICULTURE- CHANGING PERSPECTIVES**

The two textbooks from the green revolution period predictably emphasize the potential of technoscientific solutions in addressing the food security issues of newly independent India. Infrastructural development during the period 1951-1967 set the stage for Green Revolution, due to which India became a food exporting country. Farmers became increasingly dependent on external inputs, in terms of know-how, high yielding varieties of seeds, technology, machines, fertilizers and pesticides, government sponsored irrigation facilities, and marketing/procurement of crops by the government.

Textbook for General Science, published in 1958 for use in Standard III has a section titled 'Plant Life' consisting of five chapters, which is dedicated to agriculture. Instead of including everyday knowledge existing in farming communities on crops and their cultivation as in the previous textbooks, it borrowed modern terminologies. For example:

- Including English words extensively (probably because the equivalent Malayalam words are not there/not known/not in common usage). Examples are nitrate, acre, pupa, potassium, sodium, oxygen, compost, and slag.
- English words (written using Malayalam script) are used instead of widely used and known Malayalam words (e.g. using 'bone meal' instead of 'ellupodi, 'electricity' instead of 'vaidhyuhti')
- Using new units of measurement (acre, tonne)
- Knowledge unfamiliar to those unaware of Western science are extensively included. Examples: nitrogen fixing bacteria, percentage of nitrogen in atmosphere.

Information on the broader aspects of agriculture, viz. the need to increase irrigation facilities to more farmlands, sowing twice or thrice in a year instead of just once, need to use small and
large scale irrigation schemes (including dams) instead of using water wheels or ox are also included.

Similar to what happened in the industrialized nations, the period after the euphoria of Green Revolution witnessed a public discussion of its adverse effect on environment in India. In the textbook for Biology published in 1974 for standard IX, a chapter titled 'An agricultural field' discusses agriculture as a part of man's relationship with the ecosystem. This chapter is positioned after the chapters' Biosphere' and 'Human beings and Ecosystem.' Doing agriculture without disturbing ecological cycles is its major theme. All kinds of agricultures are described as artificial, as they change the natural ecosystem. Similarly, a diagram from a chapter titled “Are we polluting our surroundings?” in Science textbook for Standard V (1984) illustrates how the pesticides sprayed gets into the food chain and become harmful for humans and other beings (Figure 1).

Figure 1: A Diagram from Standard V Science textbook (1984)

The tensions between competing ideologies of that of celebrating Green Revolution science and of ecosystem awareness is seen in Basic Science textbook (Standard VIII, 1984). It discussed positive impacts of Green Revolution agriculture and pollution caused by chemical fertilizers and pesticides as different sections within a chapter.

New Economic Policies in the 1990's brought major changes in Indian agriculture. Many activists and scholars have been raising alarm on the potential crises these changes can cause, coupled with the chemically intensive high input industrial agriculture. Accordingly, after the Green Revolution period, Kerala’s agriculture fell into a stagnation. Increasing wage rates, shift in cultivation from food-grains to non-food grains, soil and environmental degradation, and problems in water resource management contributed to this decline (Kannan & Pushpangadan,
1988), apart from price fluctuations. Suicides among farmers, especially cash crop cultivators with marginal landholdings in Wayanad (a district in Kerala), had been reported as an effect of the neoliberal policies (Jeromi 2007; Mohankumar & Sharma, 2006). The link between chemically intensive agriculture and environmental degradation, biodiversity loss (Padmakumar et al., 2010) and various diseases (Kesavachandran et al., 2009; Rau et al., 2012; Rusiecki et al., 2005) got established clearly.

Many textbooks representing this phase responded to the stagnation in agriculture by invoking an individual responsibility to address this crisis. A chapter titled 'For a Healthy Society' from Standard V Science textbook (1999) asks the students why buy vegetables while we can cultivate them in our backyard, since we have favorable climate, soil and water. It also encourages students to form a 'young farmers club', and create a school vegetable garden.

Importance of agriculture in society is the focus of the chapter 'Agriculture' in Standard IX textbook for Biology (2003). Reluctance of the present generation to adopt agriculture as a vocation, equitable distribution of food, increasing profitability, expansion of related vocations parallel to agriculture, and value addition of agricultural products are discussed. Another focus is to promote the idea that growing vegetables does not require acres of land, reflecting the increasing fragmentation and reclamation of land and growth of semi-urban and urban regions in Kerala.

By mid 2000s, it became common-place for the science textbooks to discuss social aspects related to agriculture. The new discourse recognizes agricultural sector as a part of the larger socio-politico-economic-cultural and ecological system. Change in one system becomes sustainable only if other systems are also positively affected by that change and when future impacts also looks desirable- this is the major idea of this discourse. Adulteration of food, problems related to excess production and storage, ensuring equitable distribution, middle men taking advantage of farmers, hoarding, new environmental concerns related to farming- like genetic modification, paddy field reclamation by land mafia, agriculture as a profession becoming unpopular are examples of some issues discussed in the sample textbooks. For example, EVS textbook for standard IV (2009) discusses reclamation of paddy fields, sand mining from rivers, and flattening hills as interrelated environmentally hazardous activities. It states paddy fields are not just for cultivating crops, but they also support various life-forms and influences water table of a region.

In a very recent textbook published in 2015, the agricultural discourse centers around the recognition of a crisis situation in agriculture and the urgent need to address this. For example, a diagram (Figure 2) from the chapter on agriculture in this textbook illustrates the need for a ‘comprehensive approach’ in addressing the problems in agriculture.
One of the stated learning outcomes of this chapter is to ‘identify the greatness of agriculture and learn to respect farmers.’ To achieve this, farmers activities are compared with scientific process. ‘The farmer is one who applies the scientific method. Isn’t it clear now that a real farmer is, in fact, a scientist? Scientists deserve more recognition than others because they are the ones who sustain a society’, it adds. This is an interesting turn, which invokes many questions. Why tag farmers as scientists? When does an everyday activity become science or non-science? Recognition given to scientists by society seems to be the central reason that motivated textbook writers to give a scientist tag to farmers. If so, can't farmers (or any others doing any job) get social recognition without a 'scientist' tag? This section in the chapter seems to be influenced by a subgroup of the organic farming activists in Kerala who resort to romanticizing and idealizing traditional agriculture and opposing anything modern. Glorifying farmers as scientists and agriculture as great is an alternative to the ideals of green revolution science, but not substantive enough. It would have been enough to state the farmers, being reflective practitioners, bring valuable knowledge for the sustainable development of our planet. Scientists and farmers play their own roles in this. Reinforcing already existing notions like scientists have a superior status in society when compared to farmers would be counterproductive in a context like this.

The findings of the analysis are summarised in Table 3.

**Conceptions of the Nature of Science**

| External knowledge mainly produced in the western countries. People working in universities and laboratories do science. A science of linear cause and effect. Accept solutions it offers without criticism. | External knowledge produced by people working in universities and laboratories. Caution to be exercised while accepting technoscientific solutions. Agriculture is a complex activity in a complex ecosystem, so the science informing it needs to consider multiple causations and effects. | Scientific knowledge is tentative. Science can offer solutions according to changing conditions. Science needs to be supplemented with (environmental and social) values. | Science supplemented with science studies is important. Interdisciplinary approach is required in solving complex ecosystemic problems. |

**Farmers’ representation in textbook**

| Receivers of technology produced by scientists. Their traditional practices are inadequate to achieve food security. They need to be educated on modern methods. | Receivers of technology produced by scientists. Farmers are held responsible for soil degradation- their 'indiscriminate' use of fertilizers and pesticides. They need to be educated on 'scientifically' using fertilizers and pesticides. | There is dignity in a farmers’ job. They are not mere receivers of knowledge, but play active role in judging what science and technology to be used in farmlands. | Farmers to be consulted on the practical aspects of agriculture. Farmers are doing a social service. Their methods are similar to scientific methods, so farmers are scientists and hence deserve recognition in society. |

**IMPLICATIONS**

Analysis reveals that Kerala school science textbooks are historical documentations of the changes in agriculture sector. Very recent textbooks are seen participating actively in the organic farming movement. They acknowledge the changing perspectives within the discourse of science, accepting its limitations by which it once promoted soil degrading, disease causing high input agriculture. Evolution in the understanding of our relationship with the nature also gets reflected through this analysis- from something to be overpowered and utilized that is
limitless and separate, to that of its interconnectedness, limits, and inevitability of harmonious co-existence with it. Embedded in this evolution is a shift in conception of science from reductionist to holistic, which is inevitably influenced by the ‘dynamic and mutable social body of agriculture’ (Carolan, 2006). This analysis adds to the literature on how ‘textbooks offer clues to the circumstances, hands and forces that created them’ (Issit, 2004).

However, when the recent textbook resorted to glorifying farmers as scientists and using that tag to justify their social recognition, it seems the evolution of the discourse around agriculture has taken a wrong turn. ‘Rhetorically idealizing pre-industrial forms of nature as a reference point’ (Levidow, 1996) would not help in expressing the ‘holistic conceptions of the nature’ (Capra, 1996). A science supplemented with science studies, ecosystem science, and futures studies are needed for this (Carolan, 2006; Gilbert, 2016; Carter & Smith, 2003; Colucci-Gray et al., 2013). Scientific understandings from a holistic perspective, and the unique insights and practical knowledge that farmers bring, are complementary to each other in the context of sustainable development. Then, farmers and scientists are deserving of equal respect and social recognition. Here, the same discourse that finds a problem in the unpopularity of agriculture as a profession finds the need to tag farmers as scientists to be worthy of social recognition. This can very well become counterproductive. This points out the need for curriculum designers and textbook writers to be discerning of the various influences and values from the larger socio-cultural contexts.

ACKNOWLEDGEMENT

I thank Prof. G. Nagarjuna, Dr. Sanjay Chandrasekharan, Dr. Aswathy Raveendran, Prof. Leena Abraham, and Himanshu Srivastava for their suggestions.

**STRAND 7: INTRODUCTION**

**DISCOURSE AND ARGUMENTATION IN SCIENCE EDUCATION**

*Strand 7 Discourse and argumentation in science education* includes research on the understanding, supporting and promoting use of evidence and argumentation discourse in science education. The strand also includes research on scientific practices related to knowledge evaluation and communication, supporting the development of critical thinking, discourse analysis, meaning making in science classrooms and talking and writing science in the classroom.

In this E-proceedings there are sixteen contributions to *strand 7 Discourse and argumentation in science education*. Most of them concern different aspects of argumentation. Some of them are more focussed on the design of teaching and interactional analyses of classroom talk. In common is that all research is highly relevant to the field of research as well as for advancing science teaching practices. The combined picture of the research is that there are lessons to be learnt from across the world as well as across the educational system. For example, in comparing how teachers struggle to incorporate argumentation in science education teaching in different countries, we find that the struggles share some characteristics but is to some extent slightly different in different educational contexts. A common conclusion, however, is that teacher education needs to be research-based and designed to include argumentation.

**A thematic overview of the papers on discourse and argumentation**

*Incorporating argumentation as part of the professional repertoire of teachers* – This is a major theme in the contributions to this proceeding. Martín-Gámez, Prieto and Acebal investigated skills pre-service primary teachers consider important for them in order to be able to support argumentation in science classrooms and what skills they believe students can develop when they participate in science classroom argumentation. Cebrián-Robles, Franco-Mariscal and Blanco-López have in a similar vein studied the capacity of pre-service primary school teachers to evaluate argumentation. Their results show that teachers struggle the most to identify and evaluate evidence and justification. Both studies indicate that there is a need for designing specific training programs to support becoming primary school science teachers in developing their capacity to work with and include argumentation practices in science education.

Chen and Qiao contributes to the proceedings with two studies focussing the interactional processes of science argumentation classroom practices in the US. Chen and Qiao conducted a qualitative interactional analyses on how a fifth-grade teacher framed dialogic teaching to establish consensus. In the study “Strategies and resources for a fifth-grade science teacher’s uncertainty management in argumentation”, Qiao and Chen conceptualize the teacher-student interactions in a science classroom as a process of uncertainty management. Both studies provide insights into how teachers may embrace uncertainty as part of argumentation in science classroom practices through dialogic moves e.g., asking questions to challenge students’ arguments, inviting more students to join the critique process.
Two papers focus on in-service teacher training teachers’ conceptions or beliefs concerning argumentation. In the paper “Some conceptions about argumentation of in-service science teachers in Córdoba (Argentina)” Romano, Condat, Occelli, Masullo and Vleiras studied in-service secondary science teachers’ conceptions about argumentation. In their study they characterize two points of conflict between the conceptions of argumentation and the teaching practices implemented. When defining argumentation, teachers would underline the idea of providing evidence, and de-emphasize the rhetorical components. In their teaching practices, however, they would emphasize the role of the debate. Also, the Argentinian teachers associated argumentation mainly with the idea of submitting “evidence that proves knowledge”, but the most frequently used resources in classes were books and films. In other word, the teachers stressed the epistemic dimension of argumentation and its potential for critical thinking but omitted aspects related to the scientific practices and the nature of science. The study of Yamamoto and Kamiyama on Japanese teachers’ beliefs about argumentation is a quantitative study showing that in-service teachers in Japan are largely positive in relation to the value of and need for argumentation instruction but that the majority were not fully confident in their own abilities to provide effective instruction concerning argumentation.

Designing science education practices for engagement in argumentation – This theme concerns the design of formal and informal educational practices for engagement in argumentation. Smyrnaïou, Petropoulou, Georgakopoulou and Sotiriou report on the use of Toulmin’s Argument Pattern (TAP) approach as a tool for tracing the quality of argumentation in science teaching and exploring its effective application in enhancing students’ cognitive knowledge. Their findings show that there was significant improvement in the quality of students’ argumentation and cognitive development regarding their critical approach to scientific concepts. Grimm, Robisch and Möller have investigated the potentials of working with the testing of hypotheses as part of inquiry-based science education in German primary school for fostering evidence-based reasoning. Their results point to the possibility for successfully promoting evidence-based reasoning in primary science education.

Argumentation in curricula and educational policy – In the paper “Is there anything such as alternative facts: critical thinking in biology curricula”, Rafolt, Kremer and Kapelari analysed how German, Swiss and Austrian life science curricula address issues of critical thinking as an educational objective. Results show that biology curricula neither mention the term “critical thinking” explicitly, nor do they provide a clear definition of the concept or teaching instructions. Science education research needs to put more emphasis on finding out how essential research outcomes find their way into classroom teaching. Two contributions concern the aims and goals of informal science education practices and point to that aims of critical reasoning and argumentation may also be of major importance in informal practices. Ryan, Croker, Childs and Hayes investigated the main goals of STEM outreach programmes in Ireland. Their results point to that there is a wide variety of formats, goals and pedagogies used when designing outreach programmes for schools with varying goals for the outreach providers in Ireland. Rössig, Herlo, Moormann, Diekämper, Jahn and Faber report on the project ‘Visitor participation at the Museum für Naturkunde Berlin’ where they have used a co-design-process to develop new participatory tools and strategies together with staff members and visitors. The outcome of the co-design-process pointed towards integrating multiple perspectives into
research and exhibitions and debating actual social problems related to scientific work at the museum and an added emphasis to the promotion of science literacy and critical thinking.

Quality in argumentation – This is a theme where researchers seek to advance the discussion of how the quality in argumentation is perceived in research and science educational practices. Based on a study of an intervention focused on critiquing the work of peers, Ong, Duschl and Plummer stress the importance to shift from a focus on argumentation frameworks (e.g., TAP) towards a consideration of epistemic criteria used by the scientific community. Interpreting scientific argumentation as practice, implies that student participation in processes of argumentation and critique becomes more important than the use of argumentation frameworks. They assume that this could support students in the development of a more robust critical stance of critiquing their own work. They also found that the way teachers interact with students plays an important role in students’ engagement with epistemic tasks.

Analysis of classroom interaction/discourse – this theme is slightly different from the above themes where argumentation is focussed as part of science education curricula. This theme concerns detailed analyses of interaction in different types of classroom practices. Borg and Gatt report on an action research study where they examine whether adopting inquiry-based learning strategies in the Physics classrooms may contribute to more proficient use of scientific language appropriately among bilingual students in Malta. Their study shows how focus on language during inquiry has the potential to promote both understanding as well as students’ proficiency in talking science. Tagnin, Riordain and Fleming report on a study on science learning in a CLIL (Content and Language Integrated Learning) classroom setting at upper secondary level. Their study focusses on what language practices emerged and what opportunities for learning are established. The findings point to that some of these practices, such as language focus, code-switching and exploratory talk provide linguistically challenging situations may contribute to generating opportunities beneficial for science learning. An additional key finding was the dominance of an authoritative communicative approach to classroom talk potentially hinders student learning. In a similar vein, Rees, Mba and Roth report on a project seeking to support the transition to a more student-centred approach to scientific inquiry. In this study they analysed teacher-student interactions using conversation analysis of video recordings that were collected at intervals throughout a period of one year. The results point to three prominent discourse patterns, two teacher-centred and one more student-centred pattern. The findings suggest that the student-centred discourse pattern became more common as the class transitioned to more student-centred scientific inquiry and the authors suggest that the co-teaching format could be of value to teachers wishing to make a shift to a more student-centered teaching practice.

Linguistical analyses of student texts – this last theme is represented by only one contribution – that of Medeiros, Freitas, Motokane, Pereira, de Freitas and de Castro. Medeiros and her colleagues argue that incorporation of text production in science teaching is an action that may help students in understanding the specificities of scientific discourse and to grasp scientific culture. In their study they seek to analyse the effectiveness of actions that promotes scientific writing in elementary school science education by using a specific software for statistical analysis of repetitions and successions of words. The use of the software made it possible to
analyse the discourse produced by the students after the application of a specifically designed teaching sequence. The findings indicate that the student texts produced mirror a scientific discourse.

Maria Andrée and Jouni Viiri
SKILLS THAT PRE-SERVICE PRIMARY TEACHERS’ CONSIDER IMPORTANT IN ARGUMENTATION APPROACH

Carolina Martín-Gámez, Teresa Prieto and María del Carmen Acebal
University of Málaga, Málaga, Spain

Argumentation as a form of scientific discourse is a powerful tool that allows students questioning, justifying, and evaluating their and others’ claims. In science education, transmissive teaching predominates and this leads to difficulties in students’ construction of arguments and highlights limitations in teachers’ pedagogical abilities in the management of this type of activities. Also, teachers’ beliefs and perceptions have a big influence in the way they teach. Thus, the purpose has been to investigate pre-service primary teachers’ beliefs of what would be the skills they need as a core to support argumentation in science classrooms, and what skills students can develop when participate in science lessons based in argumentation. Results show that Pre-service Teachers of Primary pay little attention to the skills they will need in order to manage different methodological strategies as debate, pair work or pair discussion, that support the argumentation approach. Moreover, they lack of awareness about what is a good argument and its components, besides scientific knowledge. These results are significant because they indicate a need in designing specific training programs to support teachers in acquiring knowledge and skills about argumentation.

Keywords: argumentation, pre-service primary teachers, skills.

INTRODUCTION

Contemporary science education places a great emphasis on scientific literacy. Driver, Newton & Osborne (2000) and Sadler (2006) highlight the importance of students’ active participation in discourse in a science classroom to develop of their scientific literacy. This means introducing in science teaching some of the processes and situations that occur in the social context, which favor the involvement of students in organizational processes of thinking, communicating ideas, adopting positions, and promote their confidence in the arguments supporting their own choices while developing respect for others (Kolstø, 2001; Ratcliffe and Grace, 2003).

Argumentation is a form of scientific discourse (Erduran & Jimenez-Aleixandre, 2012; Jimenez-Aleixandre, Rodriguez & Duschl, 2000; Von Aufschnaiter, Erduran, Osborne, & Simon, 2008) and a powerful tool that allows students questioning, justifying, and evaluating their and others’ claims (Duschl & Osborne, 2002; Erduran, Dilek & Yakmaci-Guzel, 2006). However, in science education, transmissive teaching predominates, offering few opportunities for students to engage in dialogic argumentation (Duschl & Osborne, 2002). This leads to difficulties in students’ construction of arguments (Duschl & Osborne, 2002; Newton, Driver & Osborne, 1999) and highlights limitations in teachers' pedagogical abilities in the management of this type of activities (Martín-Gámez & Erduran, 2016; Newton, Driver & Osborne, 1999).
On the other hand, researches show that teachers' beliefs and perceptions have a big influence in the way they teach (Porlán et al., 2010). For these reasons, it is necessary to identify their thoughts on argumentation to design specific programs of teacher training in order to promote the knowledge and awareness they need to modify their beliefs.

METHODOLOGY

Sample and research questions

The participants of this study have been 72 pre-service Primary teachers at a Spanish university. The group consisted of 50 women and 22 men that were organized in 15 work groups from 4 to 6 members. Their ages varied from 43 to 19 years old. These students were studying the third course of the Grade of Primary Teachers and until this course, they had only had some exposure to science education in a Practicum period during three weeks.

The main purpose has been to investigate the Primary teachers’ perceptions about what would be the skills they need as a core to support argumentation in science classrooms. Specifically, we want to answer the following research questions:

- What skills do they think are fundamental in conducting science lessons based in argumentation?
- What skills do they think students can develop when they participate in science lessons based in argumentation?

An activity was proposed to the work groups at the beginning of the subject “Science Education” module of the first semester when they still hadn't got any contact with the role of discourse and argumentation in the science classroom.

Activity

The activity was developed to investigate the pre-service primary teachers’ perceptions about skills would be need to support argumentation in science classrooms and consists in reflecting about a Primary activity based in argumentation (Appendix A) that was adapted of the PED (2013). Its purpose was to set a context for participants to reflect about:

- a) why argument is important in teaching science;
- b) skills needed to conduct lessons based in argumentation;
- c) what techniques and resources could support argumentation.

After reading it, each work group should think over and reach a consensus in their answers to the following questions:

Q1. Would you use such strategies in your future lessons? Why?
Q2. Do you think this kind of lesson is common in the Primary school? If not, why?
Q3. What skills are mainly required to use this approach?
Q4. What knowledge is mainly required to use this approach?
Data analysis approach

A qualitative approach was applied with the objective of systematically describing the meaning of the written Pre-service Primary Teachers’ responses (Schreirer, 2012). The process began with every author of this work making an individual analysis of the data, in order to determine emergent aspects (Creswell, 1998). The results of each one were compared and framed in the work of Osborne, Erduran & Simon (2004). Then, a consensus was reached to describe a set of non-excluding categories to each question.

RESULTS

The analysis shows that 11 of work groups would use this kind of activities in their science classrooms. Their reasons are collected in Table 1. Only one of the groups wouldn’t use argumentation activities because they consider that this kind of activities wouldn't motivate the students. The others 3 groups would use them depending on cognitive level of students.

As it shows on Table 2, after their Practicum period, all the work groups, except one, consider that these kind of activities are infrequent in Primary (Q2) because at science classroom predominates memory learning (7 groups), the kind of textbooks activities (6 groups) or because these activities consume a lot of time classroom (2 groups).

Table 3 presents the frequencies of the work groups’ answer to question 3 (Q3). Eight groups mention only one teachers’ skill: skill to transmit scientific knowledge or skill to encourage the participation. The other 7 groups propose a minimum of 2 or 3 skills, highlighting the one of encouraging reflection and participation.

On the other hand, answers to question 4 (Q4) show that a majority of groups (12) think that teachers only need scientific knowledge to use argumentation approach. The knowledge about components of a good argument and about methodological strategies to encourage argumentation are only added by 3 work groups (Table 4).

**CONCLUSIONS**

The results presented, that focus on Pre-service Teachers of Primary’s perceptions about skills could be developed in students and about skills would be need to support argumentation in science classrooms, are a part of a wide study. The results show that most of these Pre-service Primary Teachers relate the argumentation approach to develop students’ skills of questioning of ideas. However, they don’t consider that this kind of approach will help students to develop inquiry skills and ideas justification. In addition, no one manifest that it could be a good way to promote understanding of scientific knowledge and students' learning to evaluate their own and the others ideas (Erduran, Dilek & Yakmaci-Guzel, 2006).

Furthermore, results suggest that participants think that the argumentation approach in Primary science classroom is not frequent because teachers encourage memory learning and textbooks activities. In no case they mention the specific formation that teachers should have to use this kind of approach (Newton Driver, & Osborne, 1999). So, it seems that Pre-service Teachers of Primary don’t consider that teachers need acquire some skills to manage different methodological strategies as debate, pair work or pair discussion, among others, that support the argumentation approach. Moreover, data point out that they are not aware that this approach needs also the knowledge about what is a good argument and its components, besides scientific knowledge.

The importance of identifying these perceptions lies in the influence they may have on the future teaching practices (Porlán and Martín del Pozo, 2004). Specifically, this ignorance could be translated into a teaching-learning approach in the science classroom that does not empower future students to develop these processes that are so necessary for the creation of solid and quality arguments, and thus in against what would correspond to a good way to promote the understanding of scientific knowledge (Erduran, Dilek and Yakmaci-Guzel, 2006; Jiménez-Aleixandre, 2010). So, these results are significant because they indicate the need in designing specific training programs to support teachers in acquiring knowledge and skills about argumentation. Then, Primary Teachers will be able to help to their future students to construct good arguments in Science Education.

Another reason is that …….
Finally, I think that……….

**Additional Evidence**
As the axis of the Earth is tilted, in a hemisphere the temperatures are somewhat higher than in another.
As the axis of the Earth is tilted, there are four seasons and in some countries is summer and in others is winter.
In summer, the day is longer than in winter.
As the axis of the Earth is tilted, in each hemisphere there is a cold zone, temperate zone and hot zone.
CAPACITY OF EVALUATION OF PRESERVICE ELEMENTARY SCIENCE TEACHERS IN AN ARGUMENTATION TASK

Daniel Cebrián-Robles, Antonio Joaquín Franco-Mariscal and Ángel Blanco-López

Universidad de Málaga, Didáctica de las Ciencias Experimentales, Málaga, Spain

The growing importance of argumentation in science education must also be accompanied by examples showing both teachers in service and trainee-teachers how to implement and assess argumentation in class. In this line, this study is framed within a broader research study on argumentation competency, which involves the participation of Preservice Elementary Science Teachers (PESTs) from 3rd year of the Primary Education Teaching Degree from the University of Malaga (Malaga, Spain). Specifically, this paper shows an argumentation task that involves the participation of 98 Spanish PESTs, through production and peer assessment, in order for them to internalise the criteria of a good argument, thus improving their argumentation skills. The set task is drawn from a PISA 2006 test, which addresses the possibility of reducing the hardness of a lipstick by changing its composition. PESTs are required to conduct peer assessment, which will then be compared to teacher assessment, in order to analyse the ability of the former to identify and evaluate the elements of an argument. Results show different levels of capacity for analysis and evaluation of argumentation by PESTs. In particular, they struggle the most to identify and evaluate evidence and justification. Likewise, the peer assessment-teacher assessment comparison reveals an overestimation by PESTs in relation to evidence and justification.

Keywords: argumentation, preservice elementary science teachers, peer assessment.

INTRODUCTION

Nowadays, argumentation is considered one of the main scientific practices, thus a key element in science teaching (Duschl & Osborne, 2002; Erduran & Jiménez-Aleixandre, 2008; McNeill & Pimentel, 2010). McNeil & Knight (2013) consider it necessary to explicitly work out with future pre-service teachers and teachers in service the best way to address argumentation in class. De Sá Ibraim & Justi (2016) have recently contributed a work approach in order to improve the argumentation knowledge of pre-service teachers, so that, they can arrange and lead the teaching based on argumentation (De Sá Ibraim & Justi, 2016; Karışan, Tüzün, & Zeidler, 2017; Yaman, 2017).

Different authors agree that, in order to understand and internalise the criteria for a good argument, one need to practice such criteria, by producing arguments and assessing those of others (Osborne et al., 2016). These activities should raise daily situations in appropriate contexts that allow understanding and using the discourse and scientific models, while making it possible by arguing science-related situations. These allow giving solutions and encourage the debates about authentic and interesting problems for the students (Jiménez-Aleixandre, 2002; Jiménez-Aleixandre, Rodríguez, & Duschl, 2000).
In this way, the tasks presented to students in the Programme for International Student Assessment (PISA) offer opportunities to address these contexts and develop diverse competences in young people (OECD, 2016). The ability to argue is one of the scientific competences evaluated (Bybee & McCrae, 2011). Tsai (2015) showed that one way to improve scientific competence is using online argumentation, and so to improve the score in PISA. His study took as a starting point some activities proposed in PISA to create the questions that are used to measure the argumentative capacity, since it is intended that pre-service teachers are prepared to develop these competences in adolescents.

In order to design and evaluate argumentative activities, an appropriate model for understanding argumentation is needed being the Toulmin model (1958) the most suitable model for explaining the structure of an argument. This model has been simplified by Jiménez-Aleixandre (2010) to facilitate the understanding of the essential elements that a good argument must have: evidence (E), justification (J) and conclusions (C). E is understood as the evidences necessary to support an affirmation of a certain C. J allows explaining the relationship between these E and C, while C must allow knowing the opinion and the content on a certain aspect.

A number of research studies prove that students learn to assess when they actually assess to learn (Boud, Cohen, & Sampson, 1999; Cebrián-Robles, Serrano-Angulo, & Cebrián-de-la-Serna, 2014). Boud et al. (1999) made some recommendations to conduct peer-assessments and thus achieve greater success in student learning. It is highlighted the next recommendations: the peer-assessment should be done either when the activity gives an extra motivation for the students in front of a traditional methodology or when it should not have more problems than the value that it contributes. In addition, peer-assessment and the activities should be designed in a careful manner so that assessment is not devalued, for instance, by evaluating many aspects of a single task. In general, the formative assessment significantly improves student scores once the course is finished (Black, Harrison, & Lee, 2003). Other studies argue that group work where each student can see and evaluate the argumentation of the other classmates, allows improving the quality of the arguments over time (Chin & Osborne, 2010; Evagorou & Osborne, 2013).

In short, it is assumed that teaching the argumentation and assessment, the pre-service teachers are able to identify in the statement of an activity the essential elements of an argument and so to build an instrument to evaluate the arguments. For the assessment of activities some authors use questionnaires to assess the elements of an argument (Clark & Sampson, 2008), while others prefer rubrics (Deng & Wang, 2017; Osana & Seymour, 2004; Özçinar, 2015). Considering the above ideas, this study focuses on analysing the difficulties encountered by Pre-service Elementary Science Teachers (PESTs) to assess peers’ arguments, and on comparing these assessments to those conducted by the teacher.

**METHOD**

This study is framed within a broader research study on argumentation competency (Osborne et al., 2016), which involves the participation of 98 PESTs from 3rd year of the Primary Education Teaching Degree from the University of Malaga (Malaga, Spain). Students belong to two different, randomly chosen, groups. The study shows the results of one of the tasks
performed during a training programme aimed at teaching students to argue (Cebrián-Robles, Franco-Mariscal, & Blanco-López, 2018). More specifically, the task is performed after introducing Toulmin’s model and the elements of a good argument, plus presenting several examples of tasks on argumentation and evaluation. In this study the assessment capacity implies on the one hand to identify the elements of an argument, that is, to differentiate which are the E, the J and the C in a certain argument and on the other hand to evaluate the quality of each of these elements.

The set task poses PESTs the possibility of reducing the hardness of a lipstick by changing its composition. This task was adapted and translated to Spanish from a science test by PISA 2006 (OECD, 2006, p.153) to demand in the statement the construction of a complete argument. PISA considers that “the context of cosmetics has everyday relevance for students of this age group, although it could be expected that this task would generate more interest among females than males” (OECD, 2006, p.154).

The task was: “The table below (Table 1) contains two different recipes for cosmetics you can make yourself. The lipstick is harder than the lip gloss, which is soft and creamy. In making the lip gloss and lipstick, oil and waxes are mixed together. The colouring substance and flavouring are then added (Table 1). Question: The lipstick made from this recipe is hard and not easy to use. How would you change the proportion of ingredients to make a softer lipstick? Justify your answer using evidences to support it.”

Table 1. Information provided in the statement of the argumentative task about the hardness of lipstick (OECD, 2006).

</tr>
</tbody>
</table>

It is expected that in the PESTS’ responses would include as E that "the lipstick is hard; lip gloss is soft and creamy; and the ingredients' differences between the two products". The desired J should express the following idea: "The difference between lipstick and lip gloss are the ingredients of wax (bee and palm) that in the lipstick is presented in a greater concentration. As the lipstick is harder than the lip gloss, the hardness can be reduced if we modify the amount of wax". And finally, C should be raised in terms of "It is possible to make the lipstick softer".

A basic rubric was used as a starting point for the argument's assessment of the three essentials elements of a good argument. This rubric was written in a general way to be able to adapt to
the assessment of different tasks. A specific rubric (Figure 1) was designed using the basic rubric for peer assessment and teacher assessment of PESTs in the specific case of the task about the hardness of a lipstick. The rubric shows different response levels for each element of an argument, based on a 1 to 4-5 scale, where level 4 for E, level 5 for J and level 5 for C are the most desirable levels.

Figure 1. Specific rubric to assess the task on “hardness of a lipstick”.

Once the task has been answered, PESTs have to anonymously and randomly assess the responses of two other peers, through the CoRubric electronic rubric collaborative platform (Cebrián-Robles, 2016). Figure 2 shows how the PESTs were working on the classes assessing argumentations with CoRubric.

Figure 2. Assessing with CoRubric in classes

The teacher also gives feedback to the PESTs through the individual assessment of each of them. The assessment involves identifying three elements in arguments (E, J and C) in their peers’ answers and use rubrics to assess the quality of each argument. Similarly, teachers participating in the training programme (two of the authors of this paper) are required to assess PESTs’ answers. To do so, they are to agree on the scores assigned to each answer.
An example of a response that is not well argued given by a PEST assessed by the teacher and another PEST is shown in Figure 3. In the following figures C is shown with solid lines, J and E are indicated in dashed lines, and dashed lines and dots, respectively.

![Image](Yes, modifying the wax of palm or bee but in a small amount not reaching 0.2g)

**Figure 3.** PEST A710K’s answer to the argumentation task. Teacher’s assessment: E (level 1), J (level 1), C (level 5). Assessment of another PEST: E (level 2), J (level 2), C (level 3).

The teacher’s assessment of the previous response granted a level 5 to C; and the lowest level (level 1) for E and J because of the PEST had not really used them in his argument. However, another PEST evaluated the same answer at level 3 of C (Despite the correct answer, C is scientifically inaccurate or contains errors. For instance, wrong terms have been used), and level 2 for J and E, thinking that despite having given them, they were inadequate.

The example in Figure 4 corresponds to a well-argued answer given by another PEST and assessed by both the teacher and two other PESTs (peer-assessment) at the maximum levels of the rubric.

The coincidence in the assessment of PESTs and teacher shows how the PEST A567P reached the highest levels of achievement in all cases. Thus, it is in level 5 of C, having adequately expressed it scientifically; at level 4 of E, by indicating the present evidence needed to support the C; and in level 5 of J, since it links the C exhaustively in a correct way with the E.

![Image](It could be modified the recipe to make the lipstick softer since the only difference between the two recipes is the amount of wax that is added, giving two results of different "hardness". On the one hand, lip gloss contains much less wax than lipstick and it is much softer and creamier, on the other hand, to obtain a softer lipstick, it would reduce the amount of wax as long as it was superior to that used in the lip gloss.)

**Figure 4.** PEST A567P’s answer to the argumentation task. Assessment of the teacher and another PEST: E (level 4), J (level 5), C (level 5).
RESULTS

Peer-assessment

Table 2 shows the mean of PESTs (%) in each achievement level of E, J and C; based on peer-assessment and teacher assessment of PESTs.

</tbody>
</table>

PESTs assessed E and C responses in the two highest levels (81% of E in levels 3-4 and 72% of C in levels 4-5). As for J, the response rate concentrated at low levels (60.5% in levels 3-4). Rates found in the lowest level for E, J and C did not exceed 7.3% in any case. In the case of PESTs, it was observed that the highest concentration of responses was between levels 3 and 4 with a mean of 3.14 out of 4 for E. However, for J the levels ranged between 3 and 4 with a mean of 3.57 out of 5. And, the highest concentration of answers was between 4 and 5 with a mean of 4.05 out of 5 for C. These results differ somewhat from the assessment made by the teacher, in which case J was more identified on the first levels. This may be due to the difficulty that PESTs present to identify what the J for a good argument are. However, E and C were similarly identified by PESTs and teacher.

Differences between peer-assessment and teacher assessment

The differences among the level of achievement assessed by the teacher and the levels of achievement of the PESTs for each of the elements of an argument were obtained and analyzed in order to delve into the differences between the PESTs' peer evaluations and the teacher's evaluation. The different levels were interpreted in this way: values above 0 mean that students assessed activity below the teacher's grade; values equal to zero reflect the same assessment to that of the teacher; and values less than 0 correspond with higher assessment than the teacher. For instance, if a student assessed J in 3 and the teacher scored 4, then the difference (teacher - student) is +1, that is, the teacher has assessed one level more than the one assessed in J by the PEST. The percentage of levels that differ for each of the elements of the argument, between teacher and PESTs assessments is represented in Table 3.

Figure 5 represents the total percentage of scores of the PESTs, overvalued, equal and undervalued, with respect to those of the teacher. These results differ from teacher’s assessment, who consider fewer response rates in E and J to be in the highest levels (with 40% and 51% less, respectively), and only 9% more responses in line with a very appropriate conclusion. Finally, teacher assesses higher response rates at levels 1-2 in all cases except for C.

CONCLUSIONS AND PROPOSALS FOR IMPROVEMENT

This research study shows a type of argumentation in class that aims to bring PESTs closer to their daily lives contexts. The tasks can help increase their level of motivation for science while improving their argumentative competence (Osborne et al., 2016), not only by producing arguments but also by assessing and identifying the main elements of a good argument through peer assessment. Learning to assess is a good approach to practice argumentation in class, because the students can assess to learn (Folkes & Carmichael, 2006). The aforementioned results reveal that PESTs struggle to identify and assess E and J, which are often overvalued in relation to teacher assessment. Likewise, some PESTs undervalue C, by a difference of up to two levels. This could be due to PESTs’ difficulty to clearly differentiate the three elements in an argument. Results suggest the need to train PESTs in argumentation tasks, with special emphasis on the meaning and use of E and J in arguments, as has also been concluded by other authors (Larson, Britt, & Kurby, 2009; McNeil & Knight, 2013). The strategy of peer assessment used in this study seems to have been useful to improve PESTs’ argumentation skills, as not only it makes them participate in assessment but also makes them aware of their own argumentative level, which enables them to internalise, be critical and reflect about their own arguments as well as those of others. All of which helps improve self-regulated learning and the argumentative competence.
ACKNOWLEDGEMENT

This work is part of the ‘I+D Excelencia’ Project “Development and evaluation of scientific competences through context-based and modelling teaching approaches. Case studies.” (EDU2013-41952-P), funded by the Spanish Ministry of Economy and Finance through its 2013 research call.

DIALOGIC TEACHING TO ESTABLISH CONSENSUS IN ARGUMENTATION

Ying-Chih Chen and Xue Qiao
Mary Lou Fulton Teachers College, Arizona State University, Tempe, Arizona, USA

Dialogic teaching, as opposed to monologue, not only provides opportunities for students to encounter others’ arguments but also creates a space to immerse students in negotiating ideas in order to establish consensus. Grounded in a qualitative, interpretative approach, this study explored how a fifth-grade teacher framed dialogic teaching to establish consensus through three harmonious goals while students learned about the human digestive system: social negotiation, epistemic engagement, and conceptual development. The data analysis led to the creation of a schematic model that explains the dialogic move toward consensus establishment. Central to the model is the intertwined, dynamic, and progressive nature of dialogic teaching with regard to the contexts in which teachers orchestrate these three goals to extend students’ conceptual understanding. Four themes for discussion and implications are identified from this study: (1) uncertainty creates a platform for students to discuss, debate, and debunk and further extends their knowledge, (2) comprehension is a necessary precursor to engaging students in the productive practice of constructing and critiquing arguments, (3) explicitly connecting students’ prior knowledge and everyday lived experience to developing concepts is a resource for developing “what counts as knowledge”, and (4) empowering students’ authority and accountability of knowledge is a foundation for productively framing dialogue.

Keywords: argumentation, dialogue, uncertainty

INTRODUCTION

Dialogic teaching in argumentation has received substantial attention by educators (e.g., Alexander, 2008). In science, Duschl (2008) argues (also supported by Manz, 2015) that dialogic teaching should include a three-part harmony of social goal (i.e., being able to communicate, critique, and construct ideas), epistemic goal (i.e., knowing what counts as claims and evidence), and conceptual goal (i.e., developing new knowledge and expanding current knowledge). This concept of three harmonious goals is promising not only because it addresses the structural features of scientific knowledge but also because it suggests the value of the social practices in which students construct and critique knowledge through the use of claim, evidence and reasoning in a community. Dialogic teaching creates a space for multiple voices to be discussed, debated, and debunked. The fundamental caveat of dialogic teaching is not only to elicit the interaction of disparate ideas but also to establish a consensus among individuals who may hold contradictory ideas (Alexander, 2008; Berland & Lee, 2012). This process of consensus establishment involves bringing together many individuals in dialogue, with the desire to cooperate in attempting to forge a mutual agreement through seeking and co-constructing the best explanation to a question. However, dialogic teaching toward consensus establishment remains a great challenge for teachers (Chen, Hand, & Norton-Meier, 2017; McNeill & Pimentel, 2010). Scott, Mortimer, and Aguiar (2006) claim that teachers have difficulty orchestrating varied opinions and thus avoid eliciting different ideas. Even while engaging students in eliciting ideas from one another, teachers lack the skills to challenge students’ ideas in order to help them discover the weaknesses and errors in their arguments, a
process that can lead to establishing consensus.

In this study, we seek to understand how the three harmonious goals of dialogic teaching can be simultaneously orchestrated in science classrooms. In discussing these three goals, we draw on research from linguistics and anthropology and have adopted the construct of framing to unpack how an experienced fifth-grade teacher facilitates student understanding of science core concepts about the human digestive system within dialogic inquiry through the three harmonious goals. At the end of the paper, we summarize the findings that led to a schematic model that illustrates how integrating the three goals in dialogic teaching establishes consensus.

THEORETICAL FRAMEWORK

Dialogic teaching is defined in this study as a social negotiated act in which individuals conceptually construct and critique claims supported by evidence for the sake of establishing consensus (Alexander, 2008; Chen, Park, & Hand, 2016; Dusch, 2008). Within this definition, dialogic teaching in science classrooms is conceptualized as three goals that are distinct but interdependent (see Figure 1): (1) social negotiation, students are encouraged to share, debate, and revise their ideas with teachers and peers in order to forge a consensus; (2) epistemic engagement, students use their understanding of what counts as good claim and evidence as a resource to construct their own arguments and to evaluate others’; and (3) conceptual development, students productively develop core concepts through extending their current knowledge.

First, dialogue in science classrooms is a series of social negotiation events where students, with cognitive conflict toward the same issue and a need to work cooperatively as a community, try to achieve mutually acceptable consensus (Rahwan et al., 2004). Therefore, the goal of dialogic teaching is not only to get students to exchange/interact with ideas and convince peers, but also to build a consensus.

The second goal of dialogic teaching is epistemic engagement, which refers to how students construct and critique ideas during social negotiation. Duschl (2008) and Sandoval (2014) suggest that dialogic teaching should not only focus on ontological practice about “what we know” (e.g., laws, theory), but should also emphasize epistemic engagement about “how we know what we know” and “why we believe” (e.g., explanation, justification). This goal of dialogic teaching requires students to develop understanding of what counts as a high-quality argument and how to apply this understanding to critique others’ arguments in dialogue (Chen, Hand, & McDowell, 2013; Sampson, Grooms, & Walker, 2011) and to judge peers’ critiques.

The third goal of dialogic teaching is conceptual development. Once students epistemically engage in social negotiation, they are expected to make “intellectual progress that can be inferred by, amongst other things, an improvement in the quality and sophistication of arguments and the development of new ideas and disciplinary understandings” (Scott, Mortimer, & Aguiar, 2006, p. 607). Conceptual development in such dialogic contexts likely entails uncertainty, because the critique that students receive of their own knowledge claims makes them doubt, question, and re-examine how well their ideas explain particular phenomena. If students find better ways to improve their ideas, their knowledge grows and expands.
Researchers increasingly argue that these three goals are mutually supportive of one another and are intertwined (Manz, 2015). For example, social negotiation is a resource to make students uncertain of their knowledge and to stimulate them to further examine the inconsistencies and weaknesses of that knowledge. With more sophisticated knowledge, students are able to provide more explanation for their arguments and to debate those arguments. On one hand, this process is driven by students’ epistemic understanding of what counts. On the other hand, the process drives students to develop their understanding of criteria for evaluating knowledge, that is, deciding what counts as good claims and evidence.

Figure 1 summarizes the relationship of the three goals in dialogic teaching toward establishing consensus.

METHODS

This study was conducted in Mr. J’s classroom, where the Science Talk Writing Heuristic (STWH) approach (Chen, Benus, & Yarker, 2016) was utilized to create curriculum and instructional strategies that promote students in building disciplinary core ideas. The STWH was adapted from the Science Writing Heuristic approach that was originally developed by Keys, Hand, Prain, and Collins (1999) as a means to embed a variety of writing activities that engage students in learning the content of a topic (Klein & Boscolo, 2016). Instead of heavily focusing on writing, like the SWH approach, the STWH approach places importance on the integrated use of talk and writing as tools for the argumentative practice of social negotiation and epistemic engagement of an argument. The STWH approach consists of five phases: (1) exploring big idea--generating an inquiry question, (2) designing tests--observation to gather data, (3) engaging in social negotiation to debate claim/evidence, (4) reading to compare arguments with experts, and (5) reflecting through writing. Given the purpose of this study,
i.e., to help students engage in constructing and critiquing arguments through social negotiation, my analysis focused on the third phase.

Twenty-two students were in Mr. J’s class. This study took place during a unit on the human digestive system which lasted four weeks (Chen & Steenhoek, 2014). Students were expected to understand the big idea of “how the human digestive system and human body system work together”. Given the focus of this study on exploring how Mr. J framed whole-class dialogue to balance the three harmonious goals, six 50-minute whole-class discussion sessions were videotaped. In these discussions, Mr. J orchestrated students’ presentation of their arguments, scaffolded students building stronger arguments, and further helped students develop core concepts of the unit. Data analysis consisted of four stages: (1) dividing whole-class discussion into episodes of group presentations, (2) identifying events within group presentations (episodes), (3) describing what happened, what consensus was achieved, and what the teacher did in each event, and (4) analyzing each event and summarizing events in each group utilizing a qualitative interpretative approach (Wolcott, 1994) based on the three harmonious goals.

To analyze social negotiation, I focused on how the practice of construction and critique was framed by Mr. J. Construction refers to any action students and teachers take to express, explain, elaborate, and reason ideas. Critique refers to any action students take to seek errors, weaknesses, deficiencies, and inconsistencies in an argument through challenging, debating, and defending ideas. Forman and Ford (2014) note that authority and accountability play important roles during the practice of construction and critique. Authority refers to students’ active voice or agency (Scardamalia & Bereiter, 2006) in elaborating, defending, challenging, and justifying ideas when they present their group arguments. Therefore, students are authors of knowledge they construct and have ownership of it. Accountability refers to students’ responsibility for securitizing knowledge they construct and for critiquing, improving, and revising peers’ arguments through seeking the weaknesses and errors of those arguments.

To access epistemic engagement, I focused my analysis and interpretation on how Mr. J framed students’ understanding of “what counts as good argument” and scaffolded them to apply that understanding to social negotiation so that they could develop high-quality arguments. Our previous studies (Chen et al., 2013; Chen et al., 2016) found high quality of argument can refer to the coherence or strong relationships of argument components (claim, evidence, and reasoning), appropriate interpretation or explanation of the relationship of data to evidence, and how effectively the argument addresses the research question.

To study conceptual development, I focused on how students expressed their uncertainty about their existing knowledge, how Mr. J challenged students’ existing knowledge to make them reevaluate that knowledge, and how Mr. J managed and fostered students to solve their uncertainty and thus extended their knowledge. In this study, uncertainty refers to any action students use to explicitly express, demonstrate, and generate ideas that are tentative, questioned, and doubted within a community (Jordan & McDaniel Jr, 2014). Uncertainty can result from peer critique (Radinsky, 2008) and self-awareness of limited knowledge to explain a certain situation or complete a task (Babrow & Mathias, 2009).

By examining each Event from all groups, one group was identified as representative; this group had the most Events and longest discussion, which provided rich and diverse instances
across the two rounds of social negotiation. We then focused on this group to develop in-depth narratives through which to explore how the group developed its conceptual understanding over time when epistemically immersed in social negotiation facilitated by Mr. J’s framing. This analytical move was utilized because this study attempts to capture the complex characteristics of a teacher’s framing from a particular theoretical framework, as well as the relationship between the teacher’s framing and the development of students’ understanding of science practice and concepts. As Varelas, Kane, and Wylie (2012) noted, such narrative chronological analysis is a new methodological area, and it is necessary to examine a few cases in depth in order to unpack the relationship between the discourse and time within a particular environment.

RESULTS

The interpretive analysis led to the formation of a schematic model (Figure 2) that conceptually captures the intertwined, dynamic, and progressive nature of framing the three goals. First, the findings add to current literature (e.g., Cavagnetto & Hand, 2012; Ford & Wargo, 2012; Manz, 2015) by suggesting that the three goals in Mr. J’s framing were intertwined. Students developed their understanding of disciplinary core ideas through discussing the quality of evidence and claim as well as debating the relationship among question, claim, and evidence. In turn, they also developed knowledge of “what counts” when engaging in debating relevant concepts.

![Figure 2. A schematic model of the dialogic move that conceptually captures the immersive, dynamic, and progressive nature of framing the three goals.](image-url)
Second, the findings suggest that framing the three goals is dynamic. The dynamics were influenced by and influenced how students negotiated, the aspects of epistemic engagement they practiced, and the degree of their understanding of developing concepts. For example, as students acquired sufficient understanding of target concepts, they engaged more in searching for the inconsistencies in peer arguments and took authority and accountability for discussion. In contrast, when students lacked understanding, Mr. J took a leader role to scaffold them to comprehend the concepts before re-engaging in critiquing peer arguments. This dynamic framing heavily depended on Mr. J’s in-the-moment recognition of students’ conceptual and epistemic understandings within social acts, decisions about the degree of authority and accountability he and students took, and enactment of his plan to reach the three goals.

Third, Mr. J’s framing of dialogic teaching was progressive and spiral (gradual, as opposed to rushed). That is, Mr. J gradually framed students’ understanding of the three goals and revisited each goal with more sophisticated discussion than had occurred in previous events. For example, as Mr. J framed students’ conceptual understandings, he helped them to understand the function of the human digestive system in earlier episode and revisited the concepts in detail by connecting students’ prior knowledge and everyday experience to those concepts in later episode. As Mr. J framed students’ epistemic engagement, he let them understand the difference between data and evidence before engaging in social negotiations, therefore fostering students to engage in critiquing the coherence of question, claim, and evidence earlier episode, and scaffolded students to understand what counts as solid evidence with appropriate explanation in later episode.

**DISCUSSION**

Four themes for discussion and implications are identified from this study:

1. **uncertainty creates a platform for students to discuss, debate, and debunk and further extends their knowledge**: This study demonstrated that Mr. J continuously framed dialogue around uncertainty by supporting students to search for errors in arguments, eliciting a diversity of ideas, and asking ambiguous questions. When uncertainty emerged in conjunction with social negotiation, it consequently created a platform for negotiation. Students then engaged in collaborating to solve the uncertainty. Once the uncertainty was removed, students’ knowledge was expanded and elevated to another level.

2. **comprehension is a necessary precursor to engaging students in the productive practice of constructing and critiquing arguments**: This study shows that students socially engaged in what Ford and Forman (2006) call “core scientific practice”—critiquing and co-constructing acceptable arguments within the classroom community. However, this study found that only when students could comprehend each other’s arguments and obtain sufficient knowledge could they engage in a high-quality practice of critique and construction. We suggest that unless students can comprehend peers’ arguments and the target concepts, there is little opportunity for them to engage in the high-quality practice of critique that leads to establishing mutual consensus.
(3) explicitly connecting students’ prior knowledge and everyday lived experience to developing concepts is a resource for developing “what counts as knowledge”: This study found evidence to support the connection of students’ prior knowledge and everyday lived experience to the discussion issues as epistemic resources, thereby scaffolding the development of core concepts (Hammer & Elby, 2002). The results of this study suggest that a broad set of evidence, including students’ lived experience and previous knowledge, can be framed to help them shape their reasoning process related to what and how evidence is used and explained. In other words, those resources may play critical roles for fostering students to shape raw data into evidence with explanation.

(4) empowering students’ authority and accountability of knowledge is a foundation for productively framing dialogue: students were positioned as stakeholders responsible for their contributions to the construction and critique of knowledge. Even when teachers adopt I-R-E structured questions, those questions function to empower students to generate ideas through social negotiation and to hold them accountable to those ideas.

STRATEGIES AND RESOURCES FOR A FIFTH-GRADE SCIENCE TEACHER’S UNCERTAINTY MANAGEMENT IN ARGUMENTATION

Xue Qiao and Ying-Chih Chen
Mary Lou Fulton Teachers College, Arizona State University, Tempe, Arizona, USA

This study investigated how a fifth grade science teacher managed uncertainty that emerged in students’ argumentation. The analysis focused on how the teacher used epistemic engagement and social negotiation as resources to manage uncertainty as students engaged in argumentative environments across three different science units—ecosystem, astronomy, and human body systems. Conceptualizing science education as a balance between conceptual, epistemic, and social learning goals (Duschl, 2008), we analyzed transcripts of whole class discussions during the public negotiation phase of the Science Talking-Writing Heuristic approach. Our results showed that 1) when epistemic engagement served as a resource for uncertainty management, the teacher resolved students’ uncertainty through his emphasis on coherence of argument and coherence of knowledge; 2) when social negotiation served as a resource for uncertainty management, the teacher resolved students’ uncertainty through critiquing their arguments. As our study conceptualizes the teacher-student interactions in a science classroom as a process of uncertainty management, it provides insights for science teachers into how uncertainty management through dialogic moves facilitates the development of students’ conceptual knowledge and the improvement of arguments.

Keywords: argumentation, uncertainty, dialogue

INTRODUCTION

Recent research and reform documents on science education have been emphasizing the role of argumentation in students’ development of scientific knowledge. Argumentation is defined in this study as a social negotiated act in which individuals conceptually construct and critique claims supported by evidence for the sake of establishing consensus (Berland, 2011; Chin & Osborne, 2010; Chen, Park, & Hand, 2016; Ford, 2012). As a learner makes claims and organizes evidence to tentatively explain a scientific phenomenon within a specific community, his/her argument will also be socially negotiated by others, that is, the argument will be evaluated, challenged, defended, debated, and strengthened. Through the social negotiation process, arguments become epistemically valid and accepted by a community and a consensus among learners is achieved (Ardasheva, Norton-Meier, & Hand, 2015; Nussbaum & Edwards, 2011).

Uncertainty is an individual’s subjective experience of doubting, wondering about, or being unsure about the future, the present, and the past (Jordan & McDaniel, 2014). Jordan and her colleagues (Jordan, 2010; Jordan & McDaniel, 2014) propose that the experience of uncertainty is likely to be common and important for content learning and collaborative learning tasks, as learners struggle with new disciplinary understandings and participate in new social practices. Argumentation also involves uncertainty because social negotiation makes students doubt, question, and re-examine how well their ideas explain particular phenomena (Manz, 2015). Thus, argumentation can be seen as a process of uncertainty management: as a teacher or
students themselves deal with uncertainty during argumentation, students’ conceptual knowledge increases and improves.

Studies on uncertainty in science education have investigated the cultural tools used by scientists and elementary students to identify and resolve uncertainty (Kirch, 2010); peer responses to individuals’ uncertainty management strategies in collaborative learning tasks in engineering (Jordan & McDaniel, 2014); students’ articulation of uncertainty in argumentation tasks (Buck et al, 2017; Lee et al, 2014); and what kind of classroom discourse can help students identify uncertainty in scientific arguments (Ford & Forman, 2015). Given the limited number of studies on uncertainty in science education, the topic of uncertainty and its relationship with the learning and teaching of science needs further exploration. Furthermore, although these studies have looked at the management of uncertainty across collaborative learning and argumentative contexts, they have not delved into the process of resolving uncertainty and how the resolution of uncertainty enhances students’ understanding of conceptual knowledge. To address this gap in literature, our study asks the following research question:

*How does a fifth-grade science teacher manage uncertainty that emerges during argumentation through the resources of epistemic engagement and social negotiation?*

**THEORETICAL FRAMEWORK**

**Defining uncertainty in science education**

By and large, uncertainty refers to an individual’s experience of doubting and feeling unsure. Jordan and McDaniel (2014) defines uncertainty as “an individual’s subjective experience of doubting, wondering about, or being unsure about who the future will unfold, what the present means, or how to interpret the past” (p. 492). Kirch (2010) conceptualizes uncertainty as “the psychological condition of being without conviction or of being in doubt” as well as “a mathematical object; that is, when the degree of confidence in a statement or assertion can be calculated” (p. 309). There are various sources of uncertainty, and scholars have identified two types of uncertainty according to their roots: personal uncertainty and scientific uncertainty. Personal uncertainty pertains to the individual’s level of skills and knowledge. In argumentative contexts, students’ articulation of uncertainty reveals that their conception of uncertainty is heavily influenced by their confidence in their own skills, knowledge, or self-efficacy (Buck et al, 2017).

Scientific uncertainty is directed towards the tentative nature of science, coming from the conduct of investigation and the interpretation of data. Buck et al (2017) conceptualize scientific uncertainty as consisting three spheres: empirical, signal, and conceptual uncertainty. Similarly, Metz’s (2004) investigation of children’s conceptualization of uncertainty in scientific inquiry identified five spheres of uncertainty: 1) how to achieve the desired outcome as uncertain; 2) data as uncertain (i.e., empirical uncertainty); 3) trend identified in the data as uncertain (i.e., signal uncertainty); 4) generalizability of this trend as uncertain (i.e., signal uncertainty); and 5) the theory that best explains the trend as uncertain (conceptual uncertainty). The search of scientific uncertainty plays an important role in argumentation, which involves construction and critique of arguments. According to Ford and Forman (2015),
critique is motivated by a purposeful and imaginative search for uncertainty. The search is “purposeful because at any stage of understanding, one experiences some degree of coherence and satisfaction, which must be self-consciously challenged. It is imaginative because the potential sources of uncertainty must be found and articulated. This search includes all levels of the chain of reasoning behind a scientific claim” (Ford & Forman, 2015, p. 144).

Scholars have also investigated the management of uncertainty by students and teachers in the science classroom (Ford & Forman, 2015; Jordan & McDaniel, 2014; Kirch, 2010). For example, Kirch (2010) reveals that scientists and teachers and students in the elementary classroom adopted similar cultural tools such as asking clarification questions and establishing collective understanding through conversation, to identify and resolve uncertainty in generating, observing, and interpreting data. However, different from scientists, the achievement of collective understanding of an interpretation within the elementary science classroom is complicated due to the roles that teachers and students take and the power imbalance among the roles. To facilitate students’ identification of uncertainty in the science classroom, Ford and Forman (2015) propose that instead of using an authoritarian voice which demands full compliance of students, teachers should share authority with the students. Though these studies view interpersonal interaction as the means for expressing, managing, and resolving uncertainty, there is a lack of research on the role of teachers in resolving students’ uncertainty and the resource that teachers use to resolve uncertainty. Importantly, students’ conceptual development that accompanies the resolution of uncertainty seems to be overlooked by previous research.

Balancing conceptual, epistemic and social learning goals

Duschl (2008) points out that science education should pay special attention to “the conceptual structures and cognitive processes used when reasoning scientifically, the epistemic frameworks used when developing and evaluating scientific knowledge, and the social processes and contexts that shape how knowledge is communicated, represented, argued, and debated” (p. 277). Duschl (2008) emphasizes the role that conversations play in science learning and conceptualizes classrooms as epistemic communities: “the conversations should mediate the transitions from evidence to explanations, or vice versa, and thereby unfold discovery and inquiry” (p. 280). Informed by these propositions, we argue that the identification and resolution of uncertainty are realized through dialogic interaction among the teacher and students and that the resolution of uncertainty leads to the development of students’ conceptual knowledge. Conceptualizing science teaching as a balance between conceptual, epistemological, and social learning goals, we posit that social negotiation and epistemic engagement can serve as resources for resolving uncertainty. Given students’ limited scientific knowledge and capability to resolve uncertainty on their own, we emphasize the science teacher’s role in resolving uncertainty.

METHODS

Our study was conducted in a fifth grade science classroom with 22 students in an elementary school in a Midwestern state in the United States. The participating teacher, Mr. J (pseudonym), had 10 years of teaching experience and implemented an argument-based inquiry approach-the
Science Talking-Writing Heuristic (STWH) approach (Chen, Benus, & Yarker, 2016) -to teach three different science units: ecosystem (germination), astronomy (the day and night cycle), and human body systems (the digestive system and the respiratory system). In the STWH approach, the students were immersed in an argumentative context to learn what counts as good arguments and used this understanding to generalize research questions, gather data from investigations, use evidence to support claims, and develop knowledge through debates. The STWH approach consists of five phases: (1) exploring big idea--generating an inquiry question, (2) designing tests--observation to gather data, (3) engaging in social negotiation to debate claim/evidence, (4) reading to compare arguments with experts, and (5) reflecting through writing. We focused only on the third phase of the STWH approach because this phase yielded an abundance of classroom discourse data and uncertainty was very likely to emerge when students were negotiating their arguments with each other. Over the course of 16 weeks, we observed and videotaped whole-class discussions across the three different units. The videotapes of a total of 15 lessons, each including a 50-minute whole-class discussion, were transcribed.

Our data analysis went through three steps: 1) dividing each class session into events; 2) initial coding and constructing narrative descriptions of events; 3) pattern coding. In Step 1, we divided each class session into several ‘events’. We defined events as excerpts of conversation that began with uncertainty (i.e., expression of doubt) about an idea, a scientific concept, or an argument and ended with a consensus among members in the classroom community. During Step 2, we coded Mr. J’s inputs and subsequent responses from the students to interpret the process of uncertainty being reduced through Mr. J’s use of resources of epistemic engagement and social negotiation. The unit of analysis was an utterance. We used both a priori codes (i.e., propagated stuff, free creating, fabricated stuff, direct perception) and emergent codes (i.e., coherence between the big question and argument, difference between data and evidence, evidentiary justification, need for improvement, counterevidence, making a claim, using evidence, using data, challenging, defending, reflecting, changing ideas clarification, seeking agreement) to capture elements in the two resources for uncertainty management-epistemic engagement and social negotiation in the same unit of analysis. Then, based on the codes assigned to utterances in each event, we constructed a narrative description for each event. For Step 3, we compared events across our database, checking for consistency and inconsistency with respect to the process of reducing uncertainty and modifying our initial codes and descriptions as necessary. We clustered codes into potential themes concerning how epistemic engagement and social negotiation served as resources for uncertainty reduction.

**FINDINGS**

We found that 1) when epistemic engagement served as a resource for uncertainty management, the teacher resolved students’ uncertainty through his emphasis on coherence of argument and coherence of knowledge; 2) when social negotiation served as a resource for uncertainty management, the teacher resolved students’ uncertainty through critiquing their arguments.
Epistemic engagement as a resource for uncertainty management

We identified two themes regarding how epistemic engagement contributes to Mr. J’s uncertainty management: 1) coherence of argument; 2) coherence of knowledge. Coherence of argument refers to the coherence at two levels within the structure of an argument. First, students should support the claims they make with evidence. Second, evidence should include both data and reasoning that shows their interpretation of the data and why they use the data as part of their evidence. At the first level, Mr. J emphasized evidentiary justification in his instruction, and it had become a shared practice and norm of the classroom community to use evidentiary justification as an important criterion to judge the quality of each other’s arguments. Therefore, when Mr. J used coherence of argument to deal with uncertainty that emerged in whole-class conversations, it facilitated the classroom community to reach a consensus. For example, in Event 2 in Lesson 3 of the astronomy unit, students expressed doubt about the function of the axis for causing day and night in the presenting group’s argument. Noah, a member of the presenting group, was not convinced of the importance of explaining the role of the axis that they mentioned in their claim. It seemed to her that the earth’s being a sphere and its rotation, which causes the half of the earth to face the sun and to face away from the sun, could adequately explain the phenomenon of day and night (i.e., “That's part of our reasoning, because if it was a disc, it wouldn't work.”). In response, Mr. J asked a series of questions to direct students’ attention to the lack of justification for the group’s claim that the earth’s rotation on its axis results in the day and night cycle (see Table 1):

Table 1. Excerpt illustrating Mr. J reducing uncertainty in Event 2, Astronomy Lesson 3

| Mr. J: | You're saying that the day is caused by the earth rotating on its… now it's axis, not axle? |
| Noah:  | Yeah.                                     |
| Mr. J: | You're saying you know that. How do you know that's happening? What is this axis? Where does it go? If it's imaginary, how do you know that it's there? What does it do? How does that cause day and night? Is that what you meant by show, don't tell? You told us that day is caused by earth rotating on its axis, but you didn't show us how that actually happens. |
| Micah: | Well, you're saying that you got it from past experiences. I mean, for example, how do we actually know that you learned this from past experiences? |
| Cessly: | Well they're saying what they know about it, they're not saying what's true. They're saying what they know about it. I think you could maybe explain axle and… |

In this excerpt, following Mr. J’s critique, Micah and Cessly challenged the credibility of this claim. Later in the conversation, Mr. J’s continuous critique about coherence of argument encouraged more students to share their critiques about the group’s argument. For example, Lexi commented, “The point for claim and evidence is to explain what you know, not what the experts know.” This collective request for an explanation of axis by Mr. J and his students led the presenting group to agree on the importance of researching about the axis.

The second level of coherence of argument is that students need to use reasoning to turn data into evidence and to make connections between evidence and claims. Reasoning involves the
scientific principles that explain why certain data support a claim. Thus, clarifying these scientific principles could help students interpret the data they have and reduce uncertainty about why a particular claim is made based on the data. For example, during Event 3 in Lesson 2 of the ecosystem unit, students expressed disagreement over and uncertainty about whether germination requires sunlight or darkness. To resolve this uncertainty, Mr. J explained the meaning of “requirements” to the students, “Ok, it's (let’s) think we're having a language issue. We're talking about requirements in order to germinate, as in it has to have it or it will not germinate. So, what does a seed have to have in order for it to germinate?” While Mr. J was framing students’ problem as stemming from “a language issue”, he was also clarifying the underlying scientific principle that connected the data that seeds germinated in both sunlight and darkness in the experiment to the claim: that the seed needs something means that without it germination will not happen.

*Coherence of knowledge* refers to the process of constructing new knowledge from students’ prior knowledge and using existing concepts to learn new concepts. When connections are made between prior knowledge and new knowledge, student’ uncertainty could be efficiently reduced. Throughout the unit, Mr. J had been encouraging students to seek evidence from daily life, past experiences, and their experiments and to build knowledge about the needs of seeds from what they knew. For instance, when student argued about and showed uncertainty around whether water could provide energy for seeds, Mr. J made several connections to everyday knowledge about human bodies to help students reach the agreement that water does not provide energy for living things: 1) humans try to get energy when they need food; 2) body changes food into energy; 3) humans can burn a cracker or bread and convert it into energy.

**Social negotiation as a resource for uncertainty management**

The social negotiation process of argumentation involves both construction of knowledge and critique of knowledge claims. As an essential component of negotiation, critique allows all learners in a specific community to advance to a more scientific understanding of a concept through defending and debating ideas (Ardasheva et al, 2015). We argued that critiquing students’ arguments as a resource for Mr. J’s uncertainty management because when the teacher challenged an argument presented by the students, he not only highlighted the weaknesses of the argument but established the expected model of dialogical interaction in the classroom community and scaffolded the students to critique their peers’ arguments. When the students could critique with the teacher’s encouragement, the teacher’s critique turned into the collective critique by the classroom community. For example, in Event 2 in Lesson 2 of the respiratory system subunit, Mr. J initiated uncertainty by expressing doubt over the sufficiency of evidence in the presenting group’s argument. He took the lead in challenging the presenting group’s argument, asking “How do you know that there's actually muscles and bones that work with the respiratory system?” As the presenting group failed to justify their claim, Mr. J invited more students to elaborate and extend existing critiques. The lack of adequate evidence in the proposed argument eventually became an agreement among students.
DISCUSSION

Our study investigated how an elementary science teacher’s uncertainty management, through the resources of epistemic engagement and social negotiation, facilitated the construction of knowledge and improvement of argumentation. Although we presented our results regarding these two types of resources separately, they could work simultaneously when the teacher resolved uncertainty. For example, when Mr. J was critiquing students’ arguments (i.e., social negotiation served as a resource), he also focused on the lack of coherence of argument. Our findings confirmed Ford and Forman’s (2015) conclusion that students need support from the teacher to identify uncertainty and to “know how to use their intellectual authority for supporting progress in learning” (p. 152), but we also discovered that students require support to resolve uncertainty too. In addition, our data showed that students voiced more empirical uncertainty (i.e., evidence as a source for uncertainty; Driver, Newton, & Osborne, 2000) than personal uncertainty (i.e., limits of one’s knowledge) during whole-class discussions. Buck et al (2017) found that the threshold between personal uncertainty and empirical uncertainty was thin. We added to their findings that the teacher’s emphasis on empirical uncertainty can lead to students’ personal uncertainty and therefore drive them to find more evidence to support their claims and improve the quality of their arguments. Previous research on social interaction in science classrooms has rarely focused on teachers’ uncertainty management strategies. An important implication of our study for teaching practices is that science teachers could facilitate students’ learning by engaging them in the negotiation of the meaning of each other’s ideas and dealing with uncertainty through dialogic moves (e.g., asking questions to challenge students’ arguments, inviting more students to join the critique process).

SOME CONCEPTIONS ABOUT ARGUMENTATION OF IN-SERVICE SCIENCE TEACHERS IN CÓRDOBA (ARGENTINA)

Leticia García Romano¹,², María Eugenia Condat¹, Maricel Occelli¹,², Marina Masullo¹, and Nora Valeiras¹

¹Science and Technology Teaching Department, National University of Córdoba, Córdoba, Argentina
²National Scientific and Technical Research Council, Córdoba, Argentina

Argumentation bears significant importance in science teaching and learning. In this paper, the conceptions about argumentation held by in-service secondary science teachers are characterised through the analysis of the data obtained by means of a semi-structured questionnaire. The teachers who were questioned highlight the importance of using evidence in order to defend a point of view; they indicate that they frequently use teaching devices that only include information, and that they attribute an important role to the discussion of different stands. They stress the value of argumentation for learning to think and for the scientific literacy of students, and they state that the main obstacle in terms of embarking on the teaching of argumentation is the students’ difficulty in carrying out the tasks proposed and undertaking to them.

Keywords: Beliefs – Argumentation – Teaching Practices

INTRODUCTION

Argumentation is a central process within the framework of science teaching and learning. Within this framework, Buty & Plantin (2008) state that the role of teachers is based not only on the critical feedback with respect to the arguments developed by students, but also on the management of knowledge and activities under construction, guiding them towards stabilised assertions and procedures accepted in expert communities within a study area. Likewise, according to the ideas proposed by Jiménez-Aleixandre (2010), teachers should take into account the difficulties involved in the integration of different subjects in a socio-scientific debate, by designing activities that tend to assess the greatest number of advantages and disadvantages about a topic, without lapsing into simplistic oppositions.

In this way, within the particular context of teacher training, argumentation is linked to pedagogy focused on the construction of knowledge, and not to education based on passing it on (Sandoval & Millwood, 2008).

Several research works on this topic have highlighted the importance of incorporating ongoing teacher training programmes dealing with argumentation over a long time, have led to the development of analytic frameworks in order to assess the quality of the arguments produced, and have generated teacher training opportunities that have resulted in improvements in the teaching of argumentation (Erduran, Ardac & Yakmaci-Guzel, 2006; Simon, Erduran & Osborne, 2006). Likewise, in more recent years, we can find surveys focused on specific contents or didactic strategies and on the construction of arguments by teachers (Kaya, 2013; Ozdem, Ertepınar, Cakiroğlu & Erduran, 2013), and – particularly important for our research
– surveys pointing not only to argumentative skills but also to the teachers’ pedagogical content knowledge of scientific argumentation (McNeill & Knight, 2013; McNeill, González-Howard, Katsh-Singer & Loper, 2016; Vieira, da Rocha Bernardo, Evagorou & Florentino de Melo, 2015).

However, as pointed out by Plantin (2014), there is a considerable distance between the broad knowledge developed around this topic within the scope of research and the actual lack of theoretical and practical training of teachers with respect to argumentation. One of the aspects involved in these training problems lies in the fact of how teachers conceive argumentative practices.

Considering that research on argumentation within the field of teacher training has received less attention than in other contexts, especially if this is compared with research on the argumentative processes developed by primary and secondary education students (Archila, 2012; Zohar, 2008), and taking into account the fact that there is little research in relation to students’ and teachers’ conceptions of argumentation (Jiménez-Aleixandre & Erduran, 2015), elaborating on this field of study has been considered to be relevant. According to this, the conceptions about argumentations of a group of in-service secondary science teachers in the city of Córdoba (Argentina) have been characterised in this paper.

METHOD

The study on the conceptions of argumentation was conducted from an essentially phenomenographic perspective. This approach starts from the premise that people perceive, conceptualise and understand their experiences – and the dimensions of which they are made-in qualitatively different ways (Marton, 1981; Mateos & Solé, 2012).

For data collection, a semi-structured questionnaire including questions about cadastral aspects (gender, age, degree, length of service as teachers) and six items related to argumentation was designed. The following was enquired: a) what defending a point of view in natural sciences entails for teachers (closed-ended question in which more than one option could be chosen); b) the teaching devices used in the classroom by teachers and their relation with argumentation (closed-ended question); c) the importance that teachers attribute to the performance of different tasks linked to argumentation in their classes (closed-ended question); d) whether teachers consider that there are topics with which developing argumentation is more feasible (open-ended question); e) the strengths attributed to the teaching of argumentation in science classes (open-ended question); and f) the difficulties encountered around the possibility of arguing in science classes (open-ended question). The instrument was checked by experts, and a pilot test was conducted with five teachers that were not part of the final study sample.

The questionnaire was applied to science teachers from 16 state secondary schools in the city of Córdoba (Argentina). The sample was made up of a total number of 49 teachers, of an average age of 47.4 years (SD= 8.1) with a minimum age of 29 and a maximum age of 62 years old. The analysis of the conceptions was made by taking theoretical categories as reference, and by developing analysis categories according to the regularities observed.
The study analysed whether argumentation is presented as the assessment of statements in the light of evidence (Jiménez-Aleixandre, 2010); the presence of the rhetorical component of argumentation was studied (Plantin, 2004); the presence of ideas linked to the epistemic dimension of argumentation was characterised (Leitão, 2007); and, following the proposal recommended by Adúriz-Bravo (2014), the way in which teachers justify the inclusion of argumentation in science classes was investigated. This author argues that – within the framework of science teaching – there are at least three reasons for justifying the incorporation of argumentation in school science. In the first place, there is the idea that learning how to argue is a central process in order to learn to think and construct new knowledge. Secondly, the fact of appropriating a scientific practice like argumentation is deemed to contribute to the construction of an idea of science in line with the contribution of philosophy and history of science. Finally, the role of argumentation in scientific literacy is underlined, aiming at the possibility of students participating in socio-scientific debates.

RESULTS

Upon analysing what defending a point of view within the field of natural sciences means for teachers, 79.6% pointed out that it is related to “submitting evidence that proves it”. A smaller number of teachers indicated the idea of “justifying without trying to convince others” (18.4%) and of “justifying and trying to convince everybody else that the point of view chosen is the right one” (10.2%).

Tables 1 and 2 refer to the teaching practices developed by teachers. It is to be underlined that a significant percentage of teachers indicated that they frequently use books or films that only include information (75.5%); whereas the percentage of teachers who frequently select resources that include pieces of evidence and proofs that can be used to justify a point of view is lower (57.1%). On the other hand, teachers highlighted the importance of searching for and using different sources of information in order to justify answers (91.8% and 87.8%, respectively), and they stated that, during their classes, participating in debates in which different stands are discussed is important or very important (81.6%).

</tr>
</tbody>
</table>

As regards the topics with which developing argumentation in a class is more feasible, two groups of answers can be identified: whereas some teachers underline the possibility of doing so with all topics (34.7%), another group highlights its relevance within the scope of teaching socio-scientific contents, sometimes linked to health (44.9%). Table 3 shows some examples of the teachers’ answers.

Table 3. Examples of the topics with which developing argumentation in science classes is possible in the opinion of the teachers who were questioned.

<td>Teacher No. 39: “Argumentation can be mostly used for social topics or problems (…).”</td>
</tr>
</tbody>
</table>

When it comes to indicating the strengths related to the teaching of argumentation in science classes, taking up the categories proposed by Adúriz-Bravo (2014), teachers justify its inclusion by stressing its contribution to scientific literacy (55.1%) and the possibility of learning to think (51%). The least chosen idea is the one connected with the contribution of argumentation to the construction of an idea of science in line with the philosophy and history of science (4.1 %). Table 4 shows some examples of the expressions used by teachers and included in the three categories.

With respect to the difficulties involved in the integration of argumentation in science classes, as it can be seen in Table 5, the prevailing aspect mentioned by teachers is related to the problems that students have in carrying out the tasks proposed and undertaking to them (71.4%). A smaller number of teachers referred to the challenge involved for them in preparing activities that enable students to argue (6.1%), and to the time required for carrying on with this type of classes (4.1%).

DISCUSSION AND CONCLUSIONS

According to the results obtained, we can highlight at least two points of conflict between the conceptions of argumentation and the teaching practices implemented. In the first place, when it comes to defining argumentation, teachers underline the idea of submitting evidence, and push into the background its rhetorical component; but when they refer to their practices, they state that they attribute an important role to debate. It is considered that these answers can be the result of a tension between the deslegitimization suffered by rhetoric at different times in history and the value that is currently attributed to debate in democratic societies (Plantin, 2004). Secondly, as it has already been mentioned, teachers associate argumentation mainly
with the idea of submitting evidence that proves knowledge, but the most frequently used resources in classes are books and films, which only include information. These answers establish another zone of tension between conceptions and practices.

Concerning the relation between argumentation and different types of contents, two polar stands can be observed; whereas some of the teachers take a more inclusive stand, others associate argumentation only with socio-scientific topics. Even though the latter is powerful from the point of view of scientific literacy, these differences in the conceptions held by teachers highlight the complexity of the notions that are constructed around the idea of arguing in science classes.

As regards the categories proposed by Adúriz-Bravo (2014) and taking up the contributions of Jiménez-Aleixandre (2010) and Leitão (2007), teachers stress the epistemic dimension of argumentation and its potential for critical thinking. However, they omit aspects related to the scientific work and to the nature of science that are learnt by means of argumentation.

The discussion centring on the difficulties in arguing in science classes focuses almost exclusively on the apparent students’ deficiencies, considering them to be obstacles rather than possibilities for facing the teaching practice in a different manner. This majority stand can be related with a passing-on stand, which gives priority to the amount of knowledge over the possibility of constructing knowledge. The challenges that face teachers for including argumentation in science classes are barely mentioned.

Taking into account the complexity of the situation analysed, it can be stated that teacher training in argumentation should include the problematisation of teachers’ conceptions, establishing relations between such beliefs and the different theoretical currents about argumentation, and analysing the educational implications of such theoretical approaches. Finally, it is pointed out that training should include a wide range of activities that would enable teachers to argue and design activities for their students to argue, establishing a more explicit link between argumentation and the nature of science, and to incorporate the discussion concerning which argumentation levels we want to reach and how we can do it.

TEACHER BELIEFS ABOUT ARGUMENTATION IN JAPANESE IN-SERVICE TEACHERS

Tomokazu Yamamoto¹ and Shinichi Kamiyama²
¹Hyogo University of Teacher Education, Kato, Japan
²Kobe Municipal Seiwadai Elementary School, Kobe, Japan

In recent years, in order to provide appropriate argumentation instruction to the students, it is essential for teachers to recognize the importance of argumentation, as well as to improve their own argumentation skills. Beliefs regarding argumentation held by teachers would impact their argumentation instruction. It can be thought that teacher beliefs regarding argumentation depend on the educational environments and curricula in different countries. However, such beliefs among Japanese teachers in East Asia are yet to be elucidated. In this study, using belief categories developed by Katsh-Singer, McNeill, & Lope (2016), in relation to the seven beliefs, 36 in-service teachers selected the most suitable reply from among "strongly agree," "agree," "disagree," and "strongly disagree." The results of the analysis of the questionnaire survey show significantly positive results for “The role of argumentation in the classroom,” “Classroom discussion practices,” “Using argumentation to accomplish other educational goals,” “Student ability,” and “Standards” on the teacher’s beliefs (p<.01). On the other hand, there is no significant difference (ns.) in relation to “Teacher self-efficacy” and “Environment.” One-third of the teachers provided negative answers. This study revealed that beliefs retained by in-service teachers in Japan are largely positive in relation to the value and need for argumentation instruction. Clearly, in-service teachers recognize the impact caused by the abilities and educational environments of learners. However, they are not sufficiently confident of their own abilities to provide effective instruction.

Keywords: teacher beliefs, argumentation, in-service teachers

INTRODUCTION

In recent years, it has become more important for teacher education programs that instruct argumentation to enable teachers to improve their ability to construct and evaluate arguments by themselves (e.g., McNeill & Knight, 2013; Kaya, 2013; Iordanou & Constantinou, 2014). As things stand, the lack of ability among pre-service teachers to present arguments effectively has been reported in Japan (Yamamoto et al., 2014). We have reported the development of programs for argumentation skill improvement and its effects (Yamamoto et al., 2016). It is important for teachers to improve their own argumentation skills (Zohar, 2008). Similarly, in order for teachers to provide appropriate instruction to their students, it is essential for teachers to recognize the importance of argumentation. This is because any new curriculum, instructional strategy, or technology-enhanced learning environment that is actually used depends largely on teachers’ beliefs about argumentation (Sampson & Blanchard, 2012).

For example, in relation to in-service teacher education, McNeill, Katsh-Singer, González-Howard, & Loper (2016) have pointed out that teachers’ beliefs about argumentation can impact whether and how this science practice is integrated into their classroom. They have also indicated that a high degree of importance has been placed on the need for instruction by science teachers of junior high schools based on the following order of priority: learning goals,
student background and ability, teacher self-efficacy, context, and policy and assessment. Moreover, Katsh-Singer, McNeill, & Loper (2016) investigated the beliefs of middle school geology teachers regarding argumentation based on belief categories, and they compared such beliefs using the category of socioeconomic status (SES) as a basis. As a result, it has been demonstrated that teachers believed scientific argumentation was valuable for their students, and teachers could hold varied beliefs about student capability in engaging in argumentation and the teacher’s role in supporting students in argumentation. It has been pointed out that teachers from low SES schools believed pressure from standards and state tests can impact their argumentation instructions.

It can be thought that teacher beliefs regarding argumentation depend on the educational environments and curricula in different countries. However, such beliefs among Japanese teachers in East Asia are yet to be elucidated. The purpose of this study is to clarify actual conditions concerning the beliefs about argumentation held by in-service teachers in Japan. We have thus established the following research question: “What beliefs do in-service teachers have regarding argumentation?”

**METHOD**

Most of Japanese in-service teachers don’t recognize the mean of argumentation. Argumentation is a new word for them. Recently Japanese ministry of education, culture, sports used this word at first time when they translate the summary of PISA2015. Therefore, we introduce argumentation in in-service teacher training course program (Figure 1). After the program, we performed a questionnaire survey.

**Target**

The selected targets were 36 in-service teachers in Japan (i.e., 22 from elementary schools, 3 from junior high schools, and 11 from high schools).

**Questionnaire survey**

We performed a questionnaire survey using the belief categories set forth in Katsh-Singer, McNeill, & Loper (2016). In relation to the following seven beliefs (Table 1), teachers selected the most suitable reply from among "strongly agree," "agree," “disagree,” and "strongly disagree." For this analysis, the answers “strongly agree,” and “agree” were consolidated as positive answers, while “strongly disagree” and “disagree” were consolidated as negative answers. The bias in the answer trends was ascertained using a direct probability calculation (a two-sided test). Finally, inputs on the program’s strong points and areas for improvement were freely entered.
Activity 1: Definition and significance of argumentation (20 minutes)
Through case examples from daily life and science classes, it was emphasized to the participants that the processes used in argumentation are necessary for people to obtain consensus. Moreover, participants came to understand that argumentation could be used for learning other subjects.

Activity 2: Actual conditions of argumentation among children (20 minutes)
Going by the survey results, participants came to understand that elementary school students in Japan performed poorly in argumentation.

Activity 3: Instruction and evaluation regarding argumentation (40 minutes)
The assignment read, "When the weight is changed during movement of a pendulum, will the periodicity increase?" The periodicity was actually measured, and the resulting data was used as evidence. Arguments were thereupon initiated based on the data. Moreover, in-service teachers assessed their own arguments in light of the relevant evaluation criteria.

Activity 4: The reality of argument-related study in Japan (10 minutes)
An overview regarding the actual implementation of argumentation instruction in elementary school classes was presented.

Figure 1. The activity of our program.
Table 1. Question items using the belief categories set forth in Katsh-Singer, McNeill, & Loper (2016).

Belief 1, The role of argumentation in the classroom: Argumentation plays a role in the broad learning of science and understanding the importance of related core elements (i.e., assertion, evidence, and rationalization).

Belief 2, Classroom discussion practices: Argumentation are useful in that they promote communication among and between learners as well as teachers in a classroom, and they also serve to deepen discussions.

Belief 3, Teacher self-efficacy: I am confident that I can instruct argumentation.

Belief 4, Using argumentation to accomplish other educational goals: It would be better if argumentation instruction could be provided for other educational purposes (e.g., for the development of literacy, critical thinking, knowledge, and understanding, as well as for the practice of the scientific method).

Belief 5, Student ability: Approaches regarding argumentation tend to be impacted by the abilities and backgrounds of learners (which includes family background).

Belief 6, Standards: Argumentation can correspond to the course guidelines and new types of tests.

Belief 7, Environment: Educational environment, with regard to factors such as organizational support offered to instructors, school size, and regional characteristics, tends to impact the abilities of the teachers who instruct argumentation.

RESULTS

Figure 2 shows distribution of the number of people classified by the replies they gave regarding their beliefs.

![Figure 2. Distribution of the number of people classified by the replies they gave regarding their beliefs.](image-url)
The results of the analysis of the questionnaire survey show significantly positive results for “The role of argumentation in the classroom,” “Classroom discussion practices,” “Using argumentation to accomplish other educational goals,” “Student ability,” and “Standards” on the teacher’s beliefs ($p<.01$). On the other hand, there is no significant difference (ns.) in relation to “Teacher self-efficacy” and “Environment.” One-third of the teachers provided negative answers.

Table 2 shows “representative quotes” from the free input responses. With respect to the “belief category” descriptions, we found six instances of Belief 1, one instance of Belief 2, three instances of Belief 3, twelve instances of Belief 4, six instances of Belief 5, seven instances of Belief 6, and one instance of Belief 7.

**DISCUSSION AND CONCLUSIONS**

According to the results for Belief 1, in-service teachers strongly recognize the role of argumentation in science. This is because in-service teachers understand that persuading other people and consensus-formation processes are important, and argumentation is essential (this issue is related to promotion of communication for learning, as treated in connection with Belief 2). The free input responses indicated that in-service teachers felt that argumentation would promote logical thinking as well as the language activities prioritized by the Course of Study. Language activities are stressed in all Japanese education curricula. Particularly in the sciences, it is said that “Some considerations should be given to enrich activities that pupils can organize and in which they can examine the results of observations and experiments, and can think and explain natural events and phenomena by using scientific terms and concepts” (Ministry of Education, Culture, Sports, Science and Technology, 2008). In such situations, argumentation can play an important role in using language to express thoughts and share scientific concepts. Moreover, evaluations regarding Belief 4 were largely positive. It can be assumed that in-service teachers expect that argumentation can be used for the discussion of other subjects and in other classes, in addition to the science field.

Next, many in-service teachers have recognized how the abilities and backgrounds of learners impact argumentation instruction as mentioned in connection with Belief 5. Katsh-Singer, McNeill, & Loper (2016) have pointed out that teachers often think that all students are capable of constructing arguments, although in actuality many teachers feel that some students have poor abilities in this area. This can also apply to in-service teachers in Japan. The free input responses indicate that in-service teachers hope to develop explanation skills in all their students and improve on the teaching methods they have been using. It is necessary for in-service teachers to be aware of the importance of step-by-step instruction based on the abilities and backgrounds of learners. Regarding Belief 6, new classes based on education for practical use of knowledge have become matters of focus in Japan, and the way in which assessments are carried out concerning such classes has been reviewed. In particular, many teachers pointed out that clarification of criteria for the evaluation of writing would make teaching easier. It can be speculated that there are many teachers who think that argumentation can be used in response to the aforementioned emergence of new tests.
Table 2. Representative quotes from the free input responses.

<thead>
<tr>
<th>Belief Categories</th>
<th>Representative Quotes (Answer, Teacher number)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Belief 1, The role of argumentation in the classroom</td>
<td>I learned a great deal about considering things from a logical point of view. In order to communicate effectively with somebody, it is important to adhere to logic. I believe that the cumulative effect of this training will also lead to the enrichment of language activities. (strongly agree, No.24)</td>
</tr>
<tr>
<td>Belief 2, Classroom discussion practices</td>
<td>I feel that effective argumentation can be a great tool for the enrichment of language activities. (agree, No.12)</td>
</tr>
<tr>
<td>Belief 3, Teacher self-efficacy</td>
<td>Regarding the enrichment of language activities, I have approached my practice with a degree of consciousness based on my own ideas. However, learning the theory of argumentation has helped me to see my own limitations and shortcomings with regard to my practice. (agree, No.16)\nIt would be great if we could receive instruction on how to teach argumentation skills to children. (disagree, No.18)</td>
</tr>
<tr>
<td>Belief 4, Using argumentation to accomplish other educational goals</td>
<td>Although the program’s content focused on science education, I felt that it could certainly be used for teaching reading and writing in Japanese language classes. (strongly agree, No.03)\nI feel that argumentation is a versatile skill that can be applied in many areas. (strongly agree, No.19)</td>
</tr>
<tr>
<td>Belief 5, Student ability</td>
<td>I believe that if children could learn the process of argumentation, almost all of them could acquire the ability to formulate logical explanations. (agree, No.11)\nUntil now, I had only been able to teach investigative methods by having children use keywords in their writing, but I think that applying argumentation will equip children with enhanced skills for scientific explanation. (agree, No.14)</td>
</tr>
<tr>
<td>Belief 6, Standards</td>
<td>A number of answers in National Assessment of Academic Ability are difficult to evaluate objectively, but the adoption of argumentation methods would create much clearer criteria for assessment. In other words, incorporating this method into teaching would provide children with a clear method for expressing scientific reasoning, and I think this would allow them to develop the academic abilities required of them today. (strongly agree, No.02)</td>
</tr>
<tr>
<td>Belief 7, Environment</td>
<td>In my current school, I focus on promoting teacher learning in science, and there are many aspects of the argumentation method that I can incorporate into this. Therefore, I have summarized the content of this lecture and sent it to my school. As the new head of teacher training starting in this academic year, I will certainly advise that we adopt argumentation in our teacher training program. (agree, No.04)</td>
</tr>
</tbody>
</table>

Concerning Belief 7, the answers provided were relatively negative. There were comparatively more answers that suggested that environmental factors do not have any significant impact. It is possible that the following concept has not been well recognized: argumentation instruction should be implemented in a school-wide, curriculum-based manner rather than in the particular
instructional practices employed by individual teachers. The free input included responses stating an intent to actively adopt the argumentation method in teacher training. In order to adopt argumentation instruction, it is important to complete training within the school organization and attain school consensus. Moreover, concerning Belief 3, it should be noted that teachers have the lowest confidence regarding instruction (i.e., no respondent chose "strongly agree"). It can be assumed that there is a general lack of experience with argumentation instruction. As argumentation is a teaching method that had not been used in teachers’ practice before, and they still lack the practical skills for applying this teaching method, it appears that they lack confidence for using it in teaching. It is essential to improve teacher education programs for the sake of teacher ability regarding argumentation instruction methods.

This study revealed that beliefs retained by in-service teachers in Japan are largely positive in relation to the value of and need for argumentation instruction. Clearly, in-service teachers recognize the impact caused by the abilities and educational environments of learners. However, they are not sufficiently confident of their own abilities to provide effective instruction. We were able to infer the causes for this and provide knowledge based on the causes to assist with in-service teacher education. Problems remain in that details concerning beliefs need clarification through interviews in the future.

TRACING STUDENTS’ QUALITY OF ARGUMENTATION IN SIMULATED PARLIAMENT ACTIVITIES

Zacharoula Smyrnaiou¹, Evangelia Petropoulou¹, Eleni Georgakopoulou¹ and Menelaos Sotiriou²

¹Department of Pedagogy, National Kapodistrian University of Athens, Athens, Greece
²Science View, Athens, Greece

The present research study reports the use of Toulmin’s Argument Pattern (TAP) approach as a tool for tracing the quality of argumentation in science teaching and exploring its effective application in enhancing students’ cognitive knowledge. The study is part of the European Student Parliaments project which aims at strengthening the dialogue between students and scientists throughout Europe. The context of simulated parliament procedures provides the ground for the teaching and learning of argumentation in an authentic context. In addition, it provides a structured frame for the informed and guided implementation of argumentation methodologies in science teaching. To address the research objectives analytical tools for evaluating the quality of argumentation and students’ cognitive enhancement were developed based on TAP. The research findings show that there was significant improvement in the quality of students’ argumentation and cognitive development regarding their critical approach to scientific concepts.

Keywords: Argumentation, TAP, Motivation

INTRODUCTION

Over the last decades at the heart of contemporary reform actions in science education there is a tendency to focus on the effective teaching of science and promotion of scientific literacy (SL) in a way that authentically engages students rather than focus on the content of science teaching (Eurydice Network, 2011; Karisan & Zeidler, 2017). In this context of valuing and promoting scientific literacy, the argumentation approach has come in the foreground as a core feature accommodating the epistemology of science (Smyrnaiou, et al., 2015) and enhancing the acquisition of scientific knowledge (Erduran, et al., 2004; Sandoval, 2003). In Science Teaching the argumentation approach is valued as a mainstream process in enhancing students’ conceptual understanding (Mc Neil & Pimentel, 2010), highlighting the way scientific theories and concepts are created and tracking the way we come to acquire this knowledge (Jimenez-Aleixandre, et al., 2000).

Although shaping an argument may lie on personal beliefs and attitudes it should follow and align to structured regulations and norms in terms of scientific accuracy (grounded on the scientific inquiry process), rational development within a scientific interaction and dynamism in its degree of irrefutability. In this context instructors should ground and inform their teaching on argument models since they project the analytical purpose of an argument and examine the validity, credibility and quality of the argument as a whole and of each of its components (Nussbaum, 2011). Therefore, the argumentation discourse needs to be applied not in an arbitrary way in the learning process but explicitly taught through task structuring and modeling (Scholinaki, et al., 2012; Erduran, et. al., 2004). In addition, to assure individual engagement in an argumentative process the application of authentic context is required since
it manages to raise questions of ongoing inquiry and high complexity that enhance cognitive reasoning and reflective judgement (Jiménez-Aleixandre, Erduran, 2007). In this paper our main objective is to assess students’ argumentation discourse and cognitive development on applying Toulmin’s model of argument (Toulmin, 2003) in structuring reasoning principles that lead to a clear outcome and the effectiveness of the argumentation approach in enhancing students’ knowledge construction. Towards this aim we have investigated the case study of the European Student Parliaments (EUSP) project in Greece. The Greek Student Parliament is part of the project ‘Debate Science! European Student Parliaments’, initiated by Wissenschaft im Dialog in Berlin. This project aims at strengthening the dialogue between students and the scientific community in Europe. In the simulated parliaments students are highly engaged in parliamentary decision-making and argumentation processes as well as scientific research.

THEORETICAL FRAMEWORK

Argumentation is a set of varied processes that, in its educational use, focuses on identifying transmitter-receiver and aims at the development of students' critical thinking and the ability to construct and evaluate arguments. In education practices argumentation could be the pillar of the construction of knowledge (Mc Neil & Pimentel 2010∙ NRC, 2012). Through argumentation students can understand the tentative nature of science (Smyrnaïou, 2015) and take decisions to constantly change environments (Sadler & Zeidler, 2004). Furthermore, by cultivating argumentation competence they can improve their reasoning skills. This procedure consists of sub-phases in which students participate both cognitively and emotionally. The first phase is “Planning the argumentation” in which students formulate valid arguments and correlate data with claims (see table 1). In the second phase, “Presenting the argumentations” students have to verify their knowledge, to give evidence, to control the credibility of their arguments and finally to interpret their observations. During the third level, called “Processing the opponent’s argumentation” students have to discuss with each other and exchange arguments. At the phase of “Acquiring new Knowledge” students can reinforce their knowledge (Smyrnaïou, Petropoulou, Sotiriou, 2015) and produce new frameworks. Their argumentations are evaluated through specific criteria. According to Nussbaum (2008, 2011) argumentation is defined as a thought process through which the participants create and evaluate arguments, while O’Keefe (1982) claims that an argument consists of two parts; the argument as a product which includes literal and figurative language and the argument as a process which refers to the social processes developed when interlocutors engage in a dialogue. The dialectical argumentation is present in a school classroom since students are asked to create and evaluate arguments.

The Toulmin model of argument (1958) tries to examine the structure of the argument and primarily the structure of everyday communication, namely it attempts to interpret how and why the speaker or writer adopts a claim. According to Toulmin’s model (data- warrant-rebuttal) students should present robust argumentations, both structurally complete and qualitatively solid. Furthermore, they can validate their new ideas. That means that students are able to design problems. They also bring into the foreground their own conceptualizations. Justification of students’ ideas help them to enhance their problem solving skills. This improvement is reinforced by communication. In addition, the aspect of reflection and self-
regulation is important, as students present their own ideas. Conceptual understanding and meaning generation is successful in socioscientific issues (Smyrnaou, 2015), which are linked with society (citizenship) and are related to real situations, as students become motivated to participate in a dialogue bringing together controversial areas. Students can understand the role of science in everyday life, as it becomes obvious that these domains affect their life. In addition, discursive exploration affects students’ motivation and engagement (Smyrnaou, Petropoulou, Sotiriou, 2015). An argument can be analyzed in six levels: claim, data, warrant, backing (assurances without which the warrant would have neither strength not accuracy) (Toulmin, 2003: 96), modal qualifiers, rebuttal (the conditions that may cause an argument to fail) with the first three being the most significant ones. All levels of an argument constitute compensated quarters as each one is based on the other. Each level needs to be independent and powerful for a hierarchy and an escalation to be followed. Therefore, the argument is defined as a conclusion / claim based on some supporting data (Büllow-Möller, 1989). In this sense, the argument with the reasoning is the same. As a result, it would be reasonable to assume that these argument models should also govern and guide relevant scientific educational courses. However, little research has been carried out on the structure of the arguments in collaborative learning in STEM courses or projects.

The main limitation of the Toulmin argument model according to the international literature (Forman, Larreamendy-Joerms, Stein, & Brown, 1998; Hitchcockand & Verheij, 2006; Krummheuer, 1995; Moore-Russo, Conner, & Rugg, Backa, & Zachariades, 2012; Steele, 2005; Yackel & Rasmussen, 2002; Yackel, 2001) is that this does not reveal much about the quality of each argument, as the warrant every time and its assertions) are crucial elements for its assessment. According to Godden & Walton (2007) arguments are stereotypical formulations that can be overturned and may include different types of probabilistic arguments used in everyday life. However, when these probabilistic arguments are used successfully, they can rebut the argument and evaluate it. The above model was characterized by some simplistic (Weinstein, 1990), but proved to be a particularly useful methodological tool, as it was used in all cognitive subjects (Alcock & Weber, 2005; Inglis, 2007; Inglis et al., 2008; Krummheuer, 1995; Moore -Russo, Conner, & Rugg, 2011; Steele, 2005; Stephan & Rasmussen, 2002). At the same time, this model was modified by many (Langsdorf, 2011; Prusak, Hershkowitz, and Schwarz (2012), but still retaining its basic structure.

Based on the theoretical framework of Toulmin, Erduran et al. (2004) have developed a detailed framework for evaluation-classification of arguments. Based on this context, the arguments can be classified into 5 levels. At the first level are the arguments made up of a simple claim. In the second level, arguments are framed by a claim backed by data, assumptions or reasons (which do not separate but group as justifications), but without counter-claims. At the third level, the arguments are framed by a claim backed by data, assumptions or reasons and a counter-claim. At the fourth level, the arguments are based on a claim supported by data, assumptions or reasons, from a counter-claim and explanations for cases where the argument is not rebuttals. Finally, on the fifth level, the arguments with claims, data and more than one explanation for cases where the argument is not correct (rebuttals) are classified. However, Louca & Hammer (in press) argue that the framework of Erduran et al. (2004) is not particularly clear as to how the "weak or occasional" explanations in the cases where the argument is not
rebuttals are defined in Level 3. In addition, they argue that the difference between Levels 4 and 5 is not obvious, since it is essentially a difference in the number of explanations for cases where the argument is not correct. In case of class discussions, additional rebuttals are more likely to be given by other students than by the same student. For these reasons, Louca & Hammer (in press) adopts the 4 levels of the frame of Erduran et al. (2004) with some modifications. Level 1 includes cases where arguments are made up of simple claims. Level 2 includes arguments that consist of a claim backed by data, assumptions or reasons, but without explanations for cases where the argument is not correct (rebuttals). Level 3 includes counter-claims consisting of a simple claim and Level 4 includes counterclaims that are supported by data, assumptions or reasons, and attempts to explain cases where the argument is not is rebuttals.

In Science Education, argumentation and the development of critical thinking and persuasion skills of the student are part of the dialectical argumentation. The challenge of modern pedagogical and didactic theories of learning in Natural Sciences lies in the student's ability to link school knowledge to his / her everyday life, discussing contemporary issues, empowering his / her cognitive field, and empowering himself / herself in problem-solving situations. According to Erduran et al. (2004) the development of argumentation is an important tool in the construction of scientific thought and is an integral part of the scientific discussion. A fundamental feature of theories is scientific documentation through the construction of explanations and the construction of scientific thought with the aim of producing a scientific meaning. The argument specifies the student's thinking and contributes to the construction of knowledge (Erduran et al., 2004, Eurydice Network, 2011). Scientific literacy is not arbitrary but consists of specific elements and criteria (Smyrnaou et al., 2017) which refer to the stages of scientific methodology in order to achieve learning. According to Jimenez & Erduran (2007), these skills are the basis for enculturation, in the sense that through argumentation students learn the elements of the cultural present and the principles, skills and behaviors required are necessary in the cultural environment in which they are developed. These skills can be enhanced by the development of scientific thinking through argumentative teaching. According to Scholinaki et al. (2012) in this way the teacher overcomes the so-called error stigma, the deformed knowledge, which follows the question of teacher-student answer - the evaluation of the answer by the teacher - the assumption of a single "correct" answer. Thus, participatory and cooperative learning is established, where the teacher does not aim for unilateral answers but examines how the cognitive claims are made in science, thereby fueling exploratory learning.

CONTEXT OF THE RESEARCH STUDY - THE PROJECT ‘EUROPEAN STUDENT PARLIAMENTS’

Since 2001 Wissenschaft im Dialog (“Science in Dialogue”, https://www.wissenschaft-im-dialog.de/) has organized scientific student parliaments as part of the Summer of Science (German Science Festival). Furthermore as part of the research project “Debate science” (2009 to 2011) the student parliament was thoroughly evaluated as an instrument of science communication. Based on these initiatives Wissenschaft im Dialog initiated in 2013-2014 the project “European Student Parliaments” (EUSP) (http://www.student-parliaments.eu/) that was
funded by the Robert Bosch Foundation. EUPS aim at strengthening the dialogue between students and science throughout Europe, by engaging students in problem-solving situations involving scientific issues that address current problems. In the simulated parliaments, the participating students become acquainted with parliamentary decision-making processes as well as scientific research grounded on the model of Inquiry-based learning and develop life-long and communicative skills by engaging in dialogue and debate processes aiming at the exchange and sharing of scientific points of view. During the research phase and preparation for the locally held debate event, students are supported both by their teachers as well as a scientific expert. In the 2016 European Student Parliament, students’ main topic of negotiation was “The future of Human Being”. In the context of the EUSP, approximately 2000 students from across Europe participated in 17 national parliaments. In each of 17 local or national student parliaments, taking place from September 2015 to April 2016, students discussed five to seven subtopics in five working groups: 1. The Human Brain, 2. Living and eating healthy - but how?, 3. Stem cells - the potential all-rounders? 4. Augmented human: optimizing the human, 5. Imitating nature.

In 2016, Greece took part for the second time in the EUSP project, organizing the Greek Students’ Parliaments (http://studentparliament.weebly.com/). The project was locally organized by the Pedagogical Department of the National Kapodistrian University of Athens (http://www.ppp.uoa.gr/) and the Science View Organization (http://www.scienceview.gr/) that promotes science communication activities between the scientific community and the wider public. The project was also supported by the Greek Ministry of Education and was addressed at students between 15 and 19 years old with interest in the functioning of democratic systems, science and learning about new topics. It is worth mentioning that for first time Greece attempted a finally successful idea. Through an online platform, students from different parts of the country had the opportunity to participate and listen to their views. It is especially important that students outside of Athens and Thessaloniki have supported their views, argued for them and were elected as representatives for the European Student Parliament. Typical examples are students from schools in Thasos and Alexandroupolis.

A significant number of schools had volunteered to participate from all over the country and finally 433 students from 31 schools participated in the final debate during this three-day event. On first day, students were divided into committees, and each committee started to discuss each theme. At the first meeting of each committee, the scientist first presented to all members the general framework of the subject and the scientific community’s prevailing views. Then the students discussed and presented the conclusions of their preparation. The proceedings of the committees on the first day of the meetings were completed by recording the conclusions of the day, which were given to the scientist and the plenary Parliament. Second day involved mainly working group sessions. The second day of Parliament was devoted entirely to meetings of committees. Every meeting began with scientists’ presentation of the conclusions of the first day and thereafter students interacted and exchanges views with the aim to arrive together in a final deliverable. All students presented their views as they have been formed after what they have heard from other schools the day before, but also what the scientist pointed out to them. They chose which points were consider more important to be added to the final deliverable or conflicting opinions. After the debate, students made up the final resolution. The students also
prepared the parliamentary debates on third day. Day 3 contained all parliamentary debates including a voting after the resolutions have been presented. The third day of the Hellenic Students’ Parliament of Science began again with the committees. In each committee the scientist finalized the text with Commission's final positions. Each school that participated in the subject selected a student who would present this text in the plenary of Parliament and would stand for representation of our country in the European Student Parliament of Science. Parliament's third and final day ended with the choice of the five students (one by theme) to represent our country in the European Student Parliament in July.

METHOD

During the students’ preparation phase, all participants were supported by experts in the specific fields that could share and exchange their ideas and communicate with the students and teachers. After an elaborate and remarkable preparation in their classes at school, the students were able to discuss the different sub-topics on a very high level and to express their ideas in the committee sessions with the scientists. In the plenary debate, the participants exchanged their knowledge with the other students and came up with some good final resolutions that will be presented in the following section. Finally, students were requested to answer a questionnaire expressing their views on the whole process for the debate event, as we wanted to address students’ beliefs about the argumentation approach as an effective educational practice in acquiring scientific knowledge.

For the actual realization of the debate event, students were provided with specific guidelines for its procedure, following four successive steps: (1) Reading out the claims, (2) Defence speech, (3) Attack speech(es) and (4) Response to attack speech(es). Schools that had negotiated the same topic would have to discuss and decide on the final claims/resolutions that would comprise their final argumentation basis. First, at the beginning of each debate, the proposing committee had the opportunity to read out the committee’s claims which were gathered in a structured resolution booklet template. Subsequently, the proposing committee had the opportunity to hold a defence speech and to explain the existing resolution and its contents. All committees had the opportunity to hold one or more attack speeches to elaborate and explain why some of the claims should not be accepted by the delegates. Finally, the proposing committee had the opportunity to give answers to the attack speech and to allay doubts the delegates might have. The final open debate was structured in three procedural steps: (1) Open debate, (2) Summarizing speech, response to last questions and (3) Voting. During the first procedural step, all members of all opposing committees (addressing all 5 subtopics) could raise their hands to address questions or remarks to the proposing committee which was required to give a summarizing answer to all of them. In the second procedural step, the proposing committee would hold a summarizing speech and answer the last questions and the third step involved having the chair of the debate read out the claims and ask all delegates to vote for or against a claim.

The methodological approach we have applied in our study was designed to provide us with both qualitative and quantitative measures of argumentation. That was accomplished by (1) tracing the distribution of TAPs in class discussions as an indication of the learning performance and (2) focusing on the nature of rebuttals in large-groups; assessing students’
argumentation discourse and cognitive development. The teachers who were involved in the project supported their students in the inquiry phase and preparation for the national held debate event, guiding students on the key principles of the argumentation process following Toulmin’s model of argument: claim, data, warrant, backing, rebuttal (Toulmin, 2003: 96). The teachers recorded the evolution of student argumentation in standardized reports throughout three time periods. During the Student Parliament process, there were five researchers responsible for tracking and evaluating students’ working process and argumentation methodology and they also analyzed the data from the teachers’ progress reports.

RESULTS

The main objective of this research study is to explore the use of TAP as a tool for tracing the quality of argumentation in science teaching and explore its effective application in enhancing students’ cognitive knowledge. In our research, TAP has been applied as a qualitative indicator of students’ argumentation discourse and cognitive development both in class interactions among teachers and students and in large – group discussions occurring in simulated parliament debates among student groups from different school units. TAP projects the main features of an argument in terms of claims, data, warrants, backings, and rebuttals. To measure and explore the frequency in the use of an argument’s features we indicated four levels of argumentation: (1) a claim versus a counter-claim/claim, (2) a claim versus a claim with either data, warrants, or backings, (3) a series of claims or counter-claims with either data, warrants, or backings and (4) a claim with a rebuttal/rebuttals.

From all the 76 reports filled by teachers, we can realize that students found difficult to hold arguments, as they had not realized the steps and phases of an argument. Therefore, according to the reports given to teachers at the begging of the procedure, the majority of them (40%) include only claims without data or one claim with little data supporting students’ claims. For example, students support that “it is better not to consume animal products” without giving supporting data or other students supported that “Synthetic biology does not pose risks to humans and the environment because it is first tested in the laboratory” by giving only one data to explain what they mean. A series of claims with a series of data, warrants or backings does not appear at the first phase of the procedure. At the middle level of the procedure, almost 1 month after the beginning, a second report was filled by the teachers. On these reports teachers kept writing students’ arguments while they supported their thesis. We observed that there was an increase on data, warrants and backings which students used to support their arguments. For example, students supported that “The care of Alzheimer patients should be the responsibility of the state, because the cost of taking care of a person (medication, treatments, etc.) is too great and the psychological effect of the situation on their family members is very important.” As we observed on the almost 60% of the reports students started to realize that holding an argument means that someone has a thesis and he/ she gives data to support his/ her thesis. On this level, claims with rebuttals started to appear. On third level, almost at the end of the programme and before the final three- day event, the results of the reports showed that students started no only to support their arguments with data and backings but they also hold arguments by making rebuttals. For example on the Human Brain Sections, students supported that “for Alzheimer patients’ care high-risk groups must be required to enter diagnostic procedures,
because diagnosis is now low cost and these high-risk groups include people who have not been adequately informed. On the other hand “Early diagnosis can ensure a smoother response, possibly and prevent a deterioration of a condition and the mandatory character of high risk groups creates anxiety, which can affect the results of diagnosis.” As it is observed, students started to make rebuttals to their thesis so as to discuss all the parameters of their decisions.

As a result, our research findings have indicated an improvement in students’ development of argumentation discourse since there was registered a gradual rise in frequency of all argument principles (claim, data, warrant, backings) and extensive use of the fourth level of argumentation (Table 1). In addition, during the simulated parliament event, there was also a progress in the quality of rebuttals applied in students’ argumentation discourse.

**Analysis of Students’ arguments in the Student Parliament: Stem Cells Chapter**

Throughout the year and until the Greek Student Parliament students were working on the themes they had chosen with the aim of being involved in the explanatory/scientific procedure, understanding the scientific concept and forming their own views through developing arguments regarding the issue. Students enhance their scientific skills, oral skills and skills related to building arguments, all of which are of great importance in creating an argument to support their views both in the Greek and in the European Student Parliament, in case they are chosen to represent Greece. The schoolteachers were recording the exploratory/scientific procedure, the evolution of student argumentation and communication skills at three different times: at the beginning, middle and end of the act. A recording is necessary to scientifically approach the process.

Student views on the issue of creating public and private stem cell banks constitute a characteristic example of argumentation during the Keynote Speeches. Students formed two groups in an attempt to compare the benefits these two categories of banks may offer and presented their arguments in a debate. One team was in favor of public banks in Greece. Their
argument was the following: “There should be no private stem cell banks in Greece because there is not one objective interpretation of the law but rather subjective ones”. This student argument is an example of a productive argumentation. Initially, it is formed in its complete structure. It consists of a claim “There should be no private stem cell banks in Greece” and data “there is not one objective interpretation of the law but rather subjective ones”. The claim was supported by a statement, which is again supported by a warrant. The fact that students chose this particular statement (data) over others, means that they were based on the implicit and underlying view and stereotype that “Never in Greece has anyone taken into consideration the regulatory framework of the law and the law does not apply”. This view along with the line of argument the students followed constituted a conscious process of transferring their knowledge as they were planning their participation, which was supported more during their speech at the Student Parliament. At the same time, because the social framework shapes the warrant, and the warrant loses its meaning if placed outside it, students seem to have incorporated to their answers the generally accepted notion regarding the state’s disregard for the citizens in Greece. This connection to the established view enabled students to form a social commentary. In their oral presentation, their argument was accompanied by the extension: “Legislation regarding the operation of public and private banks abroad follows a regulatory framework. On the other hand, there is no legislative or regulatory framework followed, therefore private banks cannot operate. At the same time, moral issues will emerge, since the banks will not be monitored and controlled.” In addition, a second extension was made using a poll. Students conducted their own survey with the question of whether the participant is in favor or against private stem cells banks in Greece. Their sample included individuals of all ages and of various professions (teachers, doctors, private and public sector employees etc.) in order to be objective and representative, as students mentioned. Students presented their findings in their oral presentation in the form of a pie chart to support their initial position.

Furthermore, it was also observed that students as a whole apart from forming an argument, developed communicative skills since all parties had equal opportunities to express their views, developing accurate arguments with the correct use of the linguistic code (avoiding deviations, expressing the arguments in a precise manner, and searching for relevant vocabulary). Students were respectful of different opinions, and of the rules of dialogue (same amount of time, team uniformity etc.) using non-verbal elements (eg. gestures, facial expressions, body posture, movements). Being in contact with scientists who showed students their errors and also inspired them, enriched their contact with scientific methodology. As far as their speaking in public skills are concerned, students successfully managed to express their arguments and maintain listener interest. Finally, they acquired a better understanding of scientific concepts through this procedure compared to the past and attempted to convey the meaning of scientific concepts in a simple way, using at the same time difficult terminology whenever necessary.

**DISCUSSION AND CONCLUSIONS**

In our research study we have explored though the framing of science teaching in the form of a simulated parliament the quality of argumentation in science teaching and its effective application in enhancing students’ cognitive knowledge. Students were enabled to understand and experience in an authentic context the value of formulating valid arguments and correlating
data with claims while controlling the credibility of their arguments and rebutting claims guided by concrete knowledge they had acquired. This way they managed to interpret their observations, reinforce their knowledge (Smyrnaioou, et al., 2015) and produce new frameworks as they were epistemically challenged. In this paper our main objective is to explore the structure of the argument, the effectiveness of the argumentation/debate approach in enhancing students’ knowledge construction and the impact factor of the approach in shaping their attitude towards STEM courses.

Learning science in an inquiry-based manner requires special skills from students. The ability to test hypotheses is one example: Does the result of an experiment verify or falsify the initial assumption? In order to answer this question, the ability to use evidence properly is needed. In primary science education, students need to reason about the truth of hypotheses. Previous research has shown substantial deficits in primary school children’s reasoning (Gauffroy & Barrouillet, 2011; Tröbst, Hardy & Möller, 2011; Furtak et al., 2010; Hardy et al. 2010). Some studies show that it is possible to promote children’s evidence-based reasoning in one-on-one teaching situations (e.g. Robisch, Tröbst & Möller, 2014). Yet research regarding the possibility of promoting evidence-based reasoning at the classroom level is still needed and, thus, the reason behind the present study. In our study, instructional support by scaffolding aimed at promoting evidence-based reasoning was developed (van de Pol, Volman & Beishuizen, 2012). In a control-group pretest-posttest design (N = 115 third graders), we tested to see if a study group with additional scaffolding could achieve better results in evidence-based reasoning. In order to measure the ability to use reasoning by determining the truth of hypotheses, truth-testing tasks based on Barrouillet, Gauffroy & Lecas, (2008) were administered. The initial results of our study show that the group with additional training outperformed the control group. This result supports the possibility of successfully promoting evidence-based reasoning in primary science education.

Keywords: scientific inquiry, evidence-based reasoning, primary teaching

THEORETICAL BACKGROUND AND AIMS

Testing hypotheses in primary school

Hypothesis testing is a central task in scientific experiments and one possible way to conduct a research process. When looking at some of the conventional steps of an experiment, it becomes obvious that the use of evidence-based reasoning is one necessary part of hypothesis testing. The process of an experiment may start with an astonishing observation, which leads to a research question. Next, the researcher poses a hypothesis and tests it in an experiment by investigating the results. Now reasoning comes into play: What do the results convey about the initial assumption? In order to reason properly, it is necessary to differentiate between evidence that verifies a hypothesis and things that disprove it. In the case of a refuting result, the hypothesis is conclusively rejected and a new hypothesis is needed, requiring another experiment to be started. (Klahr and Dunbar 1988, Moshman 1979, de Jong 2006) Hence, drawing the correct conclusion in relation to the initial hypothesis is a necessary requirement for testing hypotheses successfully.

In primary school, children already learn in an inquiry-based manner, which means testing their own hypotheses, running their own experiments and drawing conclusions. As a part of scientific inquiry, evidence-based reasoning is assumed to be relevant as one of the operative
components of scientific literacy (Deutsches PISA-Konsortium, 2000; Lawson, 2010). It is supposed that the use of evidence-based reasoning helps students learn in a scientific way and might also support the acquisition of scientific knowledge (Bybee 1997; Schwartz, Lederman & Crawford, 2004). This is why evidence-based reasoning is currently required in inquiry-based primary science education (Prenzel et al. 2003).

**Reasoning about truth values while testing hypotheses**

Describing the ability of hypothesis testing, Moshman (1979, S. 104) differentiates between three cognitive capacities: “(a) [...] the ability to understand conditional relationships; (b) [...] the realization that to test a hypothesis, one must seek information that would falsify it (falsification strategy); and (c) [...] the realization that hypotheses are not conclusively verified by supporting data.”

The first ability, implication comprehension, requires an understanding of the correct connection between a premise \([p]\) and a consequence \([q]\) (Moshman 1979). For example, the question, “Why do objects bounce?” could be answered by the student’s assumption, “Objects, which are filled with air, bounce”. Altogether, there are four possible combinations for the existence and non-existence of the premise (“filled with air”) and the consequence (“bouncing”). The conditional hypothesis only states something about those objects that comply with the premise. This means that the hypothesis is only verified if the object in question fulfils both the premise and the consequence (e.g. a table tennis ball, which bounces). If such an object does not also support the consequence (e.g. in the case where air is inserted into a ball of modelling clay, which does not bounce), the hypothesis is rejected. Furthermore, there are factors that are irrelevant for the examination of the initial assumption: They cannot verify or falsify the hypothesis, because they do not concur with the premise of the assumption. For example, an object that is not filled with air cannot be used to test the truth of the assumption that things bounce on account of the air inside them. In developmental research, this kind of reasoning is called reasoning about truth-values (Barrouillet, Gauffroy & Lecas 2008; Gauffroy & Barrouillet 2011).

It is possible to assume, that the ability for comprehending implications influences the strategy of falsification. This is because it is necessary to be able to differentiate between the four possible combinations regarding the existence and non-existence of the premise and its consequence. In the previous example, the modelling clay filled with air falsifies the assumption. Understanding that a single rebutting event falsifies the entire hypothesis – based on Popper’s critical rationalism – leads to the realization of the falsification strategy and is thereby one ability for evaluating the truth of a hypothesis.

Nevertheless, developmental research has highlighted substantial deficits in primary school children’s reasoning ability (Gauffroy et al., 2011; Tröbst et al., 2011). This raises the question whether reasoning about truth values can be promoted in primary science education using scaffolding strategies.
Promoting reasoning about truth values through scaffolding

The support provided for the completion of a task that learners otherwise might not be able to complete is called scaffolding. An essential characteristic of this concept is the gradual withdrawal of support (van de Pol, Volman & Beishuizen 2010; Wood, Bruner & Ross 1976). The rate of fading depends on the individual competence of each child. The concept of contingency is closely connected to this kind of behaviour. In the idea of scaffolding, a teacher’s support has to be adapted to the learners’ needs, regardless of whether a single student or a group of students are involved (van de Pol et al. 2010).

Reiser (2004) differs between two complementary mechanisms of scaffolding: structuring the task and problematizing subject matter. The structuring helps students decompose complex tasks, focus effort and monitor their own progress. Problematizing, on the other hand, poses a challenge to the learner, by eliciting articulation and decisions, surfacing gaps and disagreements (Reiser 2004).

Several studies have shown that it is possible to promote reasoning in children (English, 1997; Klauer, Meiser & Naumer, 2000; Rumain, Connel & Braine, 1983). In addition to these studies, Tröbst, Hardy & Möller (2011) and Robisch, Tröbst & Möller (2014) were able to confirm these findings in primary school children’s learning of topics in natural science. With the purpose of developing instructional support, Robisch et al. (2014) identified criteria on which the ability to reason about truth values depends. According to the tested criteria, reasoning about truth values depends mainly on the capacity of the working memory and the ability for cognitive inhibition. These findings were used to develop scaffolds such as structuring the complex reasoning process about truth values in order to disencumber working memory. The scaffolding, which included methods of structuring as well as problematizing (Reiser, 2004), was successful. However, the study was limited to one-on-one situations (Robisch et al, 2014). There is thus a current a lack of investigation regarding support for entire classrooms.

RESEARCH QUESTIONS AND HYPOTHESES

Because investigations to promote reasoning about truth values in primary science education with a focus on supporting entire classrooms still need to be conducted, we decided to examine children’s learning of reasoning skills for testing truth values by developing lessons on the topic of “the bouncing ball”. Based on the scaffolding measures developed by Robisch et al. (2014), we therefore developed two different types of instruction. We compared a well-structured program with additional scaffolds aimed at promoting reasoning about truth-values (experimental group; EG) and a well-structured program without additional scaffolds (control group; CG) in order to answer our research question:

Will the study group with additional scaffolding for reasoning about truth-values gain a higher ability for reasoning in comparison to the control group without this additional scaffolding?

In addition, we wanted to investigate whether the successful promotion of this kind of reasoning ability also leads to the ability to finally falsify a hypothesis. Thus, a second research question was posed:
Will the study group with additional scaffolding for reasoning about truth values gain a higher ability to evaluate the truth of a hypothesis in comparison to the control group without additional scaffolding?

Due to the results of Robisch et al. (2014), we expected that additional scaffolds are necessary for promoting the complex ability to reason about truth values. Therefore, we predicted that the experimental group with additional support would outperform the control group. Similarly, because of the assumption that implication comprehension influences the use of falsification strategies, we expected the same result for the second question.

**METHOD**

**Study Sample**

Altogether, four primary-school teachers participated in the study. Each of them taught two classes. A video-based test was used to check implementation. Results indicated, that one of the teachers differed from the given conditions of the study; thus, we only used data from three of the teachers (N = 115 third graders; age, M = 9.24, SD = 0.43; 69% female; professional experience of the teachers, M = 19 years, SD = 3.6). In order to balance the effects of their individual teaching styles, each teacher was assigned one study group and one control group.

**Instrument**

For the purpose of measuring reasoning about truth values, we administered truth-testing tasks based on Barrouillet et al. (2008). A material-based survey was conducted with the entire class at the same time. The students were confronted with assumptions in the form of relative clauses like, ‘Objects, which are filled with air, bounce.’ Different objects were presented to them, and they had to decide whether it verified or disproved the proposed assumption or was irrelevant for that assumption. The students were required to reason about truth values in each of the four assumptions presented to them. In each case, all four of the possible events (pq, p¬q, ¬pq, ¬p¬q) were presented once. To avoid order effects, the sequence of the event possibilities were varied.

In order to measure the students’ ability for evaluating the truth of a hypothesis, they were asked to make a decision after all of the objects had been presented, whether they could conclusively verify or falsify the assumption. This procedure was repeated for each of the four presented assumptions.

**Intervention Design**

The intervention was designed as follows (see Figure 1): All of the classes were taught seven lessons, lasting 45 minutes. Three of these lessons included the task to reason. In these three specific lessons, the study group received additional scaffolding concerning the task of reasoning about truth values. This difference formed the basis for our between-group comparisons. The topic of the lesson, duration of instruction, structure of the unit, and used material were the same in both groups. In order to examine whether the intervention was realized as planned, all lessons were videotaped. A control-group, pretest-posttest design was
used. The truth-testing tasks and the test of falsification were administered in the form of a pretest prior to the intervention, and a posttest was administered directly after the fourth lesson, when the different treatment between the two groups ended.

Figure 1. Intervention Design.

^a EG = with additional scaffolding to promote reasoning about truth values (experimental group); ^b CG = without additional scaffolding to promote reasoning about truth values (control group).

The topic of the lessons was “the bouncing ball” (see Thiel 1987) with the background of elasticity and plasticity. In the first lesson, the children made the surprising observation that a ball of modeling clay does not bounce, whereas a table-tennis ball does. This led them to the research question: “Why do objects bounce?” whereby, the children proclaimed their assumptions.

In lessons 2 through 4, the children investigated their assumptions. They experimented with different objects, checking whether these bounce or not and what they can say about their assumptions. Most of the assumptions had to be falsified. In the last three lessons, the scientifically correct concepts of elasticity and plasticity were taught.

The scaffolding in the EG included structuring as well as problematizing scaffolds. The teacher performed the procedure to test an assumption with the aid of a wooden sorting box (see Figure 2). The scaffolding material is aimed at helping the students visualize the reasoning process and helps them reduce cognitive load as well as support the ability of inhibition. In the first step, the children have to decide if the premise is fulfilled or not. If the premise is fulfilled, the object runs through the right part of the box. One example using the previous assumption (“Objects, which are filled with air, bounce.”) is that of the table tennis ball: It is filled with air, so the children check to see if it bounces. It does, therefore, it is placed in the box with the green smiley, where it says that the object verifies the assumption. Objects, which refute the assumption of ‘bouncing’ and are placed in the box with the red smiley. If the premise is not fulfilled the object is sorted out and is not used in the experiment. An example is the wooden cube. It is not filled with air, thus it is sorted into the box with the yellow smiley, which explains that the object can contribute no information about truth of the assumption.

The teacher demonstrates the process for using the sorting box focusing students’ attention toward essential thoughts like, “Is the object with air or not?”, “What do you expect the object will do following your assumption?”, “What do you see? Does the object bounce or not?”, “What does the object tell you about your assumption?”, etc. Following the teacher’s demonstration, the students test their assumptions on their own using the sorting box.
Figure 2. Wooden sorting box for visualizing the process of reasoning about truth values and four examples of objects provided to test the hypotheses (table tennis ball, burst balloon, modelling clay, wooden cube).

The students of the CG also tested their assumptions, but they worked without the help of the sorting box and did not get extra advice from the teacher as compared to the EG.

RESULTS

The descriptive data analysis shows that the ability for reasoning about truth values was promoted in both the study and the control group. A repeated measures ANOVA (between-factor groups (with, without scaffolding) and the within-subjects factor ‘time’ (pretest, posttest) shows, that the study group significantly outperformed the control group ($F(1, 113) = 10.220, p=.002, \eta^2_p =.083$). In addition, taking the within-subjects factor ‘event’ ($pq, p\neg q, \neg pq, \neg p\neg q$) into consideration, the interaction-effect time*group*event was also highly significant ($F(3, 339) = 7.074, p<.001, \eta^2_p =.059$). This can be explained by the different results regarding the four possible events. The beneficial effects appeared in the assessment of irrelevant data (see Table 1 for an overview of results and Figure 3 for an illustration of results).

The results of falsification are based on the summarized results of all four assumptions, which had to be evaluated individually concerning their truth. Both groups improved in the falsification of assumptions in the pretest-posttest comparison, whereby the study group significantly outperformed the control group.
DISCUSSION AND OUTLOOK

The results suggest that it is possible to support reasoning in primary science education about truth values. Furthermore, the children were also able to develop their ability to evaluate the truth of a hypothesis. One possible explanation for the improvements of the control group without additional scaffolding could be that these students benefited from the already strongly structured and high quality, cognitively activating teaching they received. Nonetheless, the superiority of the study group confirms the effectiveness of the additional scaffolding provided. Especially in regard to the evaluation of irrelevant objects, which are most difficult for primary school children to identify (Gauffroy & Barrouillet 2011, Robisch et al. 2014), the study group’s ability in this respect was fostered to a greater degree than in the control group.

When the results of reasoning with truth values are compared with the results of the falsification of assumptions, it is clear that the descriptive data demonstrates a similar trend. This suggests a possible relation between these two abilities, which Moshman (1979) describes as two of the central capacities needed for the cognitive process of hypothesis testing.

In addition to the data presented above, we also collected data from several other variables. Analysing these is one of the next steps in the project. We plan to explore the data for correlations between the ability to reason about truth values and other aspects of scientific literacy; for example, whether there is a relationship between reasoning and the planning of coherent experiments as well as students’ conceptual understanding. We expect positive correlations between these variables, because the ability to recognize irrelevant events should lead to a more effective planning of experiments. In theory, it is possible that the recognition of refuting events, as well as the use of falsification strategy, increases students’ dissatisfaction with their existing conceptions about a topic. According to the conceptual change theory of Posner (1982), this would help the learner to consider an alternative concept. Finally, we would like to examine whether the students were able to transfer their reasoning skills to another topic. To this end, they conducted a similar test on the topic floating and sinking, which can be used as a point of comparison.

In conclusion, it can be stated that the additional scaffolding in our study was successful. With it, the scaffolding implemented in this study is able to build a starting point for developing
further inquiry-based materials. In the future, we will develop teaching materials on the topic of ‘the bouncing ball’ and make them available to teachers with a focus on promoting reasoning. Furthermore, it is our intention to sensitize teachers to the importance of the ability of reasoning about truth values in the context of testing hypotheses so that hypothesis testing can be more widely implemented in schools as one component of scientific inquiry.

NOTES

Further results will be reported in the German article: Grimm, H., Robisch, C. & Möller, K. (submitted for publication). Förderung hypothesenbezogener Schlussfolgerungen im naturwissenschaftlichen Sachunterricht durch gezieltes Scaffolding – Gelingt dies unter Feldbedingungen? [Promoting reasoning about truth values in primary science teaching through explicit scaffolding. - Is this approach successful in the field?]

CRITICAL THINKING IN GERMAN-SPEAKING BIOLOGY CURRICULA OF AUSTRIA, GERMANY, ITALY AND SWITZERLAND

Susanne Rafolt¹, Suzanne Kapelari¹ and Kerstin Kremer²

¹University of Innsbruck, Department of Subject-Specific Education, Innsbruck, Austria
²Kiel University, Leibniz Institute for Science and Mathematics Education (IPN), Kiel, Germany

Critical thinking is a fundamental educational ideal and defined as a key competence for lifelong learning and scientific literacy. However, current societal development not only in Austria and Germany but in Europe and in the US convey the impression that although research in science education has been discussing the role science education plays in supporting students to develop critical thinking skills for decades already, we hardly know anything about whether and how these ideas are put into practice. Thus we analysed how German, Swiss and Austrian life science curricula address issues of critical thinking as an educational objective. Curricula were reviewed by using a literature derived category system in MAXQDA. Preliminary results show that biology curricula neither mention the term “Critical Thinking” explicitly, nor do they provide a clear definition of the concept or teaching instructions. Whereas the basic approaches to critical thinking are generally present, they are typically hidden between fragmented competences and skills. Some curricula blend the process of critical thinking with societal values students are supposed to adopt. Preliminary results indicate that biology teachers are left alone in their assignment for encouraging critical thinking. We assume that science education research needs to put more emphasis on finding out how essential research outcomes find their way into classroom teaching.

Keywords: critical thinking model, socioscientific issues, content-analysis

INTRODUCTION

Critical thinking is considered as an important aspect of scientific literacy (Bybee, 1997; Gunn, Grigg & Pomahac, 2008; Thompson, 2011; Osborne, 2014) and acquiring competences for lifelong learning sustainably (European Parliament and Council of the European Union, 2006, p. 4). Although critical thinking has been intensively discussed as a fundamental educational ideal for decades already, we hardly know anything about the role science education could play in supporting students to develop a conceptual understanding of critical thinking as a fundamental, multi-faceted tool for scientific knowledge creation.

According to the Austrian educational standards, science education is supposed to confront students with problems at the interface of science and society (Wiesner et al., 2017). These socioscientific issues (SSI) are open-ended, debatable, challenging and realistic (Zeidler, 2014). They produce a social or moral dilemma and require scientific knowledge as well as moral reasoning or ethical evaluation (Zeidler, 2014). Biology education, which includes environmental and life science education in secondary schools, addresses a variety of socioscientific issues, such as global sustainability goals, vaccinations, dietary habits or sex education. Dealing with SSIs in class is expected to stimulate students’ reflection on their beliefs and sharpen their wits. Living in a rapidly changing world, and with the Internet offering...
a vast amount of unfiltered information, students should use scientific literacy and thus critical thinking in order to tackle SSIs appropriately (Bybee, 1997; Osborne, 2014). However, any classroom activity asking students to “think critically” is at a great risk to become a superficial pastime if those involved either do not know which objectives to achieve or how their individual development towards these objectives can be measured.

To provide a more thorough understanding of how to promote critical thinking in science teaching and learning, we analysed how science curricula address the concept of critical thinking before focussing on teaching strategies and environments. In parallel, a multi-layered yet feasible “Synergy Model of Critical Thinking” was extracted from literature. This model will offer students and teachers a starting point to engage in a cultural sensitive discourse about what might be worth striving for in a science classroom.

Science curricula are the normative starting point of science education with a large national impact. The purpose of this work was to analyse in what assertions biology curricula of German-speaking European countries (Austria, Germany, German-speaking Switzerland and the German-speaking Italian province South Tyrol) address issues of critical thinking as an educational objective. As those curricula are predominately competence oriented and therefore addressing fragmented aspects, we will discuss those against the background of our theory-derived Synergy Model of Critical Thinking.

**THEORY**

In many countries, educational standards are oriented towards the concept of competence-based education (Bernholt, Neumann & Nentwig, 2012). For the European Parliament and Council of the European Union (2006, p. 5), key competences for lifelong learning are acquired sustainably through “critical thinking, creativity, initiative, problem solving, risk assessment, decision taking, and constructive management of feelings”, even though these aspects are not further discussed. The following “concensus statement regarding critical thinking and the ideal critical thinker” (Facione, 1990, p. 2) has been frequently cited in the international scientific literature on critical thinking:

*We understand critical thinking to be purposeful, self-regulatory judgment which results in interpretation, analysis, evaluation, and inference, as well as explanation of the evidential, conceptual, methodological, criteriological, or contextual considerations upon which that judgment is based. CT is essential as a tool of inquiry. As such, CT is a liberating force in education and a powerful resource in one’s personal and civic life. While not synonymous with good thinking, CT is a pervasive and self-rectifying human phenomenon. The ideal critical thinker is habitually inquisitive, well-informed, trustful of reason, open-minded, flexible, fair-minded in evaluation, honest in facing personal biases, prudent in making judgments, willing to reconsider, clear about issues, orderly in complex matters, diligent in seeking relevant information, reasonable in the selection of criteria, focused in inquiry, and persistent in seeking results which are as precise as the subject and the circumstances of inquiry permit. Thus, educating good critical thinkers means working toward this ideal. It combines developing CT skills with nurturing those dispositions which consistently yield useful insights and which are the basis of a rational and democratic society. (Facione, 1990, p. 2).*
This statement is collecting a wide range of aspects of critical thinking, however, practitioners might have difficulties in transferring these ideas into the science classroom. Therefore, a theory-based model of critical thinking is supposed to assist with explaining the concept to teachers, students and decision-makers (see Figure 1).

**A theory-based Synergy Model of Critical Thinking**

The model was primarily developed in German language. Thus, some aspects or terms vary from those used in the presented literature.

The model illustrates the complex interplay of various characteristics accompanying critical thinking (see Figure 1). These characteristics, namely intellectual standards, knowledge, motivation, cognitive skills, and self-regulation, are interconnected, but do not necessarily build on one another. In the model, a thorough involvement with a subject, e.g. a problem or a claim, leads to an individual and alterable positioning. This involvement is controlled by intellectual standards providing autonomy, fairness, accuracy, breadth, depth, rationality, logicalness, relevance and significance (Paul & Elder, 2014). In order to come to a thoughtful positioning, a critical thinker needs domain-specific knowledge (McPeck, 1981; Ennis, 1989; Bailin, 2002) and training (Halpern, 2014) as well as cognitive skills (Facione, 1990, 2000) affecting all other characteristics for adapting thoughts and actions to new circumstances.
or she is aware of own values and emotions and has a motivation for truth-oriented problem solving as well as an aspiration for learning and expertise (Siegel, 1988; Facione, 1990, 2000; Paul & Elder, 2014). Finally, a high level of self-regulation (Facione, 1990, 2000) affecting all other characteristics is crucial for changing perspective, but also accepting or realising something and, as a result, adapting thoughts or actions.

**Competence-based science curricula in German-speaking Europe**

In Austria, Germany and Switzerland, educational standards have been developed to increase transparency, objectivity and comparability of learning goals by linking school or teacher autonomy with obligations towards basic educational issues, and thus support teachers in giving feedback on the learning success and gaining data for curriculum and classroom development (Kremer et al., 2012; Labudde et al., 2012; Wiesner et al., 2017). These basic educational issues are oriented towards the concept of competence-based education. Considering the international literature about competences, the terminology is ambiguous when associating competences with skills, abilities, capabilities, capacities or qualifications (Hager, 2004). In German-speaking Europe, the discussion about competences is oriented towards Weinert’s (2001) concept. Following this, competence-based education means that motivational, volitional and process-oriented skills as well as problem-solving abilities in variable contexts and situations should be reached (Weinert, 2001). Based on this understanding, Austrian, Swiss and German authorities derived competence models to explain their perception of competences and assist with implementing competence-orientation in everyday teaching. Basically, all three competence concepts synergise similar aspects in terms of content, behaviour and complexity (BIFIE, 2011; EDK, 2011; Schecker & Parchmann, 2006). Table 1 summarises behavioural aspects in the Austrian, German and Swiss competence model.

**Table 1. Behavioural aspects of the competence models in German-speaking Europe (modified after BIFIE, 2011, EDK, 2011 and Schecker & Parchmann, 2006).**

Important aspects of the behavioural dimension are organising knowledge (acquiring, presenting, communicating), gaining insights (asking, investigating, interpreting) and drawing conclusions (judging, deciding, taking action). These aspects are partly congruent with single “critical thinking skills” (see Figure 1).
METHODOLOGY

For the qualitative analysis of the curricula documents, *aspects of critical thinking and teaching instructions were derived from the literature, which was used to develop the critical thinking model (see Figure 1), and summarised to categories. The curricula documents were entered onto the analysing software MAXQDA and searched for the term critical. Then, the categories were assigned to the found text passages. The categories used were intellectual standards, skills, self-regulation, positioning, and subjects (see Table 2).*

The curriculum analysis focused on German-speaking Europe, which includes Austria, Germany, the German-speaking region South Tyrol of Italy, and German-speaking Switzerland. Besides geographic and language reasons, this decision based on commonalities in terms of educational goals, especially the competence orientation, and similarities between the educational landscapes.

Austria has one national curriculum, the Italian province South Tyrol has one German-speaking framework curriculum and the German federal states as well as the Swiss cantons have individual curricula following the national educational standards (KMK, 2005a,b,c; EDK, 2011). This is why it was necessary to reduce the large amount of analysis material.

In German-speaking Europe many different school types exist, therefore the analysis was narrowed down to the so called *Gymnasium*. This school type primarily serves to provide a broad general education and prepare students for higher education at universities. Gymnasium schools are similar in all countries regarding the basic pedagogical characteristics, the degree (*Matura* or in Germany *Abitur*), and the student age (14 to 18/19).
To reduce the then still large amount of analysis material, only biology curricula, which addresses life science and environmental issues in all countries as well, were chosen, however, general educational objectives were reviewed too.

From September 2016 to July 2017 governmental and school web pages were searched for the curricula. Finally, a manageable number of fifty curricula documents was reached, including the Austrian curriculum, the South Tyrolean curriculum, the Swiss framework curriculum for “Maturitätsschulen” in addition to the curricula of thirteen Swiss cantons (Aargau, Basel-Stadt, Bern, Glarus, Lucerne, Nidwalden, Obwalden, Schaffhausen, Schwyz, Solothurn, St. Gallen, Zug, Zurich), and the curricula of all German federal states.

The heterogeneity of the curricula documents reasons against a quantitative analysis. In terms of content, all curricula documents are structured based on the same learning and pedagogical objectives, but they differ widely in terms of e.g. the level of detail. For example, the Austrian curriculum is offered in one document including the learning content of all teaching subjects as well as a long section of general educational goals applying to all subjects. The German federal states offer different documents for each subject. These include a section of general educational goals in each document as well, however, in different levels of detail. For example, some German curricula give instructions for teaching strategies, learning arrangements or even lesson planning, others just present the learning content linked with aspects of the competence model. In Austria, Germany and South Tyrol, teachers are obliged to follow learning goals and pedagogical objectives presented in the respective curriculum. In contrast, Swiss schools have more flexibility and autonomy in defining learning as well as pedagogical goals provided they follow the framework curriculum (Rahmenlehrplan für Maturitätsschulen).

RESULTS

The concept of critical thinking and how science education may contribute to its development is not explained in the reviewed curricula. However, all curricula mention terms related to “critical”, even though in varying frequencies and specification. What “being critical” or “critically doing something” means is not explained. Mainly, students should be critical towards knowledge, theories, models, data, sources, media, assumptions, ideologies or society in general, but also values. In general, critical evaluation, like judging or assessing something critically, critical reflection, critical analysis or engagement and critical questioning is emphasised. At all, the Austrian curriculum and Swiss cantons (Solothurn, Obwalden and Aargau) explicitly mention the term critical thinking, but do not provide more information, like a definition, an explanation or beneficial learning arrangements. However, the Austrian curriculum explains other educational ideas or concepts such as “multilingualism”, “reflexive coeducation”, “intercultural learning” as well as “gender-sensitive education, diversity and inclusion”.

In all curricula, basic approaches of critical thinking appear fragmented and rather as interdisciplinary than context-sensitive. The curricula focus mostly on knowledge acquisition, communication, presentation, independence or autonomy, and information seeking, rarer on positioning and merely on self-regulation.

The competence of evaluating and judging appears in relation to “value orientation” or
“scientific insights” without further explanations or instructions. For example, students are supposed to evaluate and judge the importance of a healthy lifestyle, but not specific claims and arguments that often appear in this relation. However, some curricula emphasise that students shall research a subject autonomously, reflect on different arguments and discuss them with classmates. Some aspects of “evaluation” and “interpretation”, like decoding significance, justifying procedures, querying evidence and conjecturing alternatives, are not at all or hardly present. Usually, the values students are supposed to adopt are predetermined.

**DISCUSSION**

The “concensus statement regarding critical thinking and the ideal critical thinker” (Facione, 1990, p. 2) is addressing the concept of critical thinking comprehensively. However, it is high time to develop a model of critical thinking, which can be applied in everyday teaching. Research results indicate that critical thinking should not be taught fragmentarily, instead, a thoughtful concept of context-sensitive learning situations (Ennis, 1989; Bailin, 2002) and precise instructions (Marin & Halpern, 2011) should be provided. The reviewed curricula address basic approaches of critical thinking both fragmented and interdisciplinary. This is based on the structure of the curricula, which gives a general and subject-specific section. Thus, basic approaches of critical thinking are considered as pedagogical objectives and didactic concepts. Therefore, they are presented in the general, not in the subject-specific section. In addition, these curricula refer to competence models, which are partly congruent with single “critical thinking skills” (see Figure 1 and Table 1). This is because the curricula have two parts, a general and subject-specific section. Gaining basic critical thinking skills are valued as interdisciplinary pedagogical objectives. Therefore, they are presented in the general, not in the subject-specific section. In addition, these curricula refer to competence models, which are partly congruent with single “critical thinking skills” (see Figure 1 and Table 1). However, explicit critical thinking instructions are missing in both sections. One reason might be, that it is not only challenging for teachers to support young people to become critical thinkers, but even more challenging for curriculum writers to provide an explicit, domain-specific explanation of the concept.

An everyday understanding of critical thinking might ignore the complexity of the mental capacity needed. Results of a yet unpublished study conducted in 2017 by the authors indicate, that many of Austrian pre-service biology teachers, who participated in the study (N=57), picture a critical thinker as being suspicious or even sceptical. However, scepticism and suspiciousness is not the same as being critical. Besides, being critical (in the Austrian and German cultural area) is not the same as critical thinking. We believe that being critical or thinking critically is part of most peoples’ self-concept, perhaps because it indicates intellectual independence. People may perceive themselves as being responsible citizens and thus critical thinkers. It is important to note that "much of the theoretical work and many of the pedagogical endeavours in this area are misdirected because they are based on faulty conceptions of critical thinking", which relate to "mental processes and procedural moves that can be improved through practice" and transferred to different fields (Bailin et al., 1999, p. 269). These conceptions may hinder or misguide the domain-specific implementation of critical thinking in the science classroom. If faulty conceptions of critical thinking are promoted continuously in
the classroom, it may mislead students to equate suspiciousness with the intellectually more demanding process of critical thinking.

The importance of explaining educational ideas and pedagogical objectives in the curriculum is valued in the Austrian curriculum already. Thus, we suggest to offer a cultural-sensitive and domain-specific Synergy Model of Critical Thinking to teachers and students (Ennis, 1998; Bailin & Siegel, 2003). This model will serve as a starting point to engage in a cultural sensitive discourse about what might be worth striving for in a science classroom. It is essential to give teachers a cultural independent as well as a cultural specific insight into the field of critical thinking so they can reflect on their own perceptions and increase their awareness for potential difficulties and challenges. We propose that science education research needs to put more emphasis on evaluating critical thinking under real life conditions and to provide teachers with a clear and understandable concept of critical thinking similar to the model introduced in this work (see Figure 1).

AN INVESTIGATION IN TO MAIN GOALS OF STEM OUTREACH PROGRAMMES IN IRELAND

Laurie Ryan\textsuperscript{1,2,3}, Denise Croker\textsuperscript{2,3}, Peter Childs\textsuperscript{1,2} and Sarah Hayes\textsuperscript{2,3}
\textsuperscript{1}EPI\textsuperscript{*}STEM, National Centre for STEM Education, \textsuperscript{2}Department of Chemical Sciences, \textsuperscript{3}Synthesis and Solid State Pharmaceutical Centre, University of Limerick, Limerick, Ireland.

Science, Technology Engineering and Mathematics (STEM) are critically important disciplines for modern society. STEM outreach offers the providers an opportunity to develop communications platforms and events that will challenge, inform and effectively engage the public and stakeholders in Science and engineering discourse. It offers a chance to bring together different stakeholders, which is a main goal of Science Foundation Ireland. (SFI, 2015\textsuperscript{a}). However, there is a wide variety of formats, goals and pedagogies that can be used when designing outreach programmes for schools (Veenstra, Padr\textsuperscript{ó}, & Furst-Bowe, 2012). STEM outreach providers in Ireland include universities, industries, voluntary organisations and government bodies (Davison, McCauley, Domegan & McClune, 2008), all of whom have varying goals and guidelines to follow when in the development and implementation phase of outreach programmes. This project will use a quantitative questionnaire as the main tool of data collection. 59 active outreach providers in Ireland were contacted to complete a questionnaire, of whom 30 (51\%) replied. The purpose of this questionnaire was to gain understanding of the goals that guide the development of STEM outreach activities in Ireland. This paper details the various backgrounds of STEM outreach providers, and compares these to the goals and pedagogies perceived to be of most importance when designing an outreach activity for Post-Primary schools. The results show that there are varying goals for the outreach providers in Ireland and that the background of the participants is only relevant for certain learning outcomes.

Keywords: outreach, stem outreach, science communication

RATIONALE

STEM research is high on the agenda of policy makers globally, particularly within Ireland and the European Union. This is reflected in strategy and funding call documents across both zones, with investment into strategic applied research being prioritised in Ireland as an aid towards economic recovery (OECD, 2007; SFI, 2015\textsuperscript{a}). With STEM research so high on the agenda, the responsibility of STEM outreach providers is also increasing.

STEM outreach programmes offer a chance to emphasize the relevance of STEM fields to the broader society, while also showing the incredible impact that these fields have on the lives of people in the community (Veenstra et al., 2012). This paper will focus on the goals considered important by different outreach providers in the development of material. Accordingly, it is important for outreach providers to utilize this opportunity, and create an effective programme for use in their target audience, which, for this project there will be a focus on the Post-Primary STEM outreach and engagement programmes. Science Foundation Ireland (SFI), the national STEM funding agency for Ireland, have a mandate to promote public engagement and outreach in Ireland, however they are not alone as there are numerous Higher Education institutions, government bodies and industries also promoting outreach and engagement (Davison et al.,
This work aims to evaluate how STEM outreach and engagement is currently designed in different formats for Post-Primary schools, with the aim of improving the pedagogical approach when creating outreach activities.

**BACKGROUND**

This paper is part of a larger research project which is divided into a number of cycles. The main goal of the overall project is to merge the use of STEM outreach and argumentation to create an effective programme for teachers. This paper will focus specifically on cycle one of the data collection.

- **Cycle 1** - The investigation of STEM outreach providers in Ireland. Investigating the use and understanding of argumentation in outreach (interviews with outreach personnel)
- **Cycle 2** - The implementation of a STEM outreach activity that incorporates argumentation and development of a community of practice (Teachers and Outreach Providers).
- **Cycle 3** – Re-development and re-implementation of Outreach activity. The design of an effective STEM outreach Framework which includes argumentation.

The following research question directed this paper:

- Is there an overarching goal for STEM outreach providers when designing materials for Post-Primary schools in Ireland?

In Ireland the majority of STEM education research is targeted at the formal learning environment. Formal learning is characterized by an education process which, necessarily involves the teacher, the pupils and the institution (Knappenberger, 2002). This project involves a shift away from curriculum-based, formal education. Nevertheless, that is not to say that the educational experiences cannot be linked to a curriculum. Outreach programmes are unique in the fact they can take place in formal environments, while also taking place in non-formal and informal situations depending on the goal of the programme (Dolan, 2008). Outreach allows for multiple contexts where people can pursue their curiosity without having to worry about any formal assessment against externally specified performance standards (Rennie, 2007; Schauble et al., 1996).

Although formal education is the main provider of educational experiences, the informal education sector is noted as a critical element of STEM education (NRC, 2009). This places and emphasis on the importance of creating mutually beneficial material for outreach practitioners and the formal education community. This study focuses on STEM Outreach programmes in Irish Post-Primary schools. There is an increasing importance associated with the implementation of outreach programmes in STEM education in Ireland in recent years. Recent literature has recognised that Ireland has very active informal STEM education sector, with many different experiences, activities and opportunities available to pupils all over Ireland (STEM Education Review Group [STEM-ERG], 2016).
LITERATURE

Science in STEM

Ireland has placed an immense focus on the development of STEM subjects in recent years including STEM subjects in both Primary and Post-Primary education. A brief overview of the STEM subjects available to pupils in Ireland can be seen in Table 1. This section is going to focus specifically on Science education in Post-Primary education. The reason for using Science as opposed to STEM is due to the fact there are significant overlaps across the various STEM curriculum, with Science sitting as the focal point. Science is often recognised as begin a stand-alone term covering many different disciplines, while also being used as an umbrella term for the STEM subjects (SFI, 2015b). Brown, Brown, Reardon and Merrill, (2011) note that there are common characteristics and content that unite the STEM disciplines, thus establishing the need for collaborating. While the STEM-ERG (2016) proposed that engineering and technology should be integrated into the structure of Science education at all levels. This is due to the fact the core ideas of engineering design and technology align with the core ideas in the other major Science disciplines (STEM-ERG, 2016).

Finally, the STEM outreach sector in Ireland is very much characterised by Science and Mathematics Outreach. Although there is push on STEM subjects overall, the majority of outreach is related in some way to Science and Mathematics area. Science and Mathematics have a very high uptake in schools at both leaving certificate and junior cycle levels and this could be a major factor on deciding areas to create outreach material, as they provide the opportunity to interact with more pupils.

Irelands’ Post-Primary Science Education System Overview

In Ireland Post-Primary level education there are 3 distinct learning cycles: a 3-year Junior Cycle, followed by a two-year Senior Cycle; there is also an option of taking an extra year known as the Transition Year Programme, which fits between Junior and Senior Cycle (Department of Education and Science [DES], 2004).

Ireland is in a unique position among other European regions in not having science a compulsory subject at lower secondary level (Oriacthas Library & Research Services [OL&RS], 2009). A revised Junior Cycle syllabus was launched in 2016. It incorporates the Nature of Science, together with the physical, biological, chemical worlds and earth and space (NCCA, 2015). It is a 3-year course that has been designed for a minimum of 200 hours of timetabled pupils’ engagement over three years (NCCA, 2015). It has learning outcomes as opposed to a set curriculum, while it also has different forms of assessment: classroom-based assessment, a classroom task that is sent away for marking, and a final examination.

The Transition Year (TY) Programme in Ireland does not have a prescribed national curriculum, allowing each school design its own programme according to a suggested curriculum framework laid down by the Department of Education. According to the Department of Education Guidelines (Department of Education (DE), 1993), curriculum content is a matter of selection and adaptation by the individual school with regard to the requirements of pupils. Science is not considered a core subject in the TY Programme, however, it is a subject that can be sampled by pupils in order for them to “make informed choices when making their subject choices” (PDST, n.d.). This is similar to the view carried throughout the Irish education system as Science in both Junior and Senior Cycles is not a compulsory exam subject. Generally, TY schools either offer a taster course in one or more of the Sciences offered at senior cycle or they offer a general Science course, similar to the Junior Certificate programme (Hayes, Childs & O’Dwyer, 2013). The schools tend to divide Science into the various headings of Biology, Chemistry, Physics and Agricultural Science or they opt to have a general Science course.

As shown in Table 1, there are five Leaving Certificate Science Subjects: Biology Chemistry, Physics, Agricultural Science and Physics & Chemistry. Many schools offer the four main Sciences, depending on the size of the school and the demand for the subjects. According to Osborne et al. (2003), the relationship between attitude and achievement is a key issue for consideration school science. This is something that may be seen when comparing the best answered sections of the Junior Certificate and the Leaving Certificate subject uptake. The Biology section in the Junior Certificate Science exam is the best answered section, and as an individual subject it accounts for the highest uptake in Leaving Certificate (State Examinations Commission [SEC], 2010). This pattern follows through to Chemistry with it being the second best answered section in the Junior Certificate (SEC, 2010), and from 2009 onwards Chemistry is the second most popular Science in the Leaving Certificate. At the end of the 2-year Leaving Certificate cycle, there is an overall examination of each subject, with at present no separate assessment of practical work.
Outreach in general is associated with “a meaningful and mutually beneficial collaboration with partners in education, business, public and social service.” (Ray, 1999, p.25). It brings the various stakeholders together to engage different age groups in an area that is decided upon by the provider. The main aim of Science outreach and engagement is to “increase the size and diversity of the Science workforce” (Lauresen et al, 2007, p49). It is an essential part of building scientific literacy and a crucial way to keep future scientists interested in a subject, with the overall intention of assisting in the important growth of social and economic development in Ireland (Davison et al, 2008; SFI, 2018). Walker (2007) has described Science outreach as a way of improving the recruitment and retention of pupils, while also recognising its importance for promoting the vulnerable, physical Science subjects. Universities and additional organizations have realised the impact it can have on Primary and Post-Primary pupils, and how it can help improve pupil engagement and act as a direct vehicle in supporting education in the classroom (Gomez & McCauley, 2012).

Outreach involves many different stakeholders, all of whom have similar, yet different backgrounds and aims in relation to areas of study, overall goals and funding opportunities. The majority of STEM outreach providers are looking to expose pupils to areas of STEM that they may not have experienced at school (Brawley et al. 2008). It must be remembered when designing STEM outreach, that there are many parties involved in the process, and when dealing with Post-Primary outreach teachers and pupils also play an important role. Their role can be seen in Table 2.

In Ireland, there is an increasing importance associated with the implementation of outreach programmes in STEM education. In 2017, the Minister for Training, Innovation and Skills announced funding for 44 initiatives aimed at engaging the Irish public in STEM areas (SFI, 2017). One of the key areas receiving funding included STEM informal education for schools, this area includes projects that support young people to engage with the subjects and themes of STEM outside of the formal curriculum. This gives rise to the opportunity to engage and improve pupils’ knowledge on STEM outside the classroom. Figure 1 outlines a cycle of how STEM outreach is often created in Ireland.
However, it has been noted that there are many limitations that prevent successful development and implementation of outreach (Kim & Fortner, 2007; Laursen et al., 2007; Tanner et al., 2003). Research has shown that most outreach related to Science lacks a description of terms, goals, and criteria for what success looks like (Phipps 2010). It is also stated that the lack of time spent developing outreach can be an issue when it comes to the quality of the activity (Varner, 2014). Finally, many of the funding institutions involved in developing outreach activities place a lower value on outreach than on specific publications (Komoroske et al., 2015), implying that it is a tick the box exercise, as opposed to a meaningful experience for all involved.

Figure 1. Brief outline of the chain of a STEM outreach activity in Ireland with examples.

METHOD

Data Collection

While this study incorporates a mixed method approach, this paper will focus on the use of quantitative data. The method of data collection involved a questionnaire developed for outreach providers in Ireland. The format of the overall questionnaire included a mixture of open-ended, closed and structured questions, with a specific focus on Post-Primary STEM outreach programs in Ireland. The aim of the questionnaire was to establish baseline data for the current STEM outreach practices and to gather a background on the STEM outreach practitioners in Ireland.

The questionnaires consisted of three elements:

- **Section 1** – gathered *generic information* from the participants. It focused on the gender, area of degree, education background & teaching experience

995
Section 2 – participants’ current work. It focused on the area of outreach/background, important aims and goals, and important pedagogies when creating outreach.

Section 3 - opinions on constraints they deal with. It focused on what they would improve if given the opportunity, and opinions on different pedagogies.

All quantitative data were analysed using the Statistical Package for the Social Sciences (IBM SPSS Statistics 24), while any open-ended questions will be analysed using NVivo.

Participants

When choosing a research sample there are four factors that need to be considered: the size of the sample, the representativeness of the sample, access to the sample and the sampling strategy used (Cohen, Manion & Morrison, 2007). Outreach providers from Ireland were selected using information from a previous study (Davison et al., 2008), in addition to an in-depth search of new and recently formed research centres and outreach providers which was carried out by the researcher. A sample of 59 active STEM Outreach Providers in Ireland were contacted by an email which contained the details of the study, and the requirements involved for participation. The link to the questionnaire was attached in the email. This initial email was followed up with 2 personalized email notices as a reminder to the participants. The questionnaire remained active for 8 weeks. Overall, 30 (51%) of the sample completed the questionnaire.

RESULTS

Questionnaires were sent to 59 outreach providers, and 30 (51%) replies were obtained. In terms of developing material, each outreach provider is going to have their own desired goals. These goals will be dependent on their funding bodies, area of interest and the target group of the project. However, one of the questions to the outreach providers was about the provision of guidelines when developing the material. This yielded some interesting results as 63% (n=19) of the participants stated they have guidelines to follow, while the other 37% (n=11) did not have guidelines to comply with. However, when the differences between the guidelines provided/not provided are analysed in terms of funding body/promoter, some differences can be seen below (Figure 2).

![Figure 2. Outreach Providers in Ireland guideline breakdown](image)

996
The outreach providers were then asked to state their main goals, and secondly why they are considered important. The first part of this question allowed for each respondent to describe the goals that they perceive as important. Table 3 below gives an outline of the goals that occurred in the questioning. Creating curiosity and interest is the most common goal (n=8).

</table>

The outreach providers were then asked to explain why they chose the goals from Table 3. Some outreach provider wants to encourage ‘choosing STEM subjects, it is important for Irelands Future’ (OQ2), while others ‘strive to improve/enhance scientific literacy’ (OQ1) or contribute to developing ‘Science literate citizens’ (OQ13). The majority use these goals to help pupils understand the world around them, feel confident in Science and be willing to hold a conversation on areas associated with STEM subjects (OQ6, 11, 13, 14, 18, 19, 22, 27, 28, 29). There is also a clear push for promoting and aiming to ‘inspire the next generation of scientists’ (OQ24). The remainder of respondents want to ‘create awareness’ (OQ10), ‘develop curiosity, involvement, wonder and interest’ (OQ9) and ‘for the pupils to have positive experiences around Science’ (OQ4). Finally, one of the most interesting goals being to raise ‘awareness of our research so that Irish people can take pride in the achievements of their scientists’ (OQ3).

Interestingly, 90% (n=27) of the outreach providers stated they have had teaching experience, whereas only 66% (n=20) of STEM outreach providers that stated they have a background in education. As there can be variance in teaching experience dependent on the participant, they were asked to clarify the experiences they have. Some participants have more than one experience, including laboratory demonstration, teaching, substitute teaching and lecturing. Figure 3 outlines the different levels of teaching experience.

As the study is focused on Post-Primary education, it was decided to look at the difference between outreach providers with a teaching degree and those without. When comparing the learning outcomes considered important when developing materials, there was a significant difference between outreach providers with a teaching degree and those without when it came to three outcomes. The outreach providers with a teaching degree rated Justifying Statements (p=0.05) and Practical Skills (p=0.046) as more important learning outcomes than those who

---

1 OQN = Outreach provider Questionnaire Number X
do not have a teaching degree. However, those with a teaching degree rate Definitions (p=0.020) as less important when developing materials.

**DISCUSSION**

These results differ to a previous study (Domegan, McCauley & Davison, 2010), which states that the central objectives were to increase Science numbers, create positive Science attitudes and increase the number of people choosing Science careers. However, this study wasn’t focused solely on Post-Primary Education as it looked at Science outreach as a whole. The results as shown above in Table 3 indicate that ‘curiosity and interest’ and ‘creating an experience’ are the top two goals when developing outreach material. Science has so many exciting areas that can be incorporated in order to make Science an appealing and enjoyable subject to pupils and this should be taken advantage of. Due to the fact Science in Post-Primary schools has a ‘narrow’ scope at Leaving Certificate level, this in turn leaves little opportunity for teachers to contextualize Science and explore the role of Science in our everyday lives and in society (Smith and Matthews, 2000). This leaves outreach providers with certain areas of Post-Primary education where they should focus their attention when developing their material, namely the new Junior Cycle course and Transition Year (TY).

TY offers the opportunity to depart from the syllabus and offer pupils the prospect of studying stimulating areas of Science, ones which they may not actually associate with Science. According to the Department of Education Guidelines “Transition year Science should explore the links between Science and society” while also developing a “broader understanding of the subject” (Department of Education, 1993, p.5). This directly links with the main aims of outreach and what it wants to achieve in general. Clerkin (2012) offers the view that “Transition Year is intended to be an opportunity for pupils to learn about the world outside academia” (p.3). It has been stated in recent years that one issue that tends to come to the fore in TY Science is the teachers' apparent lack of time to develop material, as there is no set curriculum (Hayes, 2011). According to previous research there is a shortage of suitable teaching materials in Science for use within this year, and “teachers must decide their own programme and produce their own resources” (Childs, 2007, p.14). This leaves a viable opening for outreach providers to develop material that both creates curiosity and interest, while also developing a
genuine learning experience for pupils and a useful piece of material that teachers can implement in a classroom. This will stop teachers’ falling in to a default of teaching “a 3-year LC (which is not allowed) or introduce them to LC material” (Childs, 2007, p.14).

Similarly, the new Junior Cycle allows for a greater variety of activities once they meet a learning outcome specified in the new specification for teachers. The new curriculum allows for pupils to develop their evidence-based understanding of the natural world and their ability to gather and evaluate evidence (NCCA, 2015). It also promotes nurturing pupils’ natural curiosity and wonder about the world around them through experiencing scientific discovery (NCCA, 2015). All of which can be utilised by outreach providers while also meeting their main goal of developing curiosity and interest. This is something that outreach providers across Ireland need to invest time in, in order to be successful.

It was noted that there are some differences in the outcomes and goals considered important by outreach providers who are qualified in STEM education and those who do not have a teaching qualification. Interviews will be used to investigate this area further.

CONCLUSION

Overall, there is not one overarching goal for outreach programmes that are being developed and implemented in Ireland. This leaves a large opening for meaningful outreach to be created that can incorporate goals and learning outcomes that generate learning and curiosity outside the formal curriculum. There are also discrepancies in guidelines between outreach providers and the various funding bodies, which allows for variance in goals and the material that can be created by outreach providers. TY and the new Junior Cycle course offers a great opportunity to create and introduce material that can be used in a Post-Primary school, without being specified in the curriculum.

FUTURE WORK

This year, cycle 2 of the project is underway. This includes interviews with the outreach providers to gather more background information on the development of an outreach activity. Following on from this, a Community of Practice will be formed between: outreach providers, teachers and the researcher in order to develop material that incorporates pedagogies to develop scientific literacy and argumentation.

ACKNOWLEDGEMENT

I would like to thank the CS Department and SSPC, in the University of Limerick, for funding and giving me an opportunity to conduct this research. I would also like to thank the outreach providers who participated in the study.

Non-formal educational institutions like museums are contributing to science education and provide the possibility for visitors to interact with researches and participate in the creation and debate of scientific knowledge. The project ‘Visitor participation at the Museum für Naturkunde Berlin’ used a Co-Design-Process to develop new participatory tools and strategies together with staff members and visitors. The outcome of the Co-Design-Process pointed towards integrating multiple perspectives into research and exhibitions and debating actual social problems related to scientific work at the museum. Tools were designed and tested. This paper describes the development of the tools as well as the first results concerning their impact on promoting science literacy and critical thinking.

Keywords: participation, science literacy, museum

INTRODUCTION

The Museum für Naturkunde Berlin (MfN) - Leibniz Institute for Evolution and Biodiversity Research is an integrated research museum with over 30 million collection items, four science programmes and permanent exhibitions, which give the public an insight into current research at the Museum. More than 100 scientists, mostly natural scientists and humanities scholars, work at the MfN. Over 600.000 visitors per year visit the Museum – with a steadily increasing number of participants in educational programmes and events.

The project ‘visitor participation’ is located in the Education Department where the conceptual design and evaluation of the museum’s educational programmes as well as research on education and science communication take place.

The project is third-party funded by the German Federal Environmental Foundation (DBU) and executed in cooperation with the Design Research Lab at the Berlin University of Arts (UdK) and the master’s degree programme ‘museum management and communication’ at the University of Applied Science (HTW) Berlin.

Our aim was to find out how museum visitors can be further involved in scientific processes and how participatory approaches can foster a deeper involvement in scientific discussions, increase scientific literacy and make fruitful use of different perspectives on exhibits and research topics. Therefore, we develop tools and formats in a Co-Design Process, then tested and evaluated them. Based on the experiences, we will create a recommendation for action on how to engage visitors with research, collections and exhibitions at museums.
THEORETICAL FRAMEWORK

Participation

We understand ‘participation’ as active taking part in processes of research, collections and exhibitions as well as engaging in current social debates that are related to questions of nature and naturalness. Our aim is to enable visitors to bring their own perspectives and content into debates and to include different views on objects and research questions and make these perspectives visible to scientists and the audience. Thus, we do not define participation at the museum in a purely educational perspective (e.g. Lynch 2011; Piontek 2012). As Nina Simon (2010) puts it: “Participatory activities should never be a ‘dumping ground’ for interactivity or visitor dialogue. In cases where visitors are actually asked to ‘do work’, that work should be useful to the institution”. Mutual learning focuses on enrichment for the participants, research communities, subsequent visitors and/or social debates on relevant topics, because activity in itself is not a manifestation of democracy (MacDonald 2002).

According to the German science barometer 2016 (Wissenschaft im Dialog) the respondents mentioned “their desire to participate – both in discussions about science and in research itself”. In this context, museums as the MfN are ideal places for participation in science because they are perceived as highly credible and neutral actors and could thus play a decisive role in shaping participation, which is not about gaining acceptance, but about promoting deliberative processes on the way to open science and strengthening participation in debates on important issues of the future (Bonn et. al 2016). Therefore, it can be considered whether the process and intermediate results of current research should be more strongly represented in exhibitions in the sense of a ‘critical science literacy’ (Hine & Medvecky 2015). In addition, greater visibility of research in exhibition spaces and museum operations can provide visitors with a better insight into the research carried out at museums.

One of the museum’s strengths, especially of a research museum as the MfN, is that social debates and their everyday relevance can be demonstrated using exhibits as an entrance point into scientific and also ethical debates. A central task for a participatory museum is to offer itself more strongly as a place for social debates on these topics. The museum can give different actors from inside and outside the institution a space in the exhibitions to extend the representation of scientific research by a socio-political dimension. In particular, it can make conflicts transparent and thus make political processes and decision-making easier to understand. An exchange of positions within these conflicts can be documented and, if possible, continued in digital space.

In times of digital filter bubbles, a museum can establish itself as a place of genuine social exchange, where people can jointly inform themselves about current knowledge and then enter into a debate. More than just presenting current knowledge, a museum can offer the possibility to discuss ethical and guideline questions of research and socially relevant aspects of application. The overlap of the specialized knowledge of scientists with the social and ethical decisions is where participation and integration of multiple perspectives is necessary and fruitful.
Design Research and Participatory Design

Finding ways of enabling individuals to engage and become active contributors to research endeavors and to new perspectives on specific issues is a challenge that has to be tackled from different disciplinary perspectives. In design research, the discourse has been shifting more and more to address the social and political aspects of design practice and research, and their underlying potential for an expansion of design’s range – from the built environment towards more general concepts of co-creating livable futures (Beuker 2016). Many authors proclaimed a ‘social turn’ in the last decade (e.g. Fuad-Luke 2009, Manzini and Jégou 2003, Wood 2007), with design no longer being understood only as the design of single objects or signs (Rittel 1987) but rather as the design of situations of usage, experiences, interactions, reflection, interventions, decision-making processes, and systems (Mareis 2010, Erlhoff & Marshall 2008). Design research explores design’s potential in fostering discourses around the topic of future orientated, socially and ecologically sustainable forms of development.

The necessity to develop a critical understanding of the frameworks of design practices becomes essential especially within human-centered and participatory design approaches. Participatory design has been gaining attention worldwide regarding experts and non-experts working together. Those who are being addressed are no longer viewed simply as users, consumers or subjects of research interest, but are seen as experts in understanding their own ways of living and working (Götze 1998; Ehn 2009; Björgvinsson et al. 2010, 2012; Sanders 2012; Joost 2015) and are thus valued partners in the development and research process. Co-design and co-creation are variations of the principle behind this practice. Often, the challenge consists in developing a common perspective of the relevant issues, building up a productive work relationship, and creating new forms of generating knowledge that is relevant for the different stakeholders.

In the project described here, the infrastructure and tools we designed are meant to engage in debates, open avenues for negotiations and bring together individuals from different backgrounds. We are interested in the ability to empathically engage in long-ranging negotiation processes as the very characteristic of civic and democratic behavior. Designerly approaches that can be allocated in this area essentially pursue the so-called politicization of citizens – through creating artifacts that trigger dialogue or support the formation of consciousness that potentially leads to action.

Science Literacy and Critical Thinking

The American Association of Museums (1992) states in its report ‘Excellence and Equity’ that museums are “institutions of public service and education, a term that includes exploration, study, observation, critical thinking, contemplation and dialogue” (p. 6). As both a natural history museum and a research museum one of the main aims is to support the development of scientific literacy of all people – no matter their age or educational and cultural background. According to Bybee (2002) the concept of scientific literacy has a long tradition and different definitions about scientific literacy exists. The Organisation for Economic Co-operation and Development (OECD) defines scientific literacy as the ability to apply natural scientific knowledge, to review natural scientific questions and to use deductive reasoning in order to
understand and come to a decision concerning the natural world and the human made changes of the world (Baumert et al. 1999). In the recent ‘Handbook of Research on Science Education’, Roberts (2007a) distinguishes in his chapter ‘Scientific Literacy/Science Literacy’ between two different perceptions of the aims and purposes on science education. According to Roberts, the first vision is directed inward science. It looks at theories and laws as products of science, as well as at the processes of science including hypotheses and experiments, whereas the second vision is directed outwards and describes situations in which “science has a role, such as decision-making about socio-scientific issues” (Roberts 2007b, p. 9). In the context of the present study, we refer to the second vision on scientific literacy because within the project visitors should deal with dilemma situations, make decisions and discuss about presented issues (see chapter 4). Indeed, education at the Museum für Naturkunde Berlin comprises both visions Roberts (2007a) identified. In addition to guided tours in which scientific knowledge plays an important role, visitors can experiment in the microscopy centre of the museum, learn how to do science and train their scientific skills. Next to the achievement of scientific knowledge and skills, reflection in science plays an important role in developing scientific literacy.

Within the project ‘visitor participation’ our focus is to foster critical thinking and to stimulate discussions and debates with citizens.

**Critical Thinking through participation**

By participating and not only interacting, as taking part in scientific discussions, ethical debates on research questions and in the research process, visitors experience science as a long-term process of re-evaluation and reflection. It is only through an understanding of the dynamic nature of scientific discovery that programmes can hope to gain real, widespread public engagement (Brand 2008). Hine and Medvecky (2015) use the term ‘unfinished science’ as an umbrella term for different concepts of science models, where the outcome is not defined and no definite outcome can be constructed, combining definitions from Latour (1987), Stafford (1999), Durant (2002) and others. They define two major strands of unfinished science: scientific controversy and science-in-the-making. Scientific controversy questions science itself and poses ethical questions. Science-in-the-making focuses on either applications of scientific findings or ongoing debates between researching on possible interpretations (Hine & Medvecky 2015).

The science museum as a place of informal science learning gives the opportunity to present science as an open process by addressing controversies and the procedural character of science. By involving visitors in current ethical debates and documenting the perspectives of visitors, the ability of critical thinking and, as Hine and Medvecky (2015) put it, critical science literacy is fostered.

Based on that, we suggest that our participatory tools enhance scientific literacy, the competence of decision making and critical thinking through a more intense involvement and discussion of research topics, ethical questions of science and application of scientific knowledge. The ‘competence to assess’ matters, roughly translated from the German term “Bewertungskompetenz” that is a crucial part of the German curriculum in science education.
and a central goal to be reached when teaching sciences in school. It means the ability to think critically, weigh arguments and assess information in order to come to an own conclusion.

DEVELOPING NEW PARTICIPATORY TOOLS AND STRATEGIES IN A CO-DESIGN-PROCESS

Project plan und status

To integrate as many perspectives as possible, the project ‘Visitor participation at the Museum für Naturkunde’ started with two Co-Design workshops, both facilitated by the Design Research Lab of the Berlin University of Arts (UdK). At the workshop staff members as well as visitors and external experts worked together to find out about the needs and requirements for participation at the Museum für Naturkunde Berlin and to develop and draft their ideas. At this early stage of the project, especially creativity techniques such as the design thinking method enabled the team to identify needs and motivations of the participants and find consensus upon the shared questions. By bringing together a heterogeneous group of people from different disciplines, including experts and lay people, the project team was able to find out about the different perspectives and expectations on participation in the museum and incorporate the different understandings, views, opinions, expertise and attitudes into the co-design process. Co-Creation is a central for reaching a certain degree of coordination and acceptance of a common understanding about what participation in the museum context should cover, and with regards to what is to be expected from participation in the museum.

Besides that, we conducted ten semi-structured interviews with staff members from the different science programmes of the museum. After analyzing the results using qualitative content analysis, a concept for a participatory MfN was developed and prototypes of tools and methods for participation were designed, pre-tested and finally tested in the exhibitions.

Figure 1. Project plan ‘Visitor participation at the Museum für Naturkunde Berlin’.
Results of the Co-Design-Process

The participants of the workshops and interviews mentioned different expectations on participation that can be grouped into three categories. From these categories we developed a three-pillar structure for participation. First of all, there is a need for space for participation. Ideas for a Science Kitchen were developed with staff members, visitors and experts for participation during one of the workshops as well as with visitors on different events. We used empty floor plans and icons representing either activities, interior equipment or a rough structure of the room. The participants were asked to design a space where they would like to actively participate and to tell the Museum, what they needed and wanted to do there. These different floor plans were evaluated. A participatory space should be cozy and comfortable with possibilities to rest, meet other visitors and museum staff members. Visitors as well as staff members wished for areas for engaging actively in science via microscopy, scientific experiments and hands-on exhibits as well as a library/digital research area.

Second, the wish for different perspectives on exhibits and research topics at the museum was expressed. This mainly meant to integrate external perspectives into the exhibition and to give visitors the possibility to interact with the objects and get insights into the research conducted at the museum. In addition, staff members had the wish to get feedback from visitors and make their own research and work processes more visible to the audience.

Third and maybe most important as it is closely connected to both other pillars of the structure is the desire to host public and political debates as well as debates that are related to the exhibitions and the scientific research at the MfN. This was expressed by both the workshop participants and interview partners.

![Diagram of three-pillar structure for a participatory Museum für Naturkunde Berlin.](image)

Development and testing of participatory tools

Based on the results of the interviews and the workshops, different tools for participation were developed, each addressing at least one of the pillars in Fig. 2. In the following, we will present three of these tools in more detail.
Drawing favorite objects

In order to integrate different perspectives on the objects and the research conducted in the MfN and to give visitors different, low-threshold opportunities to participate, we adapted and tested a drawing format similar to the Natural History Museum London (see Fig. 3). At different events visitors could pin their drawings on a pinboard gallery. Many visitors used the opportunity to point out, why they found the drawn object special and what their experience or interest was. With the drawings, visitors contributed to a collection of different perspectives on the museum exhibits. As Ainsworth et al. (2011) pointed out, drawing not only generates a deeper understanding, but also encourages discussions. In a future study we would like to further investigate how drawing object can encourage dialogues between visitors.

Figure 3. Drawing card “Which object in the exhibition is especially fascinating to you?”

Story-tent ‘Stories of the Museum’

Another participatory tool developed in the project is the installation ‘Stories of the Museum’ that collects and displays anecdotes about the museum and stories from behind the scenes, told by the scientific staff and visitors. Based on Ricouer’s (1987) ‘narrative identity’ concept, ‘Stories of the Museum’ addresses the value of storytelling for understanding research perspectives and ethical issues, their possible implications for individuals and anticipating future relations and meaningful encounters in museum contexts.

The installation consists of two listening stations, where users can browse through the different recordings by category or by tags, and a story booth – recording assembly – for life recording, which invites visitors to tell their own, museum related story and upload it to the listening stations via a local network based on the MAZI toolkit. The wireless technology and free/libre/open source software (FLOSS) along with the recording application are installed on a Raspberry PI that provides a local network: only through the presence there, at the installation, visitors can access the WiFi with the SSID “MfN” and listen to the stories.
Opinion Boxes

Our main participatory tool developed in a Co-Design-Process are the interactive ‘Opinion Boxes’ placed in the exhibitions. Visitors are invited to impart their opinion at three different stationary boxes that are related to current ethical questions/research ethics and to specific exhibited objects. Visitors had the opportunity to note their answers on an attached postcard and insert it into the interactive box. The box prototype consists of an individual multiplex construction (white melamine), sensors to detect postcards and a mechanism to eject a feedback-postcard to the user when a contribution is made. The mechanism is based on an arduino, two stepper motor drivers, three micro switches, three light barriers, two nema 17 stepper motors as well as individually designed stripboards for electronic parts.
THE OPINION BOXES AS AN INSTRUMENT FOR SCIENCE LITERACY ENHANCEMENT

The central part for enhancing (critical) science literacy through participation in debates around scientific research topics, are the opinion boxes, where controversial debates linked to research projects at the MfN are discussed with visitors. As mentioned above, museums and especially science museums are highly suitable places to focus on social and controversies related to research topics due to their high credibility. The possibility to link an object to a research topic, to social or political debates and/or ethical questions, opens up a lot of different entrance points for debates generally only held in a very abstract context using high education level discussions. A participatory approach could therefore be a chance to enhance scientific literacy, critical thinking and/or deliberative abilities as visitors are asked to develop and discuss their own opinion and to use scientific thinking.

How can we engage visitors into these debates and animate visitors to connect single exhibits to larger contexts? Most exhibitions of the Museum für Naturkunde Berlin use an aesthetic view on nature to engage visitors. Linking this low-threshold entrance with social debate is a chance to reach completely different audiences. The opinion boxes link exhibits with social debates by asking visitors ethical question on research practice and applications of research. Based on the assumption that participation is especially fruitful on the overlap of the specialized knowledge with the social and ethical decisions, the opinion boxes include questions on research practice as well as application of scientific knowledge. A poster connected to the box breaks down the focus of the box into one eyecatching question like “Is it ok to name a new species after Donald Trump?” Visitors are further asked whether taxonomists may name species after celebrities and how museums should react when exhibiting species named after war criminals. The pre-test showed that many visitors got interested in the question and longed to share their opinion, but also wanted more information and discuss the subject. When designing the box, emphasis was put on making it visible in the exhibition without disturbing the atmosphere, to make it easily accessible for everyone and to make clear, how to use it. The eyecatching question is followed by a short introductory text.

The boxes are placed in front of a selected object strongly connected with the question and visitors are asked to fill in postcards answering questions about their point of view on research controversies. The second box asks visitors for their opinion as whether science is allowed to revive extinct species and under what circumstances, while the third one enquires whether a world without mosquitoes is desirable and under what costs.

To take the later question as an example, the opinion box on taxonomy is linked closely to the taxonomic research in our museum by placing it in front of an exhibit showing a wasp, named after the Dementors in the Harry Potter books by vote of visitors. A public workshop on taxonomy as well as a public activity naming a newly discovered insect take place in connection with the box and visitors are invited to take part in these events on the postcard.

The Consortium of European Taxonomic Facilities (CETAF) mentioned in its recently published statement on responsible research and innovation (RRI), that a closer dialogue with the public is important (CETAF 2017). Through the opinion box, we established a tool to open
a dialogue and triggered a process of opinion formation. In addition, we evaluated the answers and statements of the visitors. The results from the questionnaire will be given to taxonomists in the MfN. The questions of the two other boxes were jointly developed with the research project “GenomELECTION” that compiles socio-ethical, legal, and science communication related issues of modern methods of genome editing such as CRISPR/Cas9, TALENs and zinc finger nucleases, relating to their meaning for both research and application. Debates focusing on gene technology are highly structured by assumption which makes an exchange of position not fruitful at all. Therefore the questions posed on the opinion box renounce of specific gene-terms in a first phase. Results will be confronted with a second phase in which specific references are included.

**First results from the questionnaires**

The postcards of the opinion boxes each pose three questions with three answers to choose from. On the one hand, the possible answers limit interpretations and opinions, but on the other hand give the possibility for further evaluation. As we chose questions due to their relevance to research projects at the MfN, priority was given to easy evaluation and a place for comments was added.

Each box received around 150-300 postcards per week during the test period of 15 weeks (around 3000 questionnaires per box).

About 20% of all postcards contained further comments, some very elaborated and well-thought arguments and comments to the opinion boxes themselves. About 1% visitors who filled out the questionnaire indicated their interest in further information by giving an email-address or other contact information.

The results from the questioning are edited, published on the museum’s website and passed on to the scientists at the MfN working on the subject.

Additionally, the topics of the ‘opinion boxes’ were integrated into other formats. In this sense, questions posed at the opinion box on mosquitoes have also been raised at a public event of the GenomELECTION-project titled “A world without mosquitoes?” via TED voting. Both ideas will be integrated in a communication strategy and hope to profile and shape the (following the countless reports and statements on genome editing) so much wanted ‘public’ (Vohland et al. 2017).

**First results from observation and user interviews**

The opinion boxes enjoy high popularity. Observations in the exhibitions show that only about one quarter of the visitors who engage with the box fill in a postcard while others just read the questions and sometimes start a discussion with their peers. It is therefore likely to assume that the impact is even higher than the number of postcards indicates.

The observations also indicate, that visitors clearly understand the connection between the exhibit and the box, as we observed.

Besides the observations, students of the master’s programme ‘museum management and communication’ at the University of Applied Science (HTW) Berlin conducted evaluation
interviews. The final analysis of the interviews is still in progress, but first results suggest that the opinion boxes did bring new topics to the visitors and did result in a reflection on research ethics. Most interviewees indicated that they did never or rarely think about this topic before.

**DISCUSSION**

The participatory tools developed in the project ‘Visitor participation’ aim to integrate different perspectives into the exhibitions and research of the Museum für Naturkunde Berlin. Especially the opinion boxes open ethical questions related to research and the implication of scientific methods and applications to the public. The visitors gain insights into scientific processes and discussions and are asked to participate in these discussions. As we developed the opinion boxes with scientists working on the subject, the participation is not limited to a simple interaction with the exhibit but is taken up by the research. Science is presented as a process with open questions and ethical decisions. Following Hine & Medvecky (2015), presenting science as an open and unfinished process, enhances (critical) science literacy and the ability to think critical, form one’s own opinion and discuss scientific findings.

First results show that many visitors did engage into discussions with their peers while reading the questions on the posters of the opinion boxes. As interviews with participants showed that the topics addressed in the opinion boxes and the associated events were new to most participants, we suggest that the opinion boxes do contribute to science literacy and critical thinking. The questionnaires offered the possibility to give a comment as well as provide a contact address. Few visitors (around 1%) used the possibility to provide contact information, which possibly due to a general reserved attitude towards personal data. The fact, that around 20% of the participants wanted to contribute further than just checking boxes on the questionnaire shows an interest in engaging into further exchange of opinions.

We can therefore assume that we did open the ethical, application-oriented and procedural questions of scientific knowledge production into a broader debate, providing new insights and widening the perception of science.

The first results of the evaluation also suggest that most participants based their answers to the questions mainly on their relation to nature and their knowledge.

On one occasion the questions from the associated opinion box were posed to the participants of a panel discussion. First evaluations suggest that the outcome is quite different between these two samples. This suggests that audiences reached by a panel discussion as the usual mean of public engagement in science, is quite different from the audience taking part in the opinion boxes. The boxes do offer another entrance point into a debate that is mainly held by academics and publicly shared mostly via panel discussions. Those discussions are generally rather high-level measures that presume that there is a motivation on the part of the participant to engage in these debates. The museum offers the opportunity to integrate a far broader public. It needs to be further investigated, whether the opinion boxes and similar debating tools in the exhibitions are suitable tools to reach this broad public defined as participants in the debate on important societal questions.
OUTLOOK

The Museum für Naturkunde Berlin is currently under construction and is planning to open new participatory rooms. The collective room planning and the ideas developed in the workshops will be taken as the basis for further planning. The tools tested will be further evaluated and form the basis for the extension of participatory approaches at the Museum für Naturkunde Berlin.

As the evaluation suggests that the opinion boxes are a useful tool to a) bring new subjects and controversies to the visitors and b) bring new perspectives into the public debate on complex scientific topics strongly related to everyday life as for example the debates on genome editing, it seems fruitful to further develop the exhibitions of science museums as rooms for debate. The visitors of the museum seem to generate a much broader public engagement than evening events and panel discussions can generate. Following the request of broader public participation in science and social debates, the museum seems to be a suitable place for further experimenting with participation in scientific debates.

The interest of around 20% of the participants of the opinion boxes to give a comment can be interpreted as an interest to further discuss the subject. This interest should be addressed by offering further events and formats for debating ethical questions of research at the MfN.

ACKNOWLEDGEMENTS

The project is funded by the German Federal Environmental Foundation (DBU).

Special thanks goes to Fabrizio Lamoncha for the tent structure and to Lutz Reiter for adapting the MAZI digital infrastructure and to Michael Jurisch for the development of the opinion boxes.

STUDENTS’ CRITIQUE OF EPISTEMIC DECISIONS IN SCIENTIFIC INQUIRY

Yann Shiou Ong, Richard A. Duschl, and Julia D. Plummer
Pennsylvania State University, Pennsylvania, US

There is a call for school science argumentation interventions to shift from a focus on argumentation frameworks (e.g., TAP) towards a consideration of epistemic criteria used by the scientific community. One proposal for leading students to construct scientifically sound arguments is a focus on peer critique. This paper reports initial findings from a study aimed at testing the conjecture that an intervention focused on critiquing peers’ work can lead to students achieving a more robust critical stance of critiquing their own work. The study involves two science classes in a Singapore public school offering an open-inquiry science course involving an extended investigation designed and implemented by student groups over three semesters. One class experienced the intervention curriculum that emphasises peer critique using scientific soundness criteria. Data from peer review of progress reports (i.e. recordings of group discussions and written critiques) are analysed using the Productive Disciplinary Engagement (PDE) framework. Findings indicate significant difference in number of critiques within class than across classes, but no difference in most frequently used criteria across classes. This suggests the intervention alone cannot account for such difference. Findings also suggest groups that made fewer written critiques and demonstrated less PDE in both classes had significantly less teacher interaction, implying the way teacher interacts with students plays an important role in students’ engagement with epistemic tasks.

Keywords: classroom discourse, epistemology, argumentation

SCIENTIFIC ARGUMENTATION THROUGH PEER CRITIQUE

Argumentation is a key scientific practice essential to K-12 science education in policy documents including the US Next Generation Science Standards (NGSS Lead States, 2013) and PISA 2015 Science Framework (Organisation for Economic Co-operation and Development, 2017). Prevalent argumentation instruction, such as the Claims-Evidence-Reasoning framework (McNeill & Krajcik, 2012), focuses on components that a good argument is deemed to include. However, such instructional approaches omit essential epistemic criteria that experts use to construct and evaluate arguments in their field to ensure new knowledge claims added to their field are sound or free from errors (e.g., valid and reliable). Hence, a shift towards key epistemic criteria or what Chinn and colleagues call “epistemic ideals” (Chinn, Rinehart, & Buckland, 2014) is advocated. Persuading others to accept a claim based on evidence and reasoning includes critical intermediary epistemic decisions. A scientific argument for this study is thus viewed as a coherent persuasion for the scientific soundness of a scientific knowledge claim based on epistemic decisions made during the transformation of questions, actions, and ideas addressing measurements, data, evidence, models, and explanations (Grandy & Duschl, 2008).

Interpreting scientific argumentation as a practice means that its “grasp” should not be based on just following rules, but rather, involve engagement in iterative processes of critique and construction to improve scientific claims that represent nature, which is the aim of scientific practices (Ford, 2008, 2015). Shortcomings in prevalent argumentation instruction prompted
the design of the study intervention reported in this paper around students’ productive disciplinary engagement (PDE) (Engle & Conant, 2002) in construction and critique. Forman and Ford (2014) claim students achieve a “grasp” of scientific argumentation or a critical stance through learning to critique others’ arguments before demonstrating it in their own arguments. That is, they conjecture a critical stance is first achieved interpersonally then intrapersonally. This contrasts with Engle’s (2012) conjecture that accountability to the discipline develops intrapersonally then interpersonally. That is, students get better at accounting for their own ideas before getting better at holding their own ideas accountable to peers’ ideas then finally accountable to disciplinary ideas. In this paper, a person is considered to take a critical stance on scientific arguments if he or she constructs and critiques epistemic decisions in scientific inquiry based on epistemic criteria valued by scientific communities. The epistemic criteria introduced in the instructional design and identified in our data are described in the Method section. The intervention reported is designed to examine Forman and Ford’s (2014) conjecture, which suggests an instructional design with emphasis on peer critique is promising for developing students’ scientific argumentation and critical stance. Evidence of students’ PDE in construction and critique when making epistemic decisions for their own research or critiquing others’ decisions suggests a “grasp” of scientific argumentation.

Productive Disciplinary Engagement in Construction and Critique

To evaluate the effectiveness of the intervention design, a Productive Disciplinary Engagement in Critique and Construction (PDE-CC) framework was developed by interpreting the three core dimensions of the general PDE framework (Engle & Conant, 2002) and then using existing concepts and models developed by various researchers (refer to Figure 1) to establish a coding scheme.

The engagement dimension focuses on how group members interact with each other’s ideas and the patterns of engagement are broadly described by Walton’s dialogue types (Walton, 1998). The disciplinarity dimension considers whether critical epistemic decisions in scientific inquiry (Grandy & Duschl, 2008) were discussed and the extent to which epistemic criteria valued by scientific communities were used in students’ reasoning. The epistemic and non-epistemic criteria include epistemic ideals and reliable processes in the AIR model (Chinn et al., 2014) relevant to critiquing scientific knowledge products. The AIR model accounts for how people achieve various epistemic ends through three aspects. A stands for epistemic aims (e.g., produce knowledge claims) or values (i.e. the value individuals place on an epistemic aim), I stands for epistemic ideals (i.e. standards for judging soundness of an epistemic product, which is an outcome of achieving an epistemic aim), and R stands for reliable processes (i.e. evaluation of an epistemic product based on the reliability of the process for producing it). The productivity dimension considers the extent to which group discussion leads to progress in knowledge (Bereiter & Scardamalia, 2014) by improving an epistemic decision. An epistemic decision is improved to the extent challenges (e.g., errors or problems) to the initial decision or idea are overcome (i.e. new decision or idea no longer have the identified errors or problems) or rebutted (i.e. initial decision is successfully defended and continues to hold). Based on the interpretations of the three dimensions, coding schemes were developed to capture differences in engagement, disciplinarity, and productivity of group discussions of epistemic decisions.
This paper focuses on students’ critique practice when examining two of their peers’ epistemic decisions: (ED1) data to collect and ways to collect them, and (ED2) data to select as evidence. The research questions are: RQ1. What criteria do students use to critique peers’ ED1 and ED2? and RQ2: To what extent do students demonstrate PDE in critique in their discussions?

**METHOD**

**Study Context**

The research study spanned three school semesters across grades 8 to 9 in a Singapore public school. Two science classes, an intervention (Class A) and a comparative class (Class B) participated in the study. Class A comprises Mr. Gan, group A1 (Su, Xander, and Chris) and group A2 (Victoria, Jane, and Kang). Class B comprises Ms. Lee, group B1 (Ariel, Varun, and Norman) and group B2 (Audrey, Debbie, and Livie). All names used are pseudonyms. The first author acted as a co-teacher, moving between both classes to facilitate the lessons; e.g., when the teacher was absent or when students requested assistance. Each class met once a week for 1.5 hours to design and implement an open inquiry investigation related to a physics topic of their choice. The total instruction time approximates 42 hours. Groups were asked to select a research question from a list of International Young Physicists’ Tournament (IYPT) questions (“IYPT Problems,” n.d.). Each group worked on the following research topics (associated physics concepts are listed within parentheses): A1 – wobbling suitcase (stability and centre of gravity), A2 – soap bubbles on vibrating water (ultrahydrophobicity), B1 – water lens for...
burning (optics), and B2 – pot-in-pot refrigerator (evaporative cooling). Both teachers are Physics teachers with prior experience in mentoring middle and high school students for science research and conducting physics research as undergraduates. At the point of the study, Mr. Gan has longer teaching experience (seven years), while Ms. Lee (three years’ teaching experience) has more extensive research mentoring experience as she has also mentored undergraduate students.

In Semester 1, class A experienced the intervention curriculum that emphasises peer critique of research literature, poster, and investigation plan using three scientific soundness criteria negotiated with the students: 1) Accurate and reproducible data with minimum errors that answers the research question, 2) Conclusion is tied to data interpretation, and 3) Consideration of scientifically accepted concepts and methods. Class B experienced a teacher-centred critique of the same research elements, and was given an identical list of the criteria at the beginning of Semester 2. Data for this paper comes from a peer review session where each group reviewed the progress reports made by the two groups from the other class. Each group is provided a review handout with guiding questions. Groups A1 and B1 chose to fill in an electronic version of the handout. Data include each group’s written reviews and video recordings of their discussions.

Outline of Coding Schemes

To answer RQ1, written comments on ED1 and ED2 were analysed since all groups have minimally considered these EDs up to the point they submitted their progress report. Comments were coded based on the criteria coding scheme developed by the first author (refer to Figure 2). An initial list of criteria was generated using Ideals and Reliable Processes suggested by Chinn et al. (2014), then revised based on the analysed comments. Three of the epistemic criteria - reliable and valid processes, internal coherence, and external source correspond to the scientific soundness criteria introduced to the students.

To answer RQ2, event maps were created from video recordings of each group’s discussion (Kelly, 2014). Phase units were established based on the instructional activity, such as teacher instruction for completion of peer review task or group discussion of one peer group’s report. Sequence units were identified within phase units based on the discussion topic. For example, scientific talk about a particular epistemic decision and task management talk about where to write the group’s comment on that decision count as two topics. Each group’s most salient topic pertaining to ED1 or ED2 critique was transcribed. A salient topic is one where talk on the same topic is sustained over a longer period, rather than short episodes of stating or elaborating a critique then moving on to the next topic or idea. Thus, group talk over a salient topic it is more likely to involve higher levels of engagement of interest to us. Each speaker turn was analysed for its conversation move (idea, add, support, challenge, agree, disagree or not applicable).

<th>Criteria (code)</th>
<th>Definition</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Justification (jus)</td>
<td>Whether an idea is justified using reasoning or evidence.</td>
<td>There is not enough evidence.</td>
</tr>
<tr>
<td>Reliable and valid processes (rVP)</td>
<td>The reliability or validity of the measurement or analytical process.</td>
<td>Describe the observation more specifically and precisely. E.g. number of bubbles = 5</td>
</tr>
<tr>
<td>Internal coherence (int)</td>
<td>The coherence of parts of/overall argument for a claim. Includes whether the relationship between variables is made explicit, whether reasoning is internally consistent/non-contradicting, and whether explanation or model accounts for all available data.</td>
<td>How does temperature affect size of focal point?</td>
</tr>
<tr>
<td>External source (ext)</td>
<td>Whether an idea is supported or suggested by an external source, such as an online resource, a person of authority (e.g., science teacher), referenced scientific concept or method in an article or textbook.</td>
<td>As what the teacher said, they don’t have enough information in the procedures for someone else to redo the experiment.</td>
</tr>
<tr>
<td>Communication goodness (comm)</td>
<td>How well an idea is communicated, including whether the idea/information is present, clear, or understandable, and whether scientific language and representation modes are used or used accurately.</td>
<td>What do you mean? Please elaborate.</td>
</tr>
<tr>
<td>Practicality (prac)</td>
<td>Whether an idea is practical in view of available resources, know-how. Or applicability to real life, etc.</td>
<td>Changed too many variables. Too tedious.</td>
</tr>
<tr>
<td>Personal experience (per)</td>
<td>Whether an idea agrees with one’s personal experience, such as anecdotal accounts.</td>
<td>We had so many problems just with soap concentration. They are doing 9 sets of experiments with 3 variables. They will have a lot of problems.</td>
</tr>
<tr>
<td>Others (oth)</td>
<td>Other criterion used to support or challenge a claim.</td>
<td>I couldn’t think of any other ideas.</td>
</tr>
<tr>
<td>Not applicable (NA)</td>
<td>A suggestion for alternative decision without indicating why the alternative is better than the initial decision.</td>
<td>Use a hard water bottle.</td>
</tr>

**Figure 2. Criteria coding scheme for Disciplinarity dimension.**

An illustration of how the conversation moves are interpreted is shown in the following “count bubbles” excerpt from group B2 and Ms. Lee’s discussion of group A2’s data as reported in their progress report (Table 1). Prior to the excerpt, Debbie and Audrey were critiquing group A2’s data collection methods while Livie was reviewing group A1’s report. Audrey asked Ms. Lee if data collection methods meant making a graph. Ms. Lee clarified graphs are relevant to data analysis; data collection referred to how values are taken. Ms. Lee asked what they could tell from the pictures group A2 used as data, to which Debbie replied “nothing”. This led to the “count bubbles” discussion (turns 1 to 13).

In turn 1, Ms. Lee introduces the idea that group A2 can count the bubbles present in their cluster of bubbles floating on the surface of a petri dish filled with water. This is an alternative to A2’s initial idea of showing pictures as their data. Debbie interjects Ms. Lee in turn 2, which is considered an add move. Audrey adds to the idea by specifying A2 can state the number of bubbles (turn 4). In turn 5, Debbie challenges Audrey’s claim by saying A2 did state their observation. Turn 6 sees Ms. Lee disagreeing with what Debbie said. This is followed in turn 7 by Debbie’s elaboration of her challenge (coded as challenge), and a rebuttal from Audrey in turn 8 (coded as challenge). Debbie questions if A2’s reported observation had to be “so specific” (turn 9), to which Audrey and Ms. Lee responded with supports for their idea (turns 11 and 12). The excerpt ended with Debbie’s agreement to the idea (turn 13).

The pattern of engagement is inferred based on the conversation moves made and the speaker of the move. The discussion reflects a critical stance if challenge moves are present and followed by extended discussion of the challenge raised, as indicated by further challenge or support moves, or alternative ideas (i.e. idea move) in view of the challenge presented. If the challenge moves are predominantly made by the teacher, then the critical discussion is teacher-led. Conversely, if the challenge moves are made by students and teacher, then the critical discussion is peer-led. Critical discussions are considered as describing high level of engagement in construction and critique. If the discussion mostly involved add and support moves, with few challenge moves that are not further discussed, then it is considered as idea-building. If the discussion comprises a series of question moves and responses to the question, then it is predominantly an information seeking session. Finally, if the discussion mostly
involves individual students elaborating on or explaining one idea such that multiple ideas, if any, develop in parallel, then the discussion resembles an exposition. In the “count bubbles” excerpt, the critique in turn 5 was followed by multiple challenge and support moves made by students and teacher in discussion of the critique, Thus, the excerpt is considered a peer-led critical discussion.

Two aspects are used to determine whether the discussion is disciplinary. First, relevancy of the topic to one of the four epistemic decisions is determined. This aspect is met for all the discussion topics analysed in this study since only the longest topic related to ED1 or ED2 is analysed. Second, reasons used in the support and challenge moves were categorized as one of the eight criteria listed in Figure 2. Discussions of an epistemic decision involving the use of epistemic criteria as reasons to support or challenge are considered more disciplinary. In the “count bubbles” excerpt, the reasoning in turns 5 to 8 is based on the communication goodness criterion (non-epistemic) as the clarity of information presented in A2’s data is debated. The reliable and valid processes criterion (epistemic) is evoked over turns 11 and 12 to support the suggestion for A2 to count and state the number of bubbles (turns 1 and 4): reporting number of bubbles in each cluster enables readers to tell how different the clusters are, which relates to the validity of the reported claim about cluster differences.

Finally, in the context of critiquing peer groups’ progress reports, a group discussion is minimally productive if the discussion led to making a decision, that is, making a critique of the peer group’s progress report. The discussion is moderately productive if it leads to identifying an error or problem in the initial critique or if the group addresses the critique i.e. addresses the identified error or problem through rebuttal or strengthening the support for the initial critique, such that the initial critique still holds. The discussion is highly productive if it leads to an improved decision or critique that overcomes the identified error or problem with the initial critique. The “count bubbles” excerpt is productive to the extent of addressing the critique posed (turns 5 and 7) as the initial suggestion for the peer group (turns 1 and 4) was successfully defended (turns 11 and 12).

FINDINGS

Considering students’ written critiques, class A made a total of 76 critiques (A1 = 18; A2 = 58), of which 55 (A1 = 13; A2 = 42) are on ED1 and ED2. Class B made 53 critiques (B1 = 10; B2 = 43), with 26 (B1 = 1; B2 = 25) for ED1 and ED2. Answering RQ1, ED1 and ED2 critiques fall under six categories in the Criteria coding scheme (Figure 2). The number of critiques made per group according to criteria is shown in Figure 3. Communication goodness is the most frequently used criterion by both classes (A = 27.3% of A’s ED1 and ED2 critiques; B = 69.2%) and also the top criterion used by group B2. That is, most groups critiqued that their peers did not communicate their epistemic decisions clearly or did not include scientific representations such as graphs in the progress report.

The second most frequent criterion is reliable and valid processes (A = 27.3%; B = 15.4%). This is also the most frequent criterion mentioned by group A2. Under this criterion, groups typically questioned their peers’ experimental procedures, challenging the reliability or validity of their measurements. For example, group B1 reported they experienced “sunny weather for
all 3 experiments” conducted. Group A2’s comment, “how do you know the brightness of sun ray is exactly the same?” called into question how B1 ensured the factor, brightness of sun light, remained constant for their experiments. The third most frequent criterion is justification (A = 16.4%; B = 7.7%), which is the top criterion by group A1. Students use this criterion when they ask their peers to provide reasons for their epistemic decisions, such as groups A1 and A2 both requesting group B2 to give their reason for selecting the three variables in their investigations.

Other criteria used in the students’ critique are, in descending order of frequency: internal coherence (A = 14.5%; B = 3.8%) and practicality (A = 10.9%; B = 3.8%). Two comments by group A2 are categorised as not applicable as they are suggestions for materials to use in B1’s investigation rather than critiques.

Figure 3. No. of ED1 and ED2 critiques by criteria per group.

To answer RQ2, a summary of the PDE analysis for each group, based on their most salient discussion topic, is shown in Table 2. The engagement patterns are reported in their sequence of occurrence during the most salient topic discussion. The teacher’s participation in various engagement patterns is indicated, where relevant.

Engagement Findings. A1, A2 and B2’s discussions included critical discussion where an initial critique or judgement about a peer group’s decision was challenged by another member, followed by conversation moves challenging and supporting the decision. In contrast, B1’s discussions involved only information seeking and idea-building where different members (another student or the teacher) responded to questions or added to an idea without making challenges. Other engagement patterns, such as exposition, information seeking, and/or idea-building are also observed in groups A1, A2, B2’s discussions. This indicates group conversations underwent shifts in engagement patterns. For example, B1’s discussion initially resembled information seeking led by Ms. Lee who asked a series of questions to help B1 realise the problem with A2’s data. Students in B1 then went on to discuss how to phrase their
critique, building and elaborating on the problem with A2’s data (it lacks statistics) and what data should be provided.

**Disciplinarity Findings.** All group discussions included epistemic criteria (bolded in Table 2) to various extent. Group A2 utilized the most number of epistemic criteria (four) while the other groups utilized one (A1 and B2) or two (B1) epistemic criteria. All groups also utilized one non-epistemic criteria in their discussion.

**Productivity Findings.** All group discussions involved identifying errors in their peers’ report. In addition, groups A1, A2, and B2’s discussions addressed challenges raised about the initial critique.

</tbody>
</table>

The large difference in topic duration across the groups in class A (from A1’s 1.5 min to A2’s 5 min) warrants further investigation. A check on the total amount of time spent on critiquing peer groups’ reports shows the following: A1 spent a total of 24.5 min on critiquing, while A2 spent 48 min. In class B, B1 spent 26 min while B2 spent 41 min critiquing. A review of the video recordings suggests Mr. Gan spent more discussion time with A2 while Ms. Lee spent more time with B2. Interestingly, B2 adopted the strategy of division of labour. Livie worked on critiquing one peer report mostly on her own, while Audrey and Debbie worked on another report. The students then swapped the reports. B2 students occasionally asked Ms. Lee questions as she sat at their table for most of the lesson.

**DISCUSSION AND CONCLUSIONS**

Our findings suggest groups in the same class did not make similar number of critiques. This suggests the PDE-CC intervention alone cannot account for differences in students’ written critique quantity. The findings also suggest good communication, in terms of clarity, and justification of epistemic decisions, are important in communicating scientific epistemic
decisions to peer reviewers before they can be critiqued. Furthermore, groups were able to critique the reliability and validity of their peers’ research processes, even though the groups worked on different research problems. At the class level, most critiques from class B are based on communication goodness, while most critiques from class A are based on communication goodness as well as reliability and validity of processes. A comparison of the details provided in the progress reports suggest groups A1 and A2 provided less details in their report than groups B1 and B2. During the peer review lesson, students from A1 and A2 expressed concern that their report contained too little information, as they thought their report would only be reviewed by the peer group in class A, who were familiar with their research due to several peer review activities in the previous semester. This might account for why collectively, groups B1 and B2 made so many critiques on the communication goodness of A1 and A2’s reports. Nevertheless, even with more information provided by B1 and B2, their reports were still critiqued as lacking in communication goodness by A1 and A2.

In terms of PDE-CC, groups A2 and B2’s discussions included peer-led critical discussion and thus can be considered to demonstrate greater engagement than A1 (peer-led critical discussion) and B1 (idea-building). A2 also demonstrated greater disciplinarity by holding members’ ideas accountable to more epistemic criteria valued in science (Forman & Ford, 2014) compared to the other groups. Groups A1, A2, and B2’s discussions were more productive than B1’s discussion as the initial critique in the former stood up to group members’ challenges while B1’s initial critique went unchallenged. Therefore, group A2 demonstrated the highest PDE-CC extent while group B1 demonstrated the least PDE-CC extent among the groups in the peer review session.

Furthermore, groups A1 and B1 who made less written critiques and demonstrated lesser extents of PDE-CC also had less teacher interaction time. This suggests not only does students’ awareness of, or prior practise with epistemic criteria (in the form of scientific soundness criteria), affect their engagement with an epistemic task (e.g. peer review), the way their teacher interacts play an important role, too. In addition to the teacher’s role in introducing a challenge to the discussion, his or her role in providing alternative ideas may also affect students’ PDE-CC in further discussion of the alternatives. In other words, the teacher’s interaction with students provides disciplinary framing of the epistemic practices and knowledge valued by scientific communities.

Our findings lead to more questions that warrant further investigation using more extensive data corpus from the study. To what extent does teacher’s involvement affect groups’ PDE in scientific argumentation? Are groups capable of PDE-CC when making epistemic decisions about their own inquiry without the teacher’s involvement, and under what circumstances? Does this capacity for self-sustained PDE-CC change over time? These questions contribute towards the broader research aim of figuring out whether an intervention focused on critiquing peers’ work can lead to students achieving a critical stance of critiquing their own work.
ACKNOWLEDGEMENT

The authors would like to thank the students and teachers for their participation in the study, as well as members of the Penn State College of Education SCIED Classroom Discourse Group led by Professor Greg Kelly for their valuable suggestions leading up to this paper.

REFERENCES

Language in science plays an important role in a country like Malta with two official first languages, Maltese and English. Proficiency in both languages varies with some students exposed to English mainly at school and limited at home, while others use English as their main language both at home and school. Some scientific technical terms such as energy, weight and work have different meaning in everyday language, which may explain why students who are highly proficient in English still struggle to speak and write science effectively. This study examines whether adopting inquiry-based learning strategies in the Physics classrooms is able to promote more proficient use of scientific language appropriately among bilingual students in Malta.

Keywords: inquiry, physics, scientific language

THE TECHNICAL LANGUAGE OF SCIENCE: A BARRIER?

Students need to understand scientific concepts well (Sutton, 1993) as well as be able to talk and write about them effectively. Learning science effectively thus involves more than comprehension, but also learning the technical language/vocabulary of science (Farrell, 1996; Wellington & Osborne, 2001). Otherwise, the scientific technical language ‘sets up a barrier to comprehension, which for some pupils, may appear as an impenetrable discourse beyond their ken’ (Wellington & Osborne, 2001, p.66). This makes the language of science ‘a major barrier (if not the major barrier) to most pupils learning science’ (ibid., p.2). Since learning to speak the language of science requires learners to master the language of science (Rollnick, 2000), students need to be provided with opportunities to use language, i.e. talk science. It is thus vital to provide students with opportunities to speak and use the language of science.

Language and the learning of Physics in Malta

Both English and Maltese are the official languages in Malta, even if education is mainly in English. The official policy is that lessons, textbooks and assessments of all science subjects are to be in English throughout compulsory education up to tertiary level. Despite this policy, in the Physics classrooms in Malta, many teachers tend to code switch between both languages when teaching, even if some strict use of the English language has also been reported (Mifsud, 2012). The level of proficiency in English among secondary students varies from high proficiency to limited vocabulary and understanding. This is the main reason why code switching is the most common practice in the Physics classrooms. English language proficiency among secondary level students is overall a challenge (ibid.).

The role of language in learning Physics

It has often been argued that to be scientifically literate one needs to be ‘knowledgeable about science topics, concepts, processes and methods’ (Hand, Yore, Jagger & Prain, 2010, p.49) and
also be competent in interpreting and creating science texts (Norris & Phillips, 2003). Therefore, students not only need to understand Physics, but they also need to be able to talk and write Physics. It is thus vital to provide students with opportunities to speak and use the language of science, as spoken language plays an important role in language development (Wellington & Osborne, 2001). Furthermore, the difficulty in language experienced by the students could be a result of the difference in interpretation between what the teacher says and what the students understand. It is thus necessary to provide students with opportunities to express themselves both orally and in writing, as not only can such opportunities improve their ability to “talk science”, but the teacher can also obtain immediate feedback about their understanding (Lemke, 1990). Classroom talk can be an effective teaching and learning strategy that enables students to improve their use of scientific understanding and scientific language. This begs the question of whether this can be achieved through inquiry-based learning approaches, which can act as a ‘gateway for using language to speak’ (Huerta & Jackson, 2010, p.207). Student involvement is also considered essential for scientific language acquisition (Bergman, 2013). Student involvement is a key characteristic in any inquiry setting, promoting discussions, which are powerful mechanisms in learning to talk science (Shwartz et al., 2009).

AIMS OF RESEARCH

Research has shown that when students are provided with opportunities where they have to discuss and make use of their ideas, their understanding of content is enhanced (Windale, 2001; Harris & Rooks, 2010). This provoked interest in finding out whether using more discussions within an inquiry-based approach in my classroom would result in a better understanding of Physics. The aim of this research is to find out whether adopting an inquiry-based learning approach with a focus on supporting language use (technical and everyday) might be a “vehicle” that enhances greater proficiency in talking about scientific concepts in Physics.

This research was carried out as part of my (Naomi Attard Borg) PhD research with students who had good proficiency in English. Though language barrier of everyday use of English was low among my students, they still struggled to express their ideas and to make proper use of scientific terminology when learning Physics. This study was thus guided by the following research questions:

- Does inquiry in Physics promote talk?
- Does talk support better understanding?
- What type of teacher support best enhances scientifically-based talk?

Inquiry-based learning (IBL)

Across the literature, the spectrum of IBL conceptions is rather wide-ranging. A number of authors (Tafoya, Sunal, & Knecht, 1980; Walker, 2007) have endeavored to distinguish IBL according to the type and complexity of the task, and also according to the amount of engagement and responsibility carried by students. Colburn (2000) classifies IBL lessons into structured, guided and open inquiry. Furthermore, in an inquiry based setting, learners are required to engage, explore, explain, elaborate and evaluate, (Bybee, Taylor, Gardner, Van
Scotter, Powell, Westbrook, et al., 2006). The table below (Table 1) provides a summary of the three types of inquiry and the requirements of each type.

Inquiry and scientific language

Certain words used in Physics have different meanings from their everyday use (Wessels, 2013). If students use the meaning of a word in everyday correctly, it does not automatically mean that they will equally understand it and use it correctly in other situations (Cassels & Johnstone, 1985). Students need to learn the ‘very specific ways of using these words appropriately in a scientific context’ (Schwartz, Sadler, Sonnert, & Tai, 2009, p.83). An explanation is not enough for the students to learn the scientific vocabulary (Carre’, 1981). They need to be provided with several opportunities ‘that require them to talk about science, to use scientific words and to share and construct their own meanings of these words’ (Wellington & Osborne, 2001, p.84). A good means to promote talk would be engaging in a discussion; considered to be one of the most valuable vehicles for learning the scientific language (Huang, 2006). Discussions provide the students with the opportunity to have pupil-pupil talk and teacher-pupil talk.

Discussions are fundamental in an inquiry-based setting as students have to discuss and share ideas, explain the reasons behind their choice of methods and discuss their conclusions, thus, talking science (Heitmann, Hecht, Schwanewedel, & Schipolowski, 2014). Therefore, an inquiry-based setting provides students with an opportunity to learn how to use scientific language correctly and cogently, through monitoring and instructional support.

**METHODOLOGY**

Since the aim of this research was to find out whether adopting an inquiry-based learning approach affected the students’ ability to discuss effectively and developed their proficiency in scientific language, action research was considered as the best option.

Action research is considered to be a ‘powerful tool for improving the quality of teaching and learning within a school community’ (Tillotson, 2000, p.32). In this study, as a teacher, action research was considered as a mean to develop hypotheses about my teaching and use it to enhance my teaching. Thus, I could evaluate my own pedagogy, and influencing my practice throughout the process of data collection. Research-informed changes to my practice were made, as my intention was to improve the learning of my students, and considering other ways of improving my teaching. Though action research was considered to be the most adequate methodology for this study, I was also aware of its limitations (Cohen, Manion & Morrison, 2011) that: gathering and analysing data was quite time consuming; research was not completed...
within one scholastic year; and the findings are limited to my students and me within my institution, thus cannot be generalised.

Several research tools common to the qualitative research paradigm were used, such as document collection, students’ work and also audio recordings of lessons to collect data about the lessons piloted. The data sources are explained in Table 2.

This paper targets the piloting stage of my PhD research. The pilot study was carried out in a co-ed state school with first year Physics students. Three activities based on inquiry-based learning, were carried out as pilot studies with my class of Physics students. The third activity was a follow up lesson of the second IBL.

ANALYSIS

For the first activity, a guided inquiry approach on the topic “Heat Losses” was adopted. Such an approach is normally used when students lack confidence in inquiry-based work (Colburn, 2000). Since my students lacked confidence in inquiry-based work, guided inquiry was considered to be the best approach. This activity was more oriented towards mastering factual content rather than raising questions and problem solving. Students were expected to make connections between their observations and the theory that they were previously taught and also to make use of scientific terms, such as convection currents and heat losses correctly.

The main reason for choosing this activity was to promote more discussion and scientific talk about applied phenomena. The students were divided into two groups and each group was given two model houses of identical material and a sheet to record the temperature changes was provided. Most of the talk was initiated by myself, as their facilitator/challenger and the scientific talk was also promoted by me. Throughout the discussion, the students were only able to observe patterns but unable to make connections with the content taught in the previous lessons. This was a result of the students not being used to such learning experiences and also because they struggled to express their thinking verbally. This lesson gave rise to the following
questions: Should inquiry-based activities be structured at first? Should the teaching approach be different? These questions were kept in mind when the second pilot lesson was planned and thus, for the second activity, a structured inquiry was considered to be more appropriate as ‘important aspects of a task or concept are highlighted’ (Hushman & Marley, 2015, p.372) and it also allows ‘teachers to customize and scaffold learning experiences’ (Webb, 2009, p.27), which was evidently needed from the analysis of the first pilot lesson.

The evaluation of the first activity thus guided the action planned for the following part of the pilot study, i.e. the second IBL activity, which required careful structuring, taking into consideration where and why aspects of the previous lesson had failed. I needed to be more circumspect in planning the second activity, which was about floating and sinking as a result of the density of the liquid. The questions in the handout were specifically designed to scaffold learning, by asking the students to predict which liquids would float on water and which would sink, discuss their predictions and write their explanations, carry out the experiment and observe what happens, collect data, compare the results with their predictions, explain the difference (if any) and were also encouraged to use scientific terms/concepts learned. Thus, evaluating and reflecting on the outcome of the first IBL activity through listening to the audio-recordings was invaluable.

The transcripts of the second IBL activity showed that the type of questions posed facilitated learning, however, they were not enough for deeper understanding to take place (Lombard & Schneider, 2013). Though the students understood that objects with a larger density than that of water sank, none of the students made reference to the ratio of mass per unit volume of the liquid that sank was higher than those of the liquids which floated, as the quote below highlights:

*Maple liquid went to the bottom. Letter C is the largest number so we think that maple has the largest density, greater than that of water.*

During the follow up lesson, a question and answer sequence was adopted. This was not used just to test the students’ knowledge, but mainly it aimed to guide their development of understanding. The ‘why’ questions which I posed led to utterances that gave more appropriate explanations. In fact, asking ‘why’ questions turned out to be ‘a very effective tool for students’ thinking promotion’ (Larrain, Howe & Cerda, 2014, p.12). This can be seen from the short extract below.

*Teacher:* Each bottle contains 20ml of liquid. Each bottle contains a different liquid. What do you think will happen to the bottles if I put them in a bowl full of water?

*Student A:* I think that the one containing oil would float?

*Teacher:* Can you explain why the bottle containing oil will float?

*Student B:* Oil always floats.

*Teacher:* Oil will float on water. Can you explain this in terms of density?

*Student B:* mmmm the density of oil is less than that of water? Yes?

*Student D:* Yes it is.
Teacher: All the bottles contain the same volume. Can someone tell me what other variable affects the density of an object?

Student F: Their mass.

The fact that by the third activity the students were able to explain things more clearly and made connections, suggested conclusions and made use of scientific language appropriately sheds lights on how powerful repeating activities can be. Furthermore, such a structured approach indicates that when learning is scaffolded, understanding takes place (Lombard & Schneider, 2013). Table 3 provides quotations to show how the contributions improved in quality and understanding between the first, second and third sessions.

Table 3. Quotes showing improvement in quality and understanding

The key findings of this research are summarised below:

- A structured approach seems more effective in promoting learning when compared with an approach that offers minimal guidance, especially among students not used to inquiry and talking science;
- Through a structured approach, students do not only learn facts, but also to make better connections, inquire, and also to talk about the science learned.
- Scaffolding the students’ learning tends to help them construct knowledge as well as how to talk about concepts learned;
- The teacher’s role should be that of a challenger and an intervener, as students’ thinking and reasoning are encouraged and stimulated;
- The composition of the groups is a vital factor for learning to be achieved.
DISCUSSION

The pilot study has shown that structured and guided activities indicate that they have the potential to promote gains in content understanding when compared with an approach that offers minimal guidance (Hmelo-Silver, Duncan & Chinn, 2007; Kirschner, Sweller & Clark, 2006). They have also shown that such approaches facilitated improvement in my students’ proficiency in science language, especially among students not used to inquiry and talking science. Furthermore, it was also found that when my students were encouraged to answer follow-up questions based on their answers, it served as scaffolding to support conceptual understanding. Thus, students need to be doing science, ‘with judicious teacher assistance and support’ (Hodson, 2014, p.2547) until they become more skilled and more confident before engaging in open-ended inquiries, where the role of the teacher is less active (Burgh & Nichols, 2012) since unguided inquiry gives students more independence.

This research also supports the way Foster (2014) described the role of the teacher in an inquiry setting, that is, the importance that the teacher steps back and avoids committing ideas. In fact, I adopted the role of a challenger and asked close-ended questions at the initiation stage, which helped my students put their ideas in their own words. Open-ended or divergent questions were also asked to stimulate their thinking and reasoning skills and to improve their ability to talk science. Moreover, this research showed that when my students were given more responsibility and autonomy in their learning, it tended to have a positive effect on their thinking and language development.

It is important to mention that for the pilot studies of my PhD research, which this paper targets, my students were encouraged to discuss in English, and though their English proficiency is considered to be good, the students came from Maltese speaking families. Though they are fluent in both languages, the fact that they had to share their thinking verbally in English could have been a barrier to share their ideas correctly. This will be looked into in the actual research. In fact, for the actual research, structured approaches where questions in handouts and questions posed by myself throughout the activities will be solely in English and their written answers will also have to be in English, however, the students will be encouraged to discuss in any language they feel mostly competent in.

CONCLUSION

This study has shed some insights into the close relationship between language and understanding. It showed how focus on language during inquiry has the potential to promote both understanding as well as students’ proficiency in talking science. As part of my action research, I will delve further into the role of language by promoting scientific talk and understanding.

ACCESSING SCIENCE THROUGH CLASSROOM TALK
WHEN ADOPTING A CLIL APPROACH

Laura Tagnin¹, Máire Ní Riordáin² and Mary Fleming¹
¹National University of Ireland, Galway, Ireland
²University College Cork, Cork, Ireland

Over the past two decades, CLIL (Content and Language Integrated Learning) has become an integral part of most European educational systems. However, research into CLIL has looked at it primarily through the lens of language learning research. The perspective of this research is to empirically examine CLIL through the lens of science education research. This study incorporates a qualitative approach to investigating science learning opportunities in a senior secondary science classroom in Germany that implemented a CLIL approach to teaching and learning biology through English.

We focus on the conceptualization of language-as-resource for learning and teaching science and we investigate this in the classroom talk. The research question is concerned with the following: what language practices foster opportunities for learning science in a CLIL classroom setting at upper secondary level? The methodological approach used is framed by a sociocultural perspective on learning. The empirical data gathered consist of the transcripts of five science classes of 50 minutes’ duration each, that were observed and audio-recorded. In the presentation of findings, language practices that emerged from the analyses of several classroom instances are examined. Some of these practices, such as language focus, code-switching and exploratory talk support the view that linguistically challenging situations contribute to generating opportunities beneficial for science learning. An additional key finding was the dominance of an authoritative communicative approach to classroom talk, which potentially hinders students’ learning. We argue that language has the potential to be a resource rather than a barrier in the CLIL science classroom.

Keywords: CLIL, Science learning opportunities, Language-as-resource

INTRODUCTION

The role of language in the learning of science has increasingly attracted interest among the community of science education scholars (Carlsen, 2007). In science education, language is considered an essential tool not only for communicating, but also for thinking, meaning-making and for negotiating that meaning within communities (Yore et al., 2004). Accordingly, from a socio-cultural perspective “Teaching science involves introducing students to the social language of school science.” (Chin, 2007, p. 816). However, teaching and learning the language of science often entails taking on new challenges. In particular, this is due to an increasing population of students who are learning science through a language which is not their first (Lee & Fradd, 1998). An example of this phenomenon is provided by the adoption of bilingual programs all over Europe. Since the 1990s, many European policy makers have enthusiastically adopted a bilingual education approach – namely Content and Language Integrated Learning (CLIL) – as a lever for success in foreign language learning and in the general process of Europeanisation. As a result, the teaching and learning of many school subjects, such as science, through the medium of a foreign language (often a lingua franca such as English) has become an integral part of most European educational systems (Nikula & Dalton-Puffer, 2014).
However, research into CLIL so far has been conducted mainly by language experts who have produced a body of research mostly focused on language (Paran, 2013) and the aspect of content subject competence has comparatively been under-researched (Pérez Cañado, 2017).

This study is intended to look at CLIL science classrooms from the point of view of science learning and teaching. We interpret science learning within a sociocultural theoretical framework (Kelly & Crawford, 1997; O’Loughlin, 1992; Vygotsky, 1978). Our study is based on three main assumptions. First, science has its own language. To develop scientific knowledge, students need to understand the specific use of language in science class (Lemke, 1990). Second, language is used for “interthinking”, i.e. for the joint creation of knowledge (Mercer, 2000). Third, researchers from the bilingual field agree that students’ home language is a resource that supports students’ knowledge development and their understanding of all school subjects (e.g.: Cummins, 2005; Setati, Molefe, & Langa, 2008) but no such research exists for either science education or CLIL approaches.

The focus of this study is on the conceptualization of language-as-resource for learning and teaching content, instead of language as a barrier (Chitera, 2011; Moschkovich, 2002; Planas & Civil, 2013; Planas & Setati-Phakeng, 2014; Setati et al., 2008). In particular, this study aims at investigating the relationship of a CLIL classroom setting with the creation of opportunities that may be beneficial to science learning. This relationship is explored in instances of classroom talk as similarly done by Planas (2014) in the field of mathematics education. The aim of this investigation is achieved by exemplifying classroom language practices triggered by language-related difficulties that have been revealed to support the learning of science when a CLIL approach is implemented. The research question is concerned with the following: what teacher and student language practices foster (or hinder) opportunities for learning science in a CLIL classroom setting at upper secondary level?

METHODS

This paper is derived from an on-going PhD study and refers to a part of a multiple case-study research project. The data were collected in a German secondary school (Gymnasium) that emphasises the learning of languages through both English as Foreign Language instruction (ELF) and CLIL. All the students are provided with six hours per week of ELF instruction in Grades 5 and 6 (students aged 10 to 13 years); and from Grade 7, they receive CLIL-instruction (bilingualer Fachunterricht) in history and 4 hours of ELF per week. Progressively, other bilingual subjects are added each year and are maintained until the end of Grade 11: geography starts in Grade 8 and biology in Grade 9. The school’s policy on CLIL instruction is for the students to achieve a near-native fluency in English and to also provide the students with the necessary disciplinary German vocabulary. In Grade 12 – the last year of instruction – the classroom language is German in all the subjects because the final exam (Abitur) is in German.

The participants we refer to in the present paper are the students of a Grade 11 classroom (students aged 16 to 17 years) and their female science teacher. They have been learning bilingual biology since Grade 11, two hours per week. The observed classroom consists of 14 girls and 5 boys, with good or excellent competences in the second language, in this case English.
English. The science teacher has an extensive experience of bilingual teaching gained essentially through practice.

This paper refers to the data collected during a set of five science lessons of 50 minutes’ duration each on the topic of protein synthesis, scattered throughout a period of two weeks. The teacher and students were observed and notes were taken in the form of simplified event maps inspired by the work of (Kelly, 2014) and consisting of sequence units (cohesive, thematically tied interactions) and phase units (set of sequence units usually reflecting the general topic under focus). Non-verbal events such as gestures and visuals were also noted in the maps. The participants were audio recorded as they were engaged in the classroom talk or as they were working in little groups. A follow-up interview with the teacher completed the data. The audio recorded lessons and teacher interview were transcribed. In conjunction with the written observations, analysis of the transcripts was underpinned by the work of Planas (2014) and methodologically framed by the work by Mortimer and Scott (2003), the sociocultural discourse analysis proposed by Mercer (2004), and the thematic pattern analysis of Lemke (1990). The focus of attention was on science learning and, in particular, on how access to science is socially accomplished through the medium of a foreign language. The analysis can be summarized in two stages: (1) the identification of language practices employed for teaching and learning science and (2) the study of the extent to which these practices are favourable or unfavourable to the learning of science.

RESULTS

All five observed lessons are a mix of whole-classroom dialogues led by the teacher and group writing activities. The teacher mainly uses the tool of questioning for engaging the students, both for activating and testing prior knowledges and for explaining new concepts. Among the language practices observed throughout the lessons, four of them have been selected and analysed for the purpose of this paper. These are: (1) explicit focus on language, (2) code-switching, (3) exploratory talk and (4) teacher-led authoritative dialogue. Other language practices were observed and could have been chosen instead, but the examined practices have been thought of as sufficient for a preliminary understanding of the investigated phenomenon.

To exemplify the classroom practices, we refer to three short segments of classroom talk recorded during a set of various lessons on protein synthesis and reported below (see Excerpt 1, 2 and 3 below). These segments are representative of the several instances in which the above-mentioned language practices were present. Adopting a similar approach to Planas (2014), there is no attempt at statistically summarizing the language practices within a broader set of data. Instead, they are considered representative of the general phenomenon of science learning opportunities that can be created through the use of specific language practices in a bilingual classroom.

In excerpt 1, the teacher’s explicit focus on language and the code-switching between English and the home language of students intertwine.
Excerpt 1: Teacher-led explanation (talking while drawing on the whiteboard)

1. TEACHER: We have here our t-RNA or transfer RNA. Oh, what does transfer mean?
2. DORA: Uhm... *bringen*?
3. TEACHER: Yeah, right. Any other suggestion?
4. LUDOWICA: *Übertragen*.
5. TEACHER: Perfect, can you think some other English words for transfer or *übertragen*? Maja?
6. MAIA: To carry?
7. TEACHER: Right. Mia?
8. MIA: To shuttle?
9. TEACHER: Yes! And that's really what it does! And what does the t-RNA shuttle?
10. What does the t-RNA transfer?
11. MIA: Uhm... poli..., no just... Uhm... amino acids?
12. TEACHER: Yes, of course, amino acids!

The teacher explicitly asks for the meaning of *transfer*, which is a technical term in the target language. The teacher’s interest is equally linguistic and scientific, and her question, as it is formulated, shows her awareness of the linguistic challenge of the discipline. The same awareness was explicitly formulated by the teacher when interviewed:

*I think in science we always have that emphasis [on language] because we realise – especially in biology – that biology is like learning a new language whether you are doing it in your own language or a foreign language. Mmm... there are so many new subject specific terms that it's almost like acquiring a new vocabulary.*

In excerpt 1, the teacher accepts the translation of the term as a viable explanation of its meaning. She encourages her students to find more suitable translations of the term, first in German, and then in English. We refer to this alternating use or more than one linguistic code in the classroom as code-switching (Lin, 2013). The switching from one language to the other is spontaneous when accomplished by the students, more deliberate when employed by the teacher. The teacher deliberately juxtaposes the original English term *transfer* with a translation – repeating what a student said. She asks for “*some other English words for transfer or übertragen*?” creating the impression that the German words provided by the students are not mere translations but synonyms for the English term. This approach reinforces the message that the language, any language, is basically a tool for understanding and communicating. The search for translations/synonyms occurs in the target language and the students are encouraged to find equivalent English terms to develop their understanding of the concept of transfer. At the end of excerpt 1, the teacher repeats the same question employing both the term utilised by a student and the academic term. This conveys the message that both terms are correct, while emphasising that the academic one needs to be known. In addition, it reinforces the scientific notion of t-RNA as a “carrier of something”. Repeating, looking for synonyms or translations are all suitable devices employed by both teacher and students for understanding a scientific concept, for verbally playing with it, and for enriching the linguistic repertoire that students can draw from for expressing it.

A similar use of code-switching as observed in excerpt 1 is also present in excerpt 2. Here, German words are used by the students to fill in the gaps of the clarifying questions they are
asking the teacher. Interestingly, the students feel free to use words in their mother-tongue language when seeking clarification for scientific concepts. German words are used to create simple explanations or definitions of scientific terms. Again, German everyday-words functions both as translations and as synonyms that connect the vocabulary-rich academic language to the everyday language, and thus supporting the development students’ understanding of scientific concepts and their ability to speak about them.

**Excerpt 2:** Students asking for clarification at the end of an explanation session led by the teacher.

1. NIKO: So transcription is different from... um... translation. And... translation is
2. TEACHER: ... eine Übersetzung? Uhm...from mRNA to protein?
3. NINA: And the other one, the... trans...transcription is about DNA... and RNA. Is like...
4. kopieren? Uhm... But not really the same.
5. TEACHER: You got it! But I don’t want to go back to transcription now. Let’s work
6. on translation. Noah, can you tell me where it takes place?

In excerpt 3, the students demonstrate awareness of the links between the form and the function of words also when they are not directly instructed by the teacher. Their language awareness is apparent when they focus on lexico-grammatical features of the English language, instead of on technical vocabulary. This sequence of turns in talking is taken from a longer exchange between two students while they are working in pairs on an assigned written task consisting of review questions. They debate about which preposition should be used to construct a scientifically correct statement. The students implicitly recognize that the issue is not merely linguistic but also content-related and practice different ways to verbally express a scientific notion.

**Excerpt 3:** Students are working in pairs on a written task (questions).

1. EMMA: And the protein is made...
2. FINN: ...a protein is made of amino acids.
3. EMMA: Made of or made by?
4. FINN: Made with.
5. EMMA: ((Chuckling)) Made with?
6. FINN: Yeah... A protein is made... Basically, a protein consists of amino acids.
7. EMMA: Okay.
8. FINN: And these are, as far as I've got it, not amino acid. They're just... uhm.
9. EMMA: A part of it?
10. FINN: Mm-hm. They are codons and [they] just state which amino acid should  
11. be used, but...
12. EMMA: Okay, thank you. So... these are, not amino acids.
13. FINN: No, not amino acids, but... uhm. Amino acids are carried
14. by... by it – the... the t-RNA. t-RNA carries amino acids. No, these
15. are... codons and they just – I think they...
16. EMMA: They are part of the t-RNA... and they state what amino acid should be used.

The next language practice we examine is the use of features typical of what Barnes (2008) ascribe to exploratory talk. This disjointed and hesitant kind of talk, with frequent *uhm*, pauses and tentativeness in voice intonation is visible in all three excerpts. The function of this kind of talk is to sort out ideas, to think aloud. Some features of this kind of talk, such as the use of
non-words, are used by the students to gain time when answering the teacher’s questions. This is particularly useful because the wait time the teacher allows for answering her question is usually very short or even non-existent. Other times, this kind of speech enables the student to rethink and better adjust an answer while speaking. In excerpt 1, the student answer “Uhm... poli... no just... Uhm... amino acids?” has a clear questioning intonation. The student is indeed not certain and she is thinking while answering, sorting out her own ideas as they are expressed, hearing how they sound and adjusting them accordingly. The focus is on the content she is working on, not on the form. In excerpt 3, where students are working in pairs, the exploratory type of speech is not limited to short utterances, but it develops into an exploratory dialog between two peers. At times, one student completes the sentence started by his or her peer. The two students interact as they thinking together, exploring ideas together, completing each other’s thought. This use of spoken language has been called interthinking (Littleton & Mercer, 2013).

The last practice we highlight is the teacher-led authoritative dialogue. In excerpt 1, the teacher constructs knowledge with the students by asking questions and making comments to develop their understanding of the topic. The teacher tends to ask highly directed and thematically narrow questions to which students are required to provide short answers. The interaction is highly controlled by the teacher, with the characteristic Initiation-Response-Follow up/Feedback (IRF) structure. In excerpt 2, the teacher answers and reacts to clarifying questions asked by the students. Even if the questioning is initiated by the students, the communication follows the path determined by the teacher. She only provides short answers and avoids being side tracked from her agenda as can been seen when she says “I don’t want to go back to transcription now” and moves on to the focus of the lesson.

DISCUSSION AND CONCLUSIONS

As Planas (2014) points out in a similar analysis, it is difficult to know how much the examined language practices are related to the curricular domain, or even to science learning. However, an attempt to link the same practices to the existing science education literature, within the proposed theoretical framework has been done for each of them. The selected practices will be first discussed separately and then as a whole.

Explicit focus on language

Biology is a vocabulary-rich discipline and presents linguistic demands for learners (Harmon, Hedrick, & Wood, 2005; Vallejo Jr, 2006). However, despite substantial empirical evidence that favours explicit over implicit vocabulary instruction methods (e.g. Ardasheva & Trette, 2017; August, Carlo, Dressler, & Snow, 2005; Barr, August, & Artzi, 2014), teachers at secondary level rarely incorporate the explicit teaching of science vocabulary into their ongoing practice (Miller, 2009). This phenomenon may be caused by various factors such as a lack of classroom time (Sweeny & Mason, 2011), a lack of bilingual teaching competences among content teachers (Samson & Collins, 2012), or a general lack of understanding among teachers graduated in a content-area of the academic language demands (Scarcella, 2003). However, the analysed data tell a different story, as the teacher explicitly addresses linguistic issues. She focuses on the building of academic vocabulary while engaging her students in
meaningful interactions and supporting their scientific understanding. Some researchers recommend caution when explicitly teaching language aspects in content lessons (Richardson Bruna, Vann, & Perales Escudero, 2007). For instance, Pimm (1994) argues that providing students with information about academic language may create an artificial learning environment where language is interpreted as the purpose of instruction. In our transcripts, although being explicit, the focus on language is so well incorporated in the flow of the instruction that it can hardly be mistaken by students as the substance of instruction. Moreover, the focus on language plays an instrumental role in the conceptual understanding of a scientific notion, highlighted by the teacher’s words: “And that's really what it [the t-RNA] does!”

Ultimately, the analysed material illustrates how the teacher’s understanding of academic language affects her pedagogy and students’ opportunities for science learning. It also shows how students have picked up some of her linguistic awareness and are able to employ it spontaneously and autonomously.

**Code-switching**

The use of code-switching in the classroom is often the result of a lack of language skills (Eldridge, 1996). This is probably the reason that prompted its use in the examined talk segments. However, the ultimate result of its implementation was actually not to cover a shortcoming but to turn language into a more effective learning tool. Indeed, empirical evidence from many other studies support the view that code-switching is a beneficial practice within the bilingual classroom (e.g. Garcia & Wei, 2013; Lin, 2013; Swain, Kirpatrick, & Cummins, 2011).

As can be seen in the first two excerpts presented, switching between English and German increases the students’ linguistic repertoires and, consequently, the possibility to better tackle the challenges of a vocabulary-rich subject such as biology. The students use a mixed language as an effective communicative tool that facilitates the learning process, instead of disrupting it. The difference between translations and synonyms fades as the science talk develops. In addition, students feel empowered by the knowledge that they are allowed to use their home language (Combs & Ovando, 2012) Consequently, they willingly contribute to the classroom dialogue with their answers and questions. As Moschkovich (1999) argued, this keeps the conversation smooth and the focus stays on the content. Keeping the conversation going can be particularly challenging when the instructional language is not the home language of the students. Indeed, Noorbar and Mamaghani (2016) found that being able to use the house language has a significant positive effect on students’ *willingness to communicate*, defined by MacIntyre, Dörnyei, Clément, and Noels (1998, p. 547) as the “readiness to enter into discourse” when using a second language.

**Exploratory talk**

In all the examined talk sequences, there is some feature of exploratory talk. According to Barnes (2008 p. 4), exploratory talk is “hesitant and incomplete because it enables the speaker to try out ideas, to hear how they sound, to see what others make of them”. In particular, many classroom research studies underscore the importance of the co-constructive aspect of this kind of talk (Knight & Mercer, 2015; Rojas-Drummond & Mercer, 2003). However, Barnes (2008
warns us that students only resort to it when they feel at ease and are not worried about being made fun of. The fact that students in the investigated CLIL classroom frequently adopt it suggests that the linguistic demand of this peculiar classroom setting serves as a disinhibiting factor that allows students to freely think aloud and share their thoughts.

**Teacher-led authoritative dialogue**

Finally, in excerpt 1 and 2, the teacher takes an authoritative communicative approach. Mortimer and Scott (2003, p. 34) describe this as an approach “where attention is focused on just one point of view, only one voice is heard and there is no exploration of different ideas.” According to the same authors, this type of dialogue limits the exploration of ideas and the opportunities for meaningful learning. On the other hand, this approach allows the teacher of our study to fully cover the topic, to briefly engage as much students as possible and to share and develop scientific concepts. In addition, some time is allocated for group activities where the students are able to engage with their peers, as can be seen in excerpt 3.

In order to support the development of the classroom talk, the teacher prompts dialogues with the characteristic IRF structure. This structure is regarded as pervasive in most classrooms (Wells, 1993) and its overuse is often criticised (e.g. Lemke, 1990). Other scholars, by contrast, claim that it is effective. Mercer (1992), for example, argues that the implementation of IRF sequences is justified as an effective way to monitor children's development of understanding, as a guide through the learning process and as a marker of “knowledge and experience which is considered educationally significant or valuable” (p. 219).

To sum up, the first three practices discussed here support the view that linguistically challenging situations contribute to generating opportunities that may be beneficial for science learning. It could also be argued that these practices help students to construct thematic patterns of a particular science content (Lemke, 1990). Thematic patterns represent the particular semantic relationships of which scientific knowledge is constructed. They can be verbally expressed in many ways, but the underlining meaning, or pattern, does not change. In the first excerpt, teacher and students work around the following thematic pattern: t-RNA carries amino acids. They tentatively experiment different ways to say the same thing, using different verbs and different languages. In excerpt 3, the students build up the following pattern: proteins are made of amino acids. Again, the students explore various linguistic ways to express the same meaning, or semantic pattern. This, according to Lemke, should be the main aim of science education. The author states that “we do not want students to simply parrot back the words. We want them to be able to construct the essential meanings in their own words, and in slightly different words as the situation may require” (p. 91). Lemke highlights the uselessness of using fixed words and the importance of being able to flexibly change the wording for expressing the same meanings. This is what Lemke equates to understanding concepts.

The last considered practice, the teacher-led authoritative dialogue, points to a contrasting finding, which it is often observed in bilingual science classrooms (Morton, 2012) and that – even if not without tensions (Scott, Mortimer, & Aguiar, 2006) – often translates into a missed opportunity for activating conceptual change (Mercer, 2008).
In conclusion, the use of a foreign language as the language of instruction in a science classroom can indeed generate opportunities for learning science. This is possible because the language challenges trigger classroom practices and attitudes that support the learning of science. One of these is a greater language awareness that enables the teacher to employ different strategies to make subject content and its registers more accessible to students. In addition, content learning and understanding is facilitated by linguistic practices that value the home language of the students as an additional classroom resource and that allow learners to tentatively verbalize their thoughts.

ACKNOWLEDGEMENT

The authors would like to thank the school principal, teacher, and students for participating in this study. In addition, our sincere gratitude goes to the College of Arts, Social Sciences, and Celtic Studies of the National University of Ireland, Galway for the financial support to attend the ESERA conference.

Reform recommendations for science education globally encourage shifting from teacher-centered to more student-centered pedagogical approaches. The context of this study was a project that aimed to support the transition to a more student-centered approach to scientific inquiry, using a support framework and a co-teaching format with a master teacher. Teacher-student interactions are a fundamental aspect of changing pedagogical approaches and the purpose of this study was to investigate teacher-student interactions in a classroom in the project. Teacher-student interactions were studied through investigating classroom talk using conversation analysis of video recordings that were collected at intervals throughout a period of one year. Analysis found three prominent discourse patterns, two teacher-centered and one more student-centered pattern. In this paper these discourse patterns are described. Preliminary findings suggest that the student-centered discourse pattern became more common as the class transitioned to more student-centered scientific inquiry. This work suggests that the framework and co-teaching format used in the project could be of value to teachers wishing to change to more student-centered approaches.

Keywords: Discourse; Scientific Inquiry

INTRODUCTION

Current international science education reform (BC, 2012; NGSS, 2013; Rocard, 2007; Tytler, 2007) recommends a shift from traditional teacher-centered approaches to more student-centered pedagogical approaches. This includes a shift to more student-centered scientific inquiry. Scientific inquiry refers to the particular ways of observing, thinking, investigating and validating that scientists use in their work (AAAS, 1993). In student-centered scientific inquiry, students learn to grapple with real problems collaboratively, analyze evidence, and evaluate arguments; and the role of the teacher becomes that of facilitator or guide. This approach has been shown to increase student interest, and motivation (e.g. Geier et al., 2008), and to develop students’ critical, creative thinking and innovation abilities (e.g. Haigh, 2007). However, given the traditional dominance of teacher-centered approaches in classrooms, shifting to student-centered scientific inquiry is difficult and rarely evident (e.g., Capps & Crawford, 2013). The widely adopted approach to facilitating this transition has been professional development opportunities for teachers outside the classroom (e.g. Luft 2001). Transfer of these learning experiences to produce student-centered scientific inquiry practices inside classrooms has proved to be difficult (e.g. Blanchard, Southerland, & Granger, 2009). This study takes place in the context of the Steps to Inquiry project that takes a different approach; it aims to scaffold teachers and students learning to conduct student-centered scientific inquiry in their own classrooms. The Steps to Inquiry project utilizes a framework of guiding materials (the Steps to Inquiry framework), introduced to teachers and students through a co-teaching format with a teacher expert in scientific inquiry. Since teacher-student interactions are so central to the transition to student-centered scientific inquiry (e.g. Harlen &
Allende, 2009), this study focuses on teacher-student interactions in the Steps to Inquiry project. This paper specifically focuses on teacher-student interactions in one classroom in the Steps to Inquiry project as it transitions over the course of one year. The classroom is a first grade classroom and the teacher is Mr. Holmes (pseudonym). The specific question addressed is: What patterns of classroom talk emerge and how do they change as teacher and students in a first-grade classroom transition to student-centered scientific inquiry in the Steps to Inquiry project?

**THEORETICAL PERSPECTIVE**

Since relational interactions are made evident through discourse (Vygotsky, 1978), in this study interactions between teachers and students are investigated through investigating patterns of classroom talk (Mehan, 1979; Lemke, 1991; Roth 1993). Conversation analysis (Sacks, Scheloff, & Jefferson, 1974) is our method of choice because it allows us to uncover change in the structure and dynamics of conversational patterns that emerge as teachers and students transition to student-centered scientific inquiry. CA aims to reveal the organization of talk not from any outsider’s viewpoint but from the perspective of participants. CA follows how conversation participants take up what has been done and said. In this way CA reveals participants’ interpretations of what has been said rather than those of the analyst.

**BACKGROUND**

In this section discourse patterns in classrooms that have been reported in the literature are reviewed.

**Teacher-centered discourse patterns**

The discourse pattern found to be the most common in classrooms is I-R-E; Initiate-Respond-Evaluate (Mehan, 1979). This form, sometimes called triadic dialogue, was also found to be most common in science lessons (Lemke, 1990). An example of the I-R-E pattern from our work can be seen below.

<tr>
<th>Turn 01</th>
<th>Turn 02</th>
<th>Turn 03</th>
</tr>
</thead>
<tbody>
<tr>
<td>Teacher</td>
<td>Alex</td>
<td>Teacher</td>
</tr>
</tbody>
</table>

What are variables— we talked about that— what are variables again? Alex?

Something that can change?

That’s right, something that we can change, something that we can vary.

The sequence beings with a question as interpreted by the response in turn 2 regarding the meaning of the term variables. The third turn ends the sequence and is an evaluation of the response indicating to the speaker that they have provided the correct answer. As is clear in the example, in I-R-E the question that initiates is a known-answer question (Mehan, 1979).

Although the I-R-E discourse form has its uses, for example in testing students’ recall, overuse can present a barrier for student learning (Cazden, 2001; Mercer & Dawes, 2014) because, for example, students do not get an opportunity to share their ideas and view points.
A second teacher-centered discourse form that has been described in the literature is characterised by choral responses, where the whole class responds together as a group. The choral response is sometimes seen as useful in memorization drills such as wordlists and number facts (Rosenshine, 1983) and it can be a common component in elementary classrooms (Pontefract & Hardman, 2005). Again, although this discourse form has its uses, overuse can present a barrier to student learning because it does not provide students with an opportunity to contribute their ideas.

**Student-centered discourse patterns**

In contrast to the teacher-centered discourse patterns described, in student-centered discourse patterns, teachers tend to invite students to respond to open-ended questions (Alexander, 2006; Nystand, 2001), and students’ do have an opportunity to share their ideas. One example of the kind of pattern has been described as I-R-F-R-F-, where F is short for Feedback (Mortimer & Scott, 2003). The teacher initiates (I) with an open-ended question such as ‘can you give me an example’, followed by a student’s response (R), to which the teacher provides feedback (F), this leads to a further response from a student (R), leading to further feedback from the teacher (F). Chains of dialogue are created where responses are followed and built upon (Alexander, 2010).

Shifting to student-centered pedagogical approaches should not involve shifting to the exclusive use of student-centered discourse patterns. Both student-centred and teacher-centered discourse forms are found in classrooms environments that support student learning (Alexander, 2006; Mortimer & Scott, 2003; Scott, Mortimer & Aguiar, 2006; Wells & Arauz, 2006). In such environments a balance exists, with each discourse pattern being associated with a particular function in a particular situation.

**METHODS**

**Context: The Steps to Inquiry project**

The context of the study is the Steps to Inquiry project that aims to support teacher and students learning to conduct student-centered scientific inquiry together in their own classrooms (Rees, Pardo, & Parker, 2013) using a framework of guiding materials, called the Steps to Inquiry (SI) framework (Pardo & Parker, 2010). Created by a team of teachers in Ontario, Canada, the SI framework permits a gradual release of responsibility for science investigations, from teachers to students, that parallel different levels of inquiry (Bell et al., 2005). Influenced by the Inquiry Boards (Buttemer, 2006) and the work of Goldsworthy and Feasy (1997), the SI framework utilizes a series of interactive posters and graphic organizers that teachers and students use to collect their ideas and questions, phrase testable questions, identify variables, design procedures, and conduct independent science investigations collaboratively in small groups.

In the Steps to Inquiry project, the SI framework is introduced to teachers and students new to inquiry, through a co-teaching format. This format is summarized in Table 1, in the context of the particular class in this study. In stage 1 Mr. Holmes, the teacher of the class who was new to scientific inquiry, conducted his class according to his usual practice. In stage 2, Mr. Wise, an expert in using the SI framework, led the class (with Mr. Holmes assisting) through a
scientific inquiry on the topic of motion, using the SI framework materials. In stage 3 Mr. Holmes led the class (with Mr Wise assisting) through another science inquiry, using the SI framework materials, on the topic is motion, this time using cars and tracks. In stage 4, Mr. Holmes led the class (without Mr. Wise) through an inquiry using the SI support framework, this time on the topic of magnetism. Between stages, Mr. Holmes and Mr. Wise met to plan activities and reflected on the process.

When using the SI framework, teachers focused students’ scientific inquiries on a particular beginning activity or event (such as rolling a car down a track). Students were given equipment and they were sent to work in pairs or small groups. They set up their equipment (such as a track attached to the table and a car). They observed the activity and following this the teacher called them back to the circle to share their observations. The teacher collected these by writing them on sticky notes and attaching them to a poster. The students then developed wonderings about the event, which the teacher asked them to share. The teacher again wrote them on sticky notes and attached them to the poster. In a similar manner the teacher collected students’ ideas about what they could change (independent variables) and what they could measure (dependent variables) about the event; these were posted on a second poster. Each pair or small group of students chose one variable that they would like to change (such as the size of the car) and a variable to measure (such as how far the car travels on the floor, after rolling down the track). By moving sticky notes to boxes on a third poster, the teacher created the question for a particular students’ experiment, such as: ‘If I change the shape of the car what will happen to how far it travels on the floor’. The teacher then moved all other variables that must remain the same, to a box labelled ‘controlled variable’, such as the length of the track and type of surface on the floor. Once they have performed their experiments, students shared their findings with the class.

Participants and Participation

Following ethics approval, study participants included the teachers, Mr. Wise and Mr. Holmes (pseudonyms) and the seventeen first-grade students (pseudonyms used throughout) in Mr. Holmes class. Mr. Holmes had no science background beyond high school. Mr. Wise had a degree in science and had worked as a science specialist teacher for eight years.

Data Collection

Video recordings of classroom interactions were collected during each stage of the study.
Video recordings aimed to permit the detailed description of teacher-student interactions and conversational turn-taking. Three cameras were operated simultaneously (Roth & Hsu, 2010), along with voice recorders, allowing the collection of cross-sectional data. Two fixed cameras captured the whole class from different perspectives, whereas the third (hand-held) triangulated between the two. Audio-recordings were also used to capture the interactions between teachers in planning sessions between classes. All relevant written documents (artifacts) that participants engaged with during interactions were photographed. Before data analysis, researchers completed verbatim transcription of video recordings.

Analysis of Video Recordings

The aim in analysis of classroom video-recordings was to provide detailed descriptions of recurrent discourse patterns evident during the four stages of science inquiry learning. The first step involved identification of recurring patterns (Roth & Hsu, 2010). The second step involves detailed examination and transcription (Sacks et al., 1974) conducted on selected passages (cf. Atkinson & Heritage, 1984). This analysis resulted in an in-depth description of the passages identified.

Validity and Reliability

Conversation analysis rigorously demands empirical descriptions to be accepted as valid (Roth & Hsu, 2010). Video recordings and the transcripts of them provide detailed and publicly available representations of talk-in-interaction. The transparent nature of the analysis allows for interpretations to be “traceable and repeatable” by other researchers, thus increasing their reliability (Roth & Hsu, 2010). Internal validity of conversation analysis is increased by the elaborate detail of the notation and the refusal on the part of researchers to interpret transactions according to a priori theory.

FINDINGS AND ANALYSIS

The purpose of this study was to provide detailed descriptions of recurring patterns of language use evident in a classroom undergoing transition to student-centered scientific inquiry in the SI project. Three patterns of classroom talk emerged during whole class interaction in the classroom. Pattern a) prompt-chorus, involved a chorus-response from the whole group to a prompt from the initiator (the teacher). Pattern b) I-R-E initiate-respond-evaluate, involved a query | reply turn pair followed by an evaluation (Mehan, 1979). Pattern c) I-R-A involved an acknowledgement in the third turn instead of an evaluation. I-R-A was a cumulative pattern where the acknowledgement turn led to a further further response and there was a build up of responses wherein students’ ideas were expressed. These three patterns are shown in the excerpts below (Excerpt 1, 2 and 3)
Excerpt 1

| Prompt 01 | Mr Holmes | A(.low(.)saw(.)rus (pointing to the parts of the word on the poster) (. everybody↑
| Chorus 02 | Students | A(.low(.)saw(.)rus |

The turn pair in excerpt 1 is an example of pattern a) the prompt-chorus pattern that was common in Mr Holmes class in stage 1, before introduction of scaffolded scientific inquiry. This example occurred when Mr Holmes was working with the students to ‘sound out’ the word ‘Allosaurus’ on a poster about dinosaurs. That turn 1 was interpreted as a prompt is indicated by the chorus response in turn 2, when the students repeated ununciating the parts of the word as Mr. Holmes had done. On other occasions Mr Holmes prompted by pausing before a particular word in a sentence, which was followed by the students filling in the missing word, and by pointing to words or letters on posters and pausing, which was followed by the students providing the word or letter in a chorus of responses.

This pattern of prompts with a choral response has been identified in the literature as a teacher-centered discourse form because it offers students little opportunity to contribute their thoughts and ideas (e.g. Pontefract & Hardman, 2005).

Excerpt 2

| (I) 01 | Mr Holmes | Hm::m (.O is for observe W is for (. what is W for |
| (R) 02 | Ann | Wonder |
| (E) 03 | Mr Holmes | Wonder (. correct |

The fragment in excerpt 2 is an example of pattern b) the I-R-E pattern and it was also common in stage 1 before introduction of scaffolded scientific inquiry. Turn 1 is interpreted as a question by the response in turn 2 that indicates that W is for Wonder. Turn 3 repeats the response in turn 2 and evaluates, indicating that the response is correct. This second teacher-centered form is the most common teacher-centered form in classrooms and is associated with known-answer questions (Mehan, 1979; Lemke, 1990). It leads to responses of one or two words from students and offers them no opportunity to contribute their ideas.

Excerpt 3 is an example of the I-R-A discourse pattern. There are two features of note. The first feature is the presence of acknowledgment turns, two of which, turns 7 and 9, functioned both as acknowledgments and as invitations to continue. This is indicated by their association with further elaborations (turns 7, 9). These elaborations were cumulative so that an initial I-R- routine did not end with an evaluation (to form an I-R-E sequence) but instead the acknowledgment (A) functioned as elicitation of another student turn (R) that added to the already provided reply yielding I-R-(A-R-).

This can be seen in the example in excerpt 3 where the telling of George’s story about his experiment was a combined effort between George, who had the longer turns, and the major role in telling the story (turns 02; 06; 08, 10), and Mr Holmes’ turns that were single words of acknowledgement (turns 07, 09, and 11).
The second feature of the I-R-A discourse form is the presence of clarification question and response turn pairs that lengthen the exchange. In the example this can be seen in the \{turn 03 | turn 06\} pair. Turn 03 functioned to stop the on-going reply turn by means of overlapping talk. But this turn, treated as a question (turn 06), led to the elaboration of a specific aspect of the experiment. Inspection of turn 03 shows that it directly took up an issue from the preceding turn, thereby marking it as a point of interest. Since the turn takes the form of a question, and was treated as such in the reply given (turn 06), the function of the turn was to seek a specific elaboration rather than the open-ended one that a simple acknowledgment (e.g., “right,” turn 07; or “yes,” turn 09) might provide.

DISCUSSION

This study described patterns of discourse found in a classroom transitioning to student-centered scientific inquiry in the Steps to Inquiry project. Three prominent patterns were found; two teacher-centered (prompt-chorus and I-R-E Initiate respond-evaluate) and one student-centered discourse pattern, the I-R-A initiate respond acknowledge pattern. The I-R-A pattern, more fully described as I-R-(Q-R-)(A-R-)(A-…), is similar of the previously reported I-R-F-R-F-discourse form (Scott & Mortimer, 2003) in that it has a cumulative nature. However it appears to differ from it in that it is the student who provides further information and elaboration rather than the teacher. In this study, the I-R-(Q-R-)(A-R-)(A-…) discourse pattern provided students with the opportunity to produce extended accounts of what they had done and what they were thinking.
Preliminary findings suggest that the more student-centered discourse pattern c) became more prevalent as the class transitioned. Next steps in this study involve investigating the extent of the change in discourse patterns and the manner in which the Steps to Inquiry framework and the coteaching format supported the shift. These findings could be useful for teachers working to change their approach to scientific inquiry and their mode of interacting with students.

ACKNOWLEDGEMENT

Thank you to research assistants involved in data collection, transcription and analysis. Thank you to teachers who created the Steps to Inquiry framework (including Richard Pardo, Jennifer Parker and Michael Newnham). This research was supported by a Social Sciences and Humanities Research Council of Canada Insight Development Grant.

ALCESTE SOFTWARE USAGE IN THE IDENTIFICATION OF SPEECHES FOUND IN WRITTEN TEXTS ABOUT THE DIGESTIVE SYSTEM

Michele D. F. Medeiros, Anne C. Freitas, Marcelo T. Motokane, Marcelo Pereira, Bruce S. P. de Freitas and Rafael Gil de Castro
Universidade de São Paulo, Ribeirão Preto, Brazil.

The comprehension of the processes that occur in science classes depends on adequate methodologies of analysis. This is a challenge for the Researchers in the area. The aim of this work is to identify speeches found in written texts about the digestive system from analysis of classes created by ALCESTE software. Text production took place at the end of a didactic sequence about the digestive system. The analysis performed by ALCESTE software exhibited six different classes for the texts. The categorisation of these classes indicates that the writings contain scientific terms, with detailing of the functions and structures of the digestive system. These results suggest a forthcoming of the students with scientific culture.

Keywords: ALCESTE; scientific culture; speeches;

INTRODUCTION

Science is a culture because it has specific values, language, and methodology (Cachapuz et. al., 2005). Understanding of scientific culture involves the recognition of the peculiar way that sciences produces knowledge. According to Driver et. al (1999), scientific knowledge is built and validate socially, as individuals of the scientific community share their ideas with their peers. Communication between peers follows a specific language, the scientific language, which according to Villani & Nascimento (2003) has intrinsic specific characteristics of scientific knowledge.

Scientific language differs from everyday language. It has characteristics that involves grammatical metaphors, semantic discontinuity and specific terms (Halliday and Martin, 1993). According to Mortimer, Chagas, and Alvarenga (1998), the specificities of scientific language brings it closer to written language, whereas everyday language would be closer to speech. The scientific language supports an understanding of the natural world as an alternative to that provided by common sense (Halliday & Martin, 1993; Martin & Veel, 1998). As a result, these specificities of scientific language represent a unique way of thinking, reasoning and seeing the world; permeated by peculiar contexts of norms and scientific beliefs.

For Fang (2004), to understand these particularities is to understand science. Hence, learning science means learning to use unique linguistic forms and structures that build and communicate scientific principles, knowledge, and beliefs.

Given these specificities, we understand that comprehending and using scientific language does not occur spontaneously, on the contrary, it is necessary that the process of teaching science promotes conditions for students to have access to scientific culture.

Science education should aid to bring students closer to scientific culture so that students are able to critically analyze and evaluate the scientific issues that are increasingly present in
society. Students’ alienation from the way science speaks, writes, communicates, address, and assigns meaning implies in an inadequate understanding of what scientific knowledge is and reinforces the image of infallible science and absolute truths (Fernández, 2002).

For Sasseron (2015), a school is a meeting place of different cultures, being sciences teaching an area of knowledge that makes way for the approximation of school culture with scientific culture (Vidal, 2009; Scarpa, 2009 & Gómez and Adúriz-Bravo, 2007). The approximation between these cultures constitutes one of the marks so that the student comprehends the aspects that involve the scientific making. According to the author, the approximation is through the process of Scientific Literacy, in which skills of science are presented in science classes. Thus, to scientifically literate the student allows it to approach the ways in which science produces, legitimates and disseminates knowledge.

Educational research is the didactic approach used to develop the specific skills of scientific making since a space is created for the student to be able to collect and analyze data; to raise and test hypotheses, perform explanations and argue in oral and written form. Therefore, this proposition allows the student to have contact, class after class, with interactions, instruments and discursive practices specific to scientific culture.

As aforementioned, science does not use a common everyday language but rather, specific terms. Such terms have the purpose of presenting scientific information and arguments (Schleppegrell, 2001). However, it also makes scientific writing particularly dense, technical and abstract. The technical content of scientific texts is associated with the use of technical vocabulary and verbs of the relational process. That is, these words can be verbs that describe unique activities and processes or nonverbal terms that allow scientists to describe physical objects and natural phenomena (Fang, 2004). Thus, text production in science classes is an action that helps students understand the specificities of scientific discourse and thus approach scientific culture.

To analyse the effectiveness of actions that promotes scientific writing is a challenge for research in science education. Alceste software makes a lexical analysis that involves statistical methods on the co-occurrence of terms through segmentations, hierarchical classification and correspondence analysis. Hence, such a tool traces words that reproduce different forms of discourse in relation to the search topic. This program orders elements of the corpus (word or sentence) in classes defined from the function of the word within the text, evaluating the frequency of these terms in the set. Each class has a list of characteristic words generated from statistical tests. In this manner, it is possible to both quantify and to demarcate more general categories of content. In this perspective, from the lists generated by the software, the researcher has the autonomy to analyze and infer about such categories, based on the context of the production of the text.

**METHODOLOGY**

For this study, we analyzed 140 written texts from students of elementary level. These students are from a public school. These texts are the result of an activity from an inquire didactic sequence about the digestive system. The sequence is composed of nine classes. The classes follow the same order that the food goes through the body, starting, therefore, in the mouth and
ending with the elimination of the residues. For each of the classes a problem was proposed. Problem solving enables the development of the skills specific of the scientific making. In the last class the students produced the analysed texts presented in this paper.

The texts are analyzed by software ALCESTE 4,5 (Analyse Lexicale par Contexte d’un Ensemble de Segments de Texte), a automated analysis method. This method does a statistical analysis of repetitions and successions of words in one or more texts and it creates thematic classes. It is an exploratory method without a priori categories. It is useful for giving a comprehensive overview when there are large quantities of documentation. These analyzes would be too long and exhaustive to do manually. According to Kronberger & Wagner (2013) the program classifies the corpus, dividing the textual material in Classes, formed by Units of elementary context (UCEs). The UCEs are segments of texts, approximately three lines, and that, in general, respect the score. Thus, each Class is composed by several UCEs, from the classification by the distribution of vocabularies, made by the frequency and by the $\chi^2$ distribution of the words. The software produces a graph representing the Descending Hierarchical Classification (CHD), showing the fragmentation of the text and the relations between the different classes. After this procedure, the other stages of analysis were done with the intention of understanding the meanings present in the classes.

RESULTS AND DISCUSSION

After text processing, software ALCESTE defined six different Classes of students' speeches. The following dendrogram shows which ofthese classes are, the most significant words and Chi-Square, that indicates the degree of relevance of the words in the class (Figure 1).
The set of words, as well as the UCEs that make up each of the classes, made possible an interpretive approach to analysis. Interpretation seeks to comprehend the meaning expressed by each class. The grouping of words present in each class is associated with a stage of the human digestion process, so we categorize each class as in Table 1.

The set of words presented in each class created by the software suggests that the discourse presented in the texts produced by the students refers to the scientific discourse. The texts analyzed by the software describe the processes of human digestion through the use of scientific terms and concepts.

Another feature of the scientific discourse is the detailing of the processes, which is also observed in the UCEs of each class created by the software.

The following are some examples of the contextual units produced by the software in which it is possible to identify the scientific terms and the detailing of the processes that occur during the process of food digestion.

Examples:

“then the food goes to the large intestine, in it occurs the absorption of water and the creation of the faecal cake, then passes through the rectum and exits the anus in the form of feces”. (Class 4)

“in the stomach, there is the gastric juice, composed of several substances. exiting from
the stomach, the food arrives at the small intestine. it arrives very acidic, it is neutralized by the action of sodium bicarbonate, which is produced in the pancreas, attached organ. The wall of the small intestine produces a juice called enteric, which contains substances that transform proteins and lipids”.(Class 1)

“in apple’s path, it goes first through the mouth, where it happens the physical and chemical digestion. Physical digestion happens when we grind food with our teeth. Chemical digestion occurs with the action of saliva. Saliva is produced by the salivary glands, which are attached organs of the digestive system”.(Class 2)

“thus, going to the small intestine where the nutrients go to the bloodstream being scattered throughout the body, the rest of these nutrients that are left over, go to the large intestine”. (Class 3)

“peristaltic movement food bolus is pushed by esophagus muscles and at the end of the esophagus, the passage of the food bolus is regulated and the food goes to the stomach, in the stomach the food is mixed with the gastric juice that..”.(Class 5)

“The food, as soon as coming out of the mouth, passes through the pharynx and reaches the esophagus. The esophagus is in charge of taking the food to the stomach by means of a movement called the peristaltic movement”. (Class 6)

“The wall of the small intestine produces a juice called enteric juice, it has a substance that transforms proteins and lipids. In the small intestine, it has the physical digestion of the lipids, which is with the action of the bile that is produced in the liver and stored in the gallbladder that when it comes in contact with the fats it breaks them into smaller droplets”. (Class 1)

“The digestive system begins when we begin to chew the food with the teeth that it calls physical digestion that is when we break food into small parts. still in the mouth we have the salivary glands that release the saliva that has a substance called amylase which transforms the starch. chemical digestion.”. (Class 2)

“after the small intestine goes to the large intestine. in the large intestine, there are transformations. The intestine itself absorbs water from the food, which becomes dry and turns into faeces. After the large intestine comes the anus and then comes the rectum, from where the stool comes out”.(Class 3)

“It also absorbs all nutrients and a little water. What assists in this process is the shape, which in turn helps to have a larger contact surface. and the large intestine is responsible for removing all remaining water and forming the faecal cake. And finally, the rectum and the anus.”. (Class4)

“when swallowing the fried potato, it passes from the pharynx to the esophagus that performs the peristaltic movement, directing the food to the stomach, when arriving at the stomach, it produces the gastric juice that digests the protein”.(Class 6)

Another analysed aspect is that the association of words statistically attributed by the software, in a highly significant way, indicates a conceptually correct connection, indicating that the scientific language is present in the texts produced by the students. For example, the words:
mouth, tooth, and molar (belonging to class 2) have a high association rate according to the Chi-Square test; this association corresponds to the one existing in the scientific context referring to the process of mechanical digestion that takes place in the mouth. Chemical digestion is also evidenced from the high association of words like: glands, salivary, saliva and, amylase.

Example:

“The first stage of the food is to pass through the **mouth**, where the chewing that is done by the **teeth** takes place, and there are three types of **molar** teeth, incisors and canines, it performs the function of crushing the food and also has the **salivary glands** the function of them is to release the **saliva**. In the **saliva** has **starch** that is **digested by amylase**”. – Class 2

This particular association with stages of the digestive process is also observed in the other classes, where the words in bold represent those with a high association rate by Chi-square test and which are conceptually correct.

“The **wall** of the **small intestine** produces a **juice** called **enteric juice**, it has a **substance** that transforms **proteins and lipids**. In the **small intestine** has the **physical digestion of the lipids and with the action of the bile** that is **produced in the liver** and **stored in the gallbladder** that when it comes in contact with the **fats it breaks them into smaller droplets**.” – Class 1

“the **nutrients**/ absorbed by the **bloodstream** goes to the **rest of the body**, they are scattered / all over the **body**. in the **large intestine** the fiber and water are transformed into a faecal cake, and then the faecal cake **passes through the rectum** and then is **released by the anus**.” – Class 3

“in the **large intestine** is **formed the faecal cake**, where there is an **absorption** that our **body absorbs all the water present in this faecal cake** and there, is our **feces**” – Class 4

“then the **food passes through the pharynx** that decides the division of the digestive and respiratory systems. After that, the food **goes to the esophagus making a movement called the peristaltic movement that pushes the food into the stomach**”. – Class 5

“After you swallow the food it goes to the pharynx that takes it from there to the oesophagus. The oesophagus has a movement that **helps carry food to the stomach**, **this movement is called the peristaltic movement**.” – Class 6

The use of the software made it possible to analyze the discourse produced by the students after the application of a didactic research sequence. According to the classes created by the software, we detected that the essays produced contemplate the scientific discourse. This discourse was highlighted from the observation of scientific terms and scientific concepts presented in each class; by the detailing of the human digestive processes presented in the classes; and also by the strong statical association of scientific terms that together correctly describes the processes of human digestion.
The authors Ribeiro, Bonfleur, Della Justina, Balbo, carried out a work entitled "Common Sense x Scientific Knowledge: Students' Conceptions of Basic Education on the Digestive System," which evaluated students' understanding of the digestive system. The results indicate the prevalence of common sense in detriment of scientific knowledge regarding the digestive system.

According to the authors, when asked about the food pathway throughout the digestive tube, only one of the forty analyzed answers noted the peristaltic movement and 20% of the analyzed answers cited muscle contraction without detailing the process and seventeen cited saliva. Regarding this aspect, we perceived conceptual errors and generic information. This same aspect of the digestive process is presented in the UCEs created by the software and categorized as Class 6 - Course of the food after swallowing and peristaltic movements, these, however were much closer to the scientific language.

Example:

"The tongue is a muscle that helps in swallowing the food. From pharynx the food goes to the esophagus. The esophagus makes the peristaltic movement that in turn takes the food directly to the stomach".

Another evaluated question was the "role of the mouth and teeth in the digestion process": 27.5% of the students answered that there is no other structure or substance that helps in the digestion process, besides teeth.

Answers that affirmed the existence of factors that aid in the breakdown or digestion of food did not explain how the cleavage of the food ingested occurred by the mentioned substances or structures, as: few answers said that "saliva helps in the chewing process"; 12.5% of the students answered only "the tongue and the saliva"; 20% simply answered "saliva"; and 10% "an acid in our body". We noticed an inconsistency in students' answers and even conceptual errors, since the amylase present in saliva is not an acid. By comparing the work above with the UCEs created by the software is once again noticeable the approximation of the essays analyzed by the software with the scientific language. Class 2, for instance, addresses the processes of digestion that occur in the mouth. The UCEs present in this class describes how this process occurs:

"in apple’s path, it goes first through the mouth, where it happens the physical and chemical digestion. Physical digestion happens when we grind food with our teeth. Chemical digestion occurs with the action of saliva. Saliva is produced by the salivary glands, which are attached organs of the digestive system". (Class 2)

In this UCE there’s the differentiation between chemical and physical digestion and the detailing of these processes.

Also at Class 2 of UCE:

"the food enters the mouth, it comes into contact with saliva. Saliva is produced by the salivary glands that are attached organs of the digestive system. Saliva has a substance called salivary amylase that transforms starch-containing foods"

We verify the recognition of the chemical processes that occur in the mouth, the correct
association of the nutrient that is digested by the amylase which is the starch.

In this way, the usage of ALCESTE in the demonstrated analyzes, based on the classes and UCEs generated by the software, allowed us to infer that the textual productions present peculiarities of the scientific writing. The presence of scientific language in the textual productions indicates an approximation of these students with the scientific culture. We attribute this approximation to the investigative methodology used by the teachers in the classes. Educational investigative research is considered by many authors (ZÔMPERO; LABURU, 2011) as a teaching proposition that favors the engagement of students in activities that are close to scientific activity.

Thus, applying Educational Investigative research based teaching proposals in in-classroom activities could possibly enable students to exercise a way of thinking and explaining what is proper of sciences.

Marine Deficit 'Disorder': Marine Literacy in Primary Student Teachers

*Cushla Dromgool-Regan, Noirín Burke, & Thomas McCloughlin*
STRAND 8: INTRODUCTION

SCIENTIFIC LITERACY AND SOCIO SCIENTIFIC ISSUES

Teachers’ role and skills for developing students’ scientific literacy, often through socioscientific issues were given much interest in many of the papers presented in strand 8. Hence, with a focus on teachers, studies were presented that adds to our knowledge on how in- and pre-service teachers better can organize and promote students’ development of scientific literacy and socioscientific reasoning. Among these, examples of frameworks and models for teaching scientific literacy and socioscientific issues that can be useful for professional development were discussed. To provide tools for teachers to develop a fruitful classroom communication a group of papers described the assessment and analysis of students’ socioscientific discourse. In addition, other studies described the conditions for students’ engagement in socioscientific issues to produce complex and well-grounded arguments.

Scientific literacy and socioscientific reasoning are important skills for all members of society. Hence, these skills can preferably be used without the limitations of the wall of a classroom. A number of papers brought different perspectives on authentic communication to the fore. Here the interaction with stakeholders in society for the purpose to deepen students’ knowledge and perspectives were given attention. Examples to promote students in taking further responsibility for society by engaging in societal discourses were given using diverse issues such as, for example, environmental problems, justice, and research and innovation. Among these, socioscientific issues concerning environmental problems were given much interest.

The following part of this proceeding contains eleven papers from the strand.

The paper by Sakamoto and Yamaguchi investigates how two types of socioscientific issues influence students’ informal reasoning. They found that issues that contain strong dilemmas often led to more emotive reasoning and less rationalistic reasoning than did issues that contain weaker dilemmas. Hüfner, Fiebert and Abels compare 8th grade students’ conceptions on energy resources with that of scientists. To do this, they interviewed students and analysed scientific reports on climate change. They found that there is a way to categorise both students’ and scientists conceptions of energy resources and that similarities and differences in these categories help us to indicate what to address in science education in the future concerning this topic.

The paper by Schenk and colleagues elaborates on the concept of risk and how that concept holds implications for teaching and science education research. One of the main findings is that there is a great variability in terms of how the concept of risk is understood and used, but that this variability may actually be needed. Further the authors argue that risk ought to be included in science teaching.

Vidal, Simonneaux and Levison investigate the place and role of myths in discussions of socioscientific issues among students in England, France and New Zealand. They were able to track the existence of thematic myths in specific issues, and they discuss what these findings mean for practice.
Rydberg, Olander and Sjöström study interdisciplinary teaching of controversial issues. Their findings indicate inherent tensions at different level of complexity in carrying out interdisciplinary teaching around such issues.

Bayram-Jacobs, Henze and Barendsen study how the ENGAGE material can engage students in socioscientific issues interweaving chemical concepts, society and personal life. It was found that students focused more on aspects on society and personal life than on chemical concepts. Baytelman and Constantinou investigate the influence of University students’ content knowledge on their construction of ethical arguments on different health issues. Students’ complex concept maps of content knowledge were found to predict a high quality of socioscientific arguments.

The paper by Motokane investigates students’ knowledge about three hierarchical levels of biodiversity: species diversity, ecosystem diversity and genetic diversity. In particular, the paper stresses the importance of forming relationships between the three levels and to fully understand genetic diversity to grasp the complexity of biodiversity.

Papers by Chadwick, Vidal and Dromgool-Regan examine literacy within context of socioscientific issues.

Jan Alexis Nielsen and Mats Lindahl
INFORMAL REASONING FOR SOCIO-SCIENTIFIC ISSUES CONCERNING DILEMMAS FACED BY GENETIC MEDICAL TECHNOLOGIES

Miki Sakamoto and Etsuji Yamaguchi
Kobe University, Kobe, Japan

Individuals’ negotiation of socio-scientific issues (SSI) is often investigated through the framework of informal reasoning. This study aims to examine the impact of SSI dilemma strength on informal reasoning. One hundred and twenty-one university students responded to a questionnaire in which two SSI scenarios (one strong dilemma, one weak dilemma) concerning genetic medical technologies were presented. The participants were required to state their opinions and justifications on each scenario, as well as provide hypothetical counterarguments and rebuttals. To determine the quality of informal reasoning used, students’ written arguments were analysed and classified into three categories based on the types of reasoning displayed: rationalistic, emotive, and intuitive reasoning. A comparison of responses showed that the incidence rates of different informal reasoning patterns differed depending on the SSI scenario. In scenarios with strong dilemmas, emotive reasoning was employed more frequently, while use of rationalistic reasoning was less frequent. This tendency was generally shared regardless of participants’ gender or major. Thus, dilemma strength was found to affect participants’ informal reasoning patterns, such that strong SSI dilemmas disturbed participants’ rationalistic reasoning. This tendency was prominent among the participants who agreed with the presented scenario. This study’s findings may provide suggestions for improving and evaluating the design of SSI-based interventions.

Keywords: socio-scientific issues, dilemmas, informal reasoning

INTRODUCTION

Social issues related to science have become an important issue in science education research. Socio-scientific issues (SSI) are complex social dilemmas that represent applications of scientific principles and practices. SSI are typically ill-structured problems, which are subject to multiple perspectives and involve morals, ethics, personal experiences, and other values (e.g., Sadler & Zeidler, 2005). Examples of SSI include genetic engineering, cloning, local pollution issues, and global climate change. In the last decade, science education researchers and practitioners have made significant advances in using SSI as contexts for transforming science learning (Romine, Sadler, & Kinslow, 2017; Sadler & Dawson, 2012). SSI approaches can be an effective means of supporting learning that are aligned with Vision II science literacy, which focuses on the ways in which students conceptualize and use science content and practices through explorations of complex issues (e.g., Zeidler, 2014). More recently, empirical investigations of SSI-based interventions that focus on students’ reasoning or decision-making in SSI contexts have also increased (e.g., Evagorou, Jiménez-Aleixandre, & Osborne, 2012; Lee & Grace, 2012; Venville & Dawson, 2010; Wu & Tsai, 2012).

Sadler and Zeidler (2005) conducted an SSI based investigation of the informal reasoning of college students engaged in negotiating of controversial and complex genetic engineering issues. These researchers characterized informal reasoning as rationalistic, emotive, and
intuitive. Rationalistic reasoning represented reasoning based on analyses of data or principles, emotive reasoning represented the application of emotions such as empathy and sympathy, and intuitive reasoning represented immediate or gut-level reactions. They found that their participants frequently relied on combinations of these reasoning patterns and tended to employ rationalistic patterns most frequently. Regarding these definitions, Evagorou et al. (2012) pointed out that Sadler and Zeidler’s (2005) selected term, ‘emotive’, only accounted for positive feelings towards others. To deal with arguments based on emotions that were not positive, Evagorou et al. (2012) added a second emotive category, which they labelled as emotive negative or personal. They defined this emotive category as being “consistent with the application of moral emotions. People that use this seem to care about their own well-being rather than that of others or to be driven by feelings of antagonism towards others” (p. 414).

Previous studies (e.g., Topcu, Sadler, & Yilmaz-Tuzan, 2010) have suggested that issue contexts affect the informal reasoning processes employed by individuals. The individual contexts of issues likely play a large role in shaping informal reasoning patterns; however, this proposed link has not been explicitly investigated. For example, it is not clear how factors such as the dilemma strength or the application of personal experiences in the relevant context affect an individual’s informal reasoning patterns. Strong dilemmas involving personal morals or ethics may disturb rationalistic reasoning. Examining the impact of dilemma strength on reasoning in SSI contexts may help to elucidate in greater detail the thought processes employed in SSI involving diverse values. These examinations could provide suggestions for SSI-based interventions and evaluations of their effectiveness.

The purpose of the current study was to examine how the strength of SSI dilemmas affected university students’ informal reasoning. To this end, we developed an assessment task in which the strength of SSI scenarios was manipulated. We compared the patterns of informal reasoning that emerged from each SSI context. We also examined the impact of participants’ gender and major on informal reasoning. In addition, for each scenario, the arguments provided for and against the scenario were compared in terms of informal reasoning patterns.

METHODS

Participants

A total of 121 undergraduate students participated in the study. Participants reported their age, sex, major, year of study, and any science-related classes they had taken in high school. The participants consisted of 75 males and 46 females. Among these, 28 participants were science majors and 93 were humanities majors.

SSI argument tasks

We presented two scenarios: one involved a designer baby and the other involved a baby with Huntington’s disease. Both scenarios addressed SSI related to genetic medical technologies, but we manipulated dilemma strength by introducing human survival as the main issue in the strong dilemma. Our designer baby scenario was a Japanese version of the one created by Venville and Dawson (2010). The Huntington’s disease scenario—our stronger dilemma—was based on Sadler and Zeidler’s (2005) SSI scenario and Zohar and Nemet’s (2002) Cystic
Fibrosis scenario. In this scenario, following antenatal testing, the parents decided not to deliver a child who carried the genes responsible for Huntington’s disease. For each scenario, participants were required to state their opinions (for or against the presented scenario) and justifications, and then to construct hypothetical counterarguments and rebuttals to them.

**Procedure**

We used a questionnaire to survey the students while we were lecturing the students.

**Analysis**

Based on the Venville and Dawson’s (2010) framework, descriptions of justifications and rebuttals were categorised into three reasoning patterns: rationalistic reasoning, emotive reasoning, and intuitive reasoning. Table 1 illustrates the participants’ entries, and the categories and descriptions to which they were assigned.

**Table 1. Categories, descriptions, and examples of informal reasoning from this survey.**

<table>
<thead>
<tr>
<th>Category</th>
<th>Description</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rationalistic Reasoning</td>
<td>Logical thinking, uses scientific understanding and language, reasoned-based calculations, weighs risks, benefits, advantages and disadvantages</td>
<td>Since certain characteristics are considered preferable in human society, I think acceptance of designer babies will cause adverse results. Similar genes will be propagated, which is risky. For instance, loss of gene divergence will impair survival in case of environmental change. In addition, people will lose their individuality and sense of personality, which will make personal identification difficult.</td>
</tr>
<tr>
<td>Emotive Reasoning</td>
<td>Emotional response towards stakeholders, shows care, empathy, sympathy, and concern for plight of those affected</td>
<td>It would be a pitiful scenario, where children have to live in constant fear of acquiring the disease, and the parents have to live in a continuous state of worry that their children might acquire the disease at any time.</td>
</tr>
<tr>
<td>Intuitive Reasoning</td>
<td>Considerations based on immediate reactions to the context of scenario, often exhibits a negative response, and often precedes rational or emotive reasoning</td>
<td>I think one should not terminate a life even if the baby is destined to have the disease. Modifying the human body using our limited human intellect is a blasphemy against God.</td>
</tr>
</tbody>
</table>

**RESULTS**

To determine the extent of participants’ knowledge on the selected themes, we examined the biology-related classes participants had taken in high school. Thirty-six percent of participants had taken Basic Biology, eleven percent had taken Advanced Biology, thirty-two percent had taken Biology I (Basic), and seven percent had taken Biology II (Advanced). Number of classes taken was as follows; fifty-eight percent had taken one class, fourteen percent had taken more than two classes, and twenty-eight percent had taken no classes. Participants in the third group,
who had not taken any biology-related classes, reported that they had taken physics-related or chemistry-related classes.

Figure 1 shows the distribution of opinions among participants. There were significant differences in approval rates between the scenarios ($p<.05$, exact test). In the weak dilemma, more participants opposed the use of genetic medical technologies. In both scenarios, no differences were found in agreement rates based on participant gender, major, or number of biology-related classes taken in high school. Fifty-four percent of participants were consistent in their opinions across the two scenarios.

![Figure 1. Distribution of opinions for each scenario](image)

**Impact of SSI dilemma strength on informal reasoning**

Figure 2 displays the rates at which each reasoning pattern was employed by participants in their justifications and rebuttals for each scenario. Cochran’s Q tests showed that there were overall significant differences in the incidence rates in each scenario (justifications for the weak dilemma, $Q=58.018$; rebuttals for the weak dilemma, $Q=90.830$; justifications for the strong dilemma, $Q=84.483$; rebuttals for the strong dilemma, $Q=71.402$; all $df=2$, $p<.001$.). The results of post hoc tests showed that, in justifications for the weak dilemma, rationalistic reasoning was employed significantly more often than emotive or intuitive. In rebuttals for such dilemmas, rationalistic reasoning was employed more often than emotive reasoning, and intuitive reasoning. In both justifications and rebuttals for the strong dilemma scenario, emotive reasoning was employed more often than rationalistic reasoning, and intuitive reasoning.

The comparisons of the incidence rates of each reasoning pattern between scenarios found similar significant differences. In both justifications and rebuttals, rationalistic reasoning appeared more frequently for scenarios with weak dilemmas than scenarios with strong dilemmas ($Z=13.754$, $p<.001$; $Z=19.184$, $p<.001$), and emotive reasoning appeared more frequently for scenarios with strong dilemmas ($Z=30.947$, $p<.001$; $Z=29.469$, $p<.001$). Intuitive reasoning in the justifications appeared more frequently for scenarios with weak dilemmas ($Z=8.828$, $p<.01$).

We also compared the incidence rates of reasoning patterns according to participants’ major and gender. Science majors showed significantly higher rates of rationalistic reasoning than humanities majors in rebuttals for strong dilemmas (71.4% vs. 44.7%; $p<.05$, exact test); however, no other comparisons, including the number of biology-related classes taken, resulted in any significant differences.
Impact of participants’ opinions about the scenarios on informal reasoning:

Figure 3 shows the rates of different patterns of reasoning based on participants’ opinions for weak dilemmas, and Figure 4 shows rates of reasoning patterns based on participants’ opinions for strong dilemmas. Results of chi-square tests demonstrate that for justifications and rebuttals in both scenario types emotive reasoning was used more frequently by proponents than opponents (weak dilemmas, $\chi^2(2)=12.835$, $p<.001$; $\chi^2(2)=10.084$, $p<.001$; strong dilemmas, $\chi^2(2)=41.852$, $p<.001$; $\chi^2(2)=4.388$, $p<.05$) and rationalistic reasoning was used more frequently by opponents than proponents (weak dilemmas, $\chi^2(2)=6.116$, $p<.05$; $\chi^2(2)=2.495$, n.s.; strong dilemmas, $\chi^2(2)=26.663$, $p<.001$; $\chi^2(2)=7.142$, $p<.01$). In the case of justifications, intuitive reasoning was employed more frequently among opponents than proponents (weak dilemmas, $\chi^2(2)=8.700$, $p<.01$; strong dilemmas, $\chi^2(2)=9.788$, $p<.01$). Almost no instances of intuitive reasoning were found in rebuttals.

Additionally, opponents’ reasoning and proponents’ reasoning were analysed separately. Cochran’s Q tests and post hoc tests showed that opponents employed rationalistic reasoning more frequently than emotive reasoning in justifications for strong and weak dilemmas and in rebuttals for weak dilemmas, but not in rebuttals for strong dilemmas. Among proponents, on the other hand, emotive reasoning was used more frequently than rationalistic reasoning in strong dilemmas. In fact, almost all proponents (94.5%) relied on emotive reasoning in making justifications. In weak dilemmas, rationalistic reasoning was employed more frequently than emotive reasoning for rebuttals, and both were employed to the same degree for justifications.
Comparing arguments for the two types of SSI scenarios revealed that informal reasoning pattern rates differed depending on the scenario. In strong dilemmas, emotive reasoning was used more frequently and rationalistic reasoning was used less frequently, than in weak dilemmas. This tendency was shared by all participants regardless of gender or major. Comparing the arguments provided for and against scenarios revealed that participants’ opinions about the scenarios affected their informal reasoning patterns; opponents generally relied on rationalistic reasoning, while proponents tended to use emotive reasoning. Our findings show that constructing arguments against issues might promote logical thinking to resolve the dilemmas. There were more proponents of the strong dilemmas, which may have resulted in more emotive reasoning in this type of scenario.
In summary, the strength of the dilemma in a scenario tended to affect university students’ informal reasoning regarding SSI. Even if students were capable of rationalistic reasoning in scenarios with weak dilemmas, when faced with a scenario containing a strong dilemma, students mostly relied on emotive reasoning. This tendency was prominent among the proponents, that is, the participants who agreed with the presented scenario.

CONCLUSION

Our findings may provide insight for improving the design of SSI-based interventions and evaluations. Empirical investigations of SSI interventions (e.g., Evagorou et al., 2012; Lee & Grace, 2012; Venville & Dawson, 2010) have often evaluated students’ reasoning or decision-making in SSI contexts as a learning outcome, but used assessment tasks with only one scenario. Based on our findings, we suggest using evaluation tasks with various scenarios or contexts in SSI-based interventional research. Participants’ opinions about the scenarios should also be taken into account in analysing the outcomes of SSI interventions. Overall, these findings provide important guidelines, which can be used to analyse SSI-based curriculums.

In the future, we plan to examine the consistency of students’ opinions and reasoning patterns across scenario types, and to carefully analyse the arguments provided in each scenario type, in order to identify any factors that students may use to resolve these dilemmas.

RENEWABLE ENERGY RESOURCES: HOW CAN SCIENCE EDUCATION FOSTER AN APPROPRIATE UNDERSTANDING?

Sybille Hüfner¹, Kai Niebert² and Simone Abels¹
¹Leuphana University Lueneburg, Lueneburg, Germany
²University of Zurich, Zurich, Switzerland

The increasing use of energy and its impacts on the atmosphere, the oceans, the soil and the biosphere is one of the main arguments that have been put forward for the Anthropocene age. The energy transition from non-renewable to renewable energy resources is a core strategy to avoid greenhouse gas emissions that contribute to the human-induced climate crisis, which the UN considers a major challenge for politics and society. To become scientifically literate citizens, students need to actively engage with this topic. To effectively implement the energy transition in science education, we need to know about students’ learning demands. Using the model of educational reconstruction, we gathered and compared conceptions of 8th-grade students and scientists concerning non-renewable and renewable energy resources. For this, we conducted guideline-based, problem-focused interviews with 27 students and analyzed sections of two scientific reports for scientists’ conceptions. Our results indicate that students’ and scientists’ conceptions can be structured in six categories (availability, consequences of use, producibility, conservation, naturalness, and costs). These categories can be helpful to design interventions for science classrooms.

Keywords: energy education, sustainability education, student’s conceptions

INTRODUCTION

Humans’ rising hunger for energy is strongly connected to the age of the Anthropocene and contributes to anthropogenic effects on earth systems (Steffen, Broadgate, Deutsch, Gaffney, & Ludwig, 2015). Due to increased greenhouse gas emissions, we have already exceeded the planetary boundaries relating to climate change (Steffen, Richardson, et al., 2015). The transition from non-renewable to renewable energy resources is a core strategy to contain the human-induced climate crisis, which the UN considers a major challenge for politics and society (UN, 2015). In order to foster scientific literacy in terms of active participation in societal communication and opinion making, it is important to address the topic of the energy transition in science education as well. To identify students’ learning demands, we need to inquire about their preconceptions and contrast them with scientific conceptions.

THEORETICAL BACKGROUND

The history of energy transitions is closely intertwined with the history of mankind (Bithas & Kalimeris, 2016). The transition to the utilization of fossil energy resources becoming the predominant resources for the energy supply was accompanied with the massive growth of the world’s population and other socio-economic trends. This led to an exponential increase in all of these trends since the 1950s, which triggered the process in which humans altered the earth systems in an irreversible way leading to the age of the Anthropocene (Steffen, Broadgate, et al., 2015). The first demonstration that this path taken, concerning the world’s energy supply,
has its limitations showed itself in the peak oil debate in the late sixties and the oil crises in 1973 and 1979 (Bithas & Kalimeris, 2016). These crises fell together with the time when the term ‘renewable’ was first used in reference to energy resources (Harper, 2018). Hence, the growing usage of the expression ‘renewable energy’ is closely linked to the availability of energy resources and the attempt to overcome the shortage of fossil energy resources. In the age of the Anthropocene the focus shifts from the availability of fossil energy resources to the confinement of the negative consequences of their use. From a natural scientist point of view the transition to alternative energy resources is necessary to massively decrease the emission of greenhouse gases and avoid the security risks of nuclear power plants and nuclear waste (WBGU\(^1\), 2003, 2011). Therefore, when we talk about energy transition we refer to a transition from fossil and nuclear energy resources to renewable energy resources.

Concerning the term ‘renewable energy’ there is a common agreement that energy resources derived from the sun (indirectly including wind, hydropower, biomass), geothermal heat and tidal action are labelled renewable (e.g., Ellabban, Abu-Rub, & Blaabjerg, 2014; WBGU, 2003, 2011; Spellman & Bieber, 2011). In contrast to this, other definitions of ‘renewable energy’ based on scientific criteria seem to be difficult to formulate. One example for a vague definition is renewable energy resources being characterised as ‘naturally replenished’ (e.g. Spellman and Bieber, 2011: 8). This is debatable because it could be claimed that fossil fuels are also naturally replenished, although this process takes billions of years. Furthermore, the sun is considered to be a renewable energy resource though its nuclear processes will come to an end sometime in the far future. Twidell and Weir (2015: 3) focus even more on the dynamics of the energy system and define renewable energy as a ‘naturally repetitive and persistent flow of energy’ in contrast to the non-renewable ‘static stores of energy that remain underground’. In this definition without a specific timescale it is difficult to categorise biomass since it is a chemical store of energy, only most of it decomposes over time and is so less stable (a very small amount of it entering the process of becoming fossil fuels). Therefore, Twidell and Weir (2015) use the localisation of the storage (‘underground’) as the telling point that allows a differentiation between renewable and non-renewable energy resources when it comes to biomass. Some other publications simply avoid the definition problems by implicitly assuming a common shared understanding of ‘renewable energy resources’ (WBGU, 2003, 2011).

From a linguistic point of view the term ‘renewable’ could be confusing, since the prefix re- and the suffix -able imply that a subject has to actively do something to make something ‘new’ again (Wehling, 2016). What makes it so difficult to talk about energy resources in general is that this expression does not only refer to substances like coal, crude oil or natural gas but also to immaterial systems that contain a valuable amount and form of energy. In these systems, substances are also involved, e.g. water in a dam. Nevertheless, in the literature often just the energy carriers are referred to (e.g. named as wind) meaning the system (Ellabban et al., 2014; Twidell & Weir, 2015). Before the conversion into forms intended for usage (e.g. electricity) these ‘naturally occurring’ forms of energy are called primary energy (WBGU, 2011: 111).

---

\(^1\) WBGU is the German acronym of the German Advisory Council on Global Change of the German government.
Additionally, the concept of energy itself is difficult to understand. Students often think of energy as a substance (e.g., Wernecke, Schwanwedel, & Harms, 2017). However, from a physicists’ point of view energy is an abstract concept that can only be indirectly defined or described by overall principles (Feynman, Leighton, & Sands, 2011). According to Duit (2014) there are four strongly interrelated basic ideas concerning energy that foster a scientifically appropriate understanding: transformation, conservation, transfer and degradation. Other authors add another basic idea of energy forms, and consider energy transfer and transformation to be one idea (Neumann, Viering, Boone, & Fischer, 2013). Although learning about energy seems to be complex and non-linear (Yao, Guo, & Neumann, 2017), research has shown that for students the concept of energy conservation seems to be most difficult to understand (e.g., Neumann et al., 2013; Tatar & Oktay, 2007; Yuenyong, Jones, & Sung-Ong, 2011). There seem to exist quite similar problems concerning the conservation of matter. For example, when students struggle to explain what happens with substances after a chemical reaction, e.g. when burning a substance and the products of this reaction cannot be perceived with the senses (Löfgren & Helldén, 2008). When it comes to the connection of energy and the cycling of matter, students are often not able to see this relation, especially when living and non-living systems are involved (Jin & Anderson, 2012; Lin & Hu, 2003). In the specific context of the energy transition to renewable energy resources most students do not understand that renewable energy resources produce fewer greenhouse gas emissions and how this relates to whether they are carbon-based (Cheong, Johari, Said, & Treagust, 2014).

Due to the vagueness of technical terms it is not surprising that there are studies that suggest that students are having problems with defining the phrase ‘renewable energy source’ in a scientifically appropriate way or with correctly assigning energy resources like natural gas or geothermal heat to the categories ‘renewable’ or ‘non-renewable’ (e.g., Bodzin, 2012; DeWaters & Powers, 2011). In his study, Menthe (2006) let students explain why certain energy resources are categorised as renewables or fossil fuels. He found three categories of conceptions of fossil fuels (they cause pollution, are limited, cease to exist after usage) and two categories concerning renewable energy resources (are natural, are reusable). Since the terms ‘renewable’ and ‘non-renewable’ are used to classify energy resources it remains to be researched which conceptions lead students to assign different energy resources to one of these categories. The model of educational reconstruction (MER) stresses that considering both students’ conceptions and the clarification of a specific science-related content are crucial starting points for effective learning sequences (Duit, Gropengießer, Kattmann, Komorek, & Parchmann, 2012). Within the MER, students’ conceptions are contrasted with the scientists’ conceptions. From these comparisons a suitable structure of the scientific content for education can be derived. In the case of energy transition these steps are especially relevant. As potential obstacles for understanding the scientific reasons and circumstances of the shift from non-renewable to renewable energy resources lie in the students’ conceptions as well as in difficulties related to the definitions of energy and renewable energy resources. In our research, we therefore aim to answer the questions about how students and scientists conceptualise renewable and non-renewable energy resources. From the comparison of these mental

---

2 Throughout this paper, we refer to a moderate constructivist point of view of learning and teaching. Therefore, by the term ‘conceptions’ we mean a mental construct of a phenomenon.
constructs we want to derive the learning demands of the students. Based on these results we generate recommendations about how to structure the content for science education.

RESEARCH QUESTIONS

The aim of the study is to provide recommendations for science education about how a scientifically appropriate understanding of the energy transition from non-renewable to renewable energy resources could be fostered. Based on the theoretical background and the MER presented above the following research questions were derived:

1) How do secondary school students conceptualise renewable and non-renewable energy resources?

2) How do scientists conceptualise renewable and non-renewable energy resources?

3) Which differences and similarities can be derived from the comparison of the students’ and scientists’ conceptions of renewable and non-renewable energy resources?

4) How can renewable and non-renewable energy resources as a content for science education be structured to foster an appropriate understanding?

METHOD

Our research design is based on the MER (Duit et al., 2012). Due to the explorative character of this study qualitative methods are appropriate. To investigate the learners’ conceptions, we decided to conduct problem-centred interviews, because this allows us to start with very open and general questions, influencing the students as little as possible and on the other hand allowing us to encourage the students to explain and specify their conceptions. An interview guideline developed from the theoretical background assured us that the interviews were conducted in an equivalent way and the same main questions were asked (Niebert & Gropengießer, 2014). The first author conducted all of the interviews herself, interviewing 27 students from different school types in northern Germany. For our sample we chose students from the 8th grade, since we wanted to gather conceptions the students hold after learning about basic ideas of energy and matter in chemistry, biology and physics, but not yet having applied them in the context of energy transition according to the local science curricula. To get a variety in students’ conceptions we interviewed students from three different classes in three different schools in northern Germany. We interviewed all students of these classes that had the permission of their parents and volunteered to take part in the study.

In the beginning we ran seven individual interviews. To foster the flow of speech and to put students at ease, we then switched to pair interviews. The interviews included a narrative prompt with cards that named and pictured nine different renewable and non-renewable primary energy resources (coal, oil, natural gas, biomass, uranium, wind, sun, water, and geothermal heat). The students started by commenting on the cards. After that they were asked to organise them according to their own criteria and explain their classification. If they had not already done so, the students were asked to sort the cards into the categories renewable and non-renewable energy resources.

\[ \text{As we assumed it might be confusing and hard to recognize a difference in the pictures, we decided not to differentiate between tidal energy and hydro energy, although they refer to completely different energy systems.} \]
non-renewable energy resources. The interviews were audiotaped, transcribed and anonymised.

To analyse the scientists’ conceptions, we chose sections of two reports from the German Advisory Council on Global Change (WBGU, 2003: 43-95, 2011: 110-119), as they include a wide and substantial science-based evaluation of the relevant aspects of the energy transition. To gather scientists’ conceptions of renewable energy resources in order to clarify the scientific content the analysis of these written documents is appropriate.

Transcripts and reports were analysed with qualitative content analysis (Mayring, 2002). First, we inductively identified categories that the students used to describe renewable and non-renewable resources. We analysed the transcripts of the interviews until we reached a theoretical saturation. In the next step, we deductively applied the categories we found to the report sections. In some cases, further categories had to be added inductively.

RESULTS AND DISCUSSION

By means of the qualitative content analysis of the students’ interviews and the scientific reports, we identified six categories used to characterise renewable and non-renewable energy resources (Table 1). The category availability was derived from statements describing the availability of renewable and non-renewable energy resources regardless of which kinds of aspects of availability they referred to. The category consequences of use is based on remarks about what impacts the usage of the energy resources has during the transfer and transformation into another energy form. The category producibility refers to whether a renewable or non-renewable energy resource is characterized by the ability of a subject to (re-)create or (re-)build it. Another category is the conservation of energy resources after ‘usage’, which means the energy transfer to another system. Since the category was inductively derived from the student’s statements, it does not specify whether conservation refers to energy or matter. Statements about renewables or non-renewables referring to naturalness as the characteristic feature were pooled in the category naturalness. Under the sixth category costs sequences in the reports that refer to the monetary aspects of the energy resources were summarised.

Comparing the students’ and the scientists’ conceptions we found that they share only two of these categories: availability and consequences of use. Only the students use the categories producibility, conservation and naturalness, whereas the category costs is only found in the analysed scientific reports. In general, students tend to characterise renewable and non-renewable energy resources in a dichotomous way using antagonistic expressions (Table 1). Students tend to use these as a dichotomous instrument to decide whether an energy resource is renewable or not. This often leads to inappropriate results. For example, Jana⁴ justifies wind being non-renewable by using the category ‘naturalness’ saying: ‘There is also wind on an unnatural basis, for example with air conditioning or ventilators. It is wind, but not natural wind.’ This could also explain similar problems with the assignment of different energy resources in former studies (e.g., Bodzin, 2012; DeWaters & Powers, 2011).

⁴ All names are altered.
Table 1. Categories of conceptions characterising renewable and non-renewable energy resources.

¹X means, that we found no corresponding conceptions in the material.

However, the scientists evaluate every single energy resource under multiple perspectives weighing their advantages and disadvantages. Our results correspond with the findings of Menthe (2006) since the categories he identifies for the students’ conceptions of fossil fuels (they cause pollution, are limited, ‘vanish’ after usage) and renewable energy resources (are natural, are reusable) can all be assigned to one of the overall categories (Table 1) we identified. In our research we showed that students use these categories in different, often dichotomous manifestations to characterise both renewable and non-renewable energy resources. Nevertheless, to be able to participate in the current debate and to evaluate different energy resources it is necessary for the students to gain a more holistic view. To derive more detailed recommendations about how the content could be structured, it is essential to analyse the different categories in more detail.

Availability of energy resources

Regarding the category of the availability of energy resources, some students think that for renewables it is unlimited whereas for non-renewables it is limited. For example, Olga says: ‘renewable [means] that resources are inexhaustible. [Regarding non-renewable resources] the stock is limited.’ In the view of the scientists both non-renewable and renewable energy resources are limited to various degrees in three dimensions: spatial, material and temporal (WBGU, 2011). In the students’ conceptions, another manifestation of the category availability includes a judgemental component. Karin says: ‘Renewable energies are substances that are much more common on earth, so that other scarce substances don’t become rare.’ According to the WBGU (2011), renewable and non-renewable energy resources are abundant and ‘as yet still available generous volumes of fossil fuels could prove to be an obstacle for the transformation …’ (WBGU 2011: 110).

In the light of the etymological and historical background of the term ‘renewable energy” (Bithas & Kalimeris, 2016; Harper, 2018), it seems rather natural that the category availability of the energy resources plays a prominent role for both students and scientists. Even more so since common definitions of renewables, due to the temporal correspondence of the occurrence of the expression and the shortage of energy resources, focus on their availability (e.g. Spellman & Bieber, 2011; Twidell & Weir, 2015). It is also interesting to note the differences between the students’ and the scientists’ conceptions in the statements assorted to this category. Whereas the students approach the question of the energy resources’ availability in an
Strand 8

exclusively material way, scientists also consider aspects of space and time. The narrowed perspective of the students may be caused by their everyday experiences because availability and resources often are connected to material things. Regarding the subcategories of the scientists’ conceptions within the category availability, it is striking that in contrast to the quite dichotomous view of the students the WBGU (2003, 2011) describes each energy resource as limited in a characteristic way, concerning either material or temporal or spatial distribution. This corresponds with common definitions of renewable energy resources (cf. the section theoretical background) that are based on the differences in the availability of renewable vs. non-renewable energy resources. They draw on the same three dimensions to define renewables. In the context of education this could be helpful information that allows the students to reflect on a (partially) insufficient definition of renewable energy (whether it is their own or a scientific definition) and discuss the differences within the dimensions of time, space and matter. For example, this might be enlightening in the case of biomass as an energy resource as it is difficult to include in an overall definition of renewables, because like fossil fuels it is stored energy in a chemical form. From the perspective of time biomass regenerates much faster and at a distinctively higher rate than fossil fuels. Also, there is a spatial difference between fossil fuels and biomass as an energy resource because the latter grows on the surface of the earth whereas coal, oil and natural gas are usually stored underground. Furthermore, the perspective of time, space and matter could help students to reflect upon the limitation of renewable energy resources in a way other than matter, since e.g. sun and wind are also characterised by their fluctuation and the differences in their availability according to geographical reference point.

Consequences of use

Concerning the category consequences of use, we found that students held the conceptions that renewable and non-renewable energy resources are clean and dirty or toxic and non-toxic, respectively. Accordingly, Anton states that renewable energy resources would produce ‘no toxic exhaust gases at all’ and Hugo talks about non-renewable energy resources as being ‘more harmful to the environment’, for example, oil polluting the air. In general, the students tend to refer to the conversion process of the energy resource. Only one student, Olga, calculates the consequences using a broader perspective, when she states: ‘In the long run, if you accept this bigger pollution [from building the power plants and running them] … [renewables] are much more useful’. In contrast, the WBGU scientists list consequences for all energy resources, renewable and non-renewable, presenting effects on humans (addressing health and society) and the environment (WBGU 2011). The council calculates different scenarios and takes into account the whole life cycle. For example, the scientists write about bioenergy: ‘Some … pathways can certainly produce higher greenhouse gas emissions than the use of fossil fuels’ (WBGU, 2011: 117). Still as a result of their calculation they come to the conclusion, that ‘the use of renewable energies … is usually associated with considerably lower greenhouse gas emissions than the use of fossil fuels’ (WBGU: 117).

There are different points of references within the students' and the scientists' conceptions. The students mostly talk about the transformation process when renewable or non-renewable energy resources are converted into another energy form for use (e.g. electricity), whereas the
scientists refer to the whole life cycle, e.g. calculating impacts of mining, land use, construction and disposal. A possible reason behind these different viewpoints might be that immediate consequences can be more directly observed. This goes along with a greater presence in the media, which report on the negative impacts of emissions rather than the whole life cycle and especially more prominently about accidents (e.g. the accident in the nuclear power plants in Fukushima in 2011).

Nevertheless, their different viewpoint cannot explain why students’ statements show a very unspecific view on the consequences of use, characterising non-renewable energy resources as dirty or toxic without mentioning carbon dioxide. Possibly this could be due to difficulties recognising the connection between the carbon content of the energy resources and greenhouse gas emissions (Cheong et al., 2014).

To understand the massive changes in the earth systems that led to the Anthropocene, students must be able to explain that a massive increase of the use of fossil energy resources always comes with a massive increase of carbon dioxide emissions and is a main cause for the climate crisis. Due to this interrelationship, the energy transition to carbon-free or carbon-low energy resources is a logical consequence. What might be an obstacle to viewing the outcomes is that common definitions of renewable energy resources are based on their availability not on the consequences of their use (Spellman & Bieber, 2011; Twidell & Weir, 2015).

In an education suitable to the age of the Anthropocene it is more important than ever to enable students to evaluate and to argue, enabling them to participate in society in order to shape their future. Hence, it is essential to know about the consequences of use of the different energy resources during the conversion process and to take a broader perspective including different stages of the life cycle. These different perspectives allow students to argue with people who rely on isolated observations (e.g. impacts of the production of photovoltaic systems). Additionally, students should reflect upon the definition of the term ‘renewable energy resource’ under the perspective of the consequences. For example, they could discuss alternative wordings related to outcomes like carbon-low or carbon-free or waste-free (if including nuclear energy resources).

**Producibility of energy resources**

Only the students use the criteria of producibility to distinguish renewables and non-renewables. So, Martha says: ‘Non-renewable energy is something that cannot be produced again, something like oil. … Biomass [is renewable] because when you harvest it or it gets destroyed … you can always grow it again.’

These conceptions could be caused by a literal interpretation of the term renewable. The cognitive linguist Elisabeth Wehling (2016) states that the prefix *re-* and the suffix *-able* imply that a (human) subject has to actively do something. This framing could lead to the conception our students expressed that renewable energy resources are *producible*. These interpretations contradict common definitions of renewable energy that define these energy resources as being ‘naturally replenished’ (Spellman & Bieber, 2011: 8) or refer to a constant flow of energy (Twidell & Weir, 2015).
In science education to foster an understanding that is in line with basic ideas of energy and matter we should reflect together with the students upon the term ‘renewable’, its literal meaning and its limitations.

**Conservation of energy resources after usage**

Other students focus on the observation of what happens to the material in the energy transformation process and explain the difference by the ‘conservation’ or the ‘vanishing’ of this material. Karl explains: ‘Renewable is when the water delivers energy and you can extract energy from the water again and again as long as water exists. If you burn coal and therefore get energy, you cannot burn the coal again, because it is gone. It is non-renewable.’ Karl is one example of some students that consider wind and water to be renewable because these elements are conserved. The students do not recognise that it is not the water itself that is the energy resource but the system in which the water is stored (for example in a dam) and therefore holds potential energy that can be transferred to another system. After this transformation process the water still exists, but holds less potential energy. However, for the water to get back to the dam there first has to be transferred energy (e.g. electrical energy from a pump or energy from solar radiation through the global water cycle) to this system again.

When the students talk about fossil fuels in statements placed in the category vanishing, as Karl, they describe the substance (e.g. coal) as ‘gone’ after the transformation process. Here not only the energy but also the matter is transformed and transferred to another system. These statements show that the students are unable to apply the basic idea of the conservation of matter. As Löfgren and Helldén (2008) propose, this might only be a problem of expression. So, in our case the students may want to simply stress that the reactant of the chemical reaction, the fossil energy resource, is ‘gone’ in its original form and that this process under the given conditions is irreversible. Although this conception is not scientifically inappropriate, in the context of the energy transition and the Anthropocene it is important to emphasise the conservation of matter because carbon dioxide emissions as a by-product of the transformation process are crucial (WBGU 20011, 2003).

Nevertheless, in both subcategories conservation and vanishing, the students focus on the material and do not see the connection to the energy flow: whether it is a renewable energy resource or a fossil fuel, energy is transferred to another system and the sum of this transferred energy is missing in the original system after this process. This observation agrees with the findings of earlier research that shows the problems of students to understand the relationship between energy and the cycling of matter (Jin & Anderson, 2012; Lin & Hu, 2003). A possible explanation could be, that the students understand the term ‘energy resource’ rather in a material way than looking at the systems containing the energy. That students often think of energy as a substance (Wernecke et al., 2017) could support these conceptions.

Due to the ambiguous meaning of the word ‘conservation’ in the English language it could also be assumed that students may confuse the meaning with environmental conservation. It is very unlikely that this is the case in our study since in German there are two different words in these contexts.
Considering the students’ conceptions about the conservation of renewable energy resources, from the perspective of the Anthropocene it would make sense to bring attention to the different systems renewable and non-renewable energy resources represent. This attempt should include both the flow of matter and energy during the process of transfer and transformation into another energy form humans intend to use (e.g. electricity). Special attention should be given to the unwanted by-products of the use of non-renewable energy resources, since the reactants are not only ‘gone’ or ‘used up’ but transformed to greenhouse gas emissions or nuclear waste.

**Naturalness of energy resources**

Frieda is one of the students who uses the conception of naturalness to compare renewable and non-renewable energy resources when she says: ‘Anything natural is renewable and […] anything humans have made, like getting all the oil or the uranium out, is non-renewable.’ In an age when humans shape earth systems the conceptions summarised in the category naturalness are especially interesting. Noteworthy is that there were no statements in the scientific reports that could be placed to this category. However, common definitions of renewable energy resources include aspects of naturalness in their definitions, e.g. speaking of renewables as being ‘naturally replenished’ (Spellman & Bieber, 2011: 8) or a ‘naturally repetitive and persistent flow of energy’ (Twidell & Weir, 2015: 3). Interestingly, Twidell and Weir (2015) dichotomously state for non-renewable energy resources that ‘with these sources, the energy is initially an isolated energy potential, and external action is required to initiate the supply of energy for practical purposes.’ This seems quite similar to the statement of Frieda: ‘… anything humans have made, like getting all the oil or the uranium out, is non-renewable’.

Despite the fact that this category could be used for a positive framing for renewable energy resources, as ‘natural things’ usually give us a better feeling, its value for characterising energy resources in the context of energy transition as renewable is doubt-worthy. The concept of naturalness characterising renewable energy resources could be criticised in that also the origin of non-renewable energy resources is from a natural process and that all energy resources, renewable and non-renewable, need to be made ‘useable’ for transformation into other forms of energy by human interaction. The scientific definitions that draw on naturalness intend to stress the differences in the dynamics of renewable and non-renewable energy sources, contrasting the constant flow of energy with static stores. This brings us back to the category of the availability of energy resources. In an education for a more sustainable Anthropocene it would be important to draw on availability in the sense of the potential of renewable energy resources due to their completely different dynamics, especially considering the immense potential of the direct use of solar radiation.

**Costs of energy resources**

The category costs had to be added inductively to our category system when analysing the scientific reports of the WBGU (2011, 2003). None of the students used cost factors to characterise energy resources whereas this was a prominent issue in sections of the scientific reports, distinguishing between one-off production costs, e.g. for power plants, and subsequent costs (WBGU, 2003, 2011).
We assume that the reason students did not think of categorising or comparing the given energy resources by means of this aspect was due to their young age, possibly related to the fact that they are not responsible for paying bills yet. It would be interesting to see if adults would take this aspect into account.

For an energy transition leading to a more sustainable future, the calculation and argumentation of its costs will be a decisive point. Within this category the scientists calculate aspects of production costs as well as subsequent costs. As with the category ‘consequences of use’, it is necessary to consider the whole life cycle of the different energy resources to be able to judge different scenarios of our future energy supply.

**Limitations**

It remains to be discussed whether our research design influences our findings on the overall differences of students’ and scientists’ conceptions, that is between a dichotomous versus and a more holistic view, respectively. During the interviews at some point we asked the students to sort nine cards with pictures of primary energy resources into the categories renewable and non-renewable. This might have caused more dichotomous statements in the explanations of their categorisation. Despite this, there are hints that the students would still use dichotomies. For example, Anton talks about clean and dirty energy resources even before the terms ‘renewable’ and ‘non-renewable’ are introduced by the interviewer. Nevertheless, these terms represent a dichotomy themselves and the dichotomous view is also implied by the term energy transition, as there has to be some kind of different energy supply before and after.

The cards that were provided during the interviews showing words and pictures of the primary energy resources could have supported conceptions of the students that focus on material, since the systems could not easily be derived from those pictures (for example the card water only showed water and no dam). However, the conception of energy as a substance is quite common (Wernecke et al., 2017). Also, the narrowed perspective of the students may be caused or reinforced by their everyday experiences, because energy resources are often connected to material things. To further investigate what causes these students’ conceptions a linguistic analysis of the metaphors they used would be helpful to identify the experiences these are based on.

**CONCLUSION AND RECOMMENDATIONS**

In the Anthropocene there has been a shift in the perspective on the energy transition from non-renewable to renewable energy resources. Whereas in the beginning of the Anthropocene the availability of energy resources was the main focus, nowadays the prevalent debate is about the consequences, most prominently the climate crisis, of the use of carbon-based and nuclear energy resources. Nevertheless, both of these perspectives, also found as categories within the students’ conceptions and the scientific reports, are essential to evaluate the energy transition.

To foster a scientifically appropriate understanding and enable students to participate in the ongoing debate, we recommend the following issues to be addressed in science education in the context of the energy transition:
1) Students should be encouraged to *reflect upon the term ‘renewable’ and the definition of renewable energy resources* and discuss them from the perspectives of a) availability, and b) consequences of use.

2) Science education should draw attention to the *systems* renewable and non-renewable energy resources represent. Students should reflect upon the role of energy and matter in the processes of transfer and transformation.

3) Students should consider the whole *life cycle* to balance consequences and costs for the different energy resources.

Concerning the first recommendation our research suggests that there are intrinsic problems in the term ‘renewable’ that seem to be obstacles to a scientifically appropriate understanding. Therefore, the literal meaning should be discussed and compared with the intended meaning.

The availability of the energy resources, renewable or non-renewable, will play a decisive role, especially on a global scale. Hence, it is necessary for science education to address not only the material aspects of the availability of non-renewable energy resources as found in the students’ conceptions, but all of the three dimensions found within the scientists’ conceptions: temporal and spatial distribution as well as matter. This is necessary to be able to evaluate obstacles (like fluctuating availability of solar and wind energy) for a more sustainable energy supply. The discussion about availability should also include the aspects of the potential and different dynamics of renewable and non-renewable energy resources (Twidell & Weir, 2015).

Since the term ‘renewable’ focuses on the availability of energy resources and hides aspects of the consequences of use, the term should also be reflected on from this perspective. When it comes to consequences students tend to see only the effects of the conversion process itself, whereas scientists have a broader perspective that includes all kinds of impacts on humans and the environment during the whole life cycle. Science education should include these two perspectives. Alternative wordings like carbon-free, carbon-low or waste-free should be compared with the term and discussed from these different perspectives.

Concerning the second recommendation, as other studies show (Cheong et al., 2014), also in the context of the energy transition students have difficulties to see the connection between the carbon content of energy resources and the emission of carbon dioxide. Providing opportunities to gain a more detailed view about this connection is very important for science education because without this knowledge, students are unable to understand the relationship between the energy transition and efforts to minimise the impact of climate change. An approach in science education that focuses on the systems the energy resources represent could foster an appropriate understanding that draws on basic ideas of energy and matter. It is essential that the students understand that wind or water is only an energy resource as part of a system. For example, the wind holds kinetic energy caused by compensatory wind flows resulting from solar powered convection currents or water holds potential energy because it is stored in a dam. As a consequence, students would be able to reflect upon the transfer to other systems, e.g. in a power plant. In a next step drawing on the basic ideas of the conservation of energy and the
conservation of matter, students could track and calculate the flow of energy and matter (e.g. carbon) through these systems.

Concerning the third recommendation, the energy transition leading to a more sustainable future is determined by balancing the specific consequences of the use and the costs of a certain mix of energy resources. Our research shows that students tend to focus on the conversion process. To be able to evaluate and take an active part in the debate about our future energy supply it is necessary for students to also take a broader perspective. They should be able to assess and compare the whole life cycles of the various energy resources. Since costs are a very strong argument and play an important role in determining the direction of the energy transition, it is also important to encourage students to include this perspective in their calculations, balancing internal and external costs for humans and the environment.

As citizens, we make risk decisions on a daily basis, decisions to avoid risks or to take a risk in order to gain benefits. Risk is a concept of high significance for us. Risk also figures in science education, explicitly or implicitly, for instance in teaching of socio-scientific issues. The concept of risk has received academic attention in multiple ways of which we highlight three: 1) Investigations of the use of the term in language. 2) Attempts to capture the risk concept. 3) Attempts to operationalise the risk concept quantitatively for decision-making purposes. We draw three conclusions about the concept of risk that hold implications for science education research and teaching about risk. Firstly, risk is used differently between lay and expert uses, as well as within these groups. Secondly, risk holds both subjective and objective traits. Thirdly, different decision-making contexts may require different ways to operationalise, i.e. assess, risk. We argue that if risk is incorporated in teaching, it may be valuable to make students aware of the different ways to express, frame and assess risks.

Keywords: risk, decision-making, socio-scientific issues

INTRODUCTION

As citizens we make risk decisions on a daily basis, decisions to avoid risks or to take a risk in order to gain benefits. As modernity has seen the introduction of technologies that create risks on a larger scale, not always restricted in time and space, importance of risk as a concept is increasing (Beck, 1992). This viewpoint is also corroborated for instance by the increased use of the term ‘risk’ in newspaper reporting since World War II (Zinn, 2010).

The notion of risk and risk assessment has also drawn the attention of science education researchers, and is dealt with in a variety of ways within science education research. This is particularly true for areas such as Science and Technology in Society (STS) and Socio-scientific issues (SSIs). Teaching through SSIs very often draws upon risk issues, such as nuclear power, emerging technologies or climate change. Indeed, the idea of making science education more socially responsible and contribute to science for citizenship may be traced back at least to the 1930’s (Ratcliffe, 2001), although it began to be more widely argued from the 1970’s (see Howes, 1975). The first large-scale STS-project was launched in the Netherlands in the 1970’s (Eijkelhof, 1986). Already from the beginning, the idea of including controversial issues in which both scientific and social aspects need to be considered was an important part of the STS-movement (see for instance Gaskell, 1982). By the 1980’s, the term ‘socio-scientific issues’ was established (Fleming, 1986) and has, since then, gained increased usage within science education research (Tekin, Aslan, & Yilmaz, 2016) alongside the older term ‘STS’ (see Millar, 2006). There is a growing body of research in which risk is seen as a
component of scientific literacy and, as such, relevant and important to address in science education (see e.g. Christensen, 2009; Hansen & Hammann, 2017).

However, despite half a century of risk research there is no widely accepted definition of the term ‘risk’. The word ‘risk’ is used and interpreted in a multitude of ways. Within the risk management and decision analysis literature, much effort has been targeted at providing definitions of the concept or defending a particular definition or operationalization. Yet, there exists no systematic attempt at relating this multitude of definitions, interpretations and uses to different consequences for teaching. The purpose of this paper is to outline the beginnings of such an analysis and discuss implications for science education research and teaching about risk.

METHOD

Scholarly works from a broad range of academic fields targeting the concept of risk were identified by search phrases ‘risk definition’ and ‘concept(s) of risk’ as well as by snowball sampling from works identified thereby. We identified three main themes in the retrieved literature: focus on usage (mainly from the area of linguistics), focus on capturing the concept (from areas such as philosophy, engineering, sociology, and law) and focus on quantification (mainly from engineering). For each theme a summary review was performed (presented below). The findings from this review were then discussed within a transdisciplinary team of researchers and teachers (riskedu.se) to identify potential implications for teaching. In addition, a selection of science education related works in which teaching about risk issues are touched upon were scrutinised for their descriptions of risks and uses of the word ‘risk’.

RESULTS

In this section we present an examination of the risk concept on the basis of the central academic literature. The examination is guided by the paper’s main purpose, to tease out potentially important those characteristics of the risk concept which may be important to recognise in science education.

The many uses of the word risk

The word ‘risk’, can be used both a noun and a verb. Furthermore, the noun has several different meanings, which are the focus of the present paper. Below we exemplify the polysemy of the noun ‘risk’ with two statements about what risk is from students in our studies (16-17 year olds):

‘I usually think of an act whose consequences are very problematic. For instance, to cheat on a test may be a risk, a consequence may be that you get disqualified and get poor grades.’

‘Risk of getting a disease later in life, such as cancer.’

In the second sentence, we could replace risk with the word probability: Probability of getting a disease later in life, such as cancer. But in the first sentence replacing ‘risk’ with ‘probability’ would drastically change the meaning of the statement. Polysemous words are not unusual, but
this has drawn attention in the risk research field as we often face situations where we want to
be precise about what we are talking about. For instance, in regulatory decision-making.

The polysemy of the word in everyday language can be further illustrated with the following
three (non-exhaustive) examples found in non-technical texts (Boholm, Möller & Hansson,
2016, based on Hansson, 2004; 2011):

a) Risk = an unwanted event which may or may not occur.
b) Risk = the cause of an unwanted event which may or may not occur.
c) Risk = the probability of an unwanted event which may or may not occur.

However, the word ‘risk’ also has many different technical uses. In fact, the term is used more
frequently in specialised technical contexts than in more every-day ones. A linguistic study of
the word ‘risk’ in American English showed that the frequency of ‘risk’ in academic texts was
nine times higher than in fiction and more than double that of newspaper reporting or spoken
language (Hardy & Colombini, 2011). It has also been shown that the word is strongly
associated with health and medicine (Hamilton, Adolphs & Nerlich, 2007; Zinn, 2010; Hardy
& Colombini, 2011).

Althaus (2005) and Renn (1992) both review the risk concept from a perspective of academic
discipline and illustrate how the ontological and epistemological perspectives vary.
Nevertheless, there have been efforts towards making transdisciplinary definitions of the risk
concept (e.g. Rosa 1998, Aven & Renn, 2009). Aven (2012) presents a classification of risk
definitions within different academic fields. He identified nine classes under which one or more
individual definition have been published:

1) Risk = Expected value (loss)
2) Risk = Probability of an (undesirable) event
3) Risk = Objective uncertainty
4) Risk = Uncertainty
5) Risk = Potential/possibility of a loss
6) Risk = Probability and scenarios/consequences/severity of consequences
7) Risk = Event or consequence
8) Risk = Consequences/damage/severity of these + Uncertainty
9) Risk = The effect of uncertainty on objectives

These nine classes and adhering examples of risk definitions, with references to relevant
literature, are discussed in detail in Aven (2012). For the purpose of the present paper, Aven’s
(2012) list serves as an illustration of the variability of risk concept within the academic
literature.

**Capturing the concept of risk**

Hansson (2011) identified two minimal characteristics of the risk concept. First, ‘risks refer
to undesirable events’. Second, ‘it is undetermined or at least unknown whether or not that
event will occur’. These two characteristics are reflected in the listed definitions of risk
presented in the preceding section. The element of undesirability is reflected in usage of terms
such as ‘consequence’ and ‘loss’. Even more prominent is the role of uncertainty in different
forms, as indicated by ‘objective uncertainty’, ‘probability’, ‘potential’, and (epistemic) ‘uncertainty’. Thus, when attempting to capture the concept of risk, a general understanding could be that risk in some manner refers to an undesirable event that may or may not happen (Hansson, 2011). Rosa (1998) expressed this as ‘risk is a situation or event where something of human value (including humans themselves) is at stake and where the outcome is uncertain’.

As shown by several previous works (e.g. Renn 1992, Althaus, 2005, Aven, 2012), risk is a multi-faceted phenomenon, originating in both ontological and situational activities. One important aspect that makes the concept of risk so troublesome to capture is the distinction between risk as objective and risk as subjective (Hansson, 2011; Hansen & Hammann, 2017). An objective risk concept means that risk is determined by facts about the physical world, whereas a subjective risk concept defines risk as a social construction independent of physical facts. As pointed out by Rosa (1998) risk concerns ‘something of human value’, i.e. the adversity of the possible outcome is dependent on our value judgements. Nevertheless, as also pointed out by Hansson (2011), risks do also refer to facts about the world. For example, to claim that ionizing radiation may cause tumours in humans is a statement about an outcome in the physical world. Hence, both subjective and objective aspects of risk need to be acknowledged.

Taken together, however, it may be most fruitful to discuss risk as a concept containing both objective and subjective components (Hansson, 2011). From the perspective of science education, this interplay between objective and subjective components is a potentially important factor when incorporating risk in school science education. This is because the dual nature of risk (i.e., having both subjective and objective traits) opens up for discussions on values as integral parts of any decision including risk, but even more how values and knowledge (or established facts) interact in decisions and policy making.

**Quantifying risk**

Whether risk is used in qualitative or quantitative ways, is another aspect of the polysemy of the risk concept. The everyday uses of the term seem to be mainly qualitative in nature and strictly quantitative meanings are rarely found (Boholm et al., 2016). However, even seemingly qualitative uses of risk may be partly understood also in quantitative terms, as ‘high’, ‘low’ and ‘increased’ are commonly found collocates in a number of corpora (Boholm et al., 2016; Hamilton et al., 2007). Boholm et al (2016) found that somewhat less than a third of the instances of risk in the investigated corpus implied a quantitative notion of risk through such collocates.

Specialist uses of the term as well as formal definitions from scholars in various risk related areas are both qualitative and quantitative (Althaus, 2005; Aven, 2012; SRA 2015). Four of Aven’s (2012a) classes are identified as quantitative risk definitions, namely 1, 2, 3 and 6 whereas definitions 4, 5, 7, 8, and 9 are more or less qualitative in character.

Quantitative definitions are generally a tool for risk management, and serve as operationalisations of risk and a base for decision-making. Definitions in line with e.g. risk a) or 7) (see p.3 in this paper) may not fulfil such purposes, from a risk management perspective it makes little sense to speak of reducing an event. Such a risk definition is not compatible with
the current practice of risk assessment as a basis for decision-making (Aven & Renn, 2009). However, as has been pointed out previously (Aven, 2012; SRA, 2015), definitions attempting to capture the concept of risk do not need to be operationalisations of risk in themselves (which for instance Avens’ class 1, risk = expected value is). The definition of risk needs only to be compatible with quantitative operationalisations. In other words, we can distinguish between the concept of risk and how to measure risk. It may even be reasonable to claim that this distinction needs to be made: For instance, if for a certain case available knowledge does not allow us to derive a probability distribution, it makes little sense to define the risk based on a probability distribution (i.e. objective uncertainty). In other words, the suitability of operationalisations of risk, i.e. risk assessment methods, is context dependent (SRA, 2015). Indeed, this is already implemented in risk management practice. Risk assessment models or methods differ for the assessment and management of monetary risks, risk of contagious diseases, traffic risks, or risks with different means to produce energy. These differences reflect the differences in the size of populations potentially affected, the frequency of potential adverse events, and the nature of consequences.

**IMPLICATIONS FOR TEACHING ABOUT RISK**

Based on findings made within the three themes presented above, 1) Investigations of the use of the term in language. 2) Attempts to capture the risk concept. 3) Attempts to operationalise the risk concept quantitatively for decision-making purposes, a number of potential implications for teaching about risk emerge.

First, as risk is a polysemous term, its use may confer confusion. Different meanings of the word risk are found within and between lay uses of the term, in applied expert uses as well as in academic discourse. Differences seem to be especially large between every day and specialist uses of the term. Hence, we argue that it may be of value to raise the nature of the concept of risk more specifically in the classroom.

One way to approach the multitude of specialised uses of the term risk, of which many are closely connected to risk assessment methods, may be to separate between the concept of risk and the operationalisations of risk as the latter are dependent on the context in which they are to be applied. This distinction between the concept of risk and different operationalisations of risk is relevant both in the context of risk management and when introducing risk and risk descriptions in teaching.

Finally, part of the difficulties seems to lie in the dual nature of risk as both subjective and objective, requiring interplay between knowledge and values. Risk cannot (or should not) be separated from discussions of values. On the contrary, the dual nature of risk (both subjective and objective traits) opens up for discussions on values in science and society and on the role of science in decision- and policy-making. For instance, the issue that Howes (1975) drew upon in the proposal on teaching about radiation risks was that value judgments are unavoidable when we deal with scientific uncertainty and that there are questions and issues that science most likely will never be able to resolve.
In short, we have identified three aspects of the risk concept which may be relevant for science education:

- The polysemy of the term.
- The context dependent operationalisations.
- The interaction between values and knowledge.

These three aspects could be put into play to a different degree depending on the educational aim. For instance, teaching students one or several ways to describe risk, can be one step in teaching towards making students evaluating risk related arguments or performing their own risk assessments. We call this to teach about risk directly. But risk can also come into play indirectly, as a real world example to make science content more relevant to students’ lives, as a topic for students to engage in discussions, or drawing in particular on the uncertainties in risk issues, as a way to illustrate the nature of science and how knowledge is created.

In Table 1 we list some examples of how different aspects of the risk concept may be of relevance to selected educational aims. The different educational aims are not mutually exclusive, rather later aims build upon earlier and one or several of these aims may be part of a particular teaching intervention.

The first examples concern explicitly incorporating risk in the teaching, exemplifying with risk issues (e.g. UV radiation) rather than primarily teaching about a specific risk issue. Such teaching can range from classroom discussions on risk having student conceptions of risk as a starting point to focus on the risk concept and different ways to describe risk as reviewed herein. One specific aim could be that students should understand risk (I), and to be able to
pinpoint what ‘risk’ stands for in a specific situation. For instance, how we talk about risk regarding sports, traffic or nuclear radiation. In such inquiries, the polysemy and a number of risk descriptions may be explored. A continuation could be to enable students to evaluate risk related arguments (II). For this we have to take the polysemy of risk into account, and explain the coexistence of many possible meanings for a word or phrase. Awareness of different ways to express and describe risk, and the values that come into play under different operationalisations, will help students to deconstruct, as well as formulate their own, arguments on risk-related issues. In aiming to make students (III) perform risk assessments, we may introduce students to one or several context dependent operationalisations and let them apply these.

However, risk may also be used more implicitly in teaching. Risk issues can be used as a means to offer student real-life examples of applications of scientific knowledge (IV). Risk issues that lend themselves to SSI teaching include questions that are scientific in nature but cannot be answered solely by traditional scientific methodology (compare to transscience as coined by Weinberg, 1972). Such questions may be unanswerable either because they inherently involve value issues, or because it’s not possible to design an experiment that will conclusively answer them. Connecting to radiation risks, one such issue would be the determination of an exposure limit for ionizing radiation and how to decide what could be considered an acceptable level. Since our knowledge is incomplete, for instance with regards to the shape of the dose-response curve at low doses, decisions on low-dose radiation risks are influenced by e.g. moral and socio-economic considerations (E.g. Howes, 1975; Eijkelhof, 1986). Another example is nanomaterials, for which there currently are large uncertainties about potential adverse effects on environment or health, which has to be weighed against potential benefits of using nanomaterials in different applications (Enghag & Schenk, 2016). Hence, risk issues may be used, explicitly or implicitly, as a starting point for discussions aiming to encourage student deliberations (V). Furthermore, when focussing on issues connecting to science in the making, risk issues offer opportunities to explore the nature of science as well as its opportunities and limitations with regards to creation of knowledge (VI).

A practical consideration for teachers is how to select which meanings and operationalisations of risk to focus on in their teaching. Obviously, it is reasonable to use the dominant risk definition of the relevant case as a starting point. However, in some contexts more than one way to describe risk may be relevant. For instance, in nuclear safety, we usually encounter an engineering perspective on the safety of operations, such as expected values or combinations of scenarios with their respective probabilities and consequences (see p.3, class 6). However, in issues pertaining to health of workers or the population exposed in case of an accident we will instead encounter risk descriptions from the area of toxicology and epidemiology, i.e. expected values, probabilities and objective uncertainty, as well as probability and consequence (classes 1, 2, 3, 6). Table 2 may also be used as an overview of which risk descriptions have been found relevant in previous science education works.

A simple quantitative definition such as the expected value (class 1) holds many advantages from a decision-making perspective such as being mathematisable and yielding a simple output. Assigning numbers to various scenarios allows for a comparison between risks, which
could be used for instance to prioritisation of resource allocation between different risk management efforts. However, there are many real life examples of when such a reduction does not capture a relevant decision. In real life, there are always other factors in addition to probabilities and utilities that can and should influence appraisals of risk. Nevertheless, discussing risk as probability \( \times \) consequence (i.e. expected loss) also highlights the role of exposure (as a proxy for probability) and intrinsic hazard (potential consequences). If either the exposure or the hazard is zero there is, by definition, also no risk. Hence, this way to operationalise risk could be connected to specific learning outcomes, for instance regarding personal protection from UV radiation (see also WHO, 2003).

\(^a\)One reference may fall under more than one risk description class, due to multiple different uses and/or multiple possible interpretations. Parentheses indicates that the class of risk description is found in the text but is not the same as that given as a definition in the same text.

\(^b\)Covitt et al., 2010 indicate that risk is defined to students of the described teaching efforts, however, risk is not defined for the readers of the paper.
A complement to the expected value is to use a simple matrix where categories of probability are plotted against categories of severity as exemplified in Figure 1. This semi-quantitative representation does not reduce the issue to a simple number, highlighting the contributions from probability and consequence respectively. Similar to the expected value, a risk matrix can also be a useful construct in education targeting how to reduce one’s risk. Furthermore, contrasting the expected value and this matrix (or other ways to operationalise risk) can be used as a starting point for more in-depth discussions concerning these operationalisations’ suitability as decision-making tools.

![Figure 1 An example of a risk matrix.](image)

**SUMMARY AND CONCLUSIONS**

Christensen (2009) pointed out that ‘where scientific knowledge is connected with risk, this is not the reliable or ‘certain’ knowledge of traditional science classrooms, but science surrounded by uncertainties, and this constitutes new territory for science educators’. Thus, incorporating risk in science education poses many challenges to educators. Christensen (2009) in particular highlights the uncertainty brought by complexity, the uncertainty pertaining to incomplete and/or conflicting knowledge (science-in-the-making) and that science and knowledge must be seen in a social context in risk decisions. We wish also to highlight the polysemous nature of the noun risk as a challenge to educators.

Boholm et al. (2016) point out that the polysemous nature of the noun risk, and the fact that the everyday use differs from that in technical contexts may give rise to misunderstandings that could for instance hamper risk communication or risk management efforts. Different risk definitions have also been pointed out as one potential cause behind the often-found disparities between laypersons’ and experts’ risk perception (Sjöberg, 1999a; 1999b; Slovic, 2016). These observations could be used both as an argument towards adapting specialist uses of the term towards the everyday understanding as well as an argument towards teaching about different ways to conceptualise risk in pre-university education.
The classroom may be the setting of the first time students encounter the meeting of the everyday uses of risk and the specialist uses of the same term. At this point it could be valuable to provide students with an understanding of the different definitions of risk. We do not propose to define one single meaning of ‘risk’ and excluding all other, or even to promote one definition of risk as superior to others. We argue that awareness of the risk polysemy is a topic relevant to bring up in the classroom. Furthermore, the polysemy of risk can be used as a starting point for encouraging students to discuss decision-making in risk issues from various perspectives.

In conclusion, if risk is to be incorporated in teaching, e.g. as part of an SSI, it is valuable to make students aware of the different ways to express risk. We propose that risk as a concept is discussed in relation to a selection of both qualitative and quantitative definitions as well as in relation to specific risk issues. Furthermore, risk cannot (or should not) be separated from discussions of values. If we include risk in our teaching, we need to make room for thoughts and possibly discussions on value aspects. The aim is to raise awareness of the many ways risks can be framed and assessed, and to highlight the role of both scientific knowledge and values in risk decisions.

THE ROLE OF MYTH IN STUDENTS DISCUSSING « PEST »-AGRICULTURE RELATIONS

Michel Vidal¹, Jean Simonneaux² and Ralph Levinson³

¹Montpellier SupAgro, Montpellier, France, ²Ecole Nationale Supérieure de Formation de l'Enseignement Agricole, Toulouse, France, ³University College London

Socio-scientific issues and socially acute questions enable moral judgement through rational, emotional, intuitive and imaginative thinkings. Our research focuses more specifically on the place of the myth in student discussions about controversial issues. We have analyzed the mythemes expressed through online exchanges between students from England, France and New Zealand about three ‘pest’-animal issues, the ‘pests’ in question being the Badger (England), Wolf (France) and Possum (New Zealand). We observe the expression of recurrent mythemes by issue, one demonizing the animal and encouraging its destruction or control, one protecting its proper nature, one ambivalent proposing a dialogue between the two first ones. These expressions relate to the living contexts of the students. Wolves and Possums stimulate more myths than Badgers. The potential of myths to enable critical thinking is discussed.

Keywords: myth, socio-scientific issues, socially acute questions, debate

PROBLEMATIC

Socio-Scientific Issues (SSI) and Socially Acute Questions (SAQ) respectively conceptualised by Zeidler and Sadler (2008) and Legardez and Simonneaux (2006) are designed to enable reasoning based on rational, emotional, intuitive and imaginative thinking to navigate through issues and to frame moral judgement. Research which analysed student argumentation of about SSI or SAQ focused more specifically on the links between the ethical, affective and cognitive dimensions (Fowler, Zeidler & Sadler, 2009; Sadler & Zeidler, 2002; Zeidler & Keefer, 2003; Zeidler, Sadler, Simmons & Howes, 2005; Simonneaux & Simonneaux, 2015). We propose to analyse the place of the imaginary in argumentation.

The relationship between ‘mythos’ and ‘logos’ is an old issue. Dialogue between rational thinking and mythological thinking is an integral part of this discourse (Lévi-Strauss, 1958). For the structural anthropologist Claude Lévi-Strauss (1962), the savage mind is distinguished from the civilised mind. The savage mind, sometimes referred to as ‘primitive’, or preferentially ‘mythic’, is represented as elementary or enduring. Mythic thinking, however, is present in western or civilised societies, just as much as pre-modern societies, without considering one superior to the other. Myths are conceived as the expression or outcome of processes of sacralisation which ensure unity of social groups through sharing ways of thinking or acting. Myths are not easy to discern because they are often concealed in modern societies (Cullatti, 2011). Relations between mythical thought and scientific/rational thought is re-examined in Western societies, notably through the approach of the 'imaginary' (Durand, 1963). Usually considered as a fairytale, the myth is a story where expressed beliefs and fundamental antagonistic tensions are staged, as for instance those between the necessity to protect nature and to control it. According to Durand (ibid.), the myth is a dynamic system of schemes, archetypes and symbols, creating a story. Schemes are the movement of the body, a fundamental way of expression in the world which lead to 'archetypes', primordial images. For
instance the scheme of the ascent links archetypes of the mountain peak to the head. The symbols are ambivalent, culturally instantiated. Wolf can symbolise the nourishing mother, the wilderness or the demon according to the civilisation. Consequently, according to Durand (ibid.), there is no opposition between the imaginary and our sensory perceptions of the world, imaginary and its expression through myths, dialogue with the relation that we elaborate with the world. ‘There is no disconnection between the rationality and the imaginary, the rationalism being no longer, among others, a particular polarizing structure of the field of the image’ (ibid., p.38).

The two anthropologists agree that the myth has a permanent structure instantiated in language, discourse and that it is based on constitutive unities, the mythemes which are the minimal significant semantic unity of a myth, its principle of identification and the instrument of its interpretation. The mythemes enable the myth to exist in observable forms in the discourse. It means also that a mytheme will appear in different mythical stories, as for instance the mytheme of the incestuous love which is present in the myths of Oedipe, Lot, Electre. Creating the concepts of “mythocritic” and “mythanalysis”, Durand (1996) suggests that ‘the myth would be the matrix model of any narrative, structured by fundamental schemes and archetypes of the psyche of Sapiens Sapiens”. A mythanalysis enables, in a first step, to enlighten the recurrence of the mythemes which constitute the synchronicity of a myth by the repetition of permanencies and invariants. The repetitions enable to make manifest the structure of the myth.

In a second step, the mythanalysis focuses on the diachronicity of the myth, or, in other words, how the myth is translated, interpreted according to its context at different stages in the history of cultures.

This second step seems difficult to observe if we analyse discourses of persons at a specific time and in a specific context. Nevertheless, the analysis of discourses of persons belonging to different cultures, to different ecological, social, cultural, economical contexts about the same issue may enable us potentially to observe differences or similarities of translation of myths.

This research is a first essay to observe the place of the myth in argumentations about SAQ/SSI. Our aim is not to define the structure of myths deployed by students but to identify if there are observable mythemes in students’ thinking in cross-national discussions of controversies around ‘pest’-agriculture relations and how they interact in the process of exchanges.

METHOD

Six discussions forums in the form of blogs were held between students from U.K., New Zealand and France. These were analyzed for mythic tracks incorporating both situations (e.g. 'pest-ecology relations as actors, e.g. individual animals-wolf, possum, badger). There were three different ‘pest-animal’ scenarios: (a) The relationship between the growth of possum numbers in New Zealand as an ‘invasive’ species and their effect on extant habitats. (b) The perceived threat of wolves to sheep farming in rural France. (c) The perceived threat of badgers in the United Kingdom transmitting Mycobacterium bovis to cattle.

Students were introduced to the ‘pest’-agriculture scenarios through a short summary sheet which aimed to set out the controversies although these were necessarily non-exhaustive. A summary sheet of the pest-agriculture controversy is included in the appendix. Students were
then asked to discuss the controversy and map out the issues collaboratively using eco-network maps (Abbott, 2005). In these maps actors (usually identified through nouns) are linked through ‘tasks’ (identified through verbs). To give two examples, a supermarket (actor) sells dairy products (tasks) to customers (actor). Badgers (actors) transmit M. bovis to cows (actors). M. bovis (tubercular bacteria) themselves are actors, e.g. they infect cows. This allows students to summarise their ideas but also to have a representation where they can shift actor-task relationships through negotiations. An example of a map is shown in figure 1. Having discussed the controversy, also drawing on any extra information available, e.g. through web-searches, students start the asynchronous discussion forum by introducing themselves. Three discussion forums were held (NZ-France, NZ-UK, France-UK).

These forums were read independently by three researchers from different countries (France and U.K.), and a mythanalysis of discourses was generate according to the following criteria (Durand, 1992): (1) the myth is narratively conditioned; (2) the mythemes can be identified and are generally limited in number; (3) The mytheme has a syntactic and semantic homogeneity; (4) the choice of mythemes makes it possible to highlight an encyclopedic myth; (5) the position or action verbs are the main criterion of the mytheme.

We have considered the following tracks in the talks of the students for each forum: the qualification of the human through the adjectives, the metaphors and the action and position verbs associated with the human in the issue; the qualification of the “pest”-animal and of the nature through the adjectives, the metaphors and the action and position verbs associated with them. For instance, in the sentence, “wolfs are not criminals”, “they deserve to be free”, “criminal” is a metaphor, “deserve to be” a position verb, and “free” an adjective which qualifies the wolf.

We have gathered the utterances which express the same mytheme. We have then demonstrated how diachronically during the forum the different mythemes are expressed and the number and the origin of utterances supporting each mytheme.

RESULTS

Analysis of the discussion about the Possum between French and New-Zealander students

The theme for the discussion about possums is based on a contemporary issue in the NZ where the brush tail possum, introduced from Australia in the 1870s rapidly spread throughout the country, transmitting the tubercular bacterium, *Mycobacterium bovis*, to cattle, attack New Zealand’s native bush by eating the foliage and animals, particularly the endemic birds. There are controversies about the use of the poison 1080 licensed for aerial dispersal to control possum population. First, it is considered by a part of the NZ population as a cruel method. Secondly, there is a perception that 1080 indiscriminately is dangerous for birds, livestock, deer, dogs and people and poisons the environment. Hunters see their potential trophies dead and dying in the bush.

In the discussion about the Possum issue between French and New Zealand students, we observe three mythemes: The first one is supported by verbs, adjectives and metaphors about the possum. The possum is considered as a nuisance, an environmental pest, for the country,
and even for human well being and survival. It has an inferior biological status to domestic animals. Nature’s interest lies in its native character. Humans have to exterminate Possum. This mytheme is illustrated by the following utterances (in bold, the verbs, adjectives and metaphors considered as tracks):

Ascension (NZ): « We value our animals (...) more than Possum. Possum don’t only affect our animals but they also affect the way we live »,

Tuukalikali (NZ): « Possums are just pests to society »,

Ascension (NZ): « if we keep these possums alive and around our environment, then we are basically risking our lives” / “they also affect our farmers and our companies and factories being shut down »,

Martha (F): « The possum harmed the environment too much, it would obviously all kill them »,

Paule (NZ): « Possums should be killed because they are ruining the environment (...) [possums] can also affect humans / spread diseases to humans/they are the dangerous animals that can kill and this leads to human extinction / ruin environment/the native birds will extinc »,

Killpossum (NZ): « possums are ugly, they deserve to die ».

The second mytheme is supported by verbs, adjectives and metaphors about the Possum considering this animal as a free living being equivalent to human, and about Nature having its own laws. Humans are considered dangerous and have to respect Nature’s Laws, as illustrated by the following extracts:

Carine (F): « [Humans] must let the nature do its job (...). It's a living being like you and I. They must eat and eat like us/It's a little animal who wants to live like everybody/la pire espèce au monde c'est les humains” »,

Mona (F): « I don't want them to die, it's nature »,

Clara (F): « It is normal for them the kill others animals is feed. It's nature »,

Emilia (NZ): « Possums are just as important as humans »,

Samuel (F): « Possums do deserve the free will to live/should have the right to live and be free »,

Carla (F): « all animals should be able to live in their ecosystem »,

Madfire (F): « humans destroy everything, and possums probably want us to die ».

In the third mytheme, the possum is considered as a living being that should be allowed to live, but whose numbers should be controlled according to the diseases they spread, as illustrated in the following extracts:

Carla (F): « we shouldn't kill the possums because all animals should be able to live in

\[5\] In french in the text : personal translation : « the worst specie in the world, it's the Human »
their ecosystem but I think that we should control them (...) one way we can control them is with biocontrol that makes the possums unable to reproduce »,

Emilia (NZ): « we kill them just because there infected, we can stop it from spreading by giving them treatment or medicine »,

Samuel (F): « Reproduction pill is a good idea for possums were not harming them physically but only disabling their reproduction system as doing so there will be less population of possums ».

The mythemes are expressed during the discussion are recurrent (Figure 1).

Figure 1. Expression of the mythemes during the discussion French/ New-Zealander about the Possum issue

legend: Sign in white: French talk; Sign in dark: New-Zealander talk; (X): number of talks without expression of specific mythemes

The mythemes 1 and 2 are recurrent during the discussion. Mytheme 1 is expressed 9 times by French students, once by a New Zealander student. Mytheme 2 is expressed 5 times by French students, 20 times by New Zealand students. Mytheme 3 is expressed once by a French student, once by a New-Zealander.

Mytheme 1 is expressed mainly by French students, mytheme 2 mainly by New Zealander students. Mytheme 3 is expressed only three times.

Analysis of the discussion about the Wolf between French and New-Zealander students

The theme for the discussion about wolves is based on a contemporary issue in France related to the increasing of the number of wolves, considered as a protected species according to the international Berne convention since 1993. The wolf eats wild game but also attacks flocks of sheep. There are a number of aspects to this controversy. First, the tension between on one side farmers and hunters and on the other the conservationists prioritising badger protection; secondly, the uncertainty surrounding the efficiency of sheep farming practices based on protection dogs or electric fences but also the efficiency of wolf shooting; thirdly, the uncertainty about the economical impact of the wolf presence, affecting sheep farming and at the same time promoting a form of ecotourism; fourthly, the uncertainty about the ecological interest of the wolf presence, considered as increasing or decreasing the biodiversity.

In the discussion about the Wolf issue between French and New Zealand students, three mythemes were observed: mytheme 1 is supported by verbs, adjectives and metaphors about a wolf destroying the balance of the nature and being dangerous for the human. Humans must control the wolf, it is their responsibility. This mytheme is illustrated by the following extracts:
Nepatina (NZ): « Wolves are just like guns (...) they can kill people »,

Joshua (NZ): « putting them in captivity or controlling their population/ killing some of them/ in enclosed area / making them unable to escape »,

Nepatina (NZ): « putting up barriers that prevents them from entering where people reside, also knowing restrictions with signs informing the reader that you are entering areas where wild animals are...»,

Tupoi (NZ): « taking away the wolves ».

In mytheme 2, interest in the wolf lies in its wild character, which is founded on principles of freedom and struggle. The Human has to respect the wolf and has to respect its territory. This mytheme is illustrated by the following extracts:

Inest (F): « [Wolves] they deserve to be free »

Madfire (F): « They should be free animals and eat what they want »,

Gaelle (F): « isn’t a good idea because it limits there natural instinct »,

Amandy (F): « putting wolves in captivity is very cruel, it’s like a prison »,

Amandy (F): « they must eat like us »,

ClaraLala (F): « I am against the death of the wolf because they are animals that deserve to live »,

Lesina (F): « without wolves, ecosystems can go haywire, the ecosystem will be unbalanced again ».

In mytheme 3, the wolf is considered at the same time in danger and dangerous. The human has the responsibility to control it and save it:

Tupu (NZ): « they’re an endangered animal and we need to protect them because they could become extinct due to the decrease in their population during the last few centuries. But (...) if they were to kill the wolves then I believe that they might as well kill the sheep too, I mean they’re both apart of life. taking away the wolves just because the sheep are important to providing for the economy is unfair if you think about it. the best thing to do is put the wolves in safe captivity, having both animals alive and in safe conditions ». 

The mythemes which are expressed during the discussion are recurrent (Figure 2).

The mythemes 1, 2 and 3 are redondant during the discussion. Mytheme 1 is expressed 12 times by French students, once by a New Zealand student. Mytheme 2 is expressed 4 times by New Zealand students. Mytheme 3 is expressed 8 times by New Zealand students.

Analysis of the discussion about the badger between french and english students

The theme for the discussion about badgers is based on a contemporary issue in the UK where there is a controversy about badgers transmitting the tubercular bacterium, *Mycobacterium bovis*, to cattle. There are a number of aspects to this controversy. First there is uncertainty surrounding both the scientific evidence for the transmission and the effectiveness of methods for dealing with the problem; secondly, the tension between farmers and conservationists prioritising badger protection; thirdly, a more general controversy about the influence of agro-industry in the UK.

In the discussion about the Badger issue between French and English students, two mythemes are observed: mytheme 1 is supported by verbs, adjectives and metaphors about badgers considered as a nuisance for humans and nature; nature is seen as a combination of useful and useless living beings. Humans dominate nature, and must control what is useful and useless. This mytheme is illustrated by the following extracts:

A (UK): « *humans are much higher in the animal kingdom* »,

Elpadrino (F): « *we have to kill badgers because it will disrupt the ecosystem* »,

JUL (F): « *I think the badgers are not important for the english people, they are useless* »,

S (UK): « *no other positive impact on humans apart from being a nuisance* ».

Mytheme 2 is supported by verbs, adjectives and metaphors about the nature and life as being a balance, and about humans who respecting nature, and acting justly. This mytheme is illustrated by the following extracts:

G (UK): « *Culling of badger is inhumane* »,

Zoule (FR): « *They are useful to the biomass, if they were useless, nature would have gotten rid of them* ».

The mythemes expressed during the discussion are redondant (Figure 3).

![Figure 3. Expression of the mythemes during the discussion French/English about the Badger issue](image)

The legend: Sign in white: French talk; Sign in dark: English talk; (X): number of talks without expression of specific mythemes.

The mythemes 1 and 2 are redondant during the discussion. The mytheme 1 is expressed 4 times by French students, 4 by English ones. The mytheme 2 is expressed 3 times by French students, 5 times by English ones.
DISCUSSION

The place taken by the mythemes in the discussion of students positions human actors as *homo mythicus* (Méheust, 1990). The contemporary human creates and lives myths and associate myths with lived experiences, with contextualised issues. It cannot be considered as having an anecdotal interest insofar as it is integrated or even it bases a reasoning, an argumentation. In other words, the *logos*, as the dialectical exercise of reason, does not purge the *mythos*, but both of them co-exist, with interpenetrations and singular dialogues that it deserves to be deepened, and which shows a sensible reason (Maffesoli, 1996) for the work as illustrating in the following sentence combining an imaginary of freedom and a reasoning to avoid the poison 1080 and the suffering of possums: “*possums do deserve a free live, however (...) reproduction pill is a good idea for possums were not harming them physically but only disabling their reproduction system (...) 1080 isn't good for animals, in general every animal should have the right to live and be free*”. Thus, with Durand (1963), we rehabilitate the imaginary as a place for reciprocal exchanges between instinctive, imperative and objective reasons emanating between perceptions of Nature and the social environment. We reflect on interactions between myth and rationality not through a radical duality of the human mind (the irrational mythic and the rational logos) but rather through the forms of dialogue that they co-generate.

Each discussion conveys not more than 2 to 3 mythemes. A first mytheme demonizes or depreciates the animal, considering it as dangerous for Nature and/or humans. Humans are considered more important than non-human animals. The animal is described through alterity in relation to the human. It can be reified or considered as a stranger. Nature in such case is associated with a territorial identity: animals are or native of the region, or alien and in such case depreciated. The “pest”-animal must be killed or captured. In accordance with Campion-Vincent (1990), the animal, considered as a disaster and associated with uncertainties generates discourses which could be assimilated to a call to the crusade and to the death sentence of the species.

A second mytheme “essentialises” the living (as defined by Panissal, in publication) the living, considers the animal as having a place in Nature, as been on the same level as humans, or on a higher level, and can be supported by thinking based on values as respect of freedom or justice. In other words, the animals are considered through their similarities to humans. This mytheme is associated with symbols of Nature, considered as a fragile balance. This mytheme has its own natural laws to be respected.

When a third mytheme is expressed, it appears as an attempt to elaborate a dialogue between the two first ones. The animal is considered as a living being to respect, and at the same time its danger necessitates a control of the species.

Some animals, as the Possum or the Wolf are greater triggers than the Badger. The first two are often qualified as enemies or companions, which is typical of the ambivalence of a symbol (Durand, 1963). As a companion, the animal has commonalities with the human. As an enemy, it is considered as Other. Nevertheless we can also observe some attempts of dialogue between the two polarities in a third mytheme, to realize the coincidencia oppositorum, taking in consideration the respect of the animal and the damage it can cause.
The Badger appears to stimulate the imaginary less, the myths being more related to Nature in general than to the animal itself. Or the ethological behaviors of the wolf and the possum would stimulate the creation of myths more so than the Badger, the biological instinct being considered as mythical representations (Caillois, 1972), for the humans, or, the nature of the contexts of the controversy might have an effect, considering that the badger has a central role as a mythic character in English literature.

The expression of the myth is associated with the life context of the participant. New-Zealand students express an imaginary related to the destruction of the Possum considered as a pest while the French argue for the freedom of the animal as part of Nature. Whereas the new-zealander want to control the wolf, to separate his territory from that of the man, the second summons symbols of freedom. The New-Zealand students have an imaginary based on a hierarchy between humans and animals while the French place them at the same level. We do not observe a clear difference between the French and the English students discussing the Badger. We cannot assume that the national identity is the only key-factor explaining these differences. The place where students live can also shape their imagination. In particular the situation of the French school in an urban environment can explain their positioning in favor of the wolf. The imaginary thus makes it possible to build a meaning to the world, and it is social in the sense that gives Castoriadis (2017) insofar as it creates a space of representations in which all its members participate.

We do not think it wise to expurgate myths from talk in the name of a strict rationality. Myths allow us to interpret our forms of action and thought by which humans understand themselves in this world (Ricoeur, 1960) as considered by Natanson (2001). But beyond a hermeneutic of the myth, the creation of debate between groups of students from different countries, different social contexts, has enabled confrontation of different imaginaries, different myths. It avoids a polarisation of the imaginary which would threaten the psyche of a person or a group (Durand, op.cit.). Myths are recurrent and we suggest they encourage student argumentation and problematisation of the relationships between scientific, ethical, experiential reasoning and development of critical thinking.

DIDACTICAL DILEMMAS WHILE TEACHING
CONTROVERSIAL SOCIO-SCIENTIFIC ISSUES – AN
INTERNATIONAL COMPARISON

Christian Rydberg, Clas Olander and Jesper Sjöström
Malmö University, Malmö, Sweden

This study followed groups of teachers within an Erasmus+-partnership, in which the teachers conducted an intended reflexive and interdisciplinary teaching about complex and controversial issues, including socio-scientific issues. Five schools, with students aged 12-16 years, in five different countries (Croatia, Poland, Italy, Sweden and Turkey) were involved. The overall research design was inspired by research models where researchers and practitioners cooperate and share responsibility. Iterative systematic investigations have been done, when teachers with support of a teaching model created interdisciplinary arenas in their respective context. Through focus groups and participant observation, the study aims to explore potential tensions that emerge during the enactment of the interdisciplinary teaching. Preliminary results show a variety of emerging tensions that might cause didactical dilemmas. The tensions are anchored both at macro level, concerning different types of curriculum goals and related to politics and religion, as well as those at the classroom level and at levels in between.

Keywords: socio-scientific issues, interdisciplinary teaching, environmental education, education for sustainability, teacher professional development

DIDACTICAL DILEMMAS IN INTERDISCIPLINARY TEACHING

In this study, we have followed groups of teachers who conducted an intended reflexive and interdisciplinary teaching about complex and controversial issues in line with Sjöström’s and Eilk’s (2018) Vision III for an eco-reflexive science education (Sjöström, Eilks & Zuin, 2016). Such teaching is Bildung-oriented and holistic, and ethical and political aspects of science are foregrounded (Sjöström et al., 2017). An important objective is to give all students the opportunity to develop as independent political subjects, by giving them chances to both challenge the existing views in society, examine their own stance on societal issues, as well as to enable them to take their own position (Hasslöf & Malmberg, 2015).

This study has followed groups of teachers from five schools, with students aged 12-16 years, in five different countries (Croatia, Poland, Italy, Sweden and Turkey). The schools participated in an Erasmus+-partnership with the objective to test and implement an interdisciplinary teaching about complex and controversial issues, including socio-scientific issues. The sociodilemmas (complex SSIs) the schools worked with in the study contained content from several different school subjects. This kind of teaching ought to have an important role in both natural and social sciences classrooms, as well as in technology and sustainability education (Crick, 1998; Zeidler & Keefer, 2003; Englund, Öhman, & Östman, 2008; Keirl, 2012).

This study is thus inspired by research from different fields of educational research with the ambition to induce interdisciplinary teaching about controversial issues on a structural and
socio-political level at the involved schools. The development of students’ abilities for critical thinking and decision making were highlighted as well as oral discussions between students. The teaching was furthermore also supposed to create room for the students to form their own opinions about the issues. In this study, the teaching in line with these intentions were labelled “reflexive teaching”.

The study aims to explore potential tensions that emerge during the enactment of the interdisciplinary teaching when the schools implemented the kind of teaching mentioned above. Through focus groups and participant observation in all participating countries, we ask firstly, which tensions are discernible across the different classrooms? Secondly, we make a reduction of the data and focus the Swedish teachers in the light of the international pattern. We ask “which tensions are most salient for the Swedish teachers”? These two questions are theoretically elevated and clustered in the discussion to “which didactical dilemmas may emerge during interdisciplinary teaching”. In this paper, we will primarily focus on the first question.

THEORETICAL FRAMEWORK

The international setting of this study opens opportunities for cross-cultural comparisons and analyses that could generate knowledge about teaching, teaching content, learning and socialization. Almqvist (2014) describes that teachers constantly must make judgment about which educational content to include and which methods should be used. These decisions are generally based on previous experiences. Almqvist states that it is vital for teachers to occasionally visualize and problematize what has been taken for granted in the teaching. This is the basis of “comparative didactics”, which is about making the taken for granted visible and critically reflected on, and thus acquires knowledge for teaching and learning.

Comparative didactics can be about comparing teaching within the same subjects or between different subjects as well as studying similarities and differences in teaching in different socio-cultural contexts. This can lead to more precise descriptions of the teaching and thus generate new knowledge (Almqvist, 2015). Analysis is often done in two steps, where a first step is about describing teachers’ actions in a teaching practice (Almqvist, 2008; 2014). In a second step, this description is compared with alternative descriptions followed by a critical discussion about the relation between the taken for granted didactical choices and alternative didactical choices.

This study originally presupposed an activity theory perspective on the collective and complex activity systems of the schools to examine how participants’ actions and operations are influenced and affected by both internal and external factors (Leontiev, 1978; Engeström, 1987). Different didactical contradictions and dilemmas that occur in the complexity of everyday teaching may be viewed as obstacles for successful teaching and learning, but by identifying such dilemmas and then discussing them among the teachers, this may instead be a starting point for a permanent transformation and a spark for school and professional development (Sannino & Nocon, 2008).

To gain a deeper understanding of teachers’ challenges and dilemmas, the study assumed a complementary theoretical perspective by considering this form of teaching as a “dilemmatic
space” (Fransson & Grannäs, 2013) in which the dilemmas are ever-present. The dilemmas are the result of social constructions, but the dilemmatic space is constantly in a dynamic process, where everyday positions and negotiations both redefine the dilemmas and the actors. Fransson and Grannäs described that teachers in their daily work often end up in dilemma situations. The teacher must deal with formal laws and regulations as well as more informal work routines. Furthermore, the teacher must balance different purposes of teaching towards each other, focusing on the three different functions that the education should meet: qualification, socialization and subjectification (Biesta, 2009). All this should be done at the same time and the teacher must deal with a variety of social relationships and contexts with different norms, values and expectations. This is also done in a complex and changing activity where decisions need to be taken quickly in the dynamic interactions of the classroom.

Dilemmas are sometimes regarded as individual and disconnected situations, but Fransson and Grannäs (2013) argue that dilemmas constantly are present in our lives because of the social constructions created by everyday positions and negotiations. Fransson and Grannäs use the theoretical perspective dilemmatic space (Honig, 1994) to describe this in an educational setting. Honig describes a dilemmatic space as a complex, moving and mutable system with different actors and different positions. Honig states that we should consider dilemmas as if they are always present in our life where one position oneself, and are being positioned, in various dilemmas. These positions then create peoples’ identity and action space.

**RESEARCH METHODS**

The study followed five European lower secondary schools working together over a two-year period within an EU-funded Erasmus+-partnership. With the help of a teaching model, they designed their own teaching set up based on their own school context. To support the teachers, the model did not just include student tasks; it also included a theoretical framework on how the teachers could implement an inquiry-based approach of this intended reflexive and interdisciplinary teaching (Rydbärger, 2015). This framework was based on methodological models from Bybee et al. (2006) and Presley et al. (2013). Inspiration and ideas concerning teaching about controversial and socio-scientific issues were also provided from e.g. Ekborg, Ideland and Malmberg (2009), Zeidler and Kahn (2014) and Eilks (2015).

Teachers and students worked on different controversial issues containing both scientific, technical and social science content, as well as socio-political and ethical aspects. The student tasks were inspired by the Storyline method (Bell, 2008) in which the students were placed in a scenario where they landed on an imaginary, and newly colonized, planet named PromethEUs. On this imaginary planet, students should together create a new society, which meant that the issues were mainly at a structural level. A companion meaning (Roberts & Östman, 1998) of the teaching was that students would gain insight into the fact that political decisions on complex issues like these – with both scientific, social, economic, political and ethical aspects – is not about "right or wrong". Rather, it's about weighing the advantages against the disadvantages and in this process, try to make reasonable and acceptable decisions.

The issues were deliberately chosen to be complex and controversial. They are sociodilemmas where no definite answer exists; instead all possible solutions have both positive and negative
consequences. The design of the student task strove to develop students' critical thinking abilities, which obviously are prerequisite abilities in order to be able to independently make decisions and express ethical and political standpoints. Students would also be given opportunities to take their own position in the issues and do it in a European context. The students would base their position on knowledge of human rights and fundamental democratic values, on their personal experience as well as on acquired factual knowledge regarding the issue.

The work at the schools was done in three cycles, where each of these ended with a transnational meeting with both teachers and students. In conjunction with these, data collection was done, primarily using focus group interviews. Furthermore, during a third cycle, when the schools were working on issues related to the use of robotics and biotechnology in the future, participant observations were carried out. This study applied a flexible research design and it was during the process of the research that the research questions emerged.

First, the didactical dilemmas which participants at the five schools experienced in the work with the intended reflexive teaching were studied. Focus group interviews were transcribed and the different tensions the teachers experienced where put in themes. After analyzing the data from the first cycle results was brought back to the focus group discussions in the following cycle. With this data, the preliminary themes and categories of tensions were refined. Four themes and eighteen tensions that could create didactical dilemmas emerged from the thematic analysis after the third and last cycle. The teachers’ descriptions created basis for a comparative didactic analysis where what is “taken for granted” in the teaching was made visible when both researchers and teachers studied the similarities and differences of the teaching in the various cultural contexts.

**PRELIMINARY RESULTS**

The study is still ongoing, but in the data from the international focus groups different didactical dilemmas have been identified, analyzed and grouped. The purpose of the study was at a first stage to investigate and identify the tensions teachers experienced when working with the intended reflexive teaching. In a second stage, the study aims to further explore teacher dilemmas that arise from these tensions, focusing on the dilemmas that were considered most relevant from a Swedish context. This paper will primarily focus on the first stage of the study while results from the second stage will be presented in forthcoming publications.

In the dilemmatic spaces of the intended reflexive teaching the teachers described different tensions. These tensions can cause concrete didactical dilemmas for the teachers as they plan, conduct and evaluate the teaching in the study. However, this study doesn’t intend to describe all the tensions that may exist in this form of teaching. Instead a selection was made based on the empirical evidence.

In the data from the study 18 tensions were revealed which may cause didactical dilemmas for the teacher (see further below). It should be stressed that tensions and dilemmas in a dilemmatic space never are separated from the context. Depending on one's positioning in a didactical dilemma this will affect positions in other dilemmas. Furthermore, a didactical dilemma that
from one perspective can be interpreted as a single dilemma, could in fact consists of several related dilemmas.

Below are the eighteen tensions listed. It is not easy to describe them clearly in just a single sentence and the naming should be seen more as an orientation of the tension and the character of the intrinsic didactical dilemma. A tension that causes a didactical dilemma in daily classroom teaching usually has links with other levels of education. To understand the different tensions better, and the didactical dilemmas, the eighteen were divided into the following four themes:

**Theme 1: Tensions linked to curriculum, national tests and assessment**
1. What primarily governs the planning of teaching – the social, democratic and character development goals or the overall educational goals.
2. The impact of national tests on the teaching - big or small.
3. Assessment of students during the theme day - collect evidence for future grading or not.
4. Room for teachers to choose methods and content on their own - large or limited.
5. Room to discuss controversial topics that not relate to the curriculum's core content - large or limited.

**Theme 2: Tensions linked to prevailing religious values and political views in society**
6. The influence of prevailing religious values in society on the teacher's choice of methods and content - significant or slight.
7. The influence of current political views in society on the teacher's choice of methods and content - significant or slight.

**Theme 3: Tensions linked to teachers' interdisciplinary cooperation**
8. Socio-economic challenges in relation to teachers' joint planning of new teaching methods - tangible or insignificant.
9. Potential staff meeting opportunities at school for teachers to co-plan their teaching - large or small.
10. Coordinated training of students' basic skills for a reflexive teaching between the school subjects - comprehensive or non-existent.
11. Opportunities to temporary change the regular school schedule in order to work thematically and interdisciplinary - large or limited.

**Theme 4: Tensions linked to the implementation of the teaching in the classroom**
12. The amount of time the teacher uses for self-studies of the subject matter from beyond the field of his or her domain-specific expertise - large or small.
13. The dominant work form for the discussions in the reflexive teaching – whole class or group discussions.
14. The prioritized method for pupils to retrieve relevant information regarding the current issue - through teacher mediation or through the students looking for it themselves.
15. Grouping of students for group discussions in reflexive teaching – ability grouping or homogeneous groups.
16. Adaptations for “silent” students in oral discussions in a reflexive teaching - adaptation for these or no adaptation.
17. Weather the teacher should express different viewpoint in the discussions - strong objectivity or weak objectivity.
18. Weather the teachers should express their own opinions and beliefs regarding the issue - strong neutrality or weak neutrality.
Not all the eighteen tensions will be covered below. Instead, a selection of the tensions will be discussed. These will be exemplified by didactical dilemmas that the different groups of teachers experienced that were caused by the tension.

**Tensions linked to curriculum, national tests and assessment**

The five first tensions had an emphasis on a macro level in terms of contradictions, primarily between working toward the educational goals in the curriculum, or putting more emphasis on social, democratic and character development goals. This is also linked to tensions and didactical dilemmas concerning assessment, national tests and teacher autonomy. Ways that the national curricula should be interpreted, and the significance of national tests for the everyday teaching is also regulated at the school level, depending on the emphasis the school leadership puts on them. Curricula and other national control systems are in turn influenced by internationally formulated education policies and international knowledge surveys.

For example, the Polish teachers in the study felt steered towards teaching that focuses on the educational goals, mainly on facts. The teachers described that they have syllabi with a comprehensive core content and national examinations that mostly test factual knowledge. Since they perceived that the individual teacher is accountable for poor student results, this creates limited space for teaching in line with reflexive teaching outside this project. They also expressed that it wasn’t really feasible for them to address content that isn’t explicit in the subject’s syllabus.

All teacher groups experienced didactical dilemmas related to the national steering documents and assessment systems when they used the reflexive teaching methods. They all agreed that this kind of teaching offered knowledge that would be very valuable for the students in their future lives. Still, subject content, knowledge or abilities in this weren’t always something that traditionally is stressed in either their curriculum or national tests, at least not the ways the teachers in the study interpret these.

The Swedish teachers expressed that they used to have more teacher autonomy, but during the last years they felt that their lesson planning was more and more affected by the national syllabuses and the national tests. A major difference between the Swedish teachers and the others regarding this matter was that while the teaching in the other schools had a more fact-based focus, the focus in the Swedish school was on developing students’ abilities.

The Italian teachers described that they as teachers have a freedom to choose both teaching methods and content (even if the latter was contradicted by the school’s principal). They meant that both their curriculum and their national examinations promoted teaching that not just are fact-based, but traditions and teachers’ perceived autonomy slow down the rate of change. This teacher autonomy had as consequence that the teachers feel free to continue using more traditional and fact oriented teaching methods.

**Tensions linked to prevailing religious values and political views in society**

Teachers also experienced didactical dilemmas that can be related to tensions due to the prevailing political forces in the country or to religious values in society. The teachers at the Italian school described that some staff members held strong religious values and these also
existed in the local community. When a controversial issue included an aspect that was contradicting the Catholic values, this created tensions for some of the participating teachers. As for issues about abortion and homosexuality some single teachers choose not to discuss these in their classroom. However, the other participating teachers at the Italian school did not experience any influence from religion that would stop them from discussing subjects like these in their classroom.

The teachers at the Turkish school in the study described that both the prevailing political viewpoints in the country and the religious values of society create didactical dilemmas for the teachers. If any issue had aspects that are in contradiction to strong beliefs in society, the teachers often avoided to discuss these aspects. The teachers stated that if they addressed aspects of a controversial issue not included in the syllabus, it may cause problems for them as teachers. This could lead to parents reacting and proceeding with the matter to the school authorities. As for the Polish teachers, they didn’t experience any didactical dilemmas due to influence of prevailing religious values, however they felt that the current dominating political views in their country affected them when they discussed some issues.

**Tensions linked to teachers’ interdisciplinary cooperation**

The teachers described also didactical dilemmas on intermediate levels, which among other things had to do with the teachers working interdisciplinary and how to organize this. These dilemmas were caused by more practical tensions concerning parts of the school’s organization, for example regulation about working hours and scheduling. These aspects aren’t easy for an individual school to influence and change on their own. However, these can create great resistance in a transformation process at the school since this require joint actions. As for the prerequisite for cooperation and co-planning the Swedish school stood out. Here the teachers had a couple of staff meetings each week, they had work places at the school as well as public childcare for teachers with younger children. This allowed the teachers to plan and evaluate lessons at school and they had good conditions for joint development activities.

The teachers at other schools in the study didn’t have the same possibilities. At the Turkish school, they had two shifts which meant that there wasn’t any actual space for the teachers at school when the shift was over. The Turkish teachers described that it was a challenge to work with school development since teachers were forced to work with this to a large extent individually since the teachers' lesson planning wasn’t done at school. Furthermore, the relatively young Turkish teachers who participated expressed that the lack of childcare meant that they had to prepare lessons at home at the same time as they were taking care of their children. They described that they and their spouse synchronized their working hours and combined work at home with caretaking of the children, while their spouse went to work.

In the same way as in Turkish schools, many Croatian schools have teaching shifts and thus short school days for students, with just short breaks. This means that there are basically no opportunities for the teacher to plan or meet colleagues during the school day. The time for planning was in the afternoon, since the school building was locked after lunch time and the teachers had to do the planning at home. The Croatian teachers described that a large part of the teachers at the school felt forced, for economic reasons, to have another job aside and the
short school day made this possible. This obviously affects the potential time that teachers put on preparing lessons and developing the teaching. It was described that this dilemma lead to the teachers sometimes regarded the job as a teacher's as "the second job". They of course understood that this meant that they put less time on planning and developing the teaching than they ought to.

**Tensions linked to the implementation of the teaching in the classroom**

Dilemmas also arose in the classroom teaching. For example, whether the fact-finding primarily should be done by letting the students work individually using computers, or if the teacher would present relevant facts and information about the issues through more traditional methods. Other didactical dilemmas originated from tensions regarding whether the teacher should choose a whole class or group work approaches, as well as tensions related to the teacher's objectivity and neutrality.

The Swedish teachers had a taken for granted position that it should be students themselves who find the information needed in order to take a stand in an issue. In the study, the Swedish students mainly discussed in small groups and during these discussions most of the time there were no teacher acting as discussion leader. Instead it was the students that handled the discussions themselves. Occasionally the Swedish teacher participated in the group's dissociation.

This differed from the teaching the other teacher groups conducted. Here, the teacher took a more active role and was primarily responsible for finding and highlighting the various aspects of the controversial issue. At these schools, the teacher mostly organized whole-class discussions about the issues, even if also group discussion was used. During the student-centered teaching at the Swedish school the main focus was on having the students develop their critical thinking abilities in practice. During the more teacher-centered teaching at the other schools it was the content of the issues that was put in the foreground. The teachers encountered a didactical dilemma regarding to what degree the student should be active in the information finding and discussions. A related dilemma for the teacher was how to balance learning of subject content and the development of general critical thinking abilities. The common conclusion of the teachers was that the Swedish students generally had better argumentation skills but often rather shallow knowledge about the content of the controversial issues.

During the discussions about the different controversial issues the Swedish teachers remained neutral and didn’t reveal their own opinions. However, the teachers at the other involved schools didn’t stay neutral in the same way as the Swedish teachers. Instead these teachers rather saw it as important to share their own opinions, at the same time as they pointed out that their opinion should be treated as one opinion among others. During the discussions with the students, the Swedish teachers often took the opposite view to the students. This opinion wasn’t necessarily their personal opinion; instead it was a professional standpoint in order to challenge the students’ reasoning and argumentation abilities. This approach was rarely used at the other schools during the study. Either the teachers stated his or hers view and stood by this or the
teacher had a more objective and balanced role and presented a wide range of alternative views for the students.

Some of the didactical dilemma teachers described was regarded to be more relevant to focus from a Swedish point of view. In these dilemmas, the Swedish positioning were sometimes other than the positions of the rest of the teachers’ groups in the study. The positions of the Swedish teachers in some dilemmas were strongly related to tensions about the curriculum's different goals, the influence of the national tests on the teaching and tensions around assessment. Some selected didactical dilemmas from a Swedish point of view will be examined deeper. This will be done using data from the in-depth focus group interview with the Swedish teachers, but also using empirical data from the Erasmus+-partnership. This aims to describe the essence of these didactical dilemmas, both in terms of underlying causes, as well as possible consequences, according to various positions in the dilemmatic space of this form of teaching.

**PRELIMINARY DISCUSSION**

When it comes to carrying out an interdisciplinary and intended reflexive teaching with discussions about complex and controversial issues the teacher needs to move beyond the traditional teacher role. Engeström (2008) describes that the deep social structures of an activity system are found in three different parts. It is first the rules, regulations and traditions, secondly the community that have an interest in the teaching and finally the division of labor in the classroom and at the school. These parts give the educational system an inertia that creates tensions when the teaching practice is changed; as it was in this study.

In an altered form of teaching with a partly new motive, the teacher need to be aware that previously taken for granted and operationalized actions might not be valid anymore (Almqvist, 2014). The teachers have to renegotiate their positions in the various didactical dilemmas they constantly experience in their everyday teaching. This study aimed to highlight the dilemmatic space of this form of teaching and showed didactical dilemmas that arise.

The results from this study shows that this kind of teaching is complex and the teacher needs to take many different aspects in considerations. Biesta (2015) points out that the teacher's different forms of judgement are extremely important for good teaching. He says that the teacher first needs to identify what the purposes might be for the forthcoming lesson sequence, then identify possible conflicts between the purposes and finally prioritize between the purposes.

This study shows that to handle the didactical dilemmas in the dilemmatic space of an intended reflexive teaching, it is crucial for the teachers to relate to the main purposes of education as well as other purposes in school activities. Teachers need to analyse how the different purposes are related to the goal-oriented actions that they perform daily in the teaching practice (Biesta, 2015). This way, one can discover that different purposes may sometimes conflict each other and that the different performed actions in the classroom teaching, even if they are done with good intentions, may counteract each other.

This could be illustrated by the position that the Swedish teachers took regarding to what degree the teaching would be student-centered. When the students themselves were responsible for
finding and evaluating information this created opportunity for the students to develop their critical thinking abilities in practice. This in turn was because these students had a lot of training about how to search for and evaluate information, how to reason and how to discuss. However, with this position there is a risk that the students only will obtain shallow knowledge about the content of the controversial issues since it is hard for students at this age to find relevant information on their own. If the teacher takes more responsibility for providing relevant information about different aspects of the issues, the chances for the students to get the full picture of the sociodilemma is greater. However, if the teacher takes too much responsibility the student may miss opportunities to develop his or her abilities to search for information about society from the media, the Internet and other sources.

What position the teacher should take in this specific didactical dilemma depends on the main purpose. If it is to develop critical thinking abilities in order to take well-informed standpoints in the future, then it’s wise to let the students practice the abilities and it’s ok that the student misses some content related aspects. Is the main purpose with the issue instead that the students should get knowledge and insight about different aspects of the controversial issue the teacher needs to make sure that the content of the issue is foregrounded. If the main purpose is providing an opportunity for the student to take an own stance in a current sociodilemma, then both critical thinking abilities as well as knowledge about the content of the issue is important, as well as knowledge about other aspects concerning the issue. Then the teacher needs to balance the different purposes.

As a teacher, you position yourself in the didactical dilemmas according to prior experience, current rules and norms and the surrounding social context. This is creating the dilemmatic space where different norms, values, action, decisions and roles all stand in relation to each other (Fransson, 2012). As for some of the didactical dilemmas, the teacher has actual leeway to make judgement about different didactical choice. However, the teachers’ possibility to take positions in a didactical dilemma could sometimes be limited by education policy and by the surrounding community.

Even if teaching about these issues is regarded as valuable for the students in their future lives, the subject content of the issues, as well as the abilities that are developed, are not always what is valued in grading and testing students. If a teacher feels that this type of teaching may risk students achieving a poorer result in a national test or equivalent, it becomes a didactical dilemma for the teacher. Even if the teacher agrees that a reflexive teaching about controversial issues is good for the students, he or she still needs to consider if it is worth the risk of lower scores at a traditional test. This especially if the teacher is held accountable for the results of the tests.

The results from this international study shows that prevailing religious values and dominating political views in the society could affect the teachers when working with controversial issues. Some teachers expressed that they avoided certain aspects to prevent conflicts with parents and local authorities. This highlight that some of these issues not only are challenging to deal with for the students in the classroom, but also could be challenging for the teacher in real life.

This study also points out that it requires time and discussions between teachers to transform teaching practices, especially if it is interdisciplinary teaching with controversial issues. In the
frame of this EU-funded Erasmus+-projects the teachers had this, and all involved teacher teams succeeded with their reflexive teaching. Still, the teachers expressed that outside this project there is a lack of prerequisites for joint and long-term transformation processes of their practice. This is for example due to organizational factors as lack of joint teacher training and socio-economic factors that make it hard for the teachers to find time and places to co-plan and develop the teaching together with colleagues.

CONCLUDING REMARKS

A purpose of this study was also to contribute to pre- and in-service teacher training and the results will form a basis for a discussion tool. This tool aims to provide support for teachers to develop their shared teaching knowledge. It could contribute to the development of teachers’ action competence and expand their repertoire of strategies for dealing with the didactical dilemmas that could occur in this form of teaching. The discussion tool aims to raise awareness about both possibilities and potential negative consequences with different positions in different didactical dilemmas. It will also support teachers to question what is taken for granted in their own practice. This discussion tool will be described in detail in forthcoming publications.

THE INFLUENCE OF ENGAGE MATERIALS ON STUDENTS’ LEARNING ABOUT SOCIOSCIENTIFIC ISSUES

Durdane Bayram-Jacobs¹, Ineke Henze², and Erik Barendsen¹,³

¹Radboud University, Nijmegen, the Netherlands, ²Delft University of Technology, Delft, the Netherlands, ³Open University, the Netherlands

Today’s society needs citizens who are familiar with the scientific way of thinking, and can use it in everyday life. Therefore, science education aims to engage students in socioscientific issues (SSI). In this study, two chemistry teachers used ENGAGE lesson material with 53 students to teach SSI. The study aims to investigate how successful the Engage materials are in engaging students in SSI, that is, connecting these with chemistry knowledge, personal life and society. De Groot’s Learner Report was used to gather the data, and these data were analyzed by qualitative content analysis, using Atlas.ti software. The findings indicate that the ENGAGE materials fostered students’ learning related to SSI. Especially connecting chemistry concepts, society, and personal life through SSI. This study also revealed opportunities and challenges for teaching SSI in science lessons.

Keywords: socioscientific issues (SSI), curriculum materials, students’ learning

INTRODUCTION

Problem statement and theoretical framework

Science education has a crucial role in preparing future citizens to engage with personal and public science-based issues. Currently, science education does not only aim to educate future scientists but also whole student population who are scientifically literate. That means, they can make informed decisions regarding ill-structured, complex, dilemmatic social problems which deal with scientific issues, based on understanding of concepts, principles and the processes of science (DeBoer, 2000; European Commission, 2015).

Recent research in science education addresses scientific literacy, Responsible Research and Innovation (RRI), inquiry-based learning (Osborne & Dillon, 2008) and improving student cognitive abilities, i.e. scientific skills such as examining consequences, interrogating media, estimating risks, justifying opinions, and thinking ethically (Bayram-Jacobs, 2016). Today’s society needs citizens who are familiar with the scientific way of thinking, and can use it in their everyday lives. One powerful way to do this is incorporating socioscientific issues (SSI) in science education and to engage students in SSI (Driver, Newton, & Osborne, 2000; Millar & Osborne, 1998).

Socioscientific issues

Socioscientific issues (SSI) are defined as controversial, ill-structured problems which usually do not have a single solution. Through some innovations in science and technology, society is faced with dilemmas, which are related to political, economic, social and ethical aspects. Citizens need scientific reasoning to be able to make informed decisions about scientific or technologic innovations. Besides, SSI includes ethics and moral reasoning about the social problems which base on science (Zeidler, Sadler, Simmons & Howes, 2005). Dealing with SSI
Strand 8

means more than just using scientific and social knowledge. It requires applying scientific knowledge in a social context, and in everyday life to solve a controversial SSI problem (Sadler, Barab & Scott, 2007).

Many countries incorporated SSI into their science curricula to promote scientific literacy. By discussing SSI in science lessons, it is aimed to improve students’ inquiry skills and to make connections with society. SSI based instruction is accepted as an efficient way to support students’ science learning. There is evidence that SSI based instruction (e.g. genetic modification, climate change, hydraulic fracturing, etc.) motivates students for science learning, improves their inquiry skills and offers a context to combine science knowledge with social life (Ekborg, Ideland & Malmberg, 2009; Sadler, Barab & Scott, 2007). These real-life issues are not only meaningful but also engaging for students. By discussing SSI, making their own arguments, searching for evidences and weighing up the claims students gain required knowledge and skills to be responsive citizens. Consequently, they can participate in public debates, and can make informed decisions, which make them active and responsive citizens of the society (Fowler, Zeidler & Sadler, 2009; Lewis & Leach, 2006; Ratcliffe & Grace, 2003, Simonneaux & Simonneaux, 2009).

However, it is known that teachers have difficulties to embed SSI in science lessons, to focus on skills development, and to help their students in their learning process in SSI (Evagorou, 2011; Sadler, Barab & Scott, 2007). Limited teaching time, exam driven school goals and structure, and limited curriculum materials are just a few examples to mention. Researchers and teacher trainers have been trying to support teachers through different means such as professional development courses, workshops, curriculum materials, etc. Although there were some curriculum materials produced to foster SSI-based instruction, these materials are mostly sequential materials. Therefore, their enactment requires long lesson series. On the other hand, it is known that many teachers are not open for new practices because they require long time (Serdyukov, 2017). Therefore, in the ENGAGE project we designed SSI curriculum materials by considering teacher difficulties and time constrains.

The ENGAGE Project and ENGAGE SSI Materials

The ENGAGE project was granted by European Commission under the ‘science in society’ call. The Engage project aims equipping the next generation to participate in socioscientific issues (Bayram-Jacobs, 2015). To reach this aim, the project has several strategies including designing curriculum materials that focus on SSI for science teachers. Teachers can download these SSI curriculum materials, which are open educational resources, from the project’s website (www.engagingscience.eu) as a complete package including presentation (powerpoint), teacher guide and student sheets.

The materials were designed in a stepwise way in three categories. That means, there are three types of materials: topicals (for 1 lesson), sequences (for 2-3 lessons), and projects (for >3 lessons). In this way, we allow teachers to choose the material according to their need and time. For example, science teachers who do not have any experience in using SSI, can choose to use the topicals. In this way, they have time to learn about this new teaching practice, improve their knowledge and skills for teaching with SSI and reflect on their actions in practice.
In the materials, the 5E learning cycle (Bybee, 1997; Trowbridge, Bybee & Powell, 2000) was used as a pedagogical approach to introduce SSI to students. The material framework includes SSI goals, practices, strategies (Shwartz. & Sherborne, 2016) and the following US next generation science standards (NGSS, 2013): Content big ideas, RRI big ideas, Nature of science big ideas, and Scientific practices.

The SSI materials include controversial issues, ethical values, forming opinions, making choices, and so on (Ratcliffe & Gravies, 2003). For example, the material ‘Death to Diesel’ introduces the dilemma of ‘driving cheap versus environment-friendly’, and one of the activities involved role-playing, for example persuading car buyers to boycott diesel cars. In this way, it is expected from students to connect SSI with chemistry knowledge, personal life and society (like we presented it in Figure 1).

![Chemistry concept](image)

**Figure 1. Student learning areas through overarching SSI theme**

There are studies where teachers evaluated ENGAGE materials (Bayram-Jacobs & Henze, 2016; Okada & Bayram-Jacobs, 2016) that showed that the students liked the materials. Although there is evidence that SSI-based instruction motivates students for science learning, for the ENGAGE materials this has not been studied, yet. Therefore, it is necessary to investigate the influence of the ENGAGE materials on students’ learning related to SSI.

Given that curriculum materials should be "both effective and efficient” by helping teachers to deal with implementation problems (Davis and Krajcik, 2005), the materials that were used in this study were designed to facilitate the first step of 'classroom experimentation'. This is also based on the argument that using curriculum materials has an impact on specific teaching practices (Schneider & Krajcik, 2002). Although the materials are ready-to-use, teachers may adapt them according to level, interest and needs of their students.

**AIM**

This study aims to investigate how successful the ENGAGE materials are in engaging students in SSI, that is, connecting these with chemistry knowledge, personal life and society.

This general aim gives rise to the following specific research questions:

1. To what extent did students learn about SSI?
2. How far do students connect the SSI to chemistry concepts?
3. How far do students connect the SSI to their personal lives and society?
METHOD

Participants

The participants of this study are 53 students from two secondary schools in the Netherlands, in the age of 14 to 17 years old. In two classes, the Chemistry teachers chose to use ‘Death to diesel’ ENGAGE material, among the other chemistry materials. The teachers stated that they chose this material because the science content of the material was relevant to the curriculum. This material is a topical, means that it was designed for a single lesson.

Data collection

In order to measure students’ engagement in SSI, standardized tests cannot provide valuable data. Since we want to know if students connect science knowledge to their personal and everyday life, it is needed to ask more personal questions. De Groot (1974) developed a method that includes fundamental learning experiences of students defined as “the experiences that are subjectively remembered and reported by a student to develop important insights where s/he has learned something.” Moreover, previous research (Bayram-Jacobs & Henze, 2016; Kniep &Janssen, 2014; Schrijvers, Janssen, Fialho & Rijaardsdam, 2016; Van der Meij, Broerse & Kupper, 2017) showed that this instrument is useful to study this type of student learning. The classification matrix of the instrument is represented in Table 1 (De Groot, 1974).

<table>
<thead>
<tr>
<th>Rules</th>
<th>Exceptions</th>
</tr>
</thead>
<tbody>
<tr>
<td>World</td>
<td>A. Knowledge and insights</td>
</tr>
<tr>
<td>Self</td>
<td>C. Insights into oneself: rules about myself (e.g., capacities, affinities, restrictions)</td>
</tr>
</tbody>
</table>

Therefore, in this study to investigate the influence of the ENGAGE materials on students’ learning related to SSI, the “Learner Report” (De Groot, 1974) was used as a self-reporting instrument. The Learner Report focuses on a student’s learning in two dimensions: first, about the outside world and about himself/herself, respectively. Second, distinguishing between universal facts (rules) and exceptions. This gives rise to four categories, in which students formulate so-called learning sentences of the form “I have learned that..”, see Table 1. The students filled the learner report out after the lesson where the ENGAGE material was used. On average, it took 20 minutes to complete the Learner Reports.

Data Analysis

For analysing the data, qualitative content analysis was performed by using Atlas.ti software. The learning statements were the units of analysis. First, we looked for sentences containing chemistry concepts related to the topic of the lesson. Then, we identified sentences mentioning a SSI about diesel cars, and classified sentences as referring to ‘society’, and ‘personal life’. Within these categories, we classified the content of the statements (e.g., distinguishing between societal aspects) using an inductive coding procedure. Testing and adapting the codes continued until the researchers reached consensus.
FINDINGS

Totally, 305 learning sentences were analyzed, and 16 codes were created and 167 sentences were coded. We coded 70 times ‘chemistry concept’, 87 times ‘society’, and 41 times ‘personal life’.

After the lesson with ‘Death to Diesel’ ENGAGE material, 51 of 53 students reported learning related to SSI, giving rise to 141 learning sentences containing SSI. In all of the 141 cases, the sentences contained connections to ‘diesel’ related chemical concepts such as combustion, mixture, nitrogen monoxide, nitrogen dioxide, etc.

Related to connecting SSI with chemistry concepts, society and personal life the results were presented below in Table 2. From the society related learning sentences, three groups appeared: ‘human health’, ‘environment’ and ‘human behaviour’. Personal life related learning sentences were grouped into two: ‘personal life-active’, and ‘personal life-passive’. Personal life-active refers to learning sentences where student has an active role as someone who influences the course of affairs.

### Table 2. Classification of SSI sentences

<table>
<thead>
<tr>
<th></th>
<th>Society</th>
<th></th>
<th>Personal life</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Human health</td>
<td>49</td>
<td>Personal life-active</td>
<td>38</td>
<td></td>
</tr>
<tr>
<td>Environment</td>
<td>32</td>
<td>Personal life-passive</td>
<td>4</td>
<td></td>
</tr>
<tr>
<td>Human behaviour</td>
<td>6</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Total sentences</strong></td>
<td><strong>87</strong></td>
<td></td>
<td><strong>Total sentences</strong></td>
<td><strong>41</strong></td>
</tr>
</tbody>
</table>

Some examples of students’ sentences related to connecting chemistry concepts with society:

for ‘human health’:

“I have learned that using diesel can make your life 2 years shorter and you can get blood clots that can cause heart problems and lung complaints.” (Student 22, class2)

for ‘environment’

“I have learned that diesel is worse for your health and for the environment than gasoline.” (Student 7, class1)

for human ‘behavior’:

“I think that the best way to solve it is economically, since every normal person knows that diesel is ultra bad, but because it is so much cheaper, people use it anyway.” (Student 3, class2)

An example for a learning sentence of ‘Personal life-active’:

“(I have learned) that I pay attention to where I am going to live later i.e emissions in the air that can cause to decrease your life expectancy.” (Student 19, class2)

Consequently, with the ENGAGE SSI material most of the students learned chemistry concepts, applied these into society and their personal lives. The students’ learning sentences referred more on society than personal lives. Besides, among society related sentences,
expressions about ‘human health’ were noticeable. Additionally, it also came out that the students improved some skills while applying the chemistry concepts into their personal lives and society. For example, they improved the skills; ‘interrogate media’ (f=6) and making informed decisions (f=1). For example:

“I now know that advertisements are more like bad soaps, it would be much more fun to watch.” (Student 30, class 2)

“I now know that cars are not always as economical as the manufacturers claim.” (Student 24, class 2)

“I have learned how I can judge an advertisement” (Student 16, class 1)

“(I have learned that) I should check carefully the CO₂ emission of the cars before buying one.” (Student 16, class 2).

CONCLUSIONS AND DISCUSSION

The findings of this study showed that through specially designed ENGAGE material, students learned about the dilemma of ‘driving cheap versus environment friendly’. While studying this dilemma, they connected chemistry concepts to their personal life and society. We found more society related learning sentences than chemistry concepts. This may be because the material includes more connections to society and personal life and less chemistry content. The teachers used this type of material for the first time and taught a SSI lesson for the first time. As we know from the teachers that they did not adapt the material but used it in the original format, this may have lead them to focus more on society and personal life since this is the innovative aspect and the focus of the material. Moreover, it might also show that the students are more enthusiastic to talk and write about society and their personal life than chemistry concepts.

In society related learning sentences, there was more emphasis in ‘human health’. Many students stated sentences about the damage that emission from diesel car generates. Apparently, the case in the material ‘Death to Diesel’ which is the news from the Daily Post where a mother talks about her sick son, influenced the students and motivated them to think about the damages that diesel may cause.

This study also introduced the opportunities and challenges for teaching SSI in science lessons. As the teachers mentioned to us, the students liked this different type of science lesson. They enjoyed discussing, group works, thinking about themselves, their environment and society. From our talk with the teachers we learned that the lesson was very engaging even for the less active students. Therefore, there is an opportunity to engage students more in science lessons with these type of SSI materials. On the other hand, it is difficult for teachers to make their own materials, especially when they have less experience and time. Not only this study but also our previous studies (Bayram-Jacobs & Henze, 2016; Okada & Bayram-Jacobs, 2016) showed the need of teachers for this type of materials. To scaffold their students SSI learning, teachers need complete curriculum materials.

Furthermore, we suggest that teaching with the ENGAGE materials fosters students’ learning related to SSI. However, there are other factors such as ‘teacher’ and ‘context’, which were not in the scope of this study, should be considered, too. Since all the ENGAGE materials have the
same structure and were designed with the same principles, there are benefits of using other ENGAGE materials.

Finally, in this study we repeat the question we raised in our previous study (Okada & Bayram-Jacobs, 2016) “How to ensure the sustainability of these resources and opportunities for teachers?” and this study raises a new question “How to make it easy for teachers to design their own materials?”

ACKNOWLEDGEMENT

In this research, the materials, which are developed by the “ENGAGE” project, were used. The project has received funding from the European Community’s Seventh Framework Programme FP7/2007-2013 under grant agreement No [612269].

INVESTIGATING THE RELATIONSHIP BETWEEN CONTENT KNOWLEDGE AND THE CONSTRUCTION OF ETHICAL ARGUMENTS ON SOCIO-SCIENTIFIC ISSUES

Andreani Baytelman and Costas P. Constantinou
Learning in Science Group, University of Cyprus, Nicosia, Cyprus

This study investigated the relationship between university students’ content knowledge and the construction of ethical arguments on socio-scientific issues (SSIs). Particularly, we investigated whether university students' content knowledge about value-laden, controversial SSIs, predict the number and the quality of ethical arguments that they construct. We focus particularly on this possible relationship because we hypothesized that the content knowledge could promote the ability of students to recognize when a situation, such as SSI, contains a moral aspect and be aware of how possible resolutions of the situation have the potential to affect others in a negative manner and construct relevant ethical arguments. 240 university students were asked to construct different types of supportive arguments − social, ethical, economic, scientific and others, − as well as counterarguments and rebuttals after they had read a scenario on a value-laden SSI. Participants’ content knowledge was assessed separately. Results show that university students' content knowledge predict students’ number and quality of ethical arguments that they construct on value-laden SSIs, but differences in the predictability of the content knowledge about SSIs were found. That indicates context dependence. Additional research is needed that can robustly describe the relationship between content knowledge and ethical arguments on value-laden SSIs. We discuss the significance and the educational implications of these findings.

Keywords: content knowledge, ethical arguments, socio-scientific issues.

INTRODUCTION

A long standing goal of science education reform is to promote scientific literacy for all. For many contemporary science educators, scientific literacy must entail the ability to negotiate and make decisions regarding complex, social issues with theoretical and/or conceptual links to science. These issues have been termed ‘socio-scientific issues’ (SSIs). They are usually controversial in nature but have the added element of requiring a degree of moral reasoning or the evaluation of ethical concerns in the process of arriving at decisions regarding possible resolution of those issues (Sadler & Zeidler, 2004). They are associated with morality, and moral considerations are central to their negotiation and resolution (Aikenhead, 2006; Driver, Newton & Osborne, 2000; Kolsø, 2001a; 2001b; Roberts, 2007; Zeidler & Keefer, 2003; Zeidler & Nichols, 2009; Zeidler, Sadler, et.al., 2005). Some authors have suggested that moral considerations necessarily contribute to argumentation in the context of SSIs, and several studies have revealed decision-makers’ tendencies to actually construe SSIs as moral problems (Sadler & Donnelly, 2006; Sadler & Zeidler, 2004). Additionally, Sadler and Zeidler (2004) argue that an individual in order to make informed decisions regarding SSIs, s/he needs to have considered the moral ramifications of those decisions. Conclusions drawn in ignorance of the moral and ethical dimensions of SSIs fetter the efficacy of those conclusions.
Given the significant role played by socio-scientific issues in science education, it is important to understand how learners perceive, negotiate, and resolve these issues. For example, Science educators have become interested in examining several factors, such as epistemic beliefs – which refer to individuals’ beliefs about the nature of knowledge and the process of knowing –, content knowledge, values, desires and expectations, as potential contributors to the negotiation of SSIs (Sadler & Donnelly 2006).

We extend this line of research related to SSIs and content knowledge by investigating the possible relationship between scientific content knowledge and the construction of ethical arguments on value-laden socio-scientific issues. We focus particularly on this possible relationship because we hypothesized that the content knowledge can promote the ability of students to recognize when a situation, such as SSI, contains a moral aspect and be aware of how possible resolutions of the situation have the potential to affect others in a negative manner and construct relevant ethical arguments (Fowler et al., 2009). Additionally, to our knowledge, this issue has not yet been investigated. By doing this, we hoped to understand better the role of content knowledge for the negotiation of value-laden SSIs, and explore ways to prepare future citizens to deal with such SSI-dilemmas.

Particularly, we set out to answer the following research questions: (1) Is there a relationship between university students’ content knowledge and the number of ethical arguments that they construct on a value-laden socio-scientific issue? (2) Is there a relationship between university students’ content knowledge and the quality of ethical arguments that they construct on a value-laden socio-scientific issue?

**Content knowledge and ethical arguments on socio-scientific issues**

According to Novak & Gowin (1984), a well-structured knowledge can sustain higher levels of reasoning than poorly structured knowledge. Additionally, Toulmin (1972) states that argumentation is involved with reasoning and critical thinking and is the mechanism for creating and using knowledge. On the other hand, discussions of SSIs in the science education literature are accompanied by the assumption that individuals’ content knowledge contributes significantly to their reasoning and argumentation in the context of SSIs (Sadler & Fowler, 2006; Sadler & Zeidler, 2005). However, there is some disagreement among the researchers regarding the kind of the relation between content knowledge and argumentation on SSIs.

Generally, discussions of content knowledge and SSIs in the science education literature are frequently accompanied by the assumption that an individual’s content knowledge contributes significantly to his/her reasoning and argumentation in the context of SSIs. On the other hand, there are evidence showing that conceptual understanding of an issue does not determine the quality of thinking skills used for this issue (Kuhn, 1991). For example, some researchers found relations between university students’ content knowledge and the number and quality of arguments for the negotiation and resolution of SSIs (Baytelman, Iordanou, & Constantiniou, 2016). In contrast, Means and Voss (1996) argued that content knowledge did account for a greater number of responses, but these quantitative differences did not necessary lead to higher quality of informal reasoning and argumentation.
Furthermore, the possible relationship between content knowledge and the construction of ethical arguments on value-laden SSIs has not yet been investigated, according to our knowledge. The number and the quality of ethical arguments, constructed during negotiation of value-laden SSIs, could be employed as indicator for moral sensitivity, according to the Four Component Model, developed by Rest and his colleagues (Rest et al., 1986). In particular, according to Fowler, Zeidler and Sadler (2009), the Four Component Model, provides a useful framework for exploring morality. Rest and his colleagues at the Centre for the Study of Ethical Development developed an extensive research programme related to moral development. Their design and validation of the Defining Issues Test (DIT) (Rest et al., 1974) revolutionized the study of moral reasoning. Based on findings that suggested that moral reasoning underdetermined moral behavior, Rest developed the Four Component Model. This model proposes four psychological processes that contribute to moral behavior.

The four components which define Rest’s model are described below (Fowler, Zeidler & Sadler, 2009):

(1) Moral sensitivity: Moral sensitivity is the ability to recognize when a situation contains a moral aspect. When confronted with a situation, such as SSI, a person with moral sensitivity is aware of how possible resolutions of the situation have the potential to affect others in a negative manner. Thus, a person with moral sensitivity is attuned to the feelings and reactions of others. He or she is cognizant of alternate courses of action and is able to anticipate consequences of each. He or she is able to examine aspects of a situation and the importance of each to that particular situation.

(2) Moral reason: Moral reason is the analysis that is used to determine which course of action is morally desirable in a given situation and the ability to defend that position through the use of critical thinking skills. It requires the identification of courses of action and the ability to provide justification for them.

(3) Moral commitment: Recognition of a moral situation and analysis through moral reasoning do not guarantee that a moral course of action will occur. Knowing the right thing to do and actually doing it is not the same thing. Thus, priority to moral concerns is the third component of moral development. This first requires that a person recognize that personal concerns are not always compatible with the moral course of action followed by a willingness to choose what he or she has deemed the most moral course of action.

(4) Moral courage: Closely linked to priority to moral commitment is moral courage, the fourth component. A person may recognize a moral situation, reason a moral course of action and be willing to follow the moral course of action, but at times, a person may encounter pressure from others not to do so. Though willing to follow a moral course of action (i.e. having moral commitment), a person also needs moral courage in order to do follow through.

According to the Four Component Model, moral sensitivity, that means the ability to recognize moral aspects of SSIs, is necessary but not sufficient condition for moral reasoning and moral behavior. However, we focus on this possible relationship because we hypothesized that the content knowledge could promote the ability of students to recognize when a situation, such as
SSI, contains a moral aspect and be aware of how possible resolutions of the situation have the potential to affect others in a negative manner and construct relevant ethical arguments.

In the present study, content knowledge is defined as prior domain-specific conceptual content knowledge and includes the knowledge of concepts, principles, facts and theories of a subject, but also an understanding of how concepts and principles of a subject are organized (Shulman, 1986; Kleickmann et al., 2012). The more connections that exist among facts, ideas, and procedures, the better the understanding (Hiebert & Carpenter, 1992; Hiebert & Lefevre, 1986). Additionally, according to Novak (1998) concept maps can provide evidence for a meaningful distinction of meaningful and rote learning or deep and surface understanding. Ethical arguments are all ethical-oriented socio-scientific arguments based on deontology and human and animals rights. Deontological principles such as beneficence and justice impose duties, on moral agents, that can guide their decision-making and behaviors (Sadler & Zeidler, 2004).

**METHOD**

**Participants**

Participants were 240 undergraduate university students at a public University in South Europe. Students were between the second and the fourth year of their study. All participants were elementary or early childhood education majors and were enrolled in a required science education course, within this experiment was administered. The participants were Caucasian native speakers and shared a homogeneous middle class social background. All the participants had at least 12 years of schooling before starting their university studies. With very few exceptions, all the participants had completed their secondary education in public schools.

**Data Collection**

Three different SSI-dilemmas were developed and used in the present study (a) safety and usage or not usage of vaccines, (b) consumption of bottled vs. tap water, (c) usage of underground vs. overhead high voltage lines. Our rationale for the choice of these SSI-dilemmas is the following: (a) The three different SSIs are value-laden and have different scientific, political, ethical, social and economic aspects, (b) The last decade, SSIs such as safety and usage of vaccines, high voltage lines and consumption of bottled vs. tap water have attracted increasing attention in the country of this study, therefore students might be more motivated to engage in thinking about these topics; (c) The participants of this study had already learned about vaccines, drinking water and high voltage lines in their science classes at the secondary school and they had content knowledge regarding these issues.

The content knowledge was assessed in two different levels. The first level was assessed by open-ended questions which assessed separated basic scientific concepts related to each SSI. The second level was assessed by a concept map with appropriate relationships between the relevant scientific concepts related to each SSI. In particular, to assess students’ content knowledge, students were asked to answer five open-ended questions and to construct a concept map for each SSI. For the development and validation of questionnaires, we followed four steps (a) Review of literature for the development of preliminary item pool; (b) Interviews with experts for the validation and optimization of items; (c) Pilot studies for the internal
consistency and item analysis; (d) Preliminary data analyses. The open-ended questions were scored 0-2, on the basis of their correctness and completeness, by the first author and an independent judge. For the creation of each concept map, the students were asked to use a list of ten concepts, which were provided to them, relevant to each SSI of this study, describing the appropriate relationships between the relevant concepts. We decided to use a list of ten basic concepts for each SSI, because in this way all participants had available some relevant background knowledge that they could use them if they wished. For each student’s concept map, we counted the number of appropriate concepts and the number and quality of appropriate relationships between concepts (propositions). Propositions were scored using a four-point scale (0-3).

Students’ ethical arguments were assessed using a written instrument (Baytelman & Constantinou, 2014; Baytelman, 2015). In particular, for each SSI-dilemma, students were asked to take a position and justify it by formulating supportive arguments, counterarguments and rebuttals, using different types of arguments, such as social, ethical, economic, scientific, according to their opinion. For each participant, we computed the total number and quality of valid ethical supportive arguments, ethical counterarguments and ethical rebuttals constructed. Ethical arguments are all ethical-oriented arguments based on deontology and human rights. In particular, in this study, students had to list their different types of arguments and not to write one coherent text weighing and synthesizing strategies (argument–counterargument integration, see Nussbaum et al., 2008), because we are interested in the construction of different types of arguments and not argumentation per se. The quality of ethical arguments was determined based on the scoring scheme of Sadler & Fowler (2006), using a four-point scale (0-3).

**Procedure**

Each participant participated in 2 sessions. In the first session, the content knowledge measures were administered. The first session lasted 40 min. In the second session, the SSI-scenarios, and the questionnaire for the investigation of ethical arguments on SSIs were administrated. Students were given unlimited time to carry out the second session’ tasks. The first author did the data collection.

**RESULTS**

To answer the two research questions of this study “Is there a relationship between university students’ content knowledge and the number of ethical arguments that they construct on a value-laden socio-scientific issue?” and “Is there a relationship between university students’ content knowledge and the quality of ethical arguments that they construct on a value-laden socio-scientific issue?”, multiple regression analyses were carried with the number and the quality of ethical arguments, counterarguments and rebuttals for each SSI constructed as dependent variables. Predictors of each of these equations were the results of the five open-ended questions and the concept map of the content knowledge measures.

The results of the multiple regression analyses for variables predicting scores on number and quality of ethical arguments on each SSI are shown in Tables 1 and 2. The six content
knowledge predictors together (five open-ended questions and one concept map) explained a significant amount 49.4% of the total number of ethical arguments regarding SSI1, (F(6,234)=12.02, p<.01, R²=.494), and 26% of the quality of ethical arguments on SSI1, (F(6,234)=4.32, p<.01, R²=.259). The six content knowledge predictors together (five open-ended questions and one concept map) explained a significant amount 20% of the total number of ethical arguments regarding SSI2, (F(6,234)=3.07, p<.01, R²=.20) and 25% of the quality of ethical arguments on SSI2, (F(6,234)=4.13, p<.01, R²=.251). No predictability about SSI3 was found.

**p≤.01, *p≤.05

The dominant forms of ethical arguments that university students in the present study employed were ethical arguments based on principles such as principles of justice, meaningful participation, sanctity of human life, health and human rights.
CONCLUSION

The findings of this study suggest that relationships between content knowledge about SSIs of university students and the construction of ethical arguments regarding value-laden SSI-dilemmas vary with context. So, science content knowledge is a necessary but not sufficient condition for construction of ethical arguments on SSIs (indicators for moral sensitivity) as well as for negotiation of SSIs. Fowler and Amiri (2004) also concluded that science content knowledge alone did not increase moral sensitivity. That means that more factors play a role.

However, our findings show that the content knowledge could promote the ability of students to recognize when a situation, such as SSI, contains a moral aspect and be aware of how possible resolutions of the situation have the potential to affect others in a negative manner and construct relevant ethical arguments. Additionally, our findings show that this is dependent on the scenario given to students. According to the Four Component Model, developed by Rest (Rest et al., 1986), this ability is an indicator for moral sensitivity, which is the first of the four components which contribute to moral decisions and behavior. Possible relationships between science content knowledge and moral sensitivity and context dependence were also found by Sadler (2004).

According to others authors, in addition to science content knowledge, a series of other factors emerge as important dimensions of socio-scientific decision-making. These factors include emotions, personal experiences, family biases, the impact of popular culture (Fowler, Zeidler & Sadler, 2009; Sadler & Zeidler, 2004; 2005; Sadler, 2004) and epistemic beliefs (Baytelman, 2015; Baytelman, Iordanou, & Constantinou, 2016). The interaction between content knowledge and all above factors remains an open area for future research on SSIs. Furthermore, for the relationship between content knowledge and ethical arguments on SSIs, additional research is needed that can robustly describe this relationship.

Biodiversity Education: The Importance of Knowledge on Concepts

Marcelo Tadeu Motokane
University of São Paulo - FFCLRP, Ribeirão Preto, Brazil

Brazil is a country with mega biodiversity and higher levels of destruction of forests. The preservation of biodiversity depends on education. The objective of this study is to discuss the importance of knowledge of three hierarchical levels about biodiversity. I analyzed four studies (from my coordination) about biodiversity education. I identified the hierarchical levels present on objectives, results and conclusion in these studies. I concluded that the species’ level and ecosystem’s level are more frequently. The biodiversity is a complex concept and very important to understand the preservation. The students need to understand the hierarchical levels to improve awareness about preservation, conservation and recuperation of biodiversity.

Keywords: biodiversity education, preservation, hierarchical levels of biodiversity

Introduction

Brazil is a mega biodiversity country. This biodiversity is part of our culture and is objective of many researches. Brazil has the largest number of species of plants, amphibian and primates. It is the second country with the highest number of species of mammal and reptiles. About 20% of the planet’s total biodiversity is in Brazil (Brasil, 2016). Nevertheless, there is a paradoxical situation: “while on one side biodiversity science in Brazil is clearly improving in quality and quantity, on the other side environmental degradation is reaching alarmingly high rates throughout the country” (Scarano, 2007, p. 440).

The education, and more specifically the scientific education, is a way to change this reality. However, the biodiversity is a complex concept to science and it is very difficult to teach this concept at school.

The increase of discussions on environmental issues at school creates an environmental awareness that contributes to reinforce the idea that it is necessary to teach to preserve the environment and at the same time to teach to understand scientific knowledge and its relations with society (Motokane et al., 2010). Issues involving biodiversity are the most important, and the students have many doubts about preservation (Motokane et al., 2010).

Science education is important for the general formation of a citizen capable of discussing and making decisions on environmental issues. The list of scientific papers published in Brazil and in the world is immense. Among these authors, Manzanal & Jiménez (1995) focus on the teaching of ecology concepts as a means of educating to preserve. In addition, since the 1970s, Brazilian educational documents have pointed to the need to include environmental issues in school curricula.

When we think about the teaching of science and biology and concepts pertinent to ecology, questions arise such as: What concepts are fundamental to teach? How should the organization of the curriculum be so that we can promote the education of people capable of exercising their citizenship? What are the most appropriate teaching materials?
Motokane (2000) and Grace & Ratcliffe (2002) have found similar results in investigating the concepts that biology and science teachers focus on when teaching ecology. The main areas are: ecosystem, food web, food chain, population and habitats. When teachers teach these concepts, they think that these concepts supported students to discuss biological conservation. According to Grace & Ratcliffe (2002), concepts derived from genetics, which are fundamental to the understanding of conservation problems, genetic concepts are not taught by teachers. The belief that learning basic concepts can lead to the construction of more complex concepts or even more elaborate analyzes of everyday problems is very frequent among teachers.

The learning of contents belong to different areas of the natural sciences is important because the student can understand complex phenomena present in their daily life. Biodiversity is a subject that raises a number of issues, such: What is the value of biodiversity? What happens when a population disappears? How to measure biodiversity? The wide range of meanings given to the term, coupled with the great controversy caused by conservation policies, make biodiversity a profitable topic for teaching science and biology.

According to Grace & Ratcliffe (2002), biodiversity conservation is precondition for sustainable development, and their understanding is essential for the sustainable exploitation of natural resources. The authors claim that learning something about biodiversity is learning about political and economic aspects linked with preservation and conservation.

Weelie & Wals (2002) present three perspectives on education for biodiversity. According to the authors, biodiversity provides an educational perspective that assists the understanding of nature and of itself. From this perspective, the basic idea is to promote situations that seek to make people realize the meaning of biodiversity for their lives. The key words from this perspective are pleasure, curiosity, appreciation, contemplation and care.

The second perspective presented by the authors is that of ecological literacy, which seeks to understand the intricate relationships that exist between different species and ecosystems and discuss the position of man within these ecosystems.

In the third perspective presented by Weelie & Wals (2002) it is the politics of nature. This perspective seeks to increase the equitable distribution of natural resources and promote an understanding of international policy, what treatments are given to resources, and what impacts their exploitation can bring to the environment and to the economy. The key ideas are: sustainable development, respect for pluralism, exploitation, responsibility, democratic decisions.

Weelie & Wals (2002) proposed the term ill-defined to biodiversity. “An ill-defined concept cannot be captured by single or universally applicable definitions, can be interpreted in many ways and is hard to define operational even in a specific application domain” (WEELIE & WALS, 2002, p1143). For them, biodiversity is an ill-defined because is not possible describing or interpreting the concept in a way that fits all contexts.

According to some authors (Lévêque, 1999; Almeida & El-Hani, 2006; Scarano, 2007), in biological science, the concept of biodiversity depends on the methodology of researches and the choice of organization level.
The word "BioDiversity" (BioDiversity) was created by Walter G. Rosen and Edward O. Wilson during the organization of the National Forum on BioDiversity, (September 21-24, 1986) in Washington and hosted by the National Academy of Scientists and the Smithsonian Institution. The summaries of the forum, signed by researchers from different areas, were published in 1988 in the book "BioDiversity".

The Biodiversity became popular in World Conference on Biological Diversity, in Rio de Janeiro (1992), called ECO-92. After this event, Biodiversity acquired many meanings and the school became a place to discuss the preservation, conservation e recuperation of biodiversity.

During the event, was written the document called “Convention on Biological Diversity” (CBD), also known as the "Convention on Biodiversity". In Article 2, entitled "Use of Terms", it defines:

“Biological Diversity means the variability of living organisms of all origins, including, but not limited to, terrestrial, marine and other aquatic ecosystems and the ecological complexes of which they form part; including diversity within species, between species and ecosystems.” (Brazil, 2002.)

Wilson (1997) published, in the introductory chapter of the book "Biodiversity II: understanding and protecting our biological resources", the definition of biodiversity:

“...any variation at all levels of organization, from genes within a single local population or species, to species that make up part of a local community, and finally to the very communities that make up the living part of the multifactorial ecosystems of the world. The key to biodiversity analysis is the precise definition of what level of organization one is interested in...” (Wilson, 1997. p 2)

As has been described in Lévêque (1999), the concept of biodiversity has three different levels (species diversity, genetic diversity and ecosystem diversity), but these levels are linked and they are not independent:

“Biodiversity is not a simple catalog of genes, species or environments. It have been understood as a dynamic and interactive set between different hierarchical levels. According to current theories of evolution, it is because of the existence of genetic diversity in the species that the living beings can adapt to changes of environment. Reciprocally, the genetic diversity evolves because of mutations during the time and in response to changes in the environment. The same occur with plants and animals, which constitute ecosystems and which respond to fluctuations of the environment (...). This dynamic explains that species evolve and the environments change”. (Lévêque, 1999, p. 18-19)

In this study, the question is: what is the importance of knowledge the hierarchical levels of biodiversity? The objective of this study is to discuss the importance of knowledge of three hierarchical levels about biodiversity to improve awareness about preservation, conservation and recuperation of biodiversity. This study is a synthesis of other studies from my research group.
METHOD

In our research group, we elaborate inquiry didactic sequences (Motokane, 2015) that explore the different hierarchical levels of biodiversity. We try to development activities to promote scientific literacy using argumentation. In this study, I analyzed four researches (from my coordination). The researches study the learning and teaching of biodiversity in biology classes.

I choose four studies made by my research group about discourse in science education. All studies were done in public schools. The students were different ages (12 to 16 years old). The schools are from two cities (Ribeirão Preto and Dumont), both in São Paulo State. I identified the hierarchical levels (species, genetic and ecosystem diversity) present on objectives, results and conclusion in these studies. The data of the studies are from interviews, written texts and observation of biology classes or outdoors activities. The studies are from Grandi & Motokane (2014); Grandi et al. (2014), Moraes (2016) and Castro & Motokane (2017).

FINDINGS

Now, I present the results obtained from the analysis of the studies.

1) Castro, R.G., & Motokane, M. T. (2017a). After application of inquiry didactic sequence (IDS), the students produced written texts with three levels. When we analyzed the students’ speeches, we obtained the following results: 93% talk about the species level, 69% talk about the genetic level and 48% talk about the ecosystem level. There is a high classification in texts with species diversity and genetic diversity. These finds are possible because the activities in inquiry didactic sequence promoted the genetic discourse. Genetic level is not so easy to do, because involve many genetic concepts. These concepts are more abstract, but with this inquiry didactic sequence, the students could to talk about them.

2) Moraes, T.A. (2016). The students use different levels (Table 1) when the activities allow the production of texts in different textual genders (Moraes, 2016). The textual genders are texts with socio communicative characteristics as contents, functions properties, style and composition (Marcuschi, 2007). That is important to emphasize that some textual genders do not present levels of biodiversity. This fact is because of “scientific reports” present only descriptions about the experiment. The students do not use this type of textual gender to develop their ideas about biodiversity.

Table 1. Percentage of text that present one or more hierarchical levels of biodiversity by different textual genders. (Moraes, 2016)

<td>0%</td>
</tr>
</tbody>
</table>
3) Grandi, L. A. *et al.* (2014). In this study, we analyzed the conceptions from teachers about biodiversity. We analyzed the discourse during outdoors activities in a forest. The teachers express ideas about species and ecosystem level, but do not mention genetic diversity. Species and ecosystem levels were common because the activity was about the plants composition of the forest.

4) Grandi, L. A. & Motokane, M. T. (2014). A study about the discourse in science classes, the students written about only species diversity. The authors analyzed 21 written texts. In this case, the texts are produced after outdoor activities. They written about the activities and they described what they did. When they mentioned something about biodiversity, the specie level is mentioned, but others levels no. This study is complementary of the last one.

In Table 2, I present the main results concerning the different hierarchical levels present in different studies. It is important emphasize that there are different quantities in each study. In Table 3, I present what levels are present in each study analyzed.

**DISCUSSION AND CONCLUSIONS**

The concept of biodiversity is very complex in biological science. The teachers have teach this important concept in biology and science classes. This is fundamental because the comprehension of this concept supports why the preservation, conservation and recuperation of biodiversity is important.

At basic education, the species diversity is the most common hierarchical level. Most activities have the objective to observe or to compare different individuals. The variability of external or internal characteristics are the focus of activities. The main skill for these activities is descriptions. The students are stimulated to do descriptions, but they are not stimulated to do
argumentative texts or to write about evolutionary aspects. Although the activities promote the argumentation, in classes or outdoor activities, these opportunities are not explored.

The ecosystem diversity level is the second common level. The activities present in this inquiry didactic sequences show images or description about ecosystems, biomes and landscapes. The activities can be descriptions about abiotic factors or comparisons between places. However, this level is presented without relations with other levels.

These levels (species diversity and ecosystem diversity) are more factual or concrete and these characteristics contribute to learn the levels. However, others skills like an argumentative text are not produced.

The genetic diversity is less frequently in biology or science classes. Although the didactic materials allow the comprehension about the three levels. This hierarchical level is more abstract and it uses concepts and contents from genetic, biochemistry and molecular biology. 

In Brazilian studies about difficult to understand genetics concepts, the authors (Dentillo, 2009; Pereira, Campos & Bonetti, 2010; Rosa & Silva, 2010; Klatau, Pedreira & Oliveira, 2014) indicated the lack of contextualization with the student’s quotidian, a lot of contents, the misunderstanding of terms and concepts about genetics and the lack of relation between contents of genetics and cell division.

The three levels are possible when the didactic material allow the production of different textual genders.

I concluded that the knowledge about hierarchical level of biodiversity is important to students. It is a very important when students recognize that biodiversity is a complex concept and the relation between hierarchical levels. This recognition are fundamental to students understand the importance of preservation, conservation and recuperation of Brazilian biodiversity.

ACKNOWLEDGEMENT

This study was funded by Pró-Reitoria de Pós-Graduação from University of São Paulo, FAPESP (Fundação de Amparo à Pesquisa do Estado de São Paulo). I thank Programa de Pós Graduação em Biologia Comparada da FFCLRP/USP and Programa Interunidades de Pós Graduação em Ensino de Ciências. Finally, I thank students and teachers from “Escola Municipal de Ensino Fundamental Arlinda Rosa Negri” to work together. The students of this school are the reason for this research!

ASESSMENT OF SCIENTIFIC LITERACY THROUGH SOCIOSCIENTIFIC ISUES WITH SECONDARY SCHOOL SCIENCE STUDENTS: A PILOT STUDY

Ruth Chadwick, Eilish McLoughlin and Odilla E. Finlayson
CASTeL, Dublin City University, Dublin, Ireland

Inquiry in the context of socioscientific issues (SSI) is said to develop the skills and knowledge of scientific literacy. SSI are contemporary and relevant scientific topics with moral or economic implications (Sadler 2009). In the Scottish Curriculum for Excellence students carry out inquiry in the context of SSI, the National 5 Assignment, as part of their senior phase science education (SQA 2016). This research is a pilot study that explores the student and teacher experience of the National 5 Assignment. Six biology teachers participated in the case study and provided documentation relating to 150 of their students. The methods of data collection and analysis were qualitative and included teacher questionnaires, teacher interviews and secondary document analysis relating to the teacher and the student experience. The findings indicate that the student experience is described in similar terms between the students and teachers. The focus was mainly on the skills and knowledge developed and assessed, and the process of inquiry, with less focus on the Assignment as an assessment. The teachers also discussed their teaching approach to the Assignment in terms of balancing facilitating and direct teaching. The findings from this study will be used to inform the methodological design of a wider study. This wider study will include teachers and students of biology, chemistry and physics and will compare their experience of the Assignment in the different subjects.

Keywords: socioscientific issues, scientific literacy, science education

INTRODUCTION

In the Scottish Curriculum for Excellence (CfE) students carry out an inquiry in the context of socioscientific issues (SSI) as part of their senior phase science education (SQA 2016). SSI are social issues with conceptual and procedural connections to science that can be used as the contexts for learning (Sadler 2009). SSI centre around a range of scientific, social or moral viewpoints, which may conflict with the students’ own views. This makes them personally relevant to the students (Levinson 2006, Zeidler et. al. 2009). Scientific literacy can be described in terms of the skills and knowledge of science and student engagement in inquiry exploring SSI contexts is said to these skills and knowledge (OECD 2013, Sadler 2009, Zeidler & Nichols 2009).

CfE is a curriculum for learners aged 3-18 which aims to develop “scientifically literate citizens with a lifelong interest in the sciences” (Education Scotland 2010 p253) and describes scientific literacy as:

- Developing informed social, moral and ethical views of scientific, economic and environmental issues
- Developing self-awareness through reflecting on the impact, significance and cultural importance of science and its applications to society

Keywords: socioscientific issues, scientific literacy, science education
Being able to **read and understand** essential points from sources of information including **media reports**

- **Discussing** and **debating** scientific ideas and issues
- **Reflecting critically** on information included or omitted from sources/reports including consideration of limitations of data (Education Scotland 2010)

Assessment in CfE aims to support learning, help plan next steps, inform learners and their parents, summarise achievements, monitor the education system and inform future developments (The Scottish Government 2011). Assessment in CfE is not limited to traditional, written exams. For example, the National 5 Assignment is a novel form of assessment, in which students carry out an inquiry in the context of SSI. The National 5 Assignment aims to assess a range of skills and knowledge (Table 1). Students apply their knowledge of biology, chemistry or physics to new situations and interpret information. They select, process and present information and data in a variety of forms, communicate their findings and draw valid conclusions with explanations supported by evidence (SQA 2016 p2).

(SQA 2016 pp8-19)

The number of marks available for each skill or knowledge assessed gives an indication of its emphasis or importance in the assessment. Of the 20 marks available, 14 are for demonstrating skills and six are for knowledge and understanding, although the SQA does not make it clear which of the above assessment criteria are skills and which are knowledge (SQA 2016).

In terms of demonstration of skills, students must first propose an aim or question for investigation (1 mark) and then carry out research, which includes selecting relevant sources (2 marks) and selecting relevant information from sources (2 marks). Students may also gather data through experimental investigation (no marks allocated). Once the students have gathered the data and information, high emphasis is placed on processing and presenting the data, with six marks awarded for demonstration of this skill. This skill is divided into two separate but
related aspects: presenting and processing. Presenting data/information is described by SQA (2016 p13) as presenting in appropriate formats such as summary, graph, table, chart or diagrams. Processing data/information is described by the SQA (2016 p13) as performing calculations, plotting graphs from tables, populating tables from other sources, summarising referenced text. Three marks are awarded for structuring the report appropriately. This includes using heading and sub-headings, referencing in the appropriate format and writing a clear and concise report (SQA 2016).

Students are required to use their knowledge of science to describe an application of science and its effect on society or the environment (2 marks) and draw a valid conclusion (1 mark). The SQA (2016) also describes how students are expected to apply knowledge and understanding of science to explain the underlying biology (3 marks). This means using terms and ideas at a depth appropriate to the student’s level of cognitive development and excludes any explanations or descriptions that are copied verbatim. The application and its effect on society or the environment describe the SSI context within which the student inquiry is situated.

An application is a deliberate human act, used to effect change in the world or environment and students are required to explain a clear relationship between the application and its effect on the environment or society (SQA 2016). The SQA give exemplar topics such as “the decline of the honey bees” which allows students to explore the positive and negative implications of the use of pesticides (SQA 2014). Another SSI context that is given as an exemplar by the SQA is “genetically modified crops” which again discusses multiple points of view and gives “pros” and “cons” in terms of implications for society (SQA 2014 pp45-50 course unit support notes biology). The physics exemplar topic given by the SQA, car safety contains a range of material relating to various advances in car safety and the associated benefits to society (SQA 2013).

In terms of recommended teaching approach to the Assignment, the SQA describes specified conditions for facilitating and supervising the inquiry. The student work is then externally marked by the SQA (SQA 2016). The teaching approach is described by the SQA as consisting of two stages: a research stage and a communication stage. There is also evidence in the SQA guidelines of an initial instructional stage prior to commencement of the assessment itself. The SQA states that the requirements of the assignment should be made clear to candidates at the outset and describe the importance of sharing SQA instructions and marking guidance with candidates (SQA 2016). The Assignment is recommended to take no more than eight hours, which is around two to three weeks of lessons (SQA 2016).

The SQA describes the research stage as students gathering information/data from a variety of sources including internet, books, newspapers, journals under the “supervision and control” of their teacher (SQA 2016). At this stage the students may work in groups or individually (SQA 2016). The SQA describes the role of the teacher during the research stage and uses the term ‘reasonable assistance’ to clarify to teachers how to balance support with giving too much assistance. During the research stage teachers may direct candidates to SQA materials, clarify instructions and requirements, and advise candidates on the choice of the topic or issue (SQA 2016). Teachers may also provide students with resource packs for their research. If students are to carry out an experiment during the research stage, a guided approach should be adopted with the instructions on the method provided (SQA 2016).
During the next stage, the communications stage, students produce a report of their findings under a “high degree of supervision” (SQA 2016 p6). This means that students should be in direct site of their teacher or invigilator and may not discuss their work (SQA 2016). This may be done over a number of lessons but no time limits or recommendations are stated by the SQA for this stage. Students have access to the notes and other material they collected during the research stage, for example: graphs, numerical or experimental data; data and information from the internet; published articles or extracts; notes taken from a visit or talk; notes taken from a written or audio-visual source (SQA 2016 p4-5).

**RESEARCH QUESTIONS AND METHODOLOGY**

This research presents a case study of the National 5 biology Assignment in one Scottish school and aims to investigate: *What are the student and teacher experiences of carrying out the CfE National 5 Assignment?*

Six biology teachers participated in the study and provided secondary documentation relating to 150 students, aged 15-16. The participating school is a large, mixed gender, non-denominational school, which has been rated “excellent” in all aspects by HMIE.

The following methods of data collection were used:

1. Observation of lessons;
2. Teacher post-lesson questionnaire and individual interviews with 6 participating teachers;
3. Document analysis relating to the teacher experience (e.g. lesson plans, teacher notes, quality assurance documentation).
4. Document analysis relating to the student experience (Student post-lesson evaluations with 150 students)

The teacher questionnaire consisted of open-ended questions designed to gather information regarding the teacher experience (Figure 1).

Thematic analysis of the teacher questionnaire and student lesson evaluations was carried out using the software Nvivo. The method used was based on Braun & Clarke (2006) and consisted of 6 steps:

1. Familiarisation with the data
2. Generate initial codes
3. Search for themes
4. Review themes
5. Define and name themes
6. Produce the report
When answering the questions, please focus on the student experience and the skills and knowledge you wish to develop and assess in your students.

You may attach any additional documentation you wish e.g. extracts from planners, examples of student work.

1. Provide a brief description of lesson activities, learning intentions and success criteria. Please also include an extract from your planner or other material as relevant.
2. What do you think the students learnt from this lesson/series of lessons for this stage of the assignment? Please give examples and include any evidence as relevant.
3. What about this lesson/series of lessons was successful in terms of student experience? Please give examples and include any evidence as relevant.
4. What about this lesson/series of lessons was particularly challenging for the students? Please give examples and include any evidence as relevant.
5. If you were to repeat this lesson, what changes, if any, would you make? You may wish to think about timing/pace, skills development, ethos, student interactions, feedback, questioning, materials/equipment etc.

Figure 1. Teacher questionnaire part 1

An inductive, bottom-up approach was used. A consistent approach was reached by producing a detailed codebook that could be referred to throughout the coding process, ensuring that each reference to certain topics or key words were consistently coded into the same working theme. Extracts could be coded into as many themes as were appropriate. If codes appeared more frequently, i.e. had a higher number of coded references they were deemed as more important.

FINDINGS

Thematic analysis of the teacher questionnaires and student lesson evaluations identified a number of themes relating to the student and teacher experience of carrying out the National 5 Assignment. Tables 2 and 3 show the overall themes/ sub-themes and relevant quotes showing how students and teachers discussed their experience in relation to that theme.

The student experience, as identified from the student lesson evaluations, 5 main themes were identified: personal experience; ways of working and learning; recall and apply scientific knowledge; working with sources, information and data; and Assignment as an assessment.

The students focused mainly on the skills and knowledge developed and assessed in the Assignment and the process of carrying out the inquiry. They discussed their personal experience of the Assignment, including their feelings towards the assessment. They were slightly more negative than positive. Students also discussed the ways they worked and learnt, mainly focussing on planning and carrying out research. There was less focus on carrying out experimental investigations. Students discussed carrying out research including identifying and selecting sources of information and selecting information from the chosen sources. Presentation of data and evidence gathered through research was a relatively large focus of the students. The students discussed recall and application of scientific knowledge and around half the time they linked this to the implications for society and the environment, the SSI context. The students focused little on the Assignment as an assessment.
The teacher experience consisted of three distinct themes: student experience (as viewed by the teacher), teaching approach and Assignment as an assessment (Table 3).

</table>
The teachers talked mainly about the student experience and discussed it in very similar terms to the students themselves; the same sub-themes were identified between students and teachers. When talking about their own experience, teachers discussed their pedagogical approach to the Assignment, in which they discussed using a mixture of facilitating and direct teaching and how time pressures and time management had an effect on their ability to carry out the Assignment. Teachers talked little about the National 5 Assignment as an assessment.

Figure 4 shows how the student and teacher experience overlap and diverge.

Figure 4. Student and teacher experience of the National 5 Biology Assignment

Students and teachers talked about the students’ experience in very similar terms. Regarding the students’ personal experience, the students were more negative than their teachers. Students commented on the negative emotions, e.g. “I didn’t like…” while their teachers focused on the positives, e.g. “students were self-motivated…confident”. In terms of the process of the inquiry, the students and teachers focused on highly on carrying out research and little on experimental investigations. The students focused on planning their inquiry while their teachers did not place importance on this. When describing working with sources, information and data, both the students and teachers focused highly on presenting evidence, including data and other information. They focused less so on the research process of selecting sources of data and evidence and choosing information from sources. In relation to the knowledge developed and assessed there was clear differences in how the students and their teacher discussed this. While students focused on recall and application of scientific knowledge, both with and out with the SSI context, the teachers mainly focused on the terminology of the assessment including scientific terms and Assignment specific terms. Around half the time the students discussed their knowledge in relation to the SSI context but the teachers focused little on this. The students placed more importance on the SSI context than their teachers. This may indicate that the context was personally relevant to them.
The students and teachers focused mainly on the Assignment as an assessment of skills and knowledge and little on the Assignment as an assessment. This may indicate that they placed more importance on the process of the inquiry rather than the end result or grade.

CONCLUSIONS AND IMPLICATIONS

Scientific literacy is described in terms of skills and knowledge of science and there is evidence from the student experience as described in this study, which mainly focuses on these skills and knowledge, that scientific literacy is developed through the National 5 Assignment (OECD 2013). The student experience also focuses on the process of carrying out the inquiry, the method by which the skills and knowledge of scientific literacy are developed. There was a high level of agreement between the students and teachers when talking about the student experience of the National 5 Assignment. While this could indicate that the teacher understands the student experience, it is more likely that the teacher dictated the student experience with their teaching approach. The teachers talked about their approach to teaching the Assignment in terms of a balance of facilitating and direct teaching.

This research is a pilot study contributing information to a wider case study. The findings from this pilot study will be used to inform the methodological design of a wider study. This wider study will include teachers and students of biology, chemistry and physics and will compare their experience of the Assignment in the different subjects.

ACKNOWLEDGEMENT

Many thanks to the cooperating teachers for their time and help with organisation of the project in school.

A COOPERATIVE LEARNING STRATEGY USING A
SOCIALLY ACUTE QUESTION APPROACH: CHANGES IN
STUDENTS’ ATTITUDES

Michel Vidal
Montpellier SupAgro, Montpellier, France

The pedagogical strategies based on a Socially Acute Questions (SAQ) approach are well-documented as fostering learners’ agency. However, if the emotional proximity of the SAQ is great, the learning can be weak (Simonneaux & Simonneaux, 2009). We hypothesise that the integration of a cooperative learning strategy using a very-acute SAQ enables socio-critical reasoning (Sadler, Barab & Scott, 2006). We interviewed four students from an agricultural vocational school before and after their participation in a cooperative learning strategy using the wolf’s re-appearance in the French Alps. We analysed students’ attitudes by exploring the knowledge, rationale and axiological modalisations in their discourses. This learning strategy enabled ‘cooling down’ of the SAQ and students felt their ideas were listened to and recognised. However, following the teaching of the strategy, it was found that the students only implemented some socio-critical reasoning because of confirmation bias as no expressed scepticism about the knowledge presented during the strategy was identified.

Keywords: cooperative learning, socially acute question, attitude

INTRODUCTION

Social conflicts managed by a critical pedagogy of discussion can enable self-affirmation, social integration and a recognition of the other (Lenoir, 2012). More particularly, a socially acute questions (SAQ) approach in education can foster learners’ agency, empowerment, and the modification of their behavior, especially through debates. The educational challenge of the SAQ approach is to enable students to develop an informed opinion about these issues, to be able to make choices about prevention, action, use and to be able to engage in debate them. However, when the emotional proximity of the SAQ is great, the teachers take the risk of introducing an issue where opinions are heated, making discussions difficult to control and so the learning can be weak (Simonneaux & Simonneaux, 2009). In such a context, we hypothesise that the pedagogical adaptation of a socially-very-acute question to include a cooperative learning strategy could foster an attitude enabling socio-scientific reasoning (Sadler, Barab & Scott, 2006) to occur. Socio-scientific reasoning is based on the recognition of the inherent complexity of the issue, an examination of the issue from multiple perspectives, the appreciation of on-going inquiries into the issue, the expression of skepticism about knowledge related to the issue, recognising potential bias, the consideration of the knowledge provided by different producers, and the exploration of governance modalities to manage the issue (Sadler, Barab & Scott, op.cit.; Morin & al., 2014). We consider attitude as based on four dimensions: a cognitive one through knowledge and beliefs related to the object; a conative one through the projections on the future; an affective dimension (Hovland & Rosenberg, 1960) to which we add an axiological one.

The pedagogical approach used in this research is based on an adaptation of the Cooperative Learning in Multicultural groups strategy (CLIM) (Cohen & Lotan, 1997) in the context of an
SAQ. CLIM principles include intellectually challenging and open-ended tasks around a central concept; problem solving strategies; assigning specific roles to each students; and providing opportunities for equal participation for all pupils. It has been adapted to deal about the wolf's re-appearance in the Alps with 16-17 years old students from two classes in an agricultural vocational school, one related to livestock production, the other to agri-environmental issues. As an SAQ, the wolf issue arouses debate about the production of scientific reference knowledge, has high stakes and is highly publicised. While teachers and students are familiar with this SAQ, teachers feel poorly prepared to address it (Lagardez & Simonneaux, 2006). This issue is particularly acute in the territory of the Alps and, according to the director and the teachers of the school, is a huge source of conflict between the students in the two classes.

METHOD

The pedagogical strategy was applied by one teacher over half a day and following these six steps: (1) Students in the two classes with conflicting opinions were put in groups of four people. In each group, the students had to take on the roles of «facilitator» leading the group, «time manager», «hardware manager » and «presenter» of the final results; (2) Each student individually completed a photo-montage expressing their own opinion about the issue. Then the participants discussed points of agreement and disagreement within their group without any debate in a framework of respect and non-judgment; (3) Four files were shared between the students in each group. Each file described one of the four controversial nodes of the issue (does the wolf increase or decrease biodiversity? Does the wolf have a favorable or unfavorable economic impact on the territory? Are wolf protection and regulatory techniques effective or not? Does the wolf attack people or not?) presenting two opposite researchers’ points of view. Each student had to read their file, identify the most important points with the students having the same file, and finally to present them within the group; (4) Each group received the same information describing the issue of the wolf in Scandinavian countries with the task of proposing possible solutions. Presenting the issue of the wolf in another context can enable the learner to remove the automatism of perception established by habit, thus allowing a distancing inspired by the principle of “estrangement” (Ginzburg, 2013) and to encourage reflexivity and a possible change of representations; (5) Each group made a presentation about their conclusions to their peers; and (6) Finally, all the students debated the issue of the wolf’s re-appearance in the Alps following 3 steps: firstly, each student could express their position with the other students listening. Secondly, after highlighting the points of convergence and divergence, the teacher, facilitator of the debate, facilitated discussion about the points of divergence. The students had the opportunity to express their viewpoints without judgment from their peers. Finally, the teacher asked the students to imagine ways of resolving the wolf issue in terms of each of the differing viewpoints.

Four students, two from Class 1 (N. and S.), and two from Class 2 (J. and F.) were chosen to be interviewed individually for one hour the day before and then again on the day after the CLIM strategy was used. The first semi-structured interview aimed to discover each student’s attitude towards the SAQ, the events and information which formed the basis and justification for their attitude, interactions with their peers about the SAQ, their interest in and involvement
with the pedagogical strategy, the support and the difficulties they met, their strategy used to communicate with their peers, and their own assessment about the efficacy of CLIM approach. During the second interview, the student could suggest any modifications they would have liked to have carried out on their photo-montage according to the information they experienced during the pedagogical strategy. The interviews were recorded and transcribed. Data were then analyzed to explore the dimensions of students’ attitudes before and after the CLIM approach as follows.

The cognitive dimension of the students’ attitudes was analyzed through an interpretation of two cartographies of controversy, based on the Actor-Network Theory (Akrich, Callon, & Latour, 2006) that visually expresses the actants and their interactions (France, Birdsall & Simonneaux, 2017) to unravel the diversity of participants taking part. We have inventoried in the students’ discourse the human and non-human actants mentioned in the issue, and their interactions through the action verbs they used to connect the actants. We have compared the discourses in the two cartographies.

The conative dimension of their attitude has been analysed through Mermet’s (1992) rationale that consists of four criteria. The first criterion « richness » characterizes the elements of an eco-socio-system which are important to preserve or to implement for the person. The second criterion « security » relates to the threats which can affect the richness. The third criterion of « adaptability » qualifies the conditions, actions, and concessions to be considered by the person. The fourth criterion « coherence » qualifies contradictions in the discourse. To highlight the criteria, we have made a semantic analysis of the arguments in the discourse according to the theory of Semantic Blocks (Carel, 1994). This theory considers that every utterance is argumentation, which it makes it possible to describe argumentative content conveyed by statements through normative or transgressive sequences, the former instantiating a link of cause and effect, the latter establishing an opposition. An example of Normative linking was this statement, "I protect sheep breeding against wolf because it’s an important tradition of this territory" will result in: sheep breeding as an important territorial tradition THUS protecting the sheep against the wolf. The word, THUS marks the causal link. "I protect sheep breeding with dogs YET wolf’s attacks don't decrease" will result in transgressive sequencing: protecting sheep breeding with dogs YET NEG decrease the wolf's attack. In this example the word YET marks the link of opposition and NEG is the negative effect of the protection. In these two examples, we can conclude that sheep breeding as a territorial tradition, is an example of the criterion of « richness », the attack of the wolf as a threat falls under the criterion « security », and the protection of the sheep using dogs under the criterion « adaptability ». In this way, the rationale of each student has been compared in the two discourses.

The affective and axiological dimensions in students’ discourses have been analyzed through the following axiological modalisations (Galatanu, 2003): moral-ethical judgments with the two polarities good-bad; aesthetic judgments with the two polarities beautiful-ugly; pragmatic judgments with the two polarities useful-useless; intellectual judgments with the two polarities interesting-uninteresting; and affective judgements with the two polarities happy-sad. The
axiological modalisations have been inventoried and counted. The percentages of the presence of each axiological modalization have also been compared in the two discourses.

RESULTS

The data obtained from the four interviewed students is now presented successively.

Comparison of N.’s attitude of N. in the pre- and post-discourses

The interpreted maps of controversies (Figure 1) of N. remained the same over the two discourses.

![Interpreted map of controversy according to N’s discourses](image)

11 actants and 13 action and position verbs were mentioned by N. For him, the wolf was reintroduced by ecologists but this controversial opinion has been proven to be false. N. believes that the wolf attacks sheep and breeders, but also game. These attacks, appraised by federal guards, cost the French state, but the breeders don't want any compensation. Protection dogs prevent the attacks and can also defend against tourists. The Anatolian shepherd is a better protection dog, as it respects the tourists.

As shown in Table 1, N. is scared of the wolves being released from parks because he wishes to protect pastoralism and hunting. N. thinks it is not to enough to have the wolves shot down. Furthermore, he believes that breeders are going bankrupt as they receive insufficient compensation.

Finally, there is a reduction of other game animals, and also a picture of sadist. During the first interview, he proposed regulating the number of wolves, having the right to shoot them, and to continue to use protection dogs.

During the second interview, the « adaptability » criterion changed. He wanted to gain a better understanding of the pro-wolves position, to find a solution that suits everyone, but also, illogically, to convince them to reduce the number of wolves.

The axiological modalisations in the two discourses are presented in Table 2.
Table 1. N’s rationale according to Mermet’s criteria

<td>-</td>
<td>+</td>
</tr>
<tr>
<td>Post (%)</td>
<td>7</td>
<td>8</td>
<td>0</td>
<td>12</td>
<td>0</td>
<td>22</td>
</tr>
</tbody>
</table>

While the first interview was dominated by 38% of «negative» affective modalisations, with 33% of moral-ethical ones expressing what is bad, and 15% of pragmatic ones expressing the usefulness, the second interview is dominated by 30% of positive affective modalisations, 18% of negative ones, and 22% of pragmatic expressing the utility. We can also observe 12% of intellectual modalisations expressing interest. While 87% of modalisations are in the negative polarity in the first discourse, 73% are positive in the second one.

The pedagogical strategy appears to have reduced the negative affectivity related to the issue, to have implemented a focus on the pragmatic and to have enabled a wish for the negotiation of a common solution for the different actors.

Comparison of S.’s attitude in the pre- and post-discourses

The interpreted maps of controversies (Figure 2) of S. changed over the two discourses. S. mentions in the first interview an anti-wolf system, without giving any details, which can stop and kill the wolf and save domestic animals. While farmers fight against the wolf, townsfolk, considered as pro-wolves protect it. S. adds in the second interview the actor wildlife, which can be affected by the wolves. He mentions six actants, and uses seven position and action verbs.

As shown in Table 3, in the first interview, breeding is a richness but also the wolf considered as a part of the biodiversity.

</table>

The quick development (re-introduction of the wolf and its protected status) is a threat difficult to solve because of the number of actors involved in the issue and the extremists. S. suggests that all the actors negotiate a common solution, but inconsistently, he considers citizens as Nazis. During the second interview, biodiversity is regarded as a richness which can be affected by the wolf. S. believes that the wolf costs a lot of money, and economically endangers the breeders. He suggests setting up technical monitoring to track wolf numbers so that shooting quotas can be adjusted accordingly.

The axiological modalisations in the two discourses are presented in Table 4.
Table 4. Polarity of the axiological modalisations in S’s discourses (%)

In the first interview, S.’s discourse was dominated by 26% of moral-ethical modalisations expressing what is good and 13% expressing what is bad, 15% of pragmatic expressing what is useless, and 13% of intellectual modalisations expressing what is interesting. In the second discourse, S.’s discourse was dominated by the following modalisations: pragmatic expressing what is useful (30 %), positive affective (26%), and negative affective (21%). While in the first discourse, 87% of modalisations are in the negative polarity, 72% are in positive in the second one.

S. partially changed his attitude over the two discourses. He still considered it necessary to protect the breeding and the wolf. Nevertheless, in the first discourse, he considered the wolf as a part of the biodiversity and in the second as also affecting the biodiversity. The pedagogical strategy used appears to have been able to help him more affectively express his attitudes. His attitudes that were a « negative one » seemed to be linked to an awareness of the threat to the breeding, as he said, « I was shocked by the damage that the wolf can do on farms ».

Comparison of J.’s attitude in the pre- and post-discourses

The interpreted maps of controversies (Figure 3) of J. are changed in the two discourses.

Figure 3. Interpreted map of controversy according to J’s discourses (in bold the change observed in the second one)

As shown in Figure 3 and in more detail in Table 5, the wolf, the lamb but also a secure campaign are the components of J.’s « richness ». According to her, hunters kill too many game animals. She explains that the wolf attacks hens, horses and sheep, which makes the breeders angry, and they then kill wolves. Nevertheless, the wolf can attack humans. She suggests that farmers regulate the population of wolves. However, she inconsistently considers that the wolf scares humans, and can attack them.

During the second interview, J. adds that wolf can regulate game and protect crops. She also considers that killing wolves increases the population of wolves. This information comes directly from research outlined in one of the files presented during CLIM strategy where the
wolf was presented as a useful species, regulating biodiversity. The wolf attacks livestock because there aren’t enough uninhabited areas where to live. J. proposes a reduction in hunting and creating enclosures for the wolf.

The axiological modalisations in the two discourses are presented in Table 6.

The axiological modalisations in her two discourses changed. The first discourse was dominated by the following modalisations: moral-ethical expressing what is bad (32%), negative affective (26%) and positive affective (22%). The second discourse was dominated by moral-ethical modalisations expressing what is good and bad (respectively 22 and 22%), pragmatic expressing what is useful (22 %). While in the first discourse, 63% of modalisations are in the negative polarity, in the second one 72% are in the positive one.

If J. considered in the first interview that the wolf can be a danger for the human, she nevertheless maintained a protective attitude towards the wolf and added argumentation in that sense in the second interview. The pedagogical strategy appears to have reduced a negative affectivity, to have implemented a focus on pragmatic useful account.

**Comparison of F.’s attitude in the pre- and post-discourses**

According to F. (see Figure 4), breeders who manage sheep and cows are affected by the wolf's attack. They are not compensated for all the damage and fights against politicians and economists, who are also affected by the issue of the wolf. Researchers control the wolf population. Nevertheless, the wolf regulates flora. In the second interview, F. adds that it also regulates wildlife and allowing less damaged crops. For F., it is an interesting argument because his father is crop farmer. But he also changes his mind, stating that wolf can affect biodiversity.

As shown in Table 7, the wolf helps to preserve biodiversity of flora as F.’s “richness”.
Figure 4. Interpreted map of controversies according to F’s discourses (in bold the change observed in the second discourse)

- poaching of wolves  
- cost of the measures to solve the issue | - a number of collars to regulate the number of wolves by hunters and to be adapted by area  
- monitoring and control of collar management | |

In the second interview this idea is extended as the wolf regulates wildlife, but also breeding as an economic pillar. He fears the prejudices about wolf, but also the impact of the wolf’s attacks on breeding practices, and of the financial situation of breeders. He blames a schizophrenic state policy protecting and fighting against the wolf. He suggests preserving and controlling the wolf. In the post-interview, he fears wolf poaching but also the degradation of biodiversity. He suggests a pragmatic approach to regulate the number of wolves through having a defined number of collars each year.

The axiological modalisations in the two discourses are presented in Table 8.

F.’s first discourse is dominated by the following modalisations: moral-ethical expressing what is bad (29%) and intellectual expressing what is interesting (24%). His second discourse is dominated by the pragmatic expressing what is useful (42%), and moral-ethical expressing what is bad (30%).

The pedagogical strategy appears to have made F.’s arguments more complex, as he considered the wolf both positively and negatively affecting biodiversity and farming. It also seemed to result in a focus on a pragmatic useful account.

**DISCUSSION**

The use of the CLIM strategy appears to have created changes in attitudes that we now consider in the light of the development of socio-scientific reasoning.

We observe that the pedagogical strategy increased the positive potential of the axiological modalisations of the issue even if the students did not change their opinion about the wolf and about the other actants. We hypothesise that the movement between the two axiological polarities enriches socio-scientific reasoning, allowing students to reflect on the issue between the questions what is good, what is bad, what is interesting and uninteresting, what is useful and useless to do, what makes me annoyed or happy.

More particularly, CLIM strategy seemed to cool down the socially acute question for N. and J.. N. said, “I was afraid about nervousness in the class, but everybody spoke calmly” and it provided the possibility of self-affirmation for J. who said, “we had the possibility to say that you like the wolf”. There was also the feeling of being recognized by others as J. said, “I'm glad to have been heard”. The strategy gave him the opportunity to express his opinion in a non-judgmental frame and seems to have had a cathartic effect and freed up an elaboration capacity (De Mijolla & De Mijolla, 1996). For example, this is illustrated by N., who demonstrated curiosity about the opinion of others, and about the wolf itself. He expressed that the issue is subject to on-going inquiry about wolf behaviour, and agreed to consider knowledge from other actors (as the ecologists) to find a common solution even if he stays ambivalent about convincing others with differing attitudes. Listening to others with empathy promotes openness to the other and the world (Rogers, 2005).

To listen to others can also stimulate an emotional sharing, an affective empathy (Decety, 2010), which can warm up the SAQ, which was illustrated by S.’s surprise and anger when learning about the damage created by the wolf in his colleagues’ breeding. In this way, to enable a time of confrontation is to also enable a time to make more cohesive groups of opinions. Our results can't show clearly if such emotion can affect the socio-scientific reasoning or on the contrary, stimulate interest in the SAQ, to arouse concern about the issue (Pettit, 2004), or both of them. We can hypothesise that it anchors the link with one actant (in that case the breeders) but risks the creation of disinterest or emotional distance in the perspectives of other actants, and at the same time increases concern for the issue.

The four students’ understanding of the complexity of the issue was enriched differently after the implementation of the CLIM strategy. N. didn’t appear to develop any knowledge as he
said, “I knew already well the situation”. While he mentioned the largest number of actants and interactions, compared with the three other students, he also rejected the information which contradicted his beliefs. This backfire effect (Nyhan & Reifler) maintains the persistence of the misconception. More particularly, the belief that wolf is reintroduced persists in N.’s attitude, despite evidence showing it is wrong. However the CLIM strategy should take discrediting beliefs into consideration. We suggest that introducing information not only about the current controversies, but also about relevant past controversies even if they have arrived at a clear and socially accepted answer, could assist in this case.

S. developed new knowledge during the pedagogical strategy which seemed to confirm his initial attitude about the danger of the wolf, not only for humans but also for biodiversity. J., having an attitude in favor of the protection of the wolf, added knowledge confirming the utility of the wolf for game regulation and the protection of crops. However, the file introduced during the CLIM approach about biodiversity mentioned a controversy about this issue. Two students processed this information but did not reject their beliefs. This confirmation bias usually appears when considering affective questions (Wason, 1960). If it can be considered as an obstacle to implementing a more relativistic attitude about the issue, it could also allow a student to enrich their argumentation. To implement a more relativistic attitude, we suggest discussing this bias that privileges information that confirms ideas and beliefs prior to implementing the strategy.

These four students appear to have implemented reasoning about pragmatic considerations according to what could be useful to resolve the issue. The CLIM strategy would need to incorporate an affective and moral-ethical position about wolf issue to assist further with problem solving. More particularly one of the student (N) changed his opinion about the way of governance to solve the problem. From a more regulatory approach, he implemented a more participative one.

The main findings of implementing the CLIM strategy were that it cooled down the SAQ; enriched argumentation when considering students’ initial opinions; implemented a focus to solve the issue and it supported socio-scientific reasoning. However, there did not seem to be any development of a more skeptical attitude about knowledge/research presented. When using the CLIM strategy in future, we might have to consider this strategy as a first step. We could also take into account the students’ wish to have more information about the wolf and about the rationale of actors as a lever.

Further research could be carried out to understand which steps of the CLIM approach enabled these changes and how.

MARINE DEFICIT 'DISORDER': MARINE LITERACY IN PRIMARY STUDENT TEACHERS

Cushla Dromgool-Regan¹, Noirín Burke², and Thomas McCloughlin³
Marine Institute¹, Galway Atlanticaquaria², Dublin City University³, Ireland

Marine literacy is critical for teachers to allow children to consider the marine as a source of employment in a wide range of industries which otherwise they remain unaware of. Marine literacy is something that comes about through interpersonal exchange of experience, which in the past relied on grand-/parent-to-child transmission. However, nowadays, marine literacy must now be 'taught' or learned in 'new ways'. It is hypothesised that children lack basic content knowledge as well as an integrated higher level understanding of humanity's relationship with the marine. In order to provide a baseline of student teachers' marine literacy, as future educators of future citizens, and to test the efficacy of the Ocean Literacy Questionnaire OLQ, developed by the Marine Institute, a sample of n=35, mean age= 19.8yrs, student teachers at Dublin City University completed the OLQ prior and following an intervention on marine literacy. The OLQ is a six-section multipart-question questionnaire which elicits perceptions of how ocean literacy fits into the primary school curriculum, perceived importance of content areas, and perceived barriers to implementing marine education in primary school. The resulting data was analysed using standard statistical methods for non-parametric data which established a positive differential across the implementation of the intervention. The intervention involved a pilot marine module 'Environmental Systems: The Marine Environment' being delivered by Dublin City University and the Marine Institute's Explorers Education Programme™. It is expected that as a result, the intervention will be broadened to include further marine literacy training of student teachers.

Keywords: Marine deficit disorder, marine literacy, initial teacher education

INTRODUCTION

In Ireland, Marine literacy, as a subset of scientific literacy, is critical for teachers to allow children to consider the marine as a source of employment in a wide range of industries; as the fundamental driver of our climate; of the source of food and materials; of transportation which otherwise they remain unaware of, and which have taken on renewed focus in light of the current BREXIT negotiations as of 2018. Therefore we consider marine literacy to go beyond 'knowledge': it is something that comes about through interpersonal exchange of experience, which in the past relied on person-to-person transmission. As this transmission has been interrupted, marine literacy must now be 'taught' or learned in new ways. To that end we hypothesise that young people lack basic content knowledge as well as an integrated higher level understanding of humanity's relationship with the marine and that this propagates into adulthood. It is further hypothesised that young people from specific backgrounds hold a skewed understanding of the marine environment at best, or are 'marine blind' at worst.

and Kevrekidis (2017) examined student teachers’ content knowledge of ocean sciences issues and attitudes toward the state of ‘ocean stewardship’. Boubonari, Markos, and Kevrekidis (2013) examined student teachers' knowledge, attitudes, and environmental behaviour toward marine pollution. A variety of methods have been used to explore marine education in children, notably, Lu and Liu (2015) explored integrating augmented reality, AR, technology to enhance children’s learning in marine education. It would be the authors of this work’s view that AR could be a useful tool but not replace the physical interaction with the marine environment. This work reports on a pilot study to probe the ocean literacy of pre-service / student teachers in the Republic of Ireland. The Explorers Education Programme™ (Marine_Institute, n.d.) is a successful primary school intervention, however following the review of 2015, it was decided to intervene at the source of teacher education.

**METHODOLOGY**

The Ocean Literacy Questionnaire, OLQ, developed by the Marine Institute, a sample of n=35, mean age= 19.8yrs, student teachers at Dublin City University completed the OLQ prior and following an intervention on marine literacy. The OLQ is a six-section multipart-question questionnaire which elicits perceptions of how ocean literacy fits into the primary school curriculum, perceived importance of content areas, and perceived barriers to implementing marine education in primary school.

The raw data from the OLQ was analysed in its constituent sections for both the pre- and post-test administrations. Multidimensional scaling also known as coordinate grid analysis was carried out on the data once it had been prepared by creating matrices of the scores provided by the student teachers reflecting their perceptions of certain attributes. The matrices consisted of both the pre- and post-test data combined thus all data points were involved in the algorithm. The MDS was carried out in the R environment (R_Core_Team, 2013) using the MASS package (Venables & Ripley, 2002) using the following algorithm:

```
# first row contains variable names, comma is separator
# assign the variable id to row names
# note the / instead of \ on mswindows systems
FILENAME <- read.table("c:/FILE PATHWAY", header=TRUE, sep="", row.names="id")

# Classical MDS
# N rows (objects) x p columns (variables)
# each row identified by a unique row name
d <- dist(FILENAME) # euclidean distances between the rows
fit <- cmdscale(d,eig=TRUE, k=2) # k is the number of dim
fit #view results

# plot solution
x <- fit$points[,1]
y <- fit$points[,2]
```
RESULTS

Section 1 of the OLQ prompted the student teachers for their perceptions of whether ocean literacy was relevant to which subjects of the Irish primary curriculum, before and after a short intervention (Figure 1), excepting science. Generally, but not statistically, the results showed an increased diversity of subjects which can use ocean literacy as a vehicle for learning, the most marked being geography, mathematics, physical education and religion.

It was surprising that initially, in the pre-test, student teachers did not think that the marine was pertinent to studies in geography at all, low in mathematics and physical education which might seem to be cornerstones in students' interactions with the marine environment. Physical education would include water sports of any kind but this was overlooked presumably because students understood PE to be conventional land-based sports only. Whereas it was not surprising that religious education did not feature strongly in the pre-test, it was equally surprising how this was reversed since the only input in the intervention in this regard was the recalling of the 7th century voyage of St. Brendan the Navigator and the use of remote islands as monastic centres on the western seaboard of Ireland.

The remaining sections of the OLQ were subjected to MDS and a plot of the extracted 1st and 2nd dimensions plotted on Cartesian planes. Non-metric multidimensional scaling, MDS, also known as principal co-ordinates analysis, PCA, was applied to the transposed data matrix using the ASCAL protocol in R, which uses the Takane-Young-de Leeuw S-stress – formula #1, and a plot was made of the emerging dimensions. Jaworska and Chupetlovska-Anastasova (2009)
reviewed the possibility of using MDS in a range of psychological domains, and McCloughlin (2015) explored the use of MDS in student and serving teacher perceptions of self-efficacy in teaching science. They do, however, view MDS as an 'exploratory data analysis technique' but point out its key features, namely that MDS can 'handle nominal or ordinal data, and does not require multivariate normality'. de Leeuw (2000) in a meta-review of the literature using MDS, claims that "MDS, as a set of data analysis techniques, clearly originates in psychology", and as such the early history starts with Carl Stumpf around 1880 (de Leeuw & Heiser, 1980). The most common approach to determine the elements and the underlying configuration is an iterative process, commonly referred to as the Sheppard-Kruskal algorithm. A simplified view of the MDS algorithm is as follows (Borgatti, 1997; Cízek, Härdle, & Weron, 2005; UNESCO, n.d.), but see Fahrmeir and Hamerle (1984):

1. Assign points to arbitrary coordinates in a p-dimensional space.
2. Compute Euclidean distances among all pairs of points, to form the DHAT matrix.
3. Compare the DHAT matrix with the input D matrix by evaluating the stress function.
4. Adjust coordinates of each point in the direction that maximally reduces the stress.

After determining the dissimilarity matrix $D$ and the corresponding scaling matrix $A$, an iterative process begins, which successively revises the dissimilarities and object coordinates until an adequate fit is obtained. The objective of the iterative process is to obtain a spatial representation in $p$ dimensions, such that the Euclidean distances among the objects are monotonically related to the original dissimilarities.

The iterative process comprises four steps:

Step 1 – Initial phase – selects the dimensions and determines the initial configuration and the resulting distances.

Step 2 – Non-metric phase – uses monotone regression. The estimated regression produces a new set of dissimilarities, called disparities that are monotonically related to the distances.

Step 3 – Metric phase – revises the spatial configuration to obtain new distances, which are more closely related to the disparities generated in step 2.

Step 4 – Evaluation phase – determines the goodness of fit of the distances and the disparities.

If the fit is not adequate, Steps 2 and 3 are repeated.

In the examples following, a Euclidean distance model was used which produces a projection identical to principal components analysis. The statistic allows any measure of similarity to be examined, MDS can use any distance matrix and as a result, the analysis focuses on the cases – the teachers – no information is provided about the contribution of individual questions answered (Fielding, 2007). Since the data are non-metric, they are interpreted as ‘distance-like,’ but not actual distance.

The aim of the MDS is to transform such data into a set of genuine Euclidean distances. The outcome consists of an arrangement of points in a small number of dimensions, usually two,
and located in such a way that the distances between the points relate as closely as possible to the dissimilarities between the objects. In non-metric MDS, only the rank order of entries in the data matrix – not the actual dissimilarities – is assumed to contain the significant information. Hence, the distances of the final configuration should as far as possible be in the same rank order as the original data. The purpose of the non-metric MDS algorithm is to find a configuration of points whose distances reflect as closely as possible the rank order of the data. Figure 2 is plot resulting from section 2 which concerned the student teachers’ perceptions of relevance of an external experience e.g., trips or visitors. We see two main clusters, and the fact that no one cluster is exclusively PR or PO means that the students changed their opinion as a result of the intervention or time to reflect. In Figure 3, the pre-test scores tended to overlap in pairs or three individuals indicating consensus in a range of variables: some thought that staff, the principal or board of management – equivalent to board of governors – might hinder them developing marine literacy strongly on the right and not so on the left of the figure.

**Metric_MDS**

![Metric_MDS](image)

*Figure 2. MDS plot of section 2 of OLQ, ‘PR’ refers to the pre-test scores; and ‘PO’ refers to the post-test scores.*

**CONCLUSION**

The starting point for this work was Richard Louv’s (2005) phrase ‘nature deficit disorder’ which we view as the collective term for a range of lacunae in the experiential world of modern, western, humanity. ‘Marine deficit disorder’ – while this might be understandable, or even acceptable in a completely land-locked country which lacks any connection with the marine environment including commerce and trade – it is a real issue in Ireland; which is not such a land-locked country. The relationship of Ireland with the marine is fundamental to the existence of the country, not merely because Ireland is the most westerly country and island nation in the Atlantic Ocean but because all the peoples of Ireland have moved to these western isles by crossing the sea in the hope of a better future. It behoves every citizen therefore, to be cognizant of the sea, its importance and its fragility.
Figure 3. MDS plot of section 3 of OLQ, ‘PR’ refers to the pre-test scores; and ‘PO’ refers to the post-test scores.

Much work is needed to bring student teachers to an acceptable level of marine or ocean literacy. The OLQ requires further fine-tuning in order to specifically target key indicators of marine deficit disorder. The results demonstrate disordered thought evidenced by a disconnect between the two administrations of the OLQ. In our on-going work involving a mixed methodologies framework of lab sessions / beach visit / marine aquarium / printed resource use / expert visit adapted to local conditions and linkages, we anticipate an amendment to the Irish revised Primary School Curriculum to include explicit mention of the marine in the relevant sections of the curriculum whereas at present it is left to the teacher to adapt their plans and schemes to include any mention of the marine.

The OLQ did outline deficits in marine knowledge and understanding which for people who had completed their secondary education to a high level is particularly worrying; however, rather than merely filling the gaps, intervention does enhance and adapt and restructure the students' perceptions of the marine, and the picture becomes somewhat more complex. With continuing on-going work, it is anticipated that specific key experiences at a child's development may cascade specific understandings of the marine will be elucidated.

The OLQ is available on request from the corresponding author: tom.mccloughlin@dcu.ie.

STRAND 9: INTRODUCTION

ENVIRONMENTAL, HEALTH AND OUTDOOR SCIENCE EDUCATION

As is evident from its description, strand 9 of the ESERA conference brings together an array of different perspectives on science education: environmental, health, and outdoor science education. These perspectives are grouped together not so much due to a shared research focus or methodology, but rather, on the basis of their shared interest in what might be called the ‘bigger picture’ in science education.

No doubt, this shared interest in problems such as the sustainability of the planet or the social problems of hygiene and immunisation are in part due to to the looming global crises of our time, but it is probably no coincidence that many of these studies are found within strand 9: Indeed, the opportunities for exploring and understanding this bigger picture – and humanity’s role in it – are perhaps the richest and hold the greatest potential when they are located on the outer edges or even outside the school system with its more formalised structures. Thus, in strand 9, researchers explore how topics relating to the environment and health, and how using outdoor activity and instruction, can enrich and enhance teacher and student education, and what the impact of such activities may be on career choice and behaviour change.

The ‘Science|Environment|Health Symposium’ of the special interest group no. 4 (Kelselman, Devetak, Enzinger, Fink, Heuckmann, Posega Devetak, Simon, Vesel, Zeyer) considered the value of health and medicine in science education. This includes the readiness of teachers to embrace health and medical related topics, challenges with introducing these topics, and the ability and knowledge of students to benefit from relevant content. Gavidia, Mayoral, Talavera and Sendra further discuss health education, pointing to the strong link between environment and health.

The topic of environment is also addressed by Gutierrez and Blanchard, who examine the impact of informal, at-home learning environments of middle school students and their families on climate change behaviour. The authors posit that the families were not ready to change perhaps because of the novelty of the topic of climate change. A different problem of environmental protection is addressed in an empirical study of university students in Japan, where Miyake, Kobayashi, Otsuka and Nakamura show that generally, students find it difficult to incorporate conservation into their everyday action. The authors suggest that the main reason is probably because students place a high value on gaining information in advance before participating in conservation events.

Montalbano writes that “Science education needs to face a future that includes and supports the study of sustainability”. She demonstrates how physics education can be used to conceive of sustainable solutions through student interaction with the physical world, as well as how the topic of sustainability can be used to connect classroom activity with everyday experiences. Artemi, Maidou and Polatoglou introduce initial results from their “Zero energy house” project on energy consumption and bioclimatic solutions for architecture. Maraffi, Pennesi, Acqua, Stacchiotti and Paris study different educational approaches to understand which approach helps students acquire disciplinary and transversal skills more easily in understanding soil as a non-renewable resource.
Kabapınar and Ağlarcı find that the majority of students have misconceptions about the greenhouse effect, climate change and ozone layer depletion, even to the extent of having difficulty defining these phenomena. They suggest that group learning is more effective than individual learning; this suggestion, they posit, has important implications for the design of teaching activities particularly related to environmental conservation.

In another perspective, Iwama, Kobayashi, Hatogai and Matsubara examine the differences between male and female university students’ view of life. Female students’ view of life regarding living things is higher than their male counterparts informed by their experience of raising or coming into contact with animals.

Wirth and Pietzner introduce a professional development course for chemistry teachers as well as a set of materials developed as part of the school lab that connects chemistry-related professions with environmental protection. They find that students show more interest in professions in chemistry-related fields after the school lab activity and argue that students need to be introduced to a wide range of professions within chemistry. In Hoyle and Blanchard’s study of teacher-coaches and PLC meetings, which were set up to help teachers lead after-school STEM Career Clubs in two rural middle schools in south-eastern USA, the community of practice social learning framework (enterprise, mutuality and repertoire) was critical for STEM club implementation.

Many contributions in this strand focus on the use of the outdoor and out-of-school learning in education. Pollin and Retzlaff-Fürst examine the function of school gardens as an educational resource in terms of the impact of garden work on well-being and social emotional competences of sixth grade students. In a large study, Füz and Korom conducted a survey over primary schools across Hungary to map student and teacher experiences and views on the usefulness of out-of-school learning programmes. In this study, teachers, principals and students alike observed how the social experience and the new knowledge acquired were the greatest benefits of out-of-school experiences. Kervinen, Uitto and Juuti study three secondary school biology teachers in Finland who do use fieldwork extensively, and Uitto and Nordström’s investigation of third-grade pupils’ learning process during outdoor education confirms that the outdoors is an “effective experiential learning environment, because pupils are in direct sensory-based contact with the learning environment, the content and context of the instructional topics of learning”.

In summary, we commend the work of the ESERA strand 9 contributors in taking seriously the social, health and environmental problems we all face as a global community, and in employing a diversity of methodologies in preparing science education to effectively address these problems. The work of this group of researchers shows unequivocally that preparing citizens for an uncertain future transcends the borders of the formal school system.

Albert Zeyer and Marianne Achiam
ON THE VALUE OF HEALTH AND MEDICINE IN SCIENCE EDUCATION: NOTES FROM A SCIENCE|ENVIRONMENT|HEALTH SIG SYMPOSYUM

Alla Keselman¹, Iztok Devetak², Sonja M. Enzinger³, Andreas Fink⁴, Benedikt Heuckmann⁵, Sonja Posega Devetak⁶, Uwe K. Simon⁷, Tina Vesel⁸, Albert Zeyer⁹

¹US National Library of Medicine, Bethesda, United States; ²Faculty of Education, University of Ljubljana, Ljubljana, Slovenia; ³Center for Didactics of Biology, Karl-Franzens-University Graz, Graz, Austria; ⁴Institute of Psychology, Karl-Franzens-University Graz, Graz, Austria; ⁵Centre of Biology Education, University of Münster, Münster, Germany; ⁶General and Teaching Hospital Izola, Department of Paediatrics, Izola, Slovenia; ⁷University of Teacher Education Weingarten, Weingarten, Germany; ⁸Department of Allergology, Rheumatology and Clinical Immunology, University Children's Hospital, University Medical Centre, Ljubljana, Slovenia; ⁹Bern University of Applied Sciences, Bern, Switzerland

This paper summarizes presentations and discussion from Science|Environment|Health SIG 4 ESERA 2017 symposium about the role that health and medicine education can play in science education. The presentations focus on teachers’ readiness to embrace these topics and students’ knowledge and ability to benefit from the relevant content. For example, Heuckmann investigates teachers’ beliefs about teaching about cancer in a science classroom. Devetak, et al. demonstrate positive impact of an allergy management course for education students on their understanding of allergy, attitude towards managing children’s anaphylaxis, and interest in learning more about child health. Keselman and Zeyer investigate how simple factual health brochures and texts enriched with scientific background information affect young adults’ vaccination safety beliefs. Finally, Simon presents a large study of students’ understanding of virus biology, the topic relevant to attitudes towards vaccination and antibiotics. Jointly, the contributors to this symposium show that while students’ and student teachers’ knowledge of health biology is characterized by some gaps and misconceptions, teachers hold largely positive beliefs about bringing complex health topics into the science classroom. Moreover, introducing health and medicine topics into school science has a potential of making practical impact on health attitudes and behaviors of students and teachers, and needs to be studied further. The discussion focuses on contextual challenges and enablers of situating health and medicine as a context of science education.

Keywords: health, medicine, science in society, informed citizenship, health behavior, complexity

INTRODUCTION

Health and medicine are complex domains with a great potential for making science socially and personally relevant. They can help engage students in learning science; draw them into STEM careers; and equip future non-scientists with valuable citizenship and daily living skills. Yet, for largely historic reasons, health and medicine occupy little time in a traditional science classroom (Zeyer, 2012). The ESERA Science|Environment|Health SIG 4, formed in 2015, aims to demonstrate the mutual benefit of greater alliance between health/medicine on the one hand and science education on the other, and bridge the disciplines (Zeyer & Kyburz-Graber, 2012). The SIG discourse stresses health- and environment-related nature of many existing
global challenges, the role of informed citizen in solving them, and the complexity of knowledge essential for addressing these challenges (Fensham, 2012).

This symposium, organized by ESERA Science|Environment|Health SIG 4 and comprised of four presentations, explored the promise and challenges of health and medicine in science education. Two presentations (Heuckmann, Hammann, and Aschoff; Devetak et al.) focused on teachers’ attitudes and readiness to embrace these topics. The other two (Keselman and Zeyer; Simon et al.) investigated students’ knowledge, information needs, and potential to benefit from the relevant content. The objective was to review the state of research on health and medicine in science education, sparking a discussion about gaps, future directions, and the overall agenda of the field. The symposium also placed an emphasis on discussing the impact of complexity and uncertainty inherent in health and medicine topics on bringing them into science education research and practice.

IDENTIFYING COMPLEXITY IN BIOLOGY TEACHERS’ BELIEFS ABOUT TEACHING CANCER EDUCATION

Benedikt Heuckmann
Centre of Biology Education, University of Münster, Germany

Over recent decades, studies on teachers’ behavior in the classroom and teachers’ professional development (PD) have contributed to understanding specific beliefs that facilitate or impede science teachers’ actions in the classroom (Jones & Leagon, 2014). Essentially for health topics, studies pointed out that teachers are challenged by the multi-faceted character of health topics (Tidemand & Nielsen, 2017). As it is assumed that beliefs are topic or domain specific, our research question involved investigating the beliefs that teachers hold about teaching cancer education in biology classes at secondary school.

Two characteristics indicate the emotional and factual complexity that pertains to teaching cancer education. First, the topic of cancer is of high social relevance and emotional prominence, as everyone is either directly or indirectly affected by the disease (Torre et al., 2015). Second, cancer relates to core ideas of biology such as regulation of the genes and the cell cycle, and thus, scientific knowledge is necessary to understand cancer. Studies providing insights into teachers’ beliefs on teaching cancer education showed that teachers hold beliefs which focus mainly on difficulties and barriers, and teachers are concerned about the emotional aspects of the topic of cancer (Carey, Charlton, Sloper, & While, 1995). Nevertheless, teachers are credited with a key role in the dissemination and implementation of school cancer education by health and medical education researchers (Barros et al., 2014).

In this sequential exploratory study, qualitative and quantitative measures are used to investigate German biology teachers’ beliefs about teaching cancer education. The study applied the Theory of Planned Behaviour (Fishbein & Ajzen, 2010) to identify beliefs about teaching outcomes (behavioral beliefs), social pressure (normative beliefs), and teachers’ skills and external control factors (control beliefs). The study consisted of an open-ended questionnaire (Phase 1, n=168) and in-depth interviews (Phase 2, n=11) for belief elicitation, development of closed beliefs items (Phase 3, n=58), assessment of belief salience (Phase 4, n=30) and formation of belief scales (Phase 5, n=23).
The findings presented below summarize data from Phases 4 and 5. As key results, teachers believed that teaching cancer education would have positive consequences (behavioral beliefs, 10 items, Cronbach’s α = .82), such as, for example, students learning about carcinogenic risk factors. Perceived social pressure to teach about cancer played a minor role for teachers (normative beliefs, 3 items, α = .82). For example, teachers believed that cancer researchers and physicians placed high expectations on them to teach about cancer. However, teachers were not motivated to comply with their expectations. For control beliefs, teachers were confident they possessed skills necessary to teach about cancer, for example, to answer students’ biological and medical questions (6 items, α = .80). However, teachers also believed that external aspects such as tightly packed curricula (10 items, α = .81) might be inhibiting for teaching cancer education.

The findings of the study describe the variety of different aspects teachers consider when thinking about cancer education. Prior studies have drawn a more pessimistic picture of teachers’ beliefs and have postulated affective barriers concerning teaching the topic, while the present study indicates a more ‘optimistic view,’ and affective barriers such as emotional affectedness faded in the background. The study reveals that cancer education remains a complex topic for science classrooms, with teachers emphasizing the factual complexity of cancer. In fact, teachers’ beliefs indicate readiness to introduce cancer education in the science classroom as, for example, teachers believe to possess relevant knowledge and skills. Still relatively little is known about variables that may add valuable information to further explaining teachers’ action when teaching cancer education. For this reason, we intend to analyze the role of variables such as the proximity of experience with cancer in personal and professional settings and teachers’ subject matter knowledge of cancer in future studies.

Actually, about half of the German federal state curricula describe cancer as mandatory topic for upper secondary biology classes. At the same time, PD programs such as specific teacher trainings on cancer education rarely exist. Findings about teachers’ key beliefs could be used to design targeted interventions aimed at strengthening teachers’ readiness to embrace health and medicine in the science classroom. Furthermore, this raises the interesting research questions such as what are teachers’ key beliefs about teaching cancer education and to what extent do similarities between teachers’ key beliefs exist when teaching different topics across the Science|Environment|Health area.

This paper was presented together with Marcus Hammann and Roman Asshoff (Centre of Biology Education, University of Münster, Münster Germany) at the ESERA 2017 conference.

DEVELOPING PRE-SERVICE TEACHERS’ COMPETENCIES OF STUDENTS’ ALLERGIES MANAGEMENT IN SCHOOL ENVIRONMENT

Iztok Devetak¹, Sonja Posega Devetak², and Tina Vesel³

¹University of Ljubljana, Faculty of Education, Kardeljeva pl. 16, 1000 Ljubljana; ²General and teaching hospital Izola, Department of paediatrics, Slovenia; ³Department of Allergology, Rheumatology and Clinical Immunology, University Children’s Hospital, University Medical Centre, Ljubljana, Slovenia

The research questions addressed in this study were: (1) How deeply pre-service primary school teachers understand allergic child management? and (2) Does short theoretical and practical intervention programme significantly influence pre-service teachers’ knowledge about allergy and anaphylaxis?

These questions were asked because it is important to understand teachers’ abilities to help students in a potential life-threatening situation caused by severe allergic reactions that can happen in the school environment. Allergies are one of the most common paediatric presentations, placing significant burden on the health system and contributing substantially to impaired quality of live and school absences. The most severe allergic reaction is anaphylaxis. The majority of anaphylaxis occurs outside health institutions and for that reason parents, pre-school and school employees (especially teachers) and children must be well educated about what anaphylaxis is and how it is treated before medical personnel arrive at the scene. Several studies, including EuroPrevAl study across Europe, showed low preparedness for managing a child at risk of anaphylaxis in a kindergarten or school (Le, Kummeling, Dixon, Barreales Tolosa, Ballmer-Weber, Clausen, et al., 2014). Literature shows that 20% of food allergic reactions occur in schools. Two thirds of schools have at least one allergic student who can develop anaphylaxis, and most school employees do not have sufficient knowledge to adequately respond to anaphylaxis. Some studies show that only 12% of teachers can correctly apply epinephrine auto-injector. 75% of children with anaphylaxis do not receive adequate first aid (Mahl Wahn & Niggemann, 2005). Education about how to prevent, recognize and act during allergic reaction in kindergarten or school is an important part of managing a child with food allergies (Polloni, Lazzarotto, Toniolo, Ducolin & Muraro, 2013). However, efficacy trials of different models of knowledge improvement within communities on recognizing and managing anaphylaxis training are missing (Muraro, Clark, Beyer, Borrego, Borres, Lødrup Carlsen, et al., 2010). Even shorter training courses in allergy and anaphylaxis management for school personnel significantly improve participants’ knowledge about this topic (Polloni et al., 2013), but there are insufficient data about the persistence of this knowledge after a longer time.

For answering the first research question (first phase of the study), a larger sample of 572 pre-service primary and lower secondary school teachers completed a Teachers’ Health Competences Development–Allergy Questionnaire (THCDAQ). Most of them were female (93%), with average age 21.5 (SD=2.7) years. The data obtained by the application of THCDAQ were the basis for developing the 90 minutes theoretical (about allergy and anaphylaxis) and practical (using adrenalin auto-injector) educational intervention. This intervention was applied (second phase of the study) to 62 post-graduate pre-service primary and lower secondary school teachers (all female; average age 24.8; SD=1.1). Participants answered the Teachers’ Health Competences Development–Anaphylaxis Management Questionnaire (THCDAMQ) three times: before intervention, immediately after, and 14 days after the intervention.
Key findings from the first phase of the study indicate that pre-service teachers show positive attitudes towards learning about health issues and that students would appreciate basic education during their undergraduate pre-service teacher education. Overall, there was an average understanding of allergy among the students participating in this study (59.4%; SD=16.1% success). There was no statistically significant difference in students’ basic understanding of allergy as a function of their level of education, science or non-science background, and if students have allergies according to their opinion. Continuing the study in the second phase, pre-service teachers showed positive attitudes towards learning more about different children’s health issues (91.9%). All of them expressed that child health topics were very important for each teacher and all wanted to increase their health competences. 90.3 % thought that teacher is responsible for pupils’ health issues during school time. 71 % reported that they haven’t been exposed to any activities that would promote their health competences development. The results indicated that there was a statistically significant difference in THCDAMQ scores ($\chi^2 (2, N = 37) = 48.127, p \leq .000$) between pre-intervention ($Md = 3$; IQR 2-4.5), post-intervention ($Md = 6$; IQR 6-6), 14-days follow-up ($Md = 6$; IQR 6-6).

Key findings suggest that the anaphylaxis educational programme had positive effect on students’ knowledge and attitudes towards child with allergic reactions in school. It is also important to emphasise that pre-service teachers retained their knowledge after intervention. Also other health/medical competences should be developed applying different health/medicine modules. Teachers’ quality of life should be also researched when teaching a class of students with specific health issues.

DOES INFORMATION ABOUT HPV VACCINATION HAVE AN IMPACT ON TEACHER STUDENTS’ VACCINATION JUDGEMENTS?

Alla Keselman¹ and Albert Zeyer²

1 US National Library of Medicine, Bethesda, United States
2 Bern University of Applied Sciences, Bern, Switzerland

Impacting daily life is one of the goals of science education for all students, yet little research investigates the knowledge underlying health behaviors. This study quantitatively investigates the effect of 1) a traditional HPV information brochure and 2) a brochure enhanced with additional conceptual bio-medical information - on teacher students’ beliefs about HPV vaccination importance, safety, and effectiveness.

HPV is the most frequently occurring sexually transmitted infection (Dunne et al., 2007). Some HPV strains cause cervical cancer, which is the fourth most common cancer in women worldwide. Fortunately, HPV
infection can be prevented by HPV vaccination (Centers for Disease Control, 2016). Unfortunately, despite the vaccine’s safety and effectiveness, many parents of adolescents are hesitant to vaccinate their children (Center for Disease Control, 2017). The immune system, which is essential for understanding vaccination, is extremely complex and rarely addressed in the school science in any detail. At the same time, the issue of vaccination is surrounded by much social controversy that is not scientifically based. Individuals often reject vaccines out of concerns about their safety and effectiveness, as well as scepticism about conventional medicine and public health (Thorpe, Zimmerman, Steinhart, Lewis, & Michaels, 2012). In the case of HPV, parents are also concerned about the novelty of the vaccine and the topic’s link to early adolescent sexuality.

Few studies looked in depth at the complexity of individuals’ beliefs underlying vaccine hesitancy. Public health brochures about HPV usually state that vaccines are safe and effective without addressing specific safety-related fears and explaining the underlying biological mechanisms. In a 2014 study of HPV vaccination attitudes among Swiss teacher students, Zeyer and Sidler found that receiving a standard HPV information brochure did not affect vaccine hesitancy. In follow-up interviews the authors discovered a number of concerns that were not addressed by the brochure. One such concern included an incorrect belief that HPV vaccine contains attenuated (weakened) virus that may change back into virulent form and cause HPV infection. The goal of present study was to see whether supplementing a standard brochure with biological information about HPV vaccine and its mechanism affected beliefs about vaccination safety more than the brochure alone.

The sample of the study included 232 Swiss teacher students who rated ten statements about HPV on the scale from 1 to 5, from “strongly disagree” to “strongly agree,” before and after reading the informational texts. The statements reflected four dimensions of Health Belief Model (HBM) of health behavior (Hochbaum, Rosenstock, & Kegels, 1952): Susceptibility to HPV Infection, Importance of HPV Vaccination, Safety of HPV Vaccination, and Effectiveness of HPV Vaccination. The participants were randomly assigned into one of the two conditions. Those in the “standard” condition read the text developed on the basis of a US Center for Disease Control (CDC) HPV information brochure. For those in the “extended” version, the text was supplemented by authors-developed in-depth biological explanation of the nature of HPV vaccine, as well as the mechanism through which HPV vaccine interacts with the immune system. The texts were translated into German. Participants were randomly assigned to one of the two conditions.

Each participant questionnaire yielded four scores reflecting the HBM variables mentioned above, as well as the total score. In contrast with Zeyer and Sidler (2014), results suggest that reading simple factual information about HPV had a considerable effect on the students’ HPV vaccination judgment. Repeated Measures MANOVA demonstrated highly significant overall effect of time (F(4,227)=2,783.26, p<.000), and similarly highly significant effects of time for each of the four HBM variables. However, there were no significant effects of time by text type interaction, suggesting no overall impact of the added biology information. After obtaining the whole-sample results, the authors hypothesized that participants with different initial beliefs about HPV vaccination safety might be differently affected by the biology in the extended text. Post-hoc analysis was conducted on three groups: those with “low”, “medium”, and “high” initial scores on the beliefs about HPV safety variable. Students in the “low” group initially viewed HPV vaccine as very unsafe, students in the “high” group initially viewed it as very safe, and students in the “medium” group started with mid-range view of HPV vaccination safety. This analysis revealed marginally significant (one-tailed, after Bonferroni
correction, $F=3.952$, $p<0.025$) impact of the added biology information on HPV safety beliefs of the participants with initial medium, but not low and high scores.

From the practical standpoint, the results encouragingly suggest that even a single read of a standard public health brochure may improve individuals’ beliefs about their susceptibility to HPV and the importance, effectiveness, and safety of HPV vaccine. At the same time, while positive impressions of vaccination grew after reading the texts, participants’ posttest results still demonstrated much room remaining for worry and uncertainty, making behavioral intentions unclear. In this light, the highly exploratory finding of the positive impact of the added biology information both gives hope and points to significant need for additional research. It is not surprising that a single, un-scaffolded read of biological information did not turn out to be a health communication panacea. While potentially useful, in order to be impactful, conceptual bio-medical information needs to be delivered in a meaningful way, in connection with other relevant science information, rather than in a short text or a brochure. Therefore, much more mixed-methods research is needed into mechanisms of the interaction between 1) different kinds of knowledge and 2) beliefs about vaccination safety. Research is also needed into best classroom practices of science teaching about vaccines and the immune system in ways that support conceptual and behavioral change.

This work was in part supported by the intramural research program of the US National Library of Medicine, National Institutes of Health.

A VIRUS IS A BACTERIUM: STUDENTS’ KNOWLEDGE AND BELIEFS ABOUT VIRUSES

*Uwe K. Simon³, Sonja M. Enzinger¹ and Andreas Fink²*

¹Center for Didactics of Biology, Karl-Franzens-University Graz, Graz, Austria; ²Institute of Psychology, Karl-Franzens-University Graz, Graz, Austria; ³University of Teacher Education Weingarten, Weingarten, Germany

Virus biology and transmission and protection against viral diseases is complex in several ways because of the large variety of viruses (e.g. single vs. double-stranded DNA vs. RNA-viruses), differences in the ways they interact with their respective hosts and their means of infection, as well as the fact that there is effective vaccination against some (see Keselman and Zeyer in this paper) but not against the majority of viral diseases,
which, furthermore, may exhibit a plethora of symptoms varying at different stages of the disease (e.g. HIV). Finally, viruses display extremely fast rates of mutation, making it even more difficult to develop effective treatment. In this respect, virus biology is similarly complex and fighting viral diseases similarly difficult as in the case of cancer (see Heuckmann in this paper).

In 2016, the European Commission published their newest “Antimicrobial Resistance Report”. In it, 46 % of the roughly 28 000 European citizens wrongly stated that antibiotics would be able to kill viruses, with a further eleven per cent being unsure (European Commission 2016). Knowledge about non-effectiveness of antibiotics in case of viral diseases differed widely among European states (Fig. 1). However, a large proportion of the population is obviously misinformed in many countries. Since recent studies have shown that a) the demand for getting these medicines prescribed is high (e.g. due to the need to get back to work soon) and that b) physicians often yielded to such demands due to time constraints or lack of resistance because of tiredness (Linder et al. 2014, Little et al. 2013, Tonkin-Crine et al. 2015), antibiotics are taken far too often in case of influenza or other viral diseases, which probably contributes to the increased resistance of many bacterial strains currently observed.

Yet, instead of only focussing on behavioural training of physicians as postulated by Little et al. (2013) and Tonkin-Crine et al. (2015), we should re-think the role of school education: If students left school knowing that bacteria and viruses are not the same and that antibiotics do not work against the latter, because viruses are not equipped with the metabolic processes these substances disrupt (e.g. cell wall synthesis), misuse of antibiotics might decline.

In an ongoing project, we thus study various age and socio-economic groups concerning their knowledge about viruses. Here, we summarize results from a questionnaire study performed with 133 grade 7 and 199 grade 10 high school students, and 133 first-year biology and 181 first-year non-biology university students in Austria. In this study, participants had to relate to all sorts of virus-related knowledge. For instance, they had to draw a virus and label the drawing, describe what a virus is, how viruses replicate in their hosts, how they are transmitted, how transmission could be minimized, what viral diseases are known to them and against which there exists vaccination.

Analyses were performed quantitatively (comparing knowledge levels by means of ANOVA) and qualitatively (analysing participants’ concepts concerning different virus- and health education-related items). We found a highly significant group effect for total knowledge relating to virus biology and health issues ($F(3, 642) = 44.17, p < 0.01, \eta^2 = 0.17$). Specific post-hoc tests by means of the Tukey test showed significant differences between groups ($p < .01$), except for 1st year non-biology students and grade 10 high school students. Biology students performed best, even though they had not yet encountered this topic in their courses, but they also exhibited a high number of misconceptions, including wrongly declaring a virus a pro- or eukaryotic cell, or listing malaria amongst viral diseases. Furthermore, the majority of participants felt that the virus-related knowledge they had received at school was insufficient (Simon et al. 2017).

Based on our results, we see the strong need to improve and intensify teaching virus biology and related health issues at school. Additionally, we encourage researchers worldwide to analyse their respective nation’s virus knowledge and identify key aspects to address in education. Since we have focused on high school and university students until now, we plan to repeat our analyses with data from middle school students. In future
studies we will also assess teaching units recently developed by us and other groups concerning their effectiveness in positively influencing students’ knowledge in this highly important field.

Figure 1. Knowledge about ineffectiveness of antibiotics against viruses in European Union member states. Columns represent percentage of a given answer in a certain population (overall N = 27,969; after European Commission 2016).

DISCUSSION

The four studies presented in the symposium and summarized in this paper encompass a wide range of topics pertaining to health and medicine in science education. On the positive note, the presentations showed the room and the potential for health and medicine education in the science classroom. Heuckmann and Devetak et al. showed that teachers are eager to embrace health and medicine related topics, including the very emotionally difficult ones. Studies presented in symposium also demonstrated the need for bringing health into the science classroom, uncovering gaps in lay understanding of important public-health related science concepts, such as viruses and vaccination (Simon et al.; Keselman and Zeyer).

The presentations also showcased the broad range of fruitful contexts for bringing health and medicine education into science education. In doing so, they highlighted one of the reasons for the existing dissociation
between health education and science education. Currently, health education in the school context focuses on wellness and health promotion, stressing desired positive behaviours, rather than scientific mechanisms. In contrast, all four presentations focused on understanding and managing diseases, including their medical treatment. In the discussion, symposium participants suggested that health education in the context of science education may be more appropriately represented by “lay medical education” than health promotion. Siitonen, Hämeen-Anttila, Keinonen and Vainio (2014) have already presented a concept of medicine education that mainly focuses on the correct use of remedies and drugs. The participants believe that this concept could be enlarged and the scope could be broadened, as many of the symposium’s presentations suggest. In this way, medicine education could become an important part of a new Science|Environment|Health pedagogy.

The studies and the subsequent discussion also highlighted many challenges faced by the emergent field of Science|Environment|Health. One such challenge involves identifying the depth and nature of knowledge needed for various levels of application – e.g., personal health behaviours vs. critical reasoning about health policies in society. Another challenge involves teaching students about complex and uncertain topics without misrepresenting scientific knowledge as subjective and unattainable. This raises the question of curricular sequences and prerequisites, such as whether simple issues should precede complex ones, and whether complex topics should be presented via simplified models. Yet another important aspect that needs to be addressed before health and medicine education in the science classroom is effective is teacher preparation. At the present, teachers are open to including complex health-related topics, but are not necessarily prepared for them. All of this stresses the importance of broadening research agenda of Science|Environment|Health, with complexity of research methods and approaches mirroring the complexity of the issues that need to be investigated.

VACCINATION HESITANCY AND NATURE OF SCIENCE ATTITUDES. A STRUCTURAL MODEL OF SWISS STUDENT TEACHERS’ REACTIONS TO A VACCINATION DEBATE

Albert Zeyer
Bern University of Applied Sciences, Bern, Switzerland

Not much is known about the concrete impact on vaccination decisions of arguments for and against vaccines. Structural equation modelling is a method that makes it possible to single out different pathways of influence and to analyse them quantitatively. This study investigates a hypothetical vaccination decision of 271 student teachers at a Swiss university for teacher education after reading a debate between a vaccination proponent and opponent that was published in a free local newspaper. As expected, the arguments for the vaccination had a direct and highly positive impact on the vaccination decision. However, unexpectedly, there was no direct effect of the arguments made against the vaccination. Instead, their impact was indirect, mediated by a highly negative correlation between the pro vaccination variable and the contra vaccination variable. The conclusion is reached that besides positive vaccination knowledge, attitudinal aspects — “Nature of Science Attitudes” — play an important role in vaccination hesitancy. In the field of Public Understanding of Science, the focus on improving attitudes about science and trust in scientists is called communications orientation. This approach is yet under researched and asks for educational awareness in vaccination promotion.

Keywords: vaccination, attitudes, nature of science

INTRODUCTION

This study investigates the reaction of Swiss student teachers to a debate about vaccinations that was published in a free local newspaper. The educational context was chosen because, as Dubé, Gagnon & MacDonald point out, “ensuring education and knowledge about vaccines in younger individuals (children, adolescents, young adults), possibly through school-based programmes, may provide a good opportunity to encourage future vaccine acceptance by parents and adults and minimise the potential for development of hesitancy” (2015, p. 4193). These authors indicate that more research is needed to evaluate such a strategy.

Choosing a population of future teachers meets this request in two ways. First, many of these student teachers will indeed be parents themselves in a few years. Second, once on the job, they will teach children and adolescents about health issues. Therefore, it is important to understand how they react to vaccination information in the media. This allows teacher training to be tailored to their needs. The present research has been conducted in the context of a university for teacher education, and its results are already influencing the teaching of health issues at this institution.

THEORETICAL BACKGROUND

Vaccine hesitancy is the dynamic and challenging period of indecision around accepting a vaccination. It captures the concerns about the decision to vaccinate oneself or one’s children (Jarrett et al., 2015). As the
World Health Organisation points out, the concept is complex and context-specific varying across time, place, and vaccines, including factors such as complacency, convenience, and confidence. The spectrum of hesitancy is wide and varying, going from “accepters”, who do not question vaccination at all, to the “rejecters”, who reject outright vaccination (Dubé, Gagnon & MacDonald, 2015).

Today, according to many public health experts, vaccination hesitancy is increasing among parents (Sadaf, Richards, Glanz, Salmon & Omer, 2013). A number of surveys over the past two decades conclude that, although parents generally considered immunisation to be important, a majority of them reported vaccine concerns (Salmon, Dudley, Glanz & Omer, 2015). There is a broad range of factors contributing to these concerns. For example, parents are uncomfortable about mandatory vaccination, they feel unable to control potential adverse reactions, they prefer “natural” risks to “manmade” risks, and they have little to no experience of diseases prevented by vaccines, such as polio, measles, and diphtheria (Salmon et al., 2015).

However, contrary to some experts’ explanations, parents’ decision against vaccination is not simply thoughtless, irrational, or the result of a lack of knowledge about vaccines. Detailed studies have shown that vaccine refusing parents are well-informed individuals with considerable interest in health-related issues and who actively seek information (Dubé et al., 2015).

Many communication tools that help healthcare providers to discuss vaccination with vaccine-hesitant parents have been published, but seldom have they been evaluated (Dubé, Gagnon & MacDonald, 2015). In fact, there is still a significant lack of solid empirical information on effective strategies to address vaccine hesitancy (Salmon et al., 2015). In light of this, the SAGE Working Group on Vaccine Hesitancy emphasises the importance of understanding the specific concerns of the various groups of vaccine-hesitant individuals (Dubé, Gagnon & MacDonald, 2015). In particular, there is a need for studies that tests the effectiveness of delivering information to parents through different media in order to better inform public health awareness initiatives (Sadaf et al. 2013).

**RESEARCH CONTEXT, RESEARCH QUESTION AND HYPOTHESIS**

This study makes use of an article in a free local paper, distributed to more than a million Swiss households. This free paper, provided by a Swiss supermarket chain, is very popular in Switzerland, and it is read and shared within families, particularly among parents and grand-parents. Besides containing advertisements and marketing information, it also includes highly appreciated articles about issues of daily life and health.

The article used in this study included a debate on vaccines between the *pro* and the *contra* vaccination community in Switzerland (Nidegger 2007). The *pro vaccination* exponent was a professor for paediatric infectious diseases at Basel University Hospital. The *contra vaccination* exponent was a Swiss general practitioner, well known in Switzerland for his pointed rejection of vaccines and for attracting a great number of vaccination rejecters around him. In the article, both exponents presented their viewpoints by answering an interviewer’s questions, and they also were given the opportunity to directly contest their opponent’s statements. The article includes a biographical sketch of each person but refrains from making an editorial comment.
The approach taken in this study was to give the article to the student teachers and to let them read it. Then the students had to judge seven core statements of each expert and to answer the question of how they would decide if they were parents and had to vaccinate their child. The research question was:

(RQ) How and to what extent do the judgements relate to each student’s vaccination decision?

It was hypothesised that the pro and the contra arguments would have an approximately equal but inverse influence, i.e., that consent to the pro vaccination argumentation would entail a positive vaccination decision and vice versa. Structural equation modelling provided an appropriate method for testing this hypothesis.

**METHOD**

**Questionnaire**

Seven core statements of both standpoints were identified by carefully reading the article and discussing it with students. Each statement had to be judged on a scale between 0 (full dissent) and 6 (full consent). In this way, a questionnaire with 14 items was created, 7 items representing the construct pro vaccination, and 7 questions representing the construct contra vaccination. In a pre-test with 35 students, a classical factor analysis was done. Both constructs showed high face validity and good statistical reliability (Zeyer & Knierim, 2009).

The items of the questionnaire are displayed in Tables 1 and 2. The questionnaire included an additional item (No. 15). In this item, students were asked to imagine that they were parents and how they would “generally” decide about their child’s vaccinations: “In general, would you rather accept or reject vaccination for your child?” The students had to choose between “rather accept” (1), and “rather reject” (0).

**The sample**

The definitive sample comprised 271 student teachers at a Swiss university of teacher education (descriptive measures see Table 3). Participants had enrolled in a course entitled “Health and Illness in School” taught by the author. The objective of the course was to prepare students, future Swiss school teachers, for promoting health and addressing health concerns among Swiss school children. One of the issues covered in this course was vaccination. In this context, and as an initial teaching unit, the students had to read the article in the local paper and to answer the questionnaire.

Procedure

Permission for participation and ethical approval was given by the authority of the Lucerne University of Teacher Education (Prorektorat Forschung Pädagogische Hochschule Luzern), which, in Switzerland, is the institutional board responsible for approving minimal-risk research, conducted with adult participants in an established educational setting. Before data collection, all students were informed about their right not to
participate. All participants were adults over 18 years of age. No personally identifying information was collected in the survey. There was no key connecting the answers to students. The students read the vaccination debate in the article. The questionnaire was distributed. At the end of the session, the volunteers were invited to contribute their completed questionnaire to the present study. A proctor, not connected to the course, collected contributed materials. Students not willing to contribute their materials retained them.

**Structural equation modeling**

For the statistical analysis, structural equation modelling (SEM) was used. SEM is a statistical method that takes a confirmatory approach to a structural theory underlying some phenomenon (Byrne, 2010). Hypothesised causal relations between involved factors are modelled by structural graphs and tested statistically in a simultaneous analysis of the entire system of variables. In this study, all estimates were produced using IBM SPSS AMOS 21.0 and the maximum-likelihood estimation approach (Arbuckle, 1997).

**The structural model**

The tested structural model reflected the research hypothesis. Thus, the two endogenous variables, representing the *pro vaccination* construct (ProV, 7 items) and the *contra vaccination* construct (ContraV, 7 items), were designed to model a symmetric causal impact on the vaccination decision (VDec, item 15, exogenous dummy variable). In other words, it was expected that the impact of ContraV on VDec would be negative, and the impact of ProV would be positive. A two-step process was established to test the model (Jöreskog, 1993). As a first step, the ProV and ContraV measurement models were tested through confirmatory factor analysis. In a second step, the two measurement models and the decision variable were combined into the full model for the vaccination decision.

**RESULTS**

**Descriptive measures**

The data were collected from a total of 271 students. Data were excluded if a student had not answered every question or if answers could not definitively be identified. After this raw data cleaning, the sample included 213 students (59 omitted cases, 22%), 170 females (79.8%) and 43 males (20.2%). The mean age was $M_{age}=23.2$ years (SD=3.26). The medium value of the *pro* items is 3.62 (range 0 to 6), the medium value of the *contra* items is 2.88 (range 0 to 6). Table 3 provides means and standard deviations for each item.

**The structural model**

The structural model for vaccination decisions is displayed in Figure 1. This figure includes all standardised regression weights.
All factor loadings of the measurement model were statistically highly significant (p < .001), and the corresponding signs concurred with the hypotheses. The standardised estimates confirmed the formal validity of the individual items (Bollen, 2002). Descriptively, the model worked excellently, which was indicated first by a highly acceptable goodness-of-fit index (GFI) of 0.94 (> 0.9 for good fit, for fit measures, see Arbuckle, 1997, p. 551ff). Second, the baseline comparison, the comparative fit index (CFI), was excellent (CFI=.984 (>0.9)). From an inferential point of view, the model was compatible with the data (CMIN/DF=1.199, p=.101, (1-3)). Finally, RMSEA=0.031 (<0.05) and PCLOSE=0.943 (>0.5) also indicated an excellent fit.

The explanatory power of the variable ProV was very high, as its standardised regression weight on the variable Vdec was very high and highly significant (.693, p<.001), i.e. ProV explained almost half of the variance of Vdec (48%).

However, unexpectedly, there was no significant impact of the variable ContraV on the Vdec, as the standardised regression weight was significant (p=.287). Therefore, the impact of ContraV on Vdec has been canceled (e.g. Byrne 2010).
Furthermore, there is a very high and highly significant negative covariance between ProV and ContraV (-.90, p<.001), and several error correlations between items of the same construct.

The strongly negative covariance entails an indirect effect of the variable ContraV on the variable Vdec. It can be calculated by replacing the correlation by an impact of ContraV on ProV. In this model (yielding the same goodness of fit indices as the original model), the indirect (mediated) effect of ContraV on the Vdec is significant and substantial (standardised indirect effect -.61, p < .01, two tailed, bootstrap approximation obtained by constructing two-sided, bias-corrected confidence intervals of 1000 bootstrap samples, bias corrected confidence level 90).

DISCUSSION

This study aimed to model the vaccination decision of student teachers after reading a debate between a person who supports and one who opposes vaccination. The tested structural model reflects the hypothesis that the belief in arguments of a vaccination proponent would have a direct positive impact on the (hypothetical) decision of student teachers to vaccinate their own child or not. Conversely, it was hypothesised that the belief in arguments of a vaccination opponent would have a negative impact on that decision.

The model strongly confirmed the first part of the hypothesis. The ProV variable explains 48% of the variation of the variable Vdec. The second part of the hypothesis, however, was not confirmed. In fact, there was no effect at all of the ContraV variable on Vdec. This result was unexpected. Since the contra vaccination expert strongly argues against vaccination, one could assume that a student who agrees with his arguments would be more likely to reject vaccination.

However, the model also yielded a strong negative correlation between the ProV and the ContraV variable. This means that students who believed in the pro vaccination argumentation strongly rejected the contra vaccination argumentation and vice versa. As presented in the section on results, this constellation entails an indirect effect of the ProV variable on Vdec. This indirect effect is smaller but still substantial and highly significant. In other words, the model gives two insights into the decision process:

1) Students who believe in the pro vaccination argumentation decide in favour of vaccination because they believe in the pro arguments.

2) Students who believe in the contra vaccination argumentation do not decide against vaccination because of the contra argumentation itself but because they believe less in the pro vaccination arguments.

This structure fits with the descriptive measures. The mean of the pro vaccination argumentation is higher than the mean of the contra vaccination argumentation, and the latter has a smaller, and indirect, impact on the vaccination decision than the former. Consequently, only 19% of the students decide against vaccination.

LIMITATIONS

There are some limitations with this study. One limitation is the sample, as it is a census of a school year in the University of Teacher Education. However, because these students come from every part of Central Switzerland, they very much represent the teacher population of this part of Switzerland, with students from
rural and urban areas, and also students from different socio-economic backgrounds. In addition, the majority of females in the sample reflects the fact that more women than men become teachers for primary and secondary one level. This statistical weakness has been tolerated because also in daily life, it is mainly mothers who decide the vaccination status of their children.

Another limitation is that the structural model represents a very basic decision between “acceptors” and “rejecters”. The students were forced to decide between these two alternatives, which reflect only the two extremal points of vaccination hesitancy. This simplification is a consequence of the approach of using an article that presents only arguments of acceptors and rejecters.

CONCLUSIONS

This study set out to model the impact of a debate between experts who are for and against vaccination on future teachers’ hypothetical vaccination decision. The salient result of the highly fitting model was the asymmetric impact of the pro and the contra argumentation on the decision. The pro vaccination argumentation proved to have a direct and positive impact on the decision. Students who agreed with the pro vaccination argumentation decided for vaccination. The effect of the contra vaccination argumentation was only indirect but still significant. Agreement with the contra vaccination argumentation had no direct impact on the vaccination decision, but it indirectly affected the decision by having a negative impact on agreement with the pro vaccination argumentation. We interpret this situation in terms of attitude: the effect of the contra vaccination argumentation lies in it diminishing the credibility of the contra vaccination argumentation. Qualitative research has indeed been showing that trust in the source of information and recommendations play a critical role in parents’ ultimate decisions and that the coalition concerned about vaccination challenge parents’ trust in traditional public health sources of information (Wilson, Barakat, Vohra, Ritvo, & Boon, 2008).

This result calls for two strategies in dealing with the arguments for and against vaccination, which are well known and hotly debated in the field of public understanding and public engagement of science (Bromme & Goldman 2015). The first strategy, called “learning orientation”, typically focuses on learning and understanding scientific content that, at least in principle, can be understood by the non-expert public. This approach fits with the direct positive impact of the pro vaccination argumentation on the vaccination decision. The second strategy, called “communications orientation”, focuses on improving attitudes about science and trust in scientists. This approach seems to be particularly suitable for dealing with the indirect negative attitudinal effect of the contra vaccination argumentation.

The two orientations differ in a fundamental way and normally are conceived as controversial in the field of public understanding of science (Sturgis & Allum, 2004). Interestingly, the presented model suggests that both orientations seem to be indispensable for a successful campaign to increase vaccination acceptance as they complement each other. The learning orientation obviously is present in research on vaccination hesitancy (Dubé, Gagnon & MacDonald, 2015). Indeed, learning and understanding of vaccination content is one of the factors that has been demonstrated to be efficient (Jarrett et al., 2015). The learning orientation has been investigated in a number of disciplinary communities, including Educational Psychology, Learning Sciences, and Science Education.
The communications orientation, however, aimed at attitudes and perceptions about science (so-called “Nature of Science attitudes”), seems to be a fairly new perspective for vaccination hesitancy. Nevertheless, it also has a long research tradition in Communication Sciences, Social Psychology, and to some degree in Sociology and Science and Technology studies (Bromme & Goldman 2015).

This research has been carried out in the context of teacher education in Switzerland. Qualitative research in Swiss school has already been able to document how teachers’ negative Nature of Science Attitudes can have a negative impact on the HPV vaccination decision (Zeyer, 2015; Zeyer, Keselman & Levin, 2015; Di Rocco & Zeyer, 2013).

A communications oriented teacher education can easily be developed and introduced. However, even the doctor’s or nurse’s office could be understood as an educational institution (Zeyer 2015), which would greatly help promote a positive attitude towards science and medicine, in general, and vaccination, in particular.

COMPETENCES ASSESSMENT CRITERIA IN HEALTH.

THE CASE OF HYGIENE

Valentín Gavidia, Olga Mayoral, Marta Talavera and Cristina Sendra
Dpt. Didáctica CC. Experimentales y Sociales. Universitat de València, Valencia, Spain

The integration of basic competences into the school curriculum allows emphasizing the learning that is considered essential and must have been developed at the end of compulsory education. Harlen (2010) wonders what scientific education is relevant in today's world. The author considers that it must be the one that allows making decisions that affect the health and the personal and collective well-being, the environment and the use of energy. Health is one of the important scientific topics to be developed in the school, which requires not only the learning of theoretical concepts, but also the development of behaviours that determine lifestyles. Among the various areas of health, in the present study we will focus on hygiene. On many occasions, we consider health as something completely individual, and hygiene is a good example of it: personal cleanliness, clothing, vaccines, etc. We often forget two essential aspects: giving the necessary importance to the environment where we live because it affects our own health, and the importance of our actions in the transformation of the environment. In fact, the idea of promoting the improvement of the environment in which we live implies a social vision of health, necessary to transform our environment into something healthy, that impacts positively on ourselves. Attending to this triple vision in education is not easy, nor is it easy to evaluate educational resources and highlight student learning. The present work focuses on establishing criteria to carry out this evaluation.

Keywords: health education, hygiene, competences

INTRODUCTION

There is a growing sensitivity towards the development of certain competences that go beyond the simple acquisition of knowledge. This is reflected in particular with health problems. The key competences of the school curriculum that appear in the current Organic Law for the Improvement of Educational Quality (LOMCE, 2015) make it possible to put emphasis on learning that is considered essential, with an integrative approach, oriented towards the application of acquired knowledge and that must have been developed at the end of compulsory education to achieve personal fulfilment, practice active citizenship, incorporate into adult life in a satisfactory manner and be able to develop lifelong learning throughout life.

The Organization for Economic Cooperation and Development (OECD, 2005) defines a competent person as one who has the knowledge, skills, attitudes and professional behaviour necessary to satisfactorily demonstrate the performance of a task, action or specific function in the labour sphere. In the educational field, competences overcome the traditional training in disciplinary knowledge to enter a more practical and functional training, which teaches what to do in different problematic contexts (Martínez and Echevarría, 2009). Competences make real the ability to mobilize resources to deal with existing and emerging situations and problems and, therefore, unpredictable and undefined.
The competences approach makes sense as an optimal solution to the challenges facing society that demand "mobilization of knowledge to solve problems autonomously, creatively and adapted to the context" (Manzanares, 2004), so that the differential features of competences in the educational world are: to constitute a complex and adaptive know-how to solve the problems that arise, which is not applied in a mechanical but reflective way, capable of adapting to a diversity of contexts and with an integrating character, encompassing knowledge, skills, emotions, values and attitudes. In short, all competences include knowledge, know-how and willingness to do in specific contexts and situations based on desired purposes (Delors, 1996, OECD, 2006, Pérez, 2007).

In the field of health, they present specificity: they are related to lifestyles and the ability to respond to problems or life situations from a personal and social dimension. Thus, in health competences we highlight the following characteristics: a) acquisition of personal capacities, b) development of abilities with a social facet, c) utility to face current challenges or health problems, d) prominence of the environment, e) relevance of the attitudinal aspect, or predisposition to act, and f) possibility of a consensus generalized evaluation, so that the competences achieved can be homologated.

Thus, we understand Competence in health as the capacity and determination to solve problems related to personal and collective health, using resources (skills, knowledge, experiences, behaviours, etc.) to solve them properly in a specific context.

In the field of Hygiene, attending Viñao (2010), competence is "the set of principles and practices aimed at preserving health, maintaining the body in good physical condition and preventing diseases". We often associate certain behaviours such as washing hands or brushing teeth with hygiene, but hygiene is related to many other problems that are important to know for prevention: tuberculosis, pneumonia, influenza, measles, chickenpox, parasitism, caries, sexually transmitted infections, intoxications, body posture problems, allergies and even cancer, some of whose types can be prevented by certain behaviours.

The problems that arise are the following: a) If hygiene competence is the capacity to solve problems related to it, what problems are involved? b) What do these hygiene competences consist of? and c) if the competences can be evaluated, what criteria should we use for this?

Teachers, in their educational labour, generate activities and apply resources, use textbooks, etc., whose effectiveness needs to be evaluate in order to know if they have been useful in the development of defined competences. But what criteria should we use when analysing educational resources? Moreover, as actions programmed by teachers have been directed towards the students, how can we find out if the latter have acquired the required hygiene competences?

The objective of this paper is to present criteria that are useful for evaluating educational resources, questionnaires, textbooks, etc. in relation to the achievement of competences in hygiene. At the same time, and considering that there are different levels of development of these competences, we intend that these criteria allow us to verify the different levels of acquisition of competences.
METHOD

The COMSAL research group, made up of 16 teachers from different Spanish Universities from different areas of knowledge and other Primary and Secondary Education teachers, has followed the following steps at work:

Phase 1.- Identification of the main hygiene problems recognized by health agencies and that students must know. To this end, a review of the literature was carried out, taking into account the recommendations and proposals made by international, national and regional governments on priority hygiene issues in order to select the most relevant.

Phase 2.- The research group defined a general competence in hygiene and proposed the three basic components that make it up: *Knowledge* (conceptual content), *Knowing how to do* (procedural content) and *Knowing how to be* (attitudinal and/or behavioural content). The results were contrasted by all team members until an agreement was reached.

Phase 3.- Content specification: concepts, procedures and attitudes that have to be acquired to be able to act on each hygiene problem. This specification of content, together with the definition of competence, was carried out with a Delphi methodology of 102 participants, and a face-to-face meeting of 42 experts, following the guidelines indicated by Yañez and Cuadra (2008), and Varela, Díaz and García (2012).

The selection of the participants in the Delphi study was made considering the professional activity, academic training and region of origin, preparing a heterogeneous panel of experts, trying to collect a wide diversity of opinions. The questionnaire was sent to the selected participants and they were asked to rate each item according to a Likert-type scale (1 = strongly disagree and 5 = strongly agree). For the selection of the items, the average assessment obtained as well as the standard deviation were taken into account, since this indicated the degree of consensus.

Phase 4.- Elaboration of the evaluation instrument of the hygiene competences. Taking into account the five levels of health established by Gavidia (1998), a consensus was reached in relation to what actions infer the acquisition of each level of health. Next they pointed out what they should *know*, *know how to do* and *know how to be* considered necessary to be able to carry out such actions. All this constitutes the instrument of analysis that, as a rubric, can be used to analyse texts or opinions on situations or various hygiene problems or situations.

RESULTS

Phase 1.- Identification of the main hygiene problems. As a result of the literature review related to this topic, the problematic situations to attend in compulsory education were specified (Table 1).

Phase 2.- Definition of the competence in hygiene and of the three components that comprise it: *Knowing*, *knowing how to do* and *knowing how to be*. The results, contrasted by all the members of the team, are shown in Table 2.

Phase 3.- Specification of contents, procedures and attitudes to be acquired in order to be able to act on each hygiene problem, obtained by the participation of 102 experts through a Delphi methodology, and of a face-
to-face meeting of 42 teachers and health professionals. The aforementioned contents necessary for the development of this competence in its three dimensions would exceed the purpose and permitted extent of this communication and can be found in Gavidia (2017).

Phase 4.- The instrument for the evaluation of competences is summarized in Table 3. It specifies actions that represent five different levels of competence, as well as the necessary contents in order to perform these actions.

DISCUSSION AND CONCLUSIONS

It is important to know the hygiene competences acquired by students when finishing compulsory studies, but also to evaluate the proposals made by the official curricula, and the textbooks that develop them. This is achieved through the use of appropriate instruments, questionnaires, rubrics, etc., which are elaborated and analysed through previously established criteria. If we want the competences to be generalizable, the analysis criteria must also be generalized, so they must have the maximum consensus.

It is necessary to establish standards that allow the evaluation of the achievement of competences in the different levels of health. The results presented in Table 3, developed and accepted by a good number of education and health professionals, allow us to elaborate questions of different complexity on this subject. This allows on the one hand to know the students’ way of approaching the various hygiene problems, most of which are commonplace and, on the other hand, to analyse the topics covered by the textbooks and educational resources and to know at what level they do it.

Contd.
### N-5. Personal and social development

| -Intervention on the environment to avoid the transmission of diseases and to improve the environmental conditions. |
| Measures of public health that allow to reduce the transmission of infectious diseases. |
| To maintain a healthy environment (family, school and society). |
| Collaborate in the creation and maintenance of healthy environments. |
| Develop behaviours that prevent the transmission of infectious diseases. |
| Commitment to the wholesomeness of the environment. |
| Sensitivity and solidarity towards people suffering from chronic infectious diseases and diseases of special incidence in the most socioeconomically disadvantaged countries. |
| Value public health measures. |

These evaluation criteria have been staggered into five levels. While the first levels, informative and preventive, are a declaration of intentions with little commitment, the higher levels entail an attention to the environment and a more solidary view of personal actions towards all the people with whom we live and all the elements that constitute the environment, understanding that we are part of it.

Gallego (2013) emphasizes three dimensions of health: personal, relational and environmental and makes them correspond to self-care, social adaptation and attention to the environment, applicable to any field, in our case hygiene. However, the five levels presented here correspond to five ways of working health in the School, applied to hygiene, in which each of them incorporates new variables to the previous one, so that they are increasingly more complex and complete, developing the last level a vision of Health Promotion and Salutogenesis in the School in the direction marked Antovovsky (1979) and Lindström and Eriksson (2005). The three dimensions presented by Pisa to assess competences (know the problem, know what to do, and show ability to express opinion or predisposition to action), correspond to the three dimensions necessary to adequately perform a health action corresponding to a certain level.

The elaboration of questionnaires and analysis tools according to these criteria facilitates their correction and establishes the degree of competence acquired by the respondent or by the element that is analysed.

In a previous study of textbook analysis to verify the usefulness of the present hygiene evaluation table, the following problems were detected: a) Reductionist vision: hygiene is understood as something personal, and it focuses on washing issues, oral hygiene and use of appropriate clothing. b) Little attention is paid to the postural hygiene, sleep care, care to be taken with domestic animals and prevention of cancer. c) Hygiene is mainly worked in primary education and is abandoned in secondary school. d) It does not present the socio-environmental dimension of hygiene, as if the environment did not intervene in its consideration.

EXPLORING AT-HOME LEARNING OF DIVERSE FAMILIES:
FACTORS IMPACTING INTENDED CLIMATE CHANGE
BEHAVIORS

Kristie S. Gutierrez¹ and Margaret R. Blanchard²

¹Old Dominion University, Norfolk, VA, USA
²North Carolina State University, Raleigh, NC, USA

This dissertation study examines factors related to the intended climate change behaviors in diverse, middle school students and their families in rural southeastern United States. Afterschool STEM Club students and their families utilized their homes as informal learning environments. Families discussed local and global climate change issues while viewing video documentaries and during interviews at their school sites. Using the Determinants of Behavior model of climate change, audio data was coded to examine family discussions. This population most often talked about climate change knowledge, behaviors, and the seriousness of the problem. However, perhaps due to participants’ novelty of the topic of climate change, most families were not ready to take action or change behaviors, rather, appraise the situation and respond to what they learned. This study also showed that families in rural, high poverty communities were eager to learn with and from their children, dispelling myths of lack of family involvement or interest.

Keywords: climate change, environmental education, family-school partnership

INTRODUCTION

Family interactions between students and their parents/extended family are important (LaRocque, Kleiman, & Darling, 2011). Recent evidence indicates that there is a bi-directional exchange of knowledge, values, and beliefs between parent and child (Damerell, Howe, & Milner-Gulland, 2013), not the uni-directional flow from parent to child that was traditionally held (Damerell et al., 2013; Knafo & Galansky, 2008). These findings reinforce the importance of family oriented, at-home educational activities that engage children and parents in shared activities. Climate change is one topic about which adults and students frequently hold differing beliefs and content knowledge (Leiserowitz et al., 2011).

In their study of 6th graders, Visintainer and Linn (2015) found that one of the top sources students claimed to find evidence about climate change included parents/relatives, along with science class and the media. Parents may directly express climate change knowledge (both accurate scientific information and misconceptions) or indirectly transmit other values such as worldviews and risk perceptions to their children (Mead et al., 2012). Using a risk perception attitude framework, Mead et al. (2012) found that parents’ membership in risk categories (indifference, proactive, avoidance, and responsive) was strongly associated with their children’s’ membership in the same category. Children who were categorized into either the responsive or avoidance groups sought out a greater amount of information about climate change than those who were found to be indifferent or proactive.
The theoretical framework for this study, the Determinants of Behavior (DOB) Model of Climate Change (shown in Figure 1), was developed by Patchen (2010), based on other behavior models (Ajzen, 1991; Scherer, 1999) and includes key influences on behaviors related to climate change.

This dissertation study employed an at-home climate change intervention with families of students in an after-school STEM club to examine how constructs that influence environmental behaviors (e.g., social factors, individuals’ characteristics, perceived importance of the problem, individuals responsible for change; Patchen, 2010) are discussed in participant family homes and in interviews with rural middle school students and their parents/guardians. The research questions explored for rural middle school students and their parents/guardians in the southeastern US are: (1) What underlying factors from the Determinants of Behavior (DOB) model of climate change are most often addressed by families while participating in an at-home climate change intervention? (2) How do parents and their children talk about climate change during the at-home intervention and in interviews?

**METHODS**

Middle school students in STEM after-school clubs in four rural, high poverty school districts in the southeastern United States engaged in three, two-hour climate change activities (during after-school clubs) that were linked to their local communities (e.g., local solar farms, agriculture, health) and related careers. The intervention activities included collaborative discussion with peers, laboratory activities, and interactions with climate related professionals to help students distinguish between weather and climate, the role of carbon dioxide and carbon footprints, and alternative energy options. Additionally, all parents were invited to participate in a school-site meeting led by the researcher, to help parents learn more about climate change and to engage in a climate related carbon footprint intervention activity, and to watch two climate change
documentaries in their homes and respond to questions with their children as they watched. This study examines qualitative data of a randomly selected subset of family members (n = 41) from 15 families who were invited to participate in climate change activities and discussions. The families who participated in the at-home intervention responded to the researcher-provided questions aloud while audio recording their conversations that occurred prior to, during, and following the documentary videos. Interview data was collected from twelve randomly selected families who did and did not participate in the at-home intervention.

**Context/Participants**

The ethnicity of parents and students who participated in the at-home intervention or researcher interviews included 55.9% African American, 29.4% Caucasian, 5.8% Native American, and 8.8% two or more races. These percentages were similar to the ethnicity averages in the four schools. The gender distribution of students participating in the at-home interventions and interviews was 43.5% male and 56.5% female and for parents it was 18.2% male and 81.8% female. Of the participating students in at-home interventions or interviews, the majority, 56.5%, were in 6th grade, followed by 30.4% (7th grade), 8.7% (8th grade), and 4.3% (5th grade); only one school had a 5th grade. Similarly, the 6th grade whole club representation was also high at 47.7%, followed by 7th (27.6%), and 8th (17.5%). The average percentage of free and reduced student lunches in the four participating school districts was 84.8%, indicating that the poverty level of students in these schools was substantially higher than the state average (56%).

**At-Home Materials**

Fifteen at-home intervention kits, including two DVD documentaries, Season 1/Episode 1 of Showtime’s *Years of Living Dangerously: The Dry Season* and local news documentary, *Exploring Climate Change*, a digital audio recorder, instructions and questions printouts, and microwave popcorn and individual sodas, were packaged. These materials were rotated through randomly chosen families who had agreed to participate in their homes at each of the four schools. Additionally, interviews were arranged with randomly selected families who had not done the intervention and those who had.

**STEM Club Intervention**

Students also participated in researcher-designed climate change interventions designed for three, two-hour after-school STEM Career Clubs, funded through an NSF-ITEST grant. The intervention activities included collaborative discussion with peers, laboratory activities, and interactions with climate related professionals to help students distinguish between weather and climate, the role of carbon dioxide and carbon footprints, and alternative energy options. Parents who attended the climate change focused STEM Club Parent Meeting also received an intervention. The researcher shared an hour presentation and interactive carbon footprint activity about climate change basics, including current and future health and economic implications of climate change in their local environments.

**Data Sources**

At-home intervention and interview questions were designed with the DOB model in mind, based on work by Ebi and Semenza (2008) and Semenza, Ploubidis, and George (2011). Questions addressed climate change beliefs, climate change concerns, levels of participation in the interventions, perceived changes in content knowledge and/or behaviors, and barriers to change. The audio responses from the at-home intervention and
semi-structured family interviews were coded into a priori categories outlined by the constructs and sub-constructs within the DOB framework using ATLAS.ti 6.

RESULTS

Research Question 1: Underlying factors addressed by families

Audio analyzed from both the at-home interventions and researcher interviews were coded into each of the main constructs of the DOB model. Participants most often talked about climate change Knowledge (Construct II, 26.1%), followed by Behaviors (Construct VI, 11.5%), the Seriousness of the Problem (Construct III, 10.6%) and Media (Construct I, 9.0%).

Research Question 2: How parents and their children talk about climate change

Analyses of audio from both the at-home intervention and interviews targeted constructs in the DOB framework from Figure 1. Social Influences, the impact of local and international actors or politicians, was often noted by participants, and the lack of access to materials, cost, and lack of communication was often mentioned related to climate change issues. Parents spoke about their desire to stay informed in order to help guide their children. Families discussed the normalcy of excessive energy and technology usage in their lives. Personal Characteristics were identified through various types of knowledge, most of which was at the definitional or descriptive levels. Stewardship of the environment for their family’s future was often addressed. Families mentioned elements of religious, familial, geographic, and age identities. Participants’ responses coded as Appraisals of Situation indicated that the more proximal a climate change impact was for families in the study, the more serious the problem was perceived. Solutions were at the individual levels and often
included one of the following: technological solutions, changing lifestyles, or support for public policies. Most often, families were community/familial minded and few families talked about international/national action. Conversational segments coded as **Willingness to Act** focused heavily on the financial benefits and costs for families in the study, followed by impacts on their health and lives. Emotions were expressed during the home-based activity through sounds or utterances (oh my!) and participants expressing sadness about the sickness and death of children and animals, loss of jobs, and dire thoughts of the future featured in the videos they watched. Parents were more skeptical than their children of their ability to help mitigate climate change. Families talked about how technological advances, ease of food production and distribution, and energy and transportation usage in the United States has become second-nature and more of a Habit. **Behaviors** were coded as “Can Do Behaviors,” “Currently Do Behaviors,” and “Intend to Do Behaviors.” Additionally, Table 1 provides sample qualitative data from participants for each of the sub-constructs in the DOB framework.

<td><strong>I. Social Influences</strong></td>
<td></td>
</tr>
<tr>
<td>Media</td>
<td>Deborah (African American Mother): Right, I’ve seen him in movies before.</td>
</tr>
<tr>
<td></td>
<td>[Interviewer: Iron Man?] Yea. Mmm. It opens your - when you see them, it almost kind of makes you – [Think…] OK, wait a minute, let me listen. …And what make[s] it-when you see a familiar face, you know?</td>
</tr>
<tr>
<td>Barriers and Options</td>
<td>Rita (African American Mother): Me, on the other hand, if I could change anything and if I was able to, it’s how we’ve got to have cars that use gas and stuff for transportation, try to do less transportation but right now we can’t because we’re working.</td>
</tr>
<tr>
<td>Stimuli for Action</td>
<td>Joseph (African American 6th Grade Student): [I] really want to do something about it [climate change]. [It is] getting to the point around the world that I don’t even know, carrying guns in order to go—have to be scared for their life because people want to burn trees in order to make money.</td>
</tr>
<tr>
<td>Social Norms</td>
<td>Audrey (African American Mother): I think we could probably be more energy efficient as an office. But…social norms are that you have to have that fax, and copier, and printer as opposed to having a one unit. You know, so, I think sometimes you have that mindset, and then you go into a place, an established place, and they’re not in agreeance with what you want and what your ideals are. So, you have to kind of make concessions and say, “Oh, well, I still need my job, so I have to deal with all of this.”</td>
</tr>
<tr>
<td><strong>II. Personal Characteristics</strong></td>
<td></td>
</tr>
<tr>
<td>Knowledge</td>
<td>Melissa (Caucasian Mother): Do you know what climate change is? I mean, do you know anything about climate change? It’s like due to the use of human - human use of fossil fuels. It releases carbon dioxide and gases into the air. I think it affects the sea levels, the eco-systems. Causes severe weather and droughts.</td>
</tr>
<tr>
<td>Values</td>
<td>Sarah (Caucasian Mother): You know, it’s their [kids’] future. So, I think getting them involved, even at their age now, would help teach them a responsibility and also, you know, of cleaning up our environment. And if they actually see what comes out of it, they might be more proud and more apt to start doing things themselves to help.</td>
</tr>
<tr>
<td>Identity</td>
<td>Melissa (Caucasian Mother): But what’s one way that we know that talks about the weather patterns changing and stuff? Shannon (Caucasian Daughter): The Bible. Melissa: That’s right. And as a Christian, we trust the Bible, right?... I think we do need to pray for rain and change.</td>
</tr>

III. Appraisals of Situation

<table>
<thead>
<tr>
<th>Subcategory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Seriousness of Problem</td>
<td>Audrey (African American Mother): Well I think that - look at what’s going on California [the drought] - that it’s not going to be - we’re not too far off, here in America. So understanding what’s happening there [in Syria] is not something that’s just going to stay there. I think that if we don’t do something then it could translate to here, where we’re fighting for resources as well. Right? […] And I think that ultimately if we don’t do something then that could be us. We could be engaged in a long war over a natural resource [water] that we helped diminish.</td>
</tr>
<tr>
<td>Possible Solutions</td>
<td>Shana (African American 6th Grade Female Student): Well when I grow up, I’m going to try to move and get kind of - get a house close to Wal-Mart© so then we can walk across the street and buy food so we won’t have to waste any gas or anything. So we won’t pollute the air as much.</td>
</tr>
<tr>
<td>Who Should Act</td>
<td>Elsie (Caucasian Grandmother): It’s global. - the whole world’s got to listen and just pay [attention]. Like everybody could use their contribution. Like the politicians, if they would listen more to the religious leaders and especially the scientists, if the scientists would listen to the religious leaders, they could then touch the people because the people want to follow the religious leaders more.</td>
</tr>
<tr>
<td>Benefits and Costs of Actions</td>
<td>Shana (African American 6th Grade Female Student): In the summer we sometimes walk to the store because it’s right across from us. And if we think about just riding around, we don’t use the car - the van. We just ride our bikes. And that gives us energy - I mean - and we start out with energy, I mean that gives us less energy.</td>
</tr>
<tr>
<td>Emotions</td>
<td>Janelle (African American Mother responding to the documentary): Well, what I thought was very interesting was that climate change was affecting people and they were losing their jobs. I think that was very interesting and sad. And that the climate change is that deep … once they lose their jobs, it’s a domino effect. They lose the house and everything else. So that was a very sad situation.</td>
</tr>
<tr>
<td>Efficacy of Actions</td>
<td>Deborah (African American Mother): [in response to an interview question] Yeah. So I mean, you know, me as one person there is really nothing that I can - I mean, unless we start making it [climate change] aware to some people. You know? I might be here in a room with fifteen people and somebody might be on a committee that could do something that I may not know about and I’m bringing it to their attention. I mean, maybe that’s how - but other than that, I don’t know.</td>
</tr>
<tr>
<td>V. Habit</td>
<td>Sharron (African American Mother): Well this is one thing. I use my dryer a lot and I know that emits something through that pipe that goes outside. My mother, she’s not using her dryer as much. She hangs her clothes the old-fashioned way on the wire. But I use my dryer all the time.</td>
</tr>
<tr>
<td>VI. Behavior</td>
<td>[Jackie, a Caucasian Mother of 8, shares what she learned from doing the carbon footprinting activity in the STEM Club parent meeting where she learned how many Earths it would take to support human life if everyone on Earth lived like her]: I can say, for me, since we’ve been in the STEM program, I turn the water off when I brush my teeth. I try to take smaller showers. You’re just more aware of everything because our last [parent] meeting we had to write down how many Earths it would take for one person, and it was pretty high. I think that if one person can make a change, then everybody will follow eventually, hopefully.</td>
</tr>
</tbody>
</table>
DISCUSSION AND CONCLUSIONS

Families were often becoming aware, for the first time, about climate change and how it connected to their lives. As a result of coding qualitative audio data into the Determinants of Behavior (DOB) model of climate change framework, parents and students were found to most frequently discuss information related to climate change, followed by the seriousness of the problem. Therefore, they were not at a point of taking action or changing behaviors, but appraising the situation and having some emotional responses to what they had learned. However, when families were asked if they thought that their individual actions could make a difference in climate change, it was clear that middle school students in this study believed they could make a difference even at an individual level. Yet, parents were more skeptical about their ability to be impactful and frequently noted that they would need to amass a collective effort to begin making a dent in climate change.

Parents in this study expressed a desire to become more involved with their child(ren)’s school experiences through this opportunity for after-school, at-home enrichment. This resonates with findings by Stacer and Perrucci (2013), in which parents felt more positively connected to their child’s school and felt a desire by the school for their involvement when they were more involved in the school. By having the intervention, it conveyed an interest on the part of the school to engage parents in a school related activity, connected to the STEM clubs. This demonstrates that this sort of intervention provided an invitation to parents that was positively received, corresponding to the findings of Stacer & Perrucci (2013). In this study, parents were highly interested in becoming involved in educational activities with their child(ren). Some parents indicated that they want to be able to stay abreast of what their student was learning in school so that they could be more involved in their child(ren)’s education. Other parents expressed their desire to learn more about climate change and become better informed. Thus, in future work with K-12 students, through both traditional classroom and out-of-school-time organizations, we recommend that schools provide frequent invitations and opportunities for parents to learn along with their child(ren) and that researchers further study this learning. It also suggests that initial steps may lay the groundwork for making strides on climate change action in a rural, high poverty community, especially when there are clear connections to the participants’ lives.

ACKNOWLEDGEMENT

The authors would like to thank the STEM Career Club teachers, and students and their families, for their participation. We would also like to thank the STEM Career Club university team members at NC State University from the College of Sciences and the College of Education. STUDENTS’ CONCEPT OF RELEVANCE OF BIODIVERSITY CONSERVATION AND EVERYDAY ACTION

Shiho Miyake¹, Shizuka Kobayashi², Mizuho Otsuka² and Mayuka Nakamura²

¹School of Human Sciences, Kobe College, Nishinomiya, Japan
²Department of Biosphere Sciences, School of Human Sciences, Kobe College, Nishinomiya, Japan

This research examines young people’s awareness of the relationship between their everyday actions and biodiversity conservation. Recently, ecological citizenship, which focuses on the relationship between citizens’ environmental actions and their social values, has come to be viewed as key to defending the sustainability of the future environment. In Japan, the Ministry of Environment proposed ‘My Action Declaration in Five Actions’ as a tool to improve people’s awareness of biodiversity conservation: ‘Act 1: Eat’, ‘Act 2: Feel’, ‘Act 3: Show’, ‘Act 4: Conserve’ and ‘Act 5: Select’. The authors performed an empirical study of university students to examine two issues: 1) Which actions are viewed by students as being relevant to biodiversity conservation? and 2) What elements allow students to link their own actions with biodiversity conservation? As a result of the study, some characteristics were elucidated on the relevance between their everyday actions and biodiversity conservation. The first significant finding illustrates that the connection between everyday actions and conservation is more apparent to students in relation to the ‘Show (or express)’ and ‘Select (products)’ acts than in relation to the others. In general, students find conservation difficult to incorporate into their everyday actions. This is probably due to the fact that they consider it essential to gain information in advance prior to participating in conservation events. Thus, conservation is not a casual process and involves many barriers to enabling the young generation to act. The second point is that students easily connect seasonal issues and items with actions which biodiversity conservation requires. Finally, the concept of eco-friendliness is key to revealing the relationship between everyday actions and biodiversity conservation among students.

Keywords: university students, biodiversity conservation awareness, My Action Declaration

INTRODUCTION: THE RISE OF BIODIVERSITY CONSERVATION PROMOTION

Biodiversity conservation is a global challenge requiring the transformation of people’s awareness into action for a sustainable environment. Nowadays, three dimensions are generally found to be significant in the discussion of biodiversity: genetics, species, and ecosystem diversity. One example definition is given by the United Nations Environment Programme [UNEP] report as follows (Benn, 2010).

a. Genetic diversity is all the different genes contained in all the living species, including individual plants, animals, fungi, and microorganisms.

b. Species diversity is all the different species, as well as the differences within and between different species.

c. Ecosystem diversity is all the different habitats, biological communities and ecological processes, as well as variation within individual ecosystems.
These dimensions clarify the elements that must be considered in pursuing sustainable environmental practices, whether by scientists and practitioners, government and industry, or citizens.

In the field of science education research, biodiversity conservation is also discussed as a framework that can foster scientific literacy in relation to society and provide students with benefits in terms of knowledge and acquisition of values regarding ‘how we should live sustainability’ from both scientific and non-scientific perspectives (e.g. Lindemann-Matthies et al., 2011).

However, it is hard to say to what degree the concept of biodiversity conservation has been spreading among the public. According to a Japanese public-opinion survey on environmental issues, the younger generation—individuals in their twenties—displayed less interest in the natural environment and biodiversity conservation compared with older generations (Cabinet Office, 2014). One reason may be that events for promoting conservation awareness have been aimed at children. For example, a day-long event organised by the Biodiversity Center of Japan in August 2017, including paper crafts and a specimen collection storage tour for a ‘biodiversity festival’ was targeted mainly for children and parents (Ministry of the Environment, 2017). In contrast, there are few reports of general interest conservation activities for young people in their 20s. Information on the status of conservation conception and attitudes in this group will help inform the development of such activities.

**RESEARCH FOCUS**

This research designs and evaluates an activity for the development of biodiversity conservation awareness, meant specifically to establish how the younger generation, in their twenties, view the relationship between their everyday actions and biodiversity conservation, focusing on the Japanese context.

We carried out practical research using ‘My Action Declaration’ (Table 1). This tool improves citizen consciousness of conservation and elicits an individual declaration to commit to conservation practices. It was originally proposed by the Japan Committee for United Nations Decade on Biodiversity (UNDB-J) in 2012 (United Nations Decade of Biodiversity & Japan Committee for UNDB, 2015). Since then, several sectors, including business enterprises, local government, NPOs/NGOs, and entertainers and celebrities, have played a role in spreading the campaign (e.g. Canon, Inc., n.d.; City of Izumo, 2013). While several reports on ‘My Action Declaration’ events have been made, there are no noteworthy findings on how participants linked their actions to biodiversity conservation.

Even fundamental questions like the following two, which we take up here, have not been answered.

1. Which actions are relevant for students?
2. What types of actions allow students to link their own actions with biodiversity conservation?

These two questions are the focus of this research.

**RATIONALE**

As mentioned above, while promotion of the concept of biodiversity conservation for people is significantly important, it is still underway. Since biodiversity conservation is defined in diverse ways, there is little certainty about how to provide the most effective possible activities and programmes, especially for young people in their 20s. To solve this problem, this research designed and implemented an activity for university students in which they took photographs of their everyday life activities and then scored the images for degree of relevance to biodiversity conservation.

**Focusing on relationships to everyday action**

Why is it important to focus on everyday action? Aikenhead (2006) and Cobern (2000) clarified this in terms of understanding how people gain scientific literacy. According to Aikenhead (2006), for the public people including students, scientific literacy serves as a pathway for better decision-making.

‘The wise use of knowledge, scientific or otherwise, enables people to assume social responsibilities expected of attentive citizens or key decision makers employed in public service, business, and industry. Thus decision making is often central to a humanistic science curriculum, and it serves as a vehicle to transport students into their everyday world of need-to-know science, functional science, enticed-to-know science, have-cause-to-know science, personal-curiosity science, and science-as-culture’ (p.97).

Cobern (2000) pointed out that the relevance between science and everyday life help people to interpret a process of how they acquire scientific literacy.

‘My position is that scientific literacy can be developed from a number of different perspectives on Nature–only one of which is the rather narrow perspective of typical school science curricula–and for that to happen in science education there needs to be an increased appraisal of the knowledge and values brought to the science classroom from other domains… I use the term “everyday” to indicate that what I am trying to get at are the typical, the natural thoughts of the people with whom I am conversing’ (p.17).
In summary, focusing on people’s everyday-life action is important to understand how decision-making ability and scientific literacy are developed in individuals and communities.

Furthermore, students’ attitude and behaviour toward biodiversity or socio-scientific issues are also highlighted as research targets to explore environmental education and science education approaches (e.g., Nisiforou & Charalambides, 2012; Sadler, Chambers & Zeidler, 2004). Recently, ecological citizenship, which focuses on the relationship between citizens’ environmental actions and their social values, has come to be seen as a key framework for fostering a sustainable environment in the future (Dobson, 2003). Overall, the research suggests that knowledge accumulation is necessary to develop and evaluate education tools and programmes assessing how people behave in their everyday actions as ecological citizens.

Utilization of a SNS-based tool (photo submission) familiar to young people: Photo-sharing

What kind of tool is familiar to the young people in their 20s? Several educational programs utilising ICT tools have been reported to date. In particular, in recent years, the way to use of social networking services (SNSs), especially via smartphone, has been introduced (e.g. Kim & Kim, 2013; Watermeyer, 2010). In Japan, 97.4% of first-year university students have their own smartphones (Mynavi Corporation, 2016), making their use convenient and promising. These facts suggest that using smartphones and photo-sharing are familiar tools among young people.

PROCEDURE

This study examined what kind of actions university students found to be related to biodiversity conservation, who were enrolled in an environmental sociology course. The ‘My Action Declaration’ activity was included as a part of the course. Students took a maximum of five photographs each week to record the five actions in ‘My Action Declaration’ over the course of three weeks from October to November 2016. For each photograph, the candidates awarded points on a scale from 1 (weakest relevance) to 5 (strongest relevance) to show how the photo related to each action (from Act 1 to Act 5). The date, place, and reason behind why the photo was taken were also noted as comments; the reasons suggested how the students perceived the relationship between everyday actions and biodiversity conservation. The photographs and comments were collected via ‘30days Album’, a free application that allows sharing among group members (Figure 1).

The collected data (photographs and comments) were explored from two perspectives related to the two research questions:

1. Which actions are relevant for students?
2. What types of actions allow students to link their own actions with biodiversity conservation?
RESULTS

Example photographs and their relationships with biodiversity conservation as expressed by the students

The total number of students was 98, and 449 photographs were collected from them over three weeks. Some examples of the photographs and comments on how, in the students’ perspectives, they relate to biodiversity conservation for ‘My Action Declaration’ are shown in Figure 2.

Act 4 Conserve

4-a. I participated in a museum volunteer group and found various mushrooms. There is a rich environment for mushrooms.

4-b. In order to recycle, my parent use a recycle box to collect cans.

4-c. To reduce the environmental burden at the campus festival, how to recycle food trays and dishes was explained.

Act 5 Select

5-a. I found a print on the can of coconut oil that showed this product was organic certificated.

5-b. There was an eco-mark in the detergent box. Since rinsing can be done only once, water can be saved.

5-c. I bought sesame with the organic JAS mark. This proves a food item of using organic compost without using pesticides and chemical fertilizers.

Figure 2. Example photos and comments for ‘My Action Declaration’.

Which actions are relevant for students?

Figure 3 shows the score distribution results for each action in ‘My Action Declaration’. Results indicate that Act 5 (Select) and Act 3 (Show) in particular may help students discover a strong relation between everyday actions and biodiversity conservation, as their number of five-point scores and average score were higher than for the other three actions.

Figure 3. Score distribution

In contrast, for Act 4 (Conserve), only 21 photographs acquired five points, for the lowest average score, 1.6, among the five actions. One reason why Act 4 scored so low may be attributable to a student’s remark that
there was no time and no opportunity to participate in conservation events during the three-week period. That is, this action was quite difficult to explore due to the short timeframe.

Act 1 (Eat) and Act 2 (Feel) seem to have had a middle level of relevance to the photographs among the five actions, with average scores around 2. It appears that students did not have a clear idea of how to link their photographs to biodiversity conservation via these ideas.

**What aspects allow students to link their own actions with biodiversity conservation?**

The frequency of appearance of different terms in photograph comments was extracted through a text-mining procedure. The top five most frequent nouns and verbs are shown in Table 2.

For Act 1 (Eat), ‘local’, ‘neighbourhood’, and ‘Hyogo Prefecture’ where the university located were extracted; ‘vegetables’ and ‘harvested’ were also used, indicating an interest in local supply and consumption.

For Act 2 (Feel), the terms ‘autumn leaves’, ‘Japanese pampas grass’, ‘cosmos’, and ‘blooming of the plant’ were conspicuous. Some terms in Act 3 (Show), such as ‘maple leaves’, ‘bloom’, ‘beauty’, and ‘feel’, were similar to those in Act 2. This suggests that students focused on seasonal plants.

Several terms related to conservation were shared between Act 4 and Act 5, such as ‘environment’, ‘eco’, ‘eco-mark’, and ‘use (eco-friendly products)’. There were, however, differences in this regard between Act 4 and Act 5. For example, the terms ‘participation’ and ‘campus festival’ used in Act 4 indicate personal motivation to engage in conservation activity, while the terms ‘buy’ and ‘refill’ used in Act 5 related to the behaviour of consumers.

1218
CONCLUSION

The impact of ‘My action declaration’ activity: What is the relevance of biodiversity and everyday actions for the students?

By the end of the three weeks of ‘My Action Declaration’ activities, students’ awareness of the relevance of their everyday actions in relation to biodiversity conservation seemed to have increased.

First, the results indicate that selecting or showing something more closely captured the connection between biodiversity conservation and students’ everyday activities, in their view, than eating, feeling or conserving. In particular, conservation is difficult to connect into students’ everyday actions, probably because they believe it necessary to obtain information in advance prior to participating in conservation events. Thus, teaching conservation is not an easy task and barriers exist to incorporating it into everyday life among younger generations.

However, seasons and seasonal items were easily connected to biodiversity conservation tasks by the students. Further, eco-friendly consumer activity is key to students’ comprehension of the relationship between everyday actions and biodiversity conservation.

These issues may point to lenses through which young people may view biodiversity conservation and their related choices and behavior. In future research, we intend to create and enhance educational programmes and development tools to more effectively promote ecological and environmental awareness among young citizens.

Implication for biodiversity conservation education

According to Kassas (2002), the meaning of biodiversity conservation varies depending on the position of the person or people defining it.

‘For policymakers, biodiversity is indicative and its degradation (loss of species) indicates degradation of the environment (human habitat). For advocacy groups, attention is given to particular plants or animals of concern. For scientists, the word may mean different things to agronomists, foresters, taxonomists, geneticists, bio-geographers, ecologists, etc. Biodiversity education needs to embrace all these meanings’ (p.347).

This may indicate that promoting awareness of biodiversity conservation in the public will not be so easy.

However, it was found that thinking about the relationship between the five elements of ‘My Action Declaration’ and one’s everyday actions helped people nurture a positive attitude toward conserving resources and to fostered environmentally friendly behaviours. It is desirable to develop ways to further disseminate knowledge related to biodiversity conservation to citizens in the future.

SUSTAINABILITY AND PHYSICS EDUCATION

Vera Montalbano

Department of Physical Sciences, Earth and Environment, University of Siena, Siena, Italy

Sustainability plays a central role in present and future for human societies and it has become an unavoidable issue in the policy guidelines of organizations like the EU and the UN. Science education needs to face a future that includes and supports the study of sustainability. Physics education can contribute in introducing sustainability by showing how investigation of the physical world is a necessary step in finding sustainable solutions. On the other side, sustainability can convey the interest from everyday reality to scientific concepts, involving the students in new laboratory activities. Moreover, teachers can be engaged in professional development and in active applied physics educational research. Educational actions were designed to introduce the concept of sustainability through meaningful activities in physics education. Early experiences were reserved to small groups of motivated students and few teachers were involved in laboratory. A relevant outcome was the request of developing learning paths for integrating these issues into ordinary didactic in classroom. An interdisciplinary learning path involved all students of a small high school is reported. The next step was to organize a national summer school focused on developing learning paths on topics in science relevant for sustainability, such as energy, food production and pollution in an interdisciplinary approach.

Keywords: sustainability, active learning, physics laboratory

INTRODUCTION

Sustainability as a concept relevant for human society has its origin in the Brundtland Report of 1987 (WCED, 1987). That document was concerned with the tension between the aspirations of mankind towards a better life on the one hand and the limitations imposed by nature on the other hand (see Kuhlman & Farrington, 2010 for a brief and actual review).

In August 2012, UN Secretary-General Ban Ki-moon launched the Sustainable Development Solutions Network (SDSN) to foster a global network to mobilize academia, research institutes, civil society, and the private sector in pursuit of practical solutions for sustainable development. In 2015, 193 countries adopted the 2030 Agenda for Sustainable Development and its 17 Sustainable Development Goals (SDGs) (UN, 2015). In November 2016, the EU also adopted its own sustainable development package.

Sustainability issues, such as climate change, ecosystems degradation, food insecurity and inequalities, worsen during the last decades. In nature, when an animal population manages natural resources in an unsustainable way, the final outcome frequently leads to extinction. When a human society makes use of environmental resources in an unsustainable way, the main effect can be its collapse (Diamond, 2005). In a world seeking solutions to its energy, environmental, and food challenges (Tilman et al, 2009), education for sustainable solutions has become one of the most promising and emerging priorities (McMichael et al, 2007; Wals, 2012; UNESCO, 2014; UN, 2012). The goal of introducing sustainability by using a scientific sight should be a primary issue in education.

Moreover, motivation and interest may facilitate the learning process increasing student involvement both in laboratory and in class discussions. Theoretical and empirical studies on the relationship between interest,
motivation and learning process are widespread in educational research (Alderman, 2013). From the educational point of view, it is essential to understand how and why students are involved in new topics and such approaches are effective (Trumper, 2006).

Sustainability with its multiple social, scientific and educational implications (see Figure 1) is a particularly suitable topic for increasing students' motivation and promoting an active attitude both in learning and in the behaviour of everyday life.

Figure 1. Sustainability plays a central role in present and future for human societies. Science education needs to face a future that includes and supports the study of sustainability revealing its connections with everyday life, the possible future scenarios of the society in which we live, the elements of scientific literacy necessary to understand it, the need to understand and intervene in complex real-world systems in an interdisciplinary way and the role it can play in the development of scientific knowledge and its dissemination.

Another important aspect in introducing sustainability in education is the development of transversal skills related to the understanding of how knowledge is articulated on this topic (interdisciplinary or transdisciplinary studies), how it is communicated among the possible stakeholders (e.g. use of qualitative indicators as ecological footprints) and the adoption of appropriate transnational policies.

In order to explore if this topic can be useful and effective in physics and more in general in science education, the research questions were:

1. Can sustainability be a relevant issue in motivating student in learning process in physics?
2. Is it possible to design new learning paths in which sustainability issues are useful for clarifying some relevant disciplinary knots in physics education?
3. How to promote these learning paths in classroom practice?
With the aim to answer to the first research question, some educational activities were designed to introduce the concept of sustainability in context in which students from secondary school were oriented towards physics. These experiences are described in the following section. Further actions focused on fostering sustainability as a tool for a richer science education are reported in the next section. Finally, lights and shadows about the full process in classroom will be reported.

SUSTAINABILITY FOR ORIENTING TO SCIENCE

The interdisciplinary aspects and the links with everyday life make sustainability an excellent topic for introducing to the scientific investigation of the world around us.

In particular, a match of a competition between secondary schools, entitled *USiena-Game* and performed at the university on specific themes such as Stem cells, Sustainability or European citizenship, and two summer schools of physics for selected high school students were designed and performed in the last years.

*USiena Game: a local competition for student at the university*

Initially, some activities in which the scientific sight emerged in exploring problems of sustainability were designed and tested in the competition *USiena-Game*, where about a hundred of students (age 16-17) in two successive editions have studied the materials prepared for the match and answered a series of multiple choice questions on sustainability about energy, food and pollution issues. As a by-product, students were engaged in a deeper understanding of the meaning of numbers given in the context (Is is it a measure or an estimate? Or a simulation from previous measurement?).

In Figure 2, an example of educational material is shown. The answer to the question required to use skills and knowledge in physics for the estimate of energy in the involved processes but also in biology for the energy content of a tuna can and how the tuna fish is transformed in an industry.

![Figure 2](image2.png)

**Figure 2.** Example of multiple choice question on sustainability. On the left, it is shown a question about the energy employed for transforming tuna fish in a canned food ready to be consumed (How much energy is needed to get a tuna can?). The correct answer is showed on the right side, with a short explanation.
Physics for Sustainability in Summer Schools of Physics

Since 2006, about forty students from high school are selected every year to attend a full immersion summer school of physics in Siena countryside (the Pigelleto Natural Reserve or an historical small town, such as Pienza or Vivo d'Orcia). The students (age 16-17) are proposed within the National Plan for Science Degree by a network of schools in southern Tuscany. The focus of the summer school is always on physics laboratories, active and cooperative learning, peer communication (Montalbano & Mariotti, 2014). The 2014 edition, entitled Physics for sustainability. Science and knowledge for a better world, was centered on energy, food and marine plastic debris. There was an excellent feedback by students and teachers, thus the first research question obtained a positive answer in this context. In the following year, the summer school was entitled Let’s measure the world. Physical tools for finding sustainable solutions and reached the same results.

The sustainability was introduced by using analogies for visualizing concepts, for example to distinguish between oversimplifications, sustainable situations near to a breaking point, stable sustainability subject to changes in boundary conditions that can destroy it and finally to a sustainability based to natural laws and active practices (examples are shown in Figure 3).

Figure 3. Examples of material designed for a summer school. On the left, the relevance of unsustainable use of natural resources is outlined for same ancient society collapsed in the past. On the right, different types of sustainable situations are visualized by using the analogy of a system in stable or unstable equilibrium in gravitational field in various situations.

After having introduced the concept of sustainability and why it is necessary to deal with it in order not to run the risk of making our society too fragile to variations in available natural resources, the contribution that physics can make to the understanding of sustainability issues was examined. Particular importance was given to the ability in problem posing and solving in complex real situations and to develop measurement or estimation processes of relevant quantities through the use of the scientific method.

Moreover, a laboratory on problem posing and solving was realized (Figure 4). The initial problem was to estimate a physical quantity in a real context relevant for the theme, that it had to be modeled, approximated, checked and the model had to be refined. Are there hidden variables? Which experiments can be performed for validating or confuting the hypotheses? Search for problems related to the theme in a local, intermediate and macroscopic scales. Is it possible to find sensible solutions? Which action could mitigate the actual unsustainable situation by involving my family and my friends? Or the whole school, or which other community can make the difference by assuming a responsible behaviour? The students discussed for choosing the problem and assess the physical impact.
Figure 4. Examples of problem posing and solving: on the left searching for an estimate of the number of plastic bottles necessary for constructing Plastiki, a boat made with recycled waste products, and compare it with the consume in the students' family. On the right, some images proposed in the laboratory on how to save energy by improving heat loss in the school's building or if it is sustainable to cover all trucks in the country by solar panels.

The designed activities were discussed with a small group of physics teachers and tested with 83 students. The result was a list of tested problems related to sustainability in which students can be engaged in active laboratories where relevant skills for physics education, such as problem posing and solving in complex situations, measurements, estimates, approximations, modelling, were developed in a very motivating context. Thus, the second research question obtained a very positive answer. Teachers involved in the summer schools appreciated these activities and suggested to realize a learning path on food, energy and sustainability in their school for all students.

SUSTAINABILITY AT SCHOOL: AN EDUCATIONAL CHALLENGE

For answering to the last research question, new learning paths on sustainability issue were designed and tested in two different high school. In a small one (Montalbano, 2016), all students (50 participants, age 14-18) followed an interdisciplinary learning path on energy, food and sustainability. The focus was on developing new laboratories about thermal process, saving or wasting energy in the process of food transformation.

In another high school, a large project on nuclear phenomena and sustainability in energy production engaged 144 students in a wide monitoring of environmental radioactivity.

A clear problem in fostering these new kind of teaching/learning process at school is the necessity loudly invoked by teachers in scientific matters of a professional development in all topics related to sustainability. The lack of disciplinary and interdisciplinary skills is perceived by them like the principle obstacle to a large diffusion of sustainability issues in practice in classroom.

For these reason a national summer school for in-service teachers, Science in 4D, has been designed and will be realized this year. The sustainability is one of best topic in which develop skills and laboratories in an interdisciplinary approach, which is the aim of this summer school for teachers. About forty teachers will be admitted to participate and results in physics education as well as interdisciplinary activities developed in the school will be reported.
A Pilot on Energy, Food and Sustainability.

An interdisciplinary learning path was designed and realized in a small high school with a classic and scientific section (50 students aged 14-18, 2 physics teachers and a science teacher, a lab technician) in collaboration with the university.

The trial was funded by the Regional Government as an annual project for developing and testing new learning paths at school. The main aspect considered in the designing were:

- Motivation through connection to Expo 2015;
- Introduction to sustainability (a missing topic in curriculum);
- Strong interdisciplinary Physics-Science (Chemistry and Biology);
- Revisited Physics lab, new Science and Phys Lab;
- Focus on individual and collective choice in the topic.

The supplied energy to the human body is trivialized by the indication of the calories on the packaging but it is completely disconnected from the students' scientific knowledge. Some examples of activities are the following:

- How much energy is available to the body by eating a food and which relationship with the calories listed on the package? (problem solving and Lab);
- How much energy for food processing, packaging, distribution, preparation and consumption? (problem solving and Lab);
- How much fossil fuel for obtaining a portion of spaghetti? Or a banana? (problem posing and solving);
- Can we measure these energies in laboratory or estimate them by looking for information in database or elsewhere? (Lab)
- Is my favorite menu sustainable? Which carbon or water footprint it has? (problem posing and solving).

Usually a preliminary discussion in class was followed by activities of problem posing and solving and/or through experimental activities in laboratory.

In science laboratory students designed and realized a device for measuring the caloric content of small quantities of a food (Figure 5). The apparatus consists of a metal support for the food, the combustion is initiated by a piezoelectric gas lighter away from the test tube in which there was a known amount of water. The measures of the burned mass, the initial and final temperatures of the water allowed to estimate the calories in the food.

The quantitative analysis of the data collected with the apparatus allowed to distinguish the caloric intake of the main types of food but the measures were not repeatable (they had caloric contents lower than those of the database up to even 40 times). The students identified a first problem in the water content of the food, but even by doing so the measures were not reproducible and compatible with the database.

At this point the problem was analyzed in the physics laboratory, using an apparatus similar to the Mahler calorimetric bomb with which these measurements are usually carried out. The modified bomb calorimeter allowed to obtain reproducibility in measurements and quantities were in good agreement with calories in database.
Figure 5. The experimental apparatus for evaluating the calories of foods made in the science lab, where a student was starting the combustion, on the left side. The apparatus during the combustion, on the centre. On the right side, students dehydrated food by using a flow of hot air.

The learning path showed clearly that Science Lab is focused on qualitative observations (useful and good for distinguish main contents of a food, in terms of lipids, sugars and proteins). In fact, usually teacher never proposed to estimate uncertainties for any quantity determined there. On the other side, Physics Lab is focused on quantitative measurements, uncertainties are almost every time estimated.

The two different experimental points of view are complementary and together give a much deeper insight in natural phenomena.

Thus, a clarification in basic topics was achieved, such as differences in estimates and measurements, or in qualitative lab compared to quantitative lab.

Monitoring Environment: Nuclear Phenomena and Energy Sustainability

A large project on nuclear phenomena and sustainability in energy production involved in another high school 6 classes (participants 144 student age 16-18 and 11 teachers).

This time again, the trial was funded by the Regional Government as an annual project for developing and testing new learning paths at school. The main aspect considered in the designing were similar to the pilot:

- Introduction to sustainability (a missing topic in curriculum);
- Interdisciplinary Physics-Science (Biology) and Physics-History;
- Revisited Physics lab, new Phys Lab;
- Wide monitoring of environmental radioactivity;
- Focus on individual and collective choice in the topic.

The project included, after the introduction to energy sustainability and nuclear phenomena, a monitoring of natural radioactivity extended in the school both indoors and outdoors.

The project included, after the introduction to energy sustainability and nuclear phenomena, a monitoring of natural radioactivity extended in schools both indoors and outdoors. Last year students designed a fog chamber to view ionizing radiation and a series of measurements were made in a disused mine.

Some materials produced by the students for an exhibition set up at the end of the project are shown in Figure 6.
Figure 6. Some materials produced by students for an exhibition is showed. On the left side, the experimental set-up used for monitoring natural radioactivity is shown together with some steps in lab for designing a fog chamber by using Peltier cells. On the right side, a poster summarizes the series of measures in the mine.

A National School for Science Teachers

The 2017 edition of a national school for science teacher professional development Science in 4D is dedicated to sustainability and science education (participants 27 Science teacher of secondary school). The school was entitled Science for sustainability. Sustainability for Science.

The main activities were:

- plenary lessons
- disciplinary and interdisciplinary laboratories (active learning)
- lab sharing in a final plenary session.

The lack of disciplinary and interdisciplinary skills is perceived by science teachers like the real obstacle to a large diffusion of sustainability issues in classroom practice. This school is only a first step in the right direction.

REMARKS AND CONCLUSION

The first 2 RQ obtained a positive answer from the students’ and teachers’ feedback in summer schools. Food and energy were a good choice for introducing students to sustainability. Motivation and interest were enhanced in students and in teachers too. New paths in laboratory were designed and remain available for curricular education.

A clarification in basic topics was achieved:

- Differences in estimates and measurements,
- Qualitative Lab vs. Quantitative Lab,
- Which means sustainability in this context.

Are we fostering best practice in the school? All teachers declare that they will continue these experience in the next years.
The real situation is different, good proposals can be postponed or missed for many good reasons by teachers, even the more motivated ones:

- Lacking of disciplinary and interdisciplinary skills in sustainability,
- Science teachers’ team in the school,
- Previous positive experience in designing and testing new learning path.

Our experiences showed that seeding interest and new learning paths in this field can be very difficult. Summer school for students could work if teachers are involved in designing the new labs. Competition are useless, the weak interest and motivation awaked in some students is usually ignored by their teachers. Specific projects in the school could work or not, depending by teacher team. In-service (and pre-service) professional development could be really a good starting point for answering in a positive way to the last RQ, but further investigations are needed.

ACKNOWLEDGEMENT

Few activities would had been developed and tested over the years without the careful contribution of a group of teachers of secondary school and academic colleagues. The author would like to thank Emilio Mariotti, Federico Pulselli, Ilaria Corsi, Antonella Porri, Giovanni Bianchi, Barbara Rossi and Alice Severi.

USING LEARNING MANAGEMENT SYSTEMS IN EDUCATION FOR SUSTAINABLE DEVELOPMENT: LEARNING OBJECTS IN SECONDARY SCHOOLS

Stamatia Artemi1, Anthoula Maidou2 and Hariton M. Polatoglou1

1Aristotle University of Thessaloniki, Thessaloniki, Greece
2University of Ioannina, Ioannina, Greece

Education for Sustainable Development (ESD) has become a very important issue recently in the education of students worldwide, due to the urgent environmental, societal and financial problems we are facing. Attempting to contribute in this direction the e-science group of the School of Physics of the Aristotle University of Thessaloniki, developed the project “Zero energy house”, a project on energy consumption in buildings and solutions of bioclimatic architecture. It was mainly directed to secondary school students, although it is openly available to anybody interested in the subject and is based on Learning Objects (LO) design. ESD had been more quickly adopted for adult education and lifelong learning in general, and universities used e-learning tools and Learning Management Systems (LMS) to educate students in this direction. The pedagogical approach of developing educational e-material through the scope of LO design, even though it is still relatively early to have secure results, shows quite positive results in practice. Our goal was to use the benefits which have been observed in adult education to secondary education. The following proposal describes the theoretical structure underlying this project, the tools that have been developed and used and reports the results from the implementation of this project.

Keywords: Learning Management Systems, Education for Sustainable Development, Learning Objects, Secondary Education

INTRODUCTION

Education for Sustainable Development (ESD) has become a very important issue recently, because of the urgent problems we are facing concerning our environment, societies and economies. The decade 2005-2014 was named “Decade of Education for Sustainable Development” by the United Nations and UNESCO took a leading role in this effort (UNESCO, 2004). UNESCO keeps supporting ESD, proposing an educational framework and describing its new vision towards education of 2030 through the ESD Goals (UNESCO, 2015; UNESCO, 2017). Major resources such as food, energy, clean water etc. are still a problem for many people worldwide, while fear of irreversible environmental implications necessitate for actions to ensure the sustainability of life on our planet. Agenda 2030 aims to provide an opportunity and promote the vision of sustainability and the transition to sustainable development through all forms of education, public awareness and training. ESD includes Environmental Education (EE), although it is essentially a broader approach (Reid, 2002; McKeown & Hopkins, 2003), rooted in EE, but going beyond it (Bolscho & Hauenschild, 2006). ESD includes furthermore societal and financial issues, as for example disaster risk reduction, cultural diversity, poverty reduction, gender equality issues, health promotion, peace and security, sustainable urbanization, etc.
(UNESCO, 2004). Through ESD students are encouraged to understand and assess their own values and those of the society in which they live in a sustainable context.

Today’s workplaces demand people who master complex problem solving skills. In many cases, students, even though well educated, are unable to solve real-life problems or deal with real-life issues (OECD, 2014). Being on the Sustainable Development (SD) way of thinking, and using appropriate educational tools and pedagogical methods can lead students – the future citizens of our world – to face and find solutions to complicated problems.

Traditional teaching approaches may not be suitable for the ESD, as it is important for the students to acquire additional skills that will enable them to lead a sustainable way of life. Such skills can be cultivated through participating in Problem Oriented Project Based Learning (POPBL) frameworks, i.e. trying to find solutions in daily life issues. The effectiveness of POPBL has been already tested in higher education (Lehmann et al, 2008) and huge numbers of university Departments have replaced traditional teaching methods with POPBL methods (Chandrasekaran et al, 2013; Lehmann et al, 2008; Moesby, 2005; Yasin & Rahman, 2011). Based on the above, we wanted to adapt this practice in secondary schools and observe the outcomes.

Students are more interested in active learning methods, where they can participate in the learning process - i.e. conduct experiments - like Dewey insisted in his “learning by doing” theory (Dewey, 1966). Using a combination of teaching methods and knowledge that can be directly applied, might stimulate student’s motivation, as well as enable them to target their actions at long term goals (Mulder, 2014). POPBL methods can be used for various age-groups of students, covering different context (see e.g., Ahlfieldt, Mehta, & Sellnow, 2005; Bowe, 2005; Constantino, 2002; Dahlgren & Dahlgren, 2002; Gossman, Stewart, Jaspers, & Chapman, 2007, Duffy & Cunningham, 1996). These methods involve an interdisciplinary problem and students are asked to work in groups and find an appropriate solution. In POPBL methods, teachers encourage students to use various tools and approaches like experiments, simulations, real remote experiments, or searching the internet for information. Using such a variety of tools, they can reach an understanding of the problem and propose possible solutions. Then by analyzing the merits of each solution through research, they can pinpoint an appropriate solution. Unlike usual secondary school curriculums, where Science is presented in a more theoretical way, with the POPBL method, students can tackle scientifically situations that are complicated and complex.

The POPBL methods could be approached through three principles: The cognitive learning, the content, and the collaborative learning principle (Graaff & Kolmos, 2007). Every one of these principles, includes and corresponds to certain competencies and knowledge gained by students. Namely, the cognitive learning principle includes competencies such as problem solving, project management and contextual analysis. The contents principle includes subject knowledge, technical skills, cross-disciplinary knowledge and knowledge management. The collaborative learning principle includes competencies such as collaboration, communication (oral and written) and project planning (Lehmann et al., 2008). Characteristic features of all the above competencies are flexibility and resilience (Langer 1997; Sterling, 1996), which can be achieved utilizing polymorphic contents and work and communication environments.

The examination for candidate pedagogical structures and tools suitable in achieving our ESD goal, has led us to choose a combination of teaching methods and content that can be directly applied and hopefully stimulate
student’s motivation, as well as enable the students to target their actions at long term goals (Mulder, 2014). Based on that, it is inevitable to use e-learning tools and computer based environments in the learning process (Martin & Madigan, 2006). Especially, in the case of science teaching and learning, the use of digital means and advanced technologies enhances high-order thinking and learning skills, promotes a constructivist approach, as well as information, communication, and scientific literacy skills (Cavus & Alhih, 2014). It is desirable for students to develop a more active role in the educational process, and consequently become the main actor in the learning process. Contemporary instructional approaches expect students to be active producers of knowledge (Psycharis, 2011). Learning management systems (LMS) are considered to be very appropriate e-learning systems also for Natural Sciences, as they enable representation of phenomena, foster experimental study and enable the creation of models and problem solving applications (Kidney et al., 2007; Psycharis, 2011), through a variety of multimedia representations.

A LMS is a software used for delivering, tracking and managing training/education (Cavus & Alhih, 2014). It is a system for managing educational content by teachers and students allowing all the participants to collaborate, and contribute to the effectiveness, accuracy and reliability of the educational outcome. The different LMS software applications are similar in functionality and typically include methods to manage users, roles, and course content, online communication, grading, and web-based or blended delivery of content (Cavus & Alhih, 2014).

Furthermore, LMSs are also appropriate environments to develop courses based on Learning Objects (LO). The latter are digital self-contained modules developed through a variety of presentation tools, activities and other learning experiences, reusable for everyone (Manson et al., 2008; Nash, 2005). These learning events are more compatible with the demands of the workplace and lifelong learning (Manson et al, 2008), than traditional courses, and for that reason are more suitable to ESD.

A LMS can fulfill a variety of roles in one single system, depending on the educational usage it will have. Referring to roles, Reigeluth (2008) named four major roles and four secondary roles, all of which should be seamlessly integrated into a single system. The major roles for such a LMS include recordkeeping, planning, instruction, and assessment for (and of) student learning. The secondary roles include communication, general student data, school personnel information, and LMS administration. According to the above, a LMS can be a powerful web-tool for educating students from all over the world, available for everyone to participate and collaborate with others, while learning how to examine problems and find solutions for a sustainable future.

The present proposal is based on Moodle. Moodle (Modular Object Oriented Dynamic Learning Environment) is a LMS, which was created by Dugiamas and Taylor (2003), specializing in Computer Assisted Education (CAE). The development of Moodle was based on social constructivism by emphasizing the importance of culture and context in understanding what occurs in society and constructing knowledge based on this understanding (Park, 2009).

Most of the universities from all over the world (more than 70% of them in Australia, UK, Canada, more than 50% in USA, Netherlands, Finland, etc.) use LMS and LO based learning methods and, even though it is still early, they have positive outcomes (Coates et al, 2005; De Oliveira, De Almeida Cunha & Nakayama, 2016, Diaz et al., 2013.). Therefore, we should introduce LMS in secondary education, not only because of their
educational benefits, but also to familiarize students with such learning environments, since they will definitely use them in the future.

In this work we report on the outcomes of the utilization of our project “Zero energy house” by secondary school students living urban as well as in remote areas of Greece. The research questions were: Could everyday phenomena trigger students to learn more effectively? Is it possible for students from different regions to collaborate and tackle a complex problem relating to the ESD? Are LMSs a convenient learning environment for secondary school students?

**METHOD**

In this section we will report a distance education course designed by the e-science group (http://e-science.web.auth.gr) of the Physics Department of the Aristotle University of Thessaloniki, to introduce secondary school students and teachers to zero energy houses and solutions of bioclimatic architecture. This project started as a pilot project during the year 2013-14 and it is an ongoing project. During the first two years students from 7 upper secondary high-school classes in Greece participated in this course, three on remote islands, two in the city of Thessaloniki (one experimental and one vocational) and two in other remote regions.

This project is based on LO methodology, containing a variety of methods/tools (LMS, website, simulations, remote experiments) designed to reach at each step a different learning objective. Each LO consists of a number of activities, based on formal and non-formal learning environments. LOs are relatively independent from each other and the teacher can choose any combination of them, depending on the time available, age and interests of students. We built a Learning Management System - LMS (Moodle platform) for synchronous and asynchronous access, based on a learning environment where users can explore the notions of temperature, heat, heat transfer and its processes. It contains a variety of tools that will be described below, including an educational website. The website is a vital part of the project, as it is a “portal” to Learning Objects. It includes:

- An introduction to bioclimatic architecture, giving basic information about the topic, and referrals and material for users to further their investigation,
- Several simulations, serving for the examination and testing of different scenarios, in order to familiarize users with the notions of temperature, heat, heat transfer and its processes,
- An Arduino based remote lab, where a user can perform a remote real experiment about the thermal behavior of a house model.

The LMS platform, main tool of the LO design mentioned above, hosts the main learning tools which students could use, when they follow the instructions of each proposed activity. The LMS platform is organized with weekly tasks, questionnaires, assessments, and suggestions. It includes several activities (experimental, hands-on etc.), to be performed either in or out-side the classroom and are the main tools students can use in this
The tackled issues are heat transfer, heat capacity, ventilation, sun exposure, protection from the sun, etc.

The LOs are detailed in Table 1. Figure 1 shows the LOs as they appear on the LMS environment along with the page of one particular LO. LMSs offer tools such as forum and web conference. We have included them to facilitate the collaboration among students from distant regions, exchanging information, strategies and hypotheses. These communication tools can also be used by the participating teachers and the scientific team to exchange information, practices and educational approaches.

</table>

In order to analyze the project’s outcomes, a pre & post questionnaire was developed to assess students’ knowledge and views about heat transfer and its processes. The questionnaire was thematically developed based on the three methods of heat transfer, i.e. conduction, convection and radiation. All questions were about everyday issues and experiences. There were two types of questions: multiple choice (were only one answer was correct) and open ended questions. In the latter case, researchers considered an answer as correct if it was scientifically sound.

**OUTCOMES**

Several groups of students, as mentioned above, participated and collaborated with enthusiasm in this project. In this section, we will present a number of screenshots of several activities and parts of the project. The final task for the students was to prepare a scale model of their school building and send it to us in order to perform measurements on the thermal behavior of the model at our remote lab under ambient conditions. At the remote lab we have attached several thermometers inside the scale model of the school and one thermometer outside.
All the thermometers were connected to an Arduino platform with the appropriate software. In this way the temperature of different places inside the model were measured and logged as well as the ambient temperature. These data were subsequently provided to the students to analyze them and reach scientifically sound conclusions related to the thermal behavior of the school scale model. Based on the conclusions they were asked to propose improvements to their school building, in order to have a better bioclimatic behavior of the building and thus enhancing the users’ comfort and wellbeing, while reducing energy consumption.

In Figure 2, students get familiar with temperature and heat transfer phenomena, by simple hands-on activities, that took place in their own classroom.

---

Figure 1. Screenshots of LMS - basic structure and a sample of content

Figure 2. Classroom activities
Students collaborated with the scientific team, through web conference, on a weekly basis, presenting their progress, discussing about their tasks, getting advice on how to manage the tasks ahead, learning how to use the available tools. A snapshot of such a web conference session is presented in Figure 3.

![Web Conference Session](image1)

**Figure 3. Screenshot of a web conference session**

In the following image (Figure 4), we can see students and teachers, while they measure key dimensions of their school. These measurements apart from being necessary to build the scale model of their school, made them by experience to acquire many practical skills. By appropriate scaling the measured values they went on to draw the faces of the school on the paper and then construct the model using common materials.

![Students Measuring](image2)

**Figure 4. Building measurements and house model designing and constructing**

The following image (Figure 5), is one of the completed school models, representing a school at a remote island.
Figure 5. Final school model as completed by the students.

The last image (Figure 6), is the above school building model which was sent by the students to our group’s remote lab set-up. Students could observe the continuous measurements taken by thermometers inserted in various parts of the building before and after improvements suggested by the students. For this particular model students suggested as an improvement to add seaweed under the roof, as found in traditional buildings of their area. The subsequent temperature measurements have shown that the improvement worked.

Figure 6. Screenshot of the above model when it was set-up in the remote lab, as seen in the designated webpage. The image of the school model is from the real time video of the set-up.

As for the test that was answered before and after the project, the research team collected data from 23 students and analyzed them using the SPSS software. Questions were assigned to three dimensions, where each dimension is one of the three methods of heat transfer. The Shapiro-Wilk Test showed that results in all dimensions were not normally distributed. For that reason, results of the pre- and post-test were compared with the non-parametric Wilcoxon Signed -Rank Test. In all three dimensions, students’ performance was improved with statistical significance.

Specifically the mean rating of students responding to heat conductivity questions increased statistically significant (p<0.0001) from 2.00 (SD = 0.85) to 3.30 (SD = 0.76). The mean rating in heat convection questions increased statistically significant (p < 0.0001) from 2.04 (SD = 1.04) to 3.09 (SD = 1.12). In heat radiation questions, the rating improved statistically significant (p = 0.028) from 2.04 (SD = 1.22) to 2.74 (SD = 0.62).
DISCUSSION AND CONCLUSIONS

Several groups of students, as mentioned above, participated and collaborated with enthusiasm in this project. Students collaborated with the scientific team in a weekly basis, discussing about their tasks and advising students how to manage them, learning how to use the available tools, and answering in questions that could possible incur, through web conferences. Pre/post tests were developed, where we could study quantitatively and qualitatively students’ alternative conceptions about heat transfer and its processes, based on everyday life phenomena. Based on their prior test results, we can conclude that there was progress on their conceptions, and from discussions with their teachers, students became able to discuss about their own houses, on matters like the orientation, building materials, insulation, sun protection, etc. After the completion of the course we had a final meeting with the participating teachers and students to discuss their experience from the project. The teachers found the collaboration very useful and supporting. Many asked for continuation of the collaboration on other topics. The students mentioned that they liked especially the use of computers for collaboration and the use of the Web-site and the Moodle. It was a “unique experience” for them (in their own words) differing very much from the traditional way of learning. The overall request from the students and the teachers was for continuation of the project.

SOIL IS A RESOURCE: THREE TEACHING METHODS TO ACHIEVE ONE TARGET

Sabina Maraffi¹, Daniela Pennesi¹, Alessandro Acqua¹, Lucia Stacchiotti¹, Eleonora Paris²

¹School of Science and Technology, Geology Division, University of Camerino, Italy
²Geology Division, University of Camerino, Italy

Soil is usually little covered in Italian schools. From our previous experience as teachers we realized that soil is a resource usually taken for granted by students but it is actually a limited resource and always in danger. The aim of this work is to figure out which of three teaching methods helps pupils (10-11 years old) to understand the most about the importance of soil - "it is a precious good and it is source of life for the living beings" (European paper of the Soils 1972). Moreover, studying of soil requires many details on subtopics and it also allows many interdisciplinary connections, e.g. in biology, in chemistry; environmental education (the soil is a limited resource), nutrition. This case study was carried out in collaboration with some classes of the Marche Region and Campania Region (Italy). We compare three various educational approaches and the proposed contents are the same for all three teaching methods. Findings showed that each approach has its strengths and weaknesses and that all three are effective to let pupils understand soil as a non-renewable resource; at least this is true for pupils in this age group.

Keywords: educational games, teaching approaches comparing, soil

INTRODUCTION

In 1997, the skills have been defined by the Organization for Cooperation and Economic Development (OECD) as "the ability to meet complex demands in a particular context activating psychosocial prerequisites (including cognitive and non-cognitive)"). On this perspective “to get a skill not only means to have the resources that form it, but also to be able to properly activate and orchestrate them, at the right time, in a complex situation” (Rychen and Salganik, 2007). This task presupposes a sequential development, from the proposal to the product, the introduction of necessary knowledge, of techniques and materials, the organization of the working set, the definition of product and training results, the selection of the strategies to be adopted and relevant information, and the heuristic error handling (Maraffi and Marinelli, 2016).

The aim of this work is to compare three various educational approaches: traditional lesson, cooperative laboratory and computer classroom role playing game. This comparison has been done to determine which approach could help students to acquire disciplinary and transversal skills more easily. Further during the structuring of each approach attention has been given to inclusiveness: traditional lesson ensured inclusiveness through drawing and images, Cooperative Laboratory through hands-on activities and SoilQuest provided it through multi-language tools.

On one hand soil was chosen as topic because Marche is a rural region and in the last fifty years mechanization of the agriculture and the use of pesticides have led to a loss of natural principles that regulated the proper management of soil and its protection (http://suoli.regione.marche.it/). On the other hand, it was chosen
because in the Campania region there is excessive urban concreting and a serious issue of soil pollution in *Terra dei Fuochi* (Giordano and Chiariello, 2015).

**DESCRIPTION**

Three teaching methods (traditional lesson, cooperative laboratory and role playing game – Figures 1-3) are used to show the same topic and notions simultaneously in parallel classes. The activities of the Cooperative Laboratory are the same as those carried out with the game and those shown in the SoilQuest videos. Six classes (three in Marche and three in Campania) were involved in the trial for a total of about 120 pupils. All three approaches were carried on in two hours. To assess efficacy of each activity the same individual pre-test and post-test were administered before and after each intervention.

**Traditional lesson**

Traditional lesson was performed using multi-media blackboard (MIB). On MIB a power-point file was displayed. Following it one of the authors, as teacher, explained what soil is, its structure and functions, soil constituents and why soil is a non-renewable resource. Features of conventional and organic farming were also mentioned. During the lesson pupils were involved not only in watching FAO’s videos for International year of Soil (http://www.fao.org/soils-2015/en/) but also in doing dictation and drawing. Pupils could also ask questions and elucidations about terms and words they did not know or understand; in this process the teacher fostered peer-to-peer confrontation in order to reach scientifically correct and shared definitions. Further videos and slides about air presence in soil, permeability of soil and soil-dwelling were shown and explained. Every child worked on his own (Figure 1).

**SoilQuest: a Computer Class Role Playing Game**

The educational technology uses closeness to pupils language to improve the teaching/learning process. Changing in Education is important because of changing in communication codes which passed from an analogic and sequential world to a digital and simultaneous one. Students are nowadays digital natives, they grew up with computer Games instead of fairy tales. The game is a good vehicle for education since the acquisition of knowledge and enhancing of skills now requires more actual approaches. In fact, education goals are skills instead of knowledge, because in a progressive changing world people need Learning to Learn, for Longlife Learning. Then teachers have to put students in situated learning, which reproduces reality with all its own facets. Games could be good to get situated learning in interdisciplinary and multi-language way. Computer games reproduce the virtual world with real images, as photos or videos, put players in situation
through sound effects, and engage students through storytelling. Furthermore, the use of tablets, smartphones, social networks, etc. is more comprehensible and funny for young people compared to traditional media.

Further SoilQuest is designed as user friendly: it is multilanguage for using by foreigners students, it uses simplified language for best integrating Italian L2 speakers and it includes different communication channels (visual, audio, simplified ppt notes) for best inclusion of students with disabilities.

In SoilQuest (Maraffi, Pennesi, Acqua, Stacchiotti, and Paris, 2016) participants live a graphic adventure in which they face several choices of several paths with various opportunities. Students must solve questions or quests to go on through viewing the same experiences performed in cooperative laboratory. The players interact with the system using their own smartphones and tablets with a new technology which collects the individual answers (Figure 2). At the same time the system calculates the overall response according to the criterion of the majority. Given the age range of pupils, whose capacity for abstraction is not yet fully developed, the practical proposals in video activities facilitated learning through sensorial experience. Through questions of the game, differences between urban soil, wood soil, agricultural intensive and organic farming soils were emphasized.

The adventure path was targeted to 10-11 yr old pupils. Storytelling was centered on a little boy who goes to meet a friend of his, passing through different kinds of soils and some pictures were drawn with children style. Pupils could watch lab videos or make their own experiments in their classroom to understand the differences between urban soil and farming soil. Then they could realize differences between soils with less or more anthropic transformations.

**Cooperative laboratory**

Cooperative laboratory path was organized considering the pedagogical and didactic aspects based on active and cooperative learning. The main purpose is to touch and observe what students commonly trample. Each experiment is easily replicable in class with poor materials. Pupils worked in group and performed experiments about air presence in soil, different permeability and colour between different kind of soils (more or less rich in humus), soil components and differences between traditional farming and organic one (Figure 3). Experiments were the same as those shown on role playing game only as video. The following table shows in detail the various laboratory activities made with pupils (Table 1.).

RESULTS AND DISCUSSION

Findings highlight not only general remarks but also strengths and weaknesses of each approach as shown in Table 2. Overall students demonstrated a high level of concentration in their activity, but also an emotional involvement. Moreover the study of the environment and the territory contributes to increase the awareness of the planet as a complex and fragile system. All three approaches gave the chance to correlate themselves with environmental education (which is a new requirement in Italian curriculum at school, Indicazioni Nazionali, 2012). The global comparison between pre-tests and post-tests was useful to emphasize the effectiveness of the chosen topic. Furthermore, students’ awareness that soil is a non-renewable resource shifts from 32.4% to 81.1% (Figure 7a and b).

Table 2. Strengths and weaknesses of three used approaches

Traditional lesson

During the lesson pupils were particularly involved in viewing videos, in asking questions and looking for answers, in dictation and drawing. These activities contribute to stimulate active learning and to enhance students’ motivation, increasing knowledge and competences. Students with learning difficulties or who were less prone to attention in the classroom found difficulties during the explanation of notions and specific language. However, peer-to-peer discussion promoted a best understanding of the most complex parts of the topic for every student. Anyway, as far as we know this approach is effective to let pupils understand soil as a nonrenewable resource.
Computer Class Role Playing Game

The Game is meant as a teaching tool is a situation-learning mode that requires the student to mobilize its resources to find solutions that require skills rather than simple knowledge (Maraffi and Sacerdoti, 2016). Students are asked to recover their previous knowledge, there is an encouragement of the use of complex cognitive processes (reasoning, transfer, critical thinking, creative thinking) (Maraffi and Marinelli, 2016), learning into meaningful and real contexts, stimulation of students’ interest and enhancement of students’ abilities. In children aged 10 to 11 years SoilQuest proved to be a great tool to engage, to introduce the topic and capture students’ interest. Experimental results are comparable with cooperative laboratory ones, since active teaching is good for engaging and fruitful learning. Students showed much appreciation for interactivity: the chance of changing adventure’s path, score growth and immediate answer feedbacks, kept attention alive for the whole activity.

Cooperative Laboratory

Active handling of water, soil and mulch was the most involving phase in cooperative laboratory. Since some students were not used to work in groups some organization difficulties were detected such as timeliness and division of tasks within the group. Nevertheless, cooperative laboratory contributes to stimulate active learning and to enhance students’ motivation, increasing knowledge and competences.

Figure 8 compares the outputs of the three approaches.

![Figure 8. Answer comparison among three different approaches](image)

CONCLUSION

It is important to point out that the chosen topic revealed to be of large interest in the schools. It is a transversal topic, suitable for all ages, even if we wanted to concentrate on the 10-11 aged group, because we think that environmental education early awareness is important. In fact, as shown in Figures 7 and 8, each approach has made great contribution to remove misconceptions about soil, regardless of the kind of approach (Traditional
From the comparison between the three teaching approaches we can see that approaches including real or virtual lab activities keep pupils interested and involved much longer (Figure 8). They also contribute to achieve, rather than simple notions and knowledge, key-competences of citizenship (Recommendation 2006/962/EC on key competences for lifelong learning): Science and Technology skills (Soil features, lab and digital skills) and Social and Civic responsibility (environmental education and awareness of the anthropic alteration on the environment). Above all the acquisition of these competences is important considering the context of the schools that participated in the experimentation (Marche and Campania). Our future goal will be to improve teaching actions to further increase awareness in tomorrow’s citizens.

EFFECTIVENESS OF TEACHING INTERVENTIONS BASED ON SOCIOCULTURAL CONSTRUCTIVISM ON ENVIRONMENTAL PROBLEMS: GROUP LEARNING VERSUS INDIVIDUAL LEARNING

Filiz Kabapınar and Oya Ağlarca
Marmara University, Atatürk Faculty of Education, İstanbul, Turkey

The present study aimed to investigate high school students’ ideas related to the major environmental problems and develop their ideas with different teaching interventions based on sociocultural constructivist paradigm. Case study and experimental designs were used in the study. In the first part of the study, high school students’ (n=100) ideas were determined with an open-ended questionnaire designed by the authors. In the second part, two teaching interventions based on sociocultural constructivism were designed and implemented to the 10th grade students whom preconceptions were determined prior to the study. One of the intervention focused on global climate change and the other was about ozone layer depletion. With these interventions, we intended to develop students’ views of environmental problems as well as to investigate whether group learning or individual learning was more effective than the other. The data collection tools of the study were open-ended questionnaire about environmental problems, interviews and worksheets of the teaching interventions. Written answers and the interview transcripts were analyzed with content analysis. The quantitative data were analyzed with The Wilcoxon signed-ranks test and Mann-Whitney U test in SPSS program. The results of the study showed that high school students held a range of alternative ideas. They linked environmental problems which were irrelevant with wrong cause-effect chains and had naïve views about environmental problems including global climate change and ozone layer depletion. The results showed that both of the interventions were effective in developing students’ ideas of global climate change and ozone layer depletion.

Keywords: Environmental problems, science education, high school students

INTRODUCTION

Environmental issues have become among the major problems at worldwide level. Individuals have a great influence on environmental and global problems because they can act in order to produce effective solutions even at the individual level. Alternatively, act sometimes means just as the opposite; people can add to the existing problems. Therefore, individuals who have knowledge about the causes, consequences and possible solutions of environmental problems are strongly needed. Raising environmentally literate people is one of the reasons behind the emphasis for environmental education. The main aim of science education programs is to raise scientifically literate students. Scientifically literate students are expected to use their scientific knowledge in everyday life decision-making processes (Bell & Lederman, 2003). Science education programs also help students to have scientific knowledge about environmental problems, their causes, consequences and solutions of these problems. However, studies have shown that students’ ideas are limited as well as embedded with alternative conceptions (Boyes & Stanisstreet, 1993; 1997; Khalid, 2001; Ünal &
Their existing ideas prevent students from taking actions expected from them at the individual level (Boyes, Chuckran, & Stanisstreet, 1993; Boyes, Stanisstreet, & Papantoniou, 1999; Khalid, 2001; McNeill & Vaughn, 2012). For instance, students usually confuse some major environmental issues with each other such as greenhouse effect, global climate change, ozone layer depletion and acid rain (Boyes & Stanisstreet 1997; Christidou & Koulaidis, 1996; Cordero, 2001; Khalid, 2001; Rye, Rubba, & Wiesenmayer, 1997). They could not differentiate between global warming and greenhouse effect, and global warming and climate change. They also hold different erroneous models for the causes, the effects and the relationship between environmental phenomena such as destruction of the ozone layer resulting from increased greenhouse effect or global warming (Boyes & Stanisstreet, 1993), global climate change resulting from increased UV radiation, ozone layer depletion resulting from air pollutants (CO₂ and NO₂) or global warming, global warming resulting from the hole in the ozone layer (Boyes, Stanisstreet, & Papantoniou, 1999). Studies conducted with teachers and prospective teachers showed that the same alternative conceptions have also existed in their minds (Dove, 1996; Hillman, Stanisstreet, & Boyes, 1996; Groves & Pugh, 1999; Michail, Stamou, & Stamou, 2007). Within the domain of the related research, it becomes clear that major points related to greenhouse effect, global climate change and ozone layer depletion have not been fully studied. After determining the understandings and alternative conceptions of high school students, it will be possible to develop these ideas toward more scientifically acceptable ones via specifically designed interventions. Therefore, in the first part of the study, we aimed to find out high school students’ ideas about the causes, consequences and possible solutions of the main environmental problems. In the second part of the study, we designed two different teaching interventions based on sociocultural constructivism and investigated their feasibility and effectiveness on developing students’ ideas.

**PURPOSE OF THE STUDY**

This study aimed to investigate high school students’ ideas of environmental problems and to develop their views with different teaching interventions based on the related themes. In this respect; the research questions are listed as:

1. What are high school students’ ideas related to the greenhouse effect, global climate change and ozone layer depletion?
2. What are high school students’ mental models of ozone layer depletion?
3. How do high school students’ ideas and mental models change after the teaching interventions based on sociocultural constructivism?
4. Does the effectiveness of the teaching interventions based on sociocultural constructivism differentiate according to classroom implementation (group learning versus individual learning)?

**METHODOLOGY**

The study was constructed as a mixed method research design. Case study and experimental design were both used to answer the research questions in a detailed way (Yin, 2003). In the first part of the study, high school students from different state schools (n=100) have participated voluntarily. In the second part of the study, two
teaching interventions were designed and implemented to the 10th graders (15-16 years old). The intervention on global climate change was conducted with 90 students; half of which was assigned to the individual learning and the rest was assigned to the group learning. The second intervention was based on ozone layer depletion. Both of the interventions were implemented in order to develop students’ views on concepts aforementioned as well as to explore the effectiveness of social group learning. Firstly, a questionnaire with 9 open-ended and 3 multiple-choice questions (e.g. Which of them is not among the greenhouse gases?) was developed by the authors. In the questionnaire, some of the open-ended questions asked the participants to explain a range of concepts such as greenhouse effect, global climate change, ozone layer, ozone layer depletion, whereas some of them asked them to explain the relationship between different environmental problems and their possible solutions to these problems. One of the questions was as in the form of drawing. This question aimed to find out participants’ visualizations of the ozone layer depletion and to explain their drawings verbally. Face-to-face interviews were also conducted so as to investigate the mental models of the participants thoroughly.

The qualitative data gathered from the questionnaire and the interviews were analyzed by content analysis. Participants’ answers were coded separately by the authors and an expert from the department of science education to establish inter-rater reliability (Miles & Huberman, 1994; Glesne & Peskin, 1992). In order to determine the agreement between the coders, the percentages of agreement were calculated and the coherence was 90% on the basis of questions. The Wilcoxon signed-ranks test in SPSS was used to analyse the changes in pre and post interventions within the groups. Besides, Mann-Whitney U test in SPSS was used to test the differences between both groups’ post-test results.

**INTERVENTION**

Teaching interventions were designed in order to provide verbal and visual materials accompanied by questions that encourage students to construct their own view on the issue at hand. The interventions were designed in the line of Vygotskian constructivist view of knowledge whereby scaffolding was at the heart of instruction. Teaching materials where students get out of the bits of ideas were designed. The materials started with newspaper articles about environmental problems about global climate change and ozone layer depletion (Figures 1 and 2). This was followed by different visual and verbal clues to develop students’ existing ideas toward the scientifically acceptable ones. Students answered the questions in the materials after reading the newspaper articles. They answered individually or collaboratively depending on which group they were assigned in. There are three examples given in order to show some parts of the interventions. The article below is about global climate change. It mentions about the melting of ice layers in the Polar Regions. This was followed by a graph on which the World’s average temperature increases over 150 years was presented.

The article (Figure 2) is about greenhouse effect; and it shows favorable effects of greenhouse gases and their drawbacks. The article gives examples for this by using data related to some planets. It reveals the relationship between the average temperatures and their atmospheric compounds. According to the article, Mars has a thin layer of CO$_2$ gas in its atmosphere, most of the CO$_2$ is found to be in the solid form. During winter, the temperature is cold enough for the CO$_2$ in the atmosphere to condense into ice on the surface. That is the reason behind the average temperature of Mars is about -50 degrees Celsius. On the contrary, Venus has a very thick
layer of CO₂ gas that forms 96 percent of the atmosphere. Therefore, the temperature of Venus is nearly 420 degrees Celsius.

Figure 1. Newspaper article on global climate (Translation of Figure 1: Melting Ice Layers in the Polar Regions: The authorities are talking about terrible scenarios because of global warming. These scenarios mostly include melting ice in the Polar Regions. However, the problem is more serious than this. Global warming could also lead to major problems such as famine and drought in a long term. This also may cause hotter summers and flooding; scientists predict that “winters will be vanished by 2080 under these circumstances.”)

Figure 2. Newspaper article on greenhouse effect (Translation of Figure 2: The advantages and disadvantages of greenhouse effect—Mars is too cold, Venus is too hot, and Earth’s Temperature is Ideal: Mars has a thin layer of atmosphere; CO₂ gas is found to be in the solid form. There is no greenhouse gas in Mars, this is why the average temperature of Mars is -50 degrees Celsius. On the contrary, Venus has a very thick layer of CO₂ gas that forms 96 percent of the atmosphere. This means Venus has a strong greenhouse effect and all of the sunlight is completely trapped inside. Therefore, the temperature of Venus is nearly 420 degrees of Celsius. On the other hand, Earth’s average temperature is about 15.6 degrees Celsius and that makes it a habitable planet.)
Finally, the worksheet below (Figure 3) is about ozone layer depletion. The participants answered some questions about the ozone gas concentrations in different parts of the model and they were asked to discuss the meaning of the ozone layer depletion whether it was a hole, fracture or decrease in the gas concentration (scientifically accepted idea). Questions ask students whether the density of A, B, C and D region is the same (question 1) and where the density of the ozone gas is the least (question 2).

Figure 3. Worksheet on ozone layer depletion (Translation of Figure 3: You can see the ozone layer surrounding the Earth in the figure. Q1. Do A, B, C and D parts have the same amount of ozone gas concentration? Why? Q2. In which part, the ozone gas concentration is the least? Q3. In which part, the ozone layer depletion has occurred? Q4. How does the amount of ozone molecules change in the parts?)

FINDINGS

Findings revealed that high school students’ ideas were embedded with a number of misconceptions before the interventions. The results of the interventions stated that both of the interventions were effective in reducing misconceptions and developing views of the aforementioned environmental concepts.

Participants’ initial ideas before the interventions

There were misconceptions about the environmental problems before the intervention. A small percentage of the students (n=7; 7%) described greenhouse effect correctly. The majority (n=63; 63%) could not give a correct definition of global climate change whereas only 10 of the students gave a correct description. Almost all of the students stated that greenhouse effect and global climate change were linked to each other. Also, there were some serious misconceptions about the ozone layer and ozone layer depletion. Majority of the students thought that ozone layer consisted of a mixture of gases such as $\text{O}_2-\text{O}_3-\text{N}_2$ (43%, n=43), $\text{O}_2-\text{O}_3-\text{N}_2$ (n=18). Interviews revealed that some students imagined the ozone layer as solid. One of the student’s written answer was shown below (Figure 4) - this student thought that ozone layer was in a solid form.
Majority of the students defined ozone layer depletion as a hole in the layer or fracture of the ozone layer. Analysis of their drawings also indicated that most of them imagined ozone layer depletion as a hole, thinning or fracture, instead of decreasing of ozone gas concentration. Some of the drawings that showed depletion as a hole or thinning were given in Figure 5.

Most of the students (n=70; 70%) stated that global climate change and ozone layer depletion were related to each other as can be illustrated in the excerpts below (Figure 6). The first two of the students believed that global climate change occurred due to the hole in the ozone layer. Thus, the global climate change (the result) resulted from the ozone layer depletion (the reason). On the contrary, the third student thought that global climate change caused fractions in the ozone layer. Thus, the relationship between the two global issues was reverse for this student.

Only a small percentage of the students stated that there was no relationship between two environmental problems (scientifically acceptable way of thinking) prior to instruction.
The effectiveness of the interventions

The results of the interventions showed that both of the interventions were effective in reducing misconceptions and developing views of the aforementioned environmental concepts. Also, there were no statistically differences between the groups; however, the social group scores were higher than the other group.

As can be seen in Table 1, intervention based on social constructivism implemented as group was effective in developing participants’ understanding on environmental problems.

Table 1. The effectiveness of the interventions based on sociocultural constructivism

</tbody>
</table>

The results of the interventions stated that both of the interventions were effective in reducing misconceptions and developing students’ views of the aforementioned environmental problems. After the intervention on global climate change, students started to define the greenhouse effect and global climate change correctly. They also started to explain their roles on global issues. After completing the second intervention on ozone layer depletion, students provided correct drawings related to ozone layer depletion and its formation as can be seen in Figure 7.

Figure 7. Student Drawings. (Translation: The Ozone layer absorbs harmful rays prevent them from entering the Earth’s atmosphere. The depletion forms in the ozone layer and therefore, the layer could not protect us from harmful rays.)
They were also able to differentiate between the greenhouse effect and ozone layer depletion or ozone layer depletion and global warming. Thus, it is possible to say that the two teaching interventions were effective in leading students to develop their ideas. The comparison of the individual groups and social groups based on interventions revealed that there were no significant differences between them. However, the scores of students in social groups were higher than the individual groups, albeit statistically insignificant.

**DISCUSSION AND IMPLICATIONS**

Environmental problems are among the biggest problems that threaten the Earth. Even though these problems affect our lives and health, we are mostly causing the problems by destroying nature and by not taking some actions at the individual level. However, we can understand the causes, the effects and possible solutions of the problems with environmental education; therefore we can take action against them. The results of the study showed that students had misconceptions about greenhouse effect, global climate change and ozone layer depletion since they had difficulty in even defining whereas only a limited number of students stated correct answers. The results also indicated that students possessed different conceptual models for ozone layer depletion. Majority of them thought that layer had a hole or a fracture. However, some of the participants gave correct explanations by saying there was a decrease in ozone gas concentration. The results of the study are in line with the literature which demonstrated that same alternative conceptions were also existed (Boyes & Stanisstreet 1997; Christidou & Koulaidis, 1996; Cordero, 2001; Khalid, 2001; Rye, Rubba, & Wiesenmayer, 1997).

The results gathered from the interventions revealed that the activities were effective in developing students’ views of global climate change and ozone layer depletion. There were no significant differences between the social groups and individual groups. However, the social groups’ results were much higher than the other group in both teaching interventions. This result stated that even though both of the groups were implemented the same worksheets, the discussions among the students helped them to gain better understanding as compared to the individual thinking. This could be taken as a sign for effectiveness of pair discussion over individual thinking and meaning making.

Considering the aforementioned problems in environmental education and effectiveness of the interventions, teachers need activities and sources specifically designed to teach environmental issues. Directing teachers to the reliable sources and supporting them with teaching activities specifically designed to teach environmental issues should be priority for science education programs. Also, interactions between the students should be enhanced based on the assumptions of social constructivist theory of learning.

DEVELOPING VIEWS OF LIFE THROUGH NATURE-BASED EXPERIENCES AND EXPERIENCE ON LIVING THINGS

Junko Iwama¹, Tatsushi Kobayashi², Taro Hatogai³ and Shizuo Matsubara¹

¹Toin University of Yokohama, Yokohama, Japan, ²Joetsu University of Education, Joetsu, Japan, ³Tokyo Metropolitan University, Hachioji, Japan

The “view of life” that is the theme of this research does not refer to people’s views or philosophies about everyday life or the nature human existence; rather, the ‘life’ we describe here is tangible life, covering all living things and the state of being animate. In the research, university students were asked to respond to a questionnaire survey regarding their “nature-based experiences, etc., and view of life”. The effects and significance of their experiences with nature and living things on the developing of their view of life were considered as well as responses between male and female students. The research results are as follows: (1) Gender differences are perceived about “nature-based experiences”, “experiences capturing/gathering animals”, and they are effective in developing view of life with regard to living things. (2) As female students’ view of life with regard to living things is higher than male students’, then “experience raising/contact with animals” is effective in developing a view of life than “experiences capturing/gathering animals”. (3) Nature-based experience, learning experience on living things and experiences of breeding or contact with animals can be an effective medium for developing view of life. (4) Students’ view of life with regard to plants is lower than animals, especially withering of wild plants. We can conclude that sensing living things and developing view of life through experiences is important for science and biology education. It is a future problem how to develop view of life with regard to plants on aspects of the view of biodiversity and environmental education.

Keywords: experiential learning; nature-based experiences; view of life

INTRODUCTION

John Dewey made some philosophical considerations about education based experiences. He said “A primary responsibility of educators is that they not only be aware of the general principle of the shaping of actual experience by environing conditions, but that they also recognize in the concrete what surrounding are conducive to having experiences that lead to growth” (Dewey, 1938).

In Japanese science education, many researchers have already suggested the importance of nature-based experiences and experiential learning as well as the need for guidance with regard to respect for life. Furthermore, curriculum guidelines also stipulate developing in children the sentiment of a love for nature and an understanding of things and phenomena through actual sensations and experiences.

Kobayashi et al. (1992) pointed out that experiences are very important, reporting that “field experiences perceived using the five senses not only develop sensibility and enthusiasm, which are the foundation of scientific learning, but also link with knowledge acquired later, becoming the foundation for living knowledge and concept formation.” Furthermore, Furusawa et al. (2013) reported that “direct experience has a huge effect on the developing of general understanding of living things”, and Hatogai (2011) emphasized the need for developing a view of life within science education as well as guidance for respect for life. However, until now there has been no research that examines experiences with nature/living things and a view of life and then
statistically clarifies the relationships between the two.

In this research, a survey was conducted among university students—who were thought to embody the results of primary and secondary education—with regard to their “nature-based experiences, etc., and their view of life”. The results of the survey were analyzed and the significance of developing an understanding of life and a view of life through experiences in science education was considered.

METHODS

In this research, a questionnaire survey was conducted among university undergraduate and graduate students regarding the relationship between “nature-based experiences, etc., and view of life”. The following is an overview of the survey.

Questionnaire subjects and period: We investigated Japanese university students’ opinions by questionnaire. The questionnaire is based on Iwama et al. (2014).

Date: May 2011 to April 2016

Survey content: Question (1) of the questionnaire asked students about their “experiences”, such as “nature-based experiences”, in their lives so far; while Question (2) asked about their “view of life”. The question items regarding “experiences” were limited to experiences that do not involve the use of tools such as microscopes or binoculars to ensure that the content comprised experiences that can be had in nature or within everyday life (Table 1).

1. Question (1). Survey regarding “experience”: the question presented 16 items asking about respondents’ experiences playing within nature, observing wild animals and plants, raising animals and plants, and seeing animals give birth and lay/hatch eggs, etc., to which the subjects responded by selecting the most applicable answer from “Happened often”, “Happened occasionally”, “Did not happen often” and “Virtually never happened”.

2. Question (2). Survey regarding “view of life”: the question asked respondents about “what times they experienced the sensation of life”. It presented 14 items regarding the germination/growth/withering of plants, and the birth/growth/death of animals, etc., to which the subjects responded by selecting the most applicable answer from “Agree (feel so)”, “Slightly agree”, “Slightly disagree”, and “Disagree (do not feel so)”.

3. In 2014, we analyzed the factor structure of the response sheets, we conducted an exploratory factor analysis (maximum likelihood estimation and promax rotation) regarding the aggregate results for both experiences and views of life. “Experience factors” and “life factors” were identified and the coefficient of correlation between the factors was calculated. In addition, a path analysis was conducted of the validity of the structure of causal relationships. For statistical analysis, SPSS21.0 and Amos18.0 were used. In this research, we analyze differences from survey between male and female students.
Table 1. Questions in the questionnaire about “experiences” and “view of life”

**Questions**  
**Items for “experiences”**
1. Have you ever played in the mountains, along rivers, or at the beach? (PMR: Played in the mountains or along rivers)  
2. Have you ever seen wild animals in the mountains or fields? (SWA: Saw wild animals)  
3. Have you ever picked flowers in the mountains or fields or gathered nuts as you played? (PFN: Played with flowers or nuts)  
4. Have you ever observed wildflowers/native grasses? (OGW: Observed native grass/wildflowers)  
5. Have you ever caught insects? (CAI: Caught insects)  
6. Have you ever fished for and/or caught fish? (CAF: Caught fish)  
7. Have you ever grown plants from seeds? (GPS: Grew plants from seeds)  
8. Have you ever kept animals at your home? (TWA: Touched warm animals)  
9. Have you ever kept animals at your home? (RAH: Raised animals at home)  
10. Have you ever raised animals at school? (RAS: Raised animals at school)  
11. Have you ever seen egg-laying/egg-hatching? (SEL: Saw egg-laying/egg-hatching)  
12. Have you ever seen the birth of mammals? (SBM: Saw the birth of mammals)  
14. Have you ever been to a zoo or botanical garden? (WZB: Went to a zoo or botanical garden)  
15. Have you ever been to a museum? (WEM: Went to a museum)  
16. Have you ever watched TV programs, etc., on wild creatures? (SWF: Saw a wildlife film)

**Items for “view of life”**
1. When seeing plants germinate and/or grow (PGG: Plant germination and growth)  
2. When plants you were cultivating withered (WCP: Withering of cultivated plants)  
3. When seeing wild plants growing in the mountains/fields or along the roadside (LWP: When looking at wild plants)  
4. When seeing plants withered in the mountains/fields or along the roadside (WWP: Withering of wild plants)  
5. When seeing wild animals in the mountains or fields (LWA: When looking at wild animals)  
6. When seeing animals dead in the mountains/fields or along the roadside (DWA: Deaths of wild animals)  
7. When seeing herbivore meals (HEM: Herbivore meals)  
8. When seeing carnivore meals (CAM: Carnivore meals)  
9. When seeing animals lay/hatch eggs (ALE: Animals laying/hatching eggs)  
10. When raising animals (WRA: When raising animals)  
11. When looking at the birth or growth of mammals (BGM: Birth and growth of mammals)  
12. When looking at animals raising their young (ARY: Animals raising their young)  
13. When touching or holding warm animals such as dogs, cats, or birds (TWA: When touching a warm animal)  
14. When an animal you were raising died (DDA: Death of domesticated animals)

**RESULTS**

Survey on experiences such as nature-based experiences and view of life

Table 2 presents the aggregate of the positive answers to the questions regarding “what times [the respondents] experienced the sensation of life” for the section of the survey examining subjects’ “view of life”.

Figure 1a and 1b presents the survey results for the section regarding “experiences” in graph form. Figure 1a shows the results for male students and Figure 1b shows the results for female students. The values in parenthesis at the end of each item are average values (arithmetic averages), with values for each response allocated as follows; 4 points for “Happened often”, 3 points for “Happened occasionally”, 2 points for “Did not happen often” and 1 point for “Virtually never happened”.

Furthermore, Figure 2a and 2b presents the survey results for the section regarding “view of life” in graph form. Figure 2a shows the results for male students and Figure 2b shows the results for female students. The values in parenthesis at the end of each item are average values (arithmetic averages), with values for each
response allocated as follows; 4 points for “Agree”, 3 points for “Slightly agree”, 2 points for “Slightly disagree” and 1 point for “Disagree”.

(1) Situations in which respondents experienced the sensation of life

The situation in which respondents most experienced the sensation of life was the “Birth or growth of animals (mammals)”, with 561 of the 607 respondents (92.4%) giving this response (Table 2). The second-highest response was “Animals laying/hatching eggs” (551 respondents; 90.8%); the third-highest response was “Animals raising their young” (548 respondents; 90.3%); the fourth-highest response was “Deaths of domesticated animals” (540 respondents; 89.0%); the fifth-highest response was “When touching a warm animal” (525 respondents; 86.0%); and the sixth-highest response was “When raising animals” (515 respondents; 84.8%). While the six highest-ranking responses were concerned with animals, the seventh-highest response was “Plant germination and growth” (494 respondents; 81.4%). The lowest-ranking response was “Withering of wild plants” (291 respondents; 47.9%), with approximately 50% to 80% of respondents replying that they “experiencing the sensation of life” for items related to the germination, growth, and withering of plants.

(2) Survey regarding Items for “experiences”

For Item 1, “Played in the mountains or along rivers (PMR)”, 289 (184+105) of the 311 male respondents (average value 3.50) and 269 (143+126) of the 296 female respondents (average value 3.37) gave affirmative responses, saying the experience had “Happened often” or “Happened occasionally” (Figure 1). There is a significant difference at the 0.05 level.

Note: AV: Average values 607 university students (311 male, 296 female)
The answers which are significant differences at the 0.01 level are as follows. For Item 2, “Saw wild animals (SWA)”, 283 male respondents (average value 3.5) and 257 female respondents (average value 3.34) responded affirmatively; for Item 5, “Caught insects (CAI)”, 272 male respondents (average value 3.50) and 227 female respondents (average value 3.18) responded affirmatively; for Item 6, “Caught fish (CAF)”, 238 male respondents (average value 3.20) and 193 female respondents (average value 2.80) responded affirmatively; and for Item 13, “Looked at a plant/animal pictorial book (LPA)”, 267 male respondents (average value 3.33) and 225 female respondents (average value 3.15) gave affirmative responses. And the significant differences at the 0.05 level are as follows. For Item 4, “Observed native grass/wildflowers (OGW)”, 252 male respondents (average value 3.28) and 266 female respondents (average value 3.42) responded affirmatively; for Item 7, “Grew plants from seeds (GPS)”, 259 male respondents (average value 3.28) and 275 female respondents (average value 3.42) responded affirmatively; for Item 12, “Saw the birth of mammals (SBM)”, 112 male respondents (average value 2.14) and 85 female respondents (average value 1.92) responded affirmatively; and for Item 14, “Went to a zoo or botanical garden (WZB)”, 282 male respondents (average value 3.40) and 283 female respondents (average value 3.54) gave affirmative responses. Thus the experiences about “Saw wild animals”, “Caught insects”, “Caught fish” were higher for male than female respondents, and the experiences about “Observed native grass/wildflowers” and “Grew plants from seeds” were slightly higher for female than male respondents.

Furthermore, the items with which respondents had had little experience were Item 11 “Saw egg-laying/egg-hatching” and Item 12 “Saw the birth of a mammal”, and the number of students that had experienced watching “Saw the birth of mammals” was the lowest of all responses (average value male 2.14, female 1.92).

(3) Survey regarding Items for “view of life”

For Question (2), “In what situations do you experience the sensation of life?”, the items with the highest average value were Item 11, “Birth and growth of mammals (BGM)”, 277 (182+95) of the 311 male respondents (average value 3.46) and 284 (215+69) of the 296 female respondents (average value 3.68) gave affirmative responses as “Agree (feel so)” or “Slightly agree” (Figure 2). For Item 9, “Animals laying/hatching eggs (ALE)”, 277 male respondents (average value 3.44) and 274 female respondents (average value 3.61). For Item 12, “Animals raising their young (ARY)”, 275 male respondents (average value 3.35) and 273 female respondents (average value 3.50). For Item 14, “Deaths of domesticated animals (DDA)”, 269 male respondents (average value 3.41) and 271 female respondents (average value 3.57). For Item 13, “When touching a warm animal (TWA)”, 263 male respondents (average value 3.28) and 262 female respondents (average value 3.49). For Item 10, “When raising animals (RAA)”, 256 male respondents (average value 3.23) and 259 female respondents (average value 3.40). For Item 1, “Plant germination and growth (PGG)”, 235 male respondents (average value 3.06) and 259 female respondents (average value 3.32). There are significant differences between male and female from ranking no.1 to 7 Items at the 0.01 level. As average value, female students’ view of life with regard to living things is higher than male students’.

Note: AV: Average values, SD: standard deviation, t-test: Significant difference (P) *:0.05 significance level; **:0.01 significance level
Table 5 is a modified version of the original paper Iwama et al. (2014), “Journal of Research in Science Education”. When factor analysis (maximum-likelihood method; promax rotation) was carried out on the response results for all of the questionnaire subjects with Question (1) items as the items for “experiences”, four factors were identified: “learning experiences”, “nature-based experiences”, “experiences capturing/ gathering animals”, and “experiences raising/ having contact with animals”. The cumulative eigenvalue was 10.50 and the cumulative contribution ratio was 65.61% (Table 5). The goodness-of-fit for the factor analysis was $\chi^2 = 178.161, df = 62, and p = 0.000$; the $\alpha$ coefficients for the four factors identified were $\alpha = 0.825, \alpha = 0.852, \alpha = 0.768, and \alpha = 0.710$, respectively, confirming reliability. Similarly, when factor analysis (maximum-likelihood method; promax rotation) was carried out on the response results for all of the questionnaire subjects with Question (2) items as the items for “view of life”, three factors were identified: “lives of animals”, “lives and deaths of plants”, and “deaths of animals”. The cumulative eigenvalue was 8.09 and the cumulative contribution ratio was 57.79% (Table 4). The goodness-of-fit for the factor analysis was $\chi^2 = 256.653, df = 52, and p = 0.000$; the $\alpha$ coefficients for the four factors identified were $\alpha = 0.816, \alpha = 0.765, and \alpha = 0.711$, respectively, confirming reliability.

We analyze about “experiences” and “view of life” using these factors.

Table 6 shows a cross-correlation of synthetic variables for “experiences” and “view of life” for male and female students. The simple total of scores for items including each of the factors was calculated as the scores for each factor, and when the correlation coefficient for each relationship was calculated, the correlation was found to be significant (1% standard) for all 21 factor combinations. (Table 6, **:0.01 significance level; *:0.05 significance level; correlation coefficients are shown in the table.)

In other words, “learning experiences”, “nature-based experiences”, “experiences capturing/ gathering animals”, and “experiences raising/ having contact with animals” have a significant correlation with “lives of animals”, “lives and deaths of plants”, and “deaths of animals”, and these experiences are effective factors in developing a “view of life”.

When the relationships between the experience-related factor, “learning experiences”, and each “view of life” factor were calculated using correlation coefficients, the correlation coefficients for “learning experiences (LE)” and each factor for male respondents were “lives of animals (LA)” ($r = 0.419**$), “lives and deaths of plants (PL)” ($r = 0.287**$), “deaths of animals (DA)” ($r = 0.249**$); and female respondents were “lives of animals” ($r = 0.329**$), “lives and deaths of plants” ($r = 0.347**$), and “deaths of animals” ($r = 0.237$).

Furthermore, when the relationships between the experience-related factor, “nature-based experiences (NE)”, and each “view of life” factor were calculated using correlation coefficients, the correlation coefficients for “nature-based experiences” and each factor for male respondents were “lives of animals” ($r = 0.351**$), “lives and deaths of plants” ($r = 0.302**$), and “deaths of animals” ($r = 0.249**$); and female respondents were “lives of animals” ($r = 0.280**$), “lives and deaths of plants” ($r = 0.330**$), and “deaths of animals” ($r = 0.200**$).

Test for correlation: “upper triangle; male respondents /lower triangle; female respondents”

Numbers: correlation coefficients. Determination: *:*0.05 significance level; **:*0.01 significance level
Next, when the relationships between the experience-related factors, “experiences capturing/ gathering animals (CE)” and “experiences raising/ having contact with animals (RE)” and each “view of life” factor were calculated using correlation coefficients, the correlation coefficients for “experiences capturing/ gathering animals” and each factor for male respondents were “lives of animals” ($r = 0.299**$) and “deaths of animals” ($r = 0.236**$); in contrast, the correlation coefficients for “experiences capturing/ gathering animals” and each factor for female respondents were “lives of animals” ($r = 0.269**$) and “deaths of animals” ($r = 0.184**$). Furthermore, the correlation coefficients for “experiences raising/ having contact with animals” and each factor for University A students were “lives of animals” ($r = 0.369**$) and “deaths of animals” ($r = 0.330**$); in contrast, the correlation coefficients for “experiences raising/ having contact with animals” and each factor for students of the other universities were “lives of animals” ($r = 0.358**$) and “deaths of animals” ($r = 0.188**$).

Thus the research results show that male students had higher positive correlations for all animal’s factor of “view of life” related to experiences than female students. And female students had higher positive correlations for all plant’s factor of “view of life” related to experiences than male students. As for this result, we were thought that male students had much experience for the wild animal, and female students much experience for the plant.

**CONCLUSIONS**

The results of a survey questionnaire of university students that was conducted regarding “experiences and view of life” showed that the question item for which respondents most replied that they “experience the sensation of life” was “birth or growth of animals (mammals)” followed by “animals raising their young”, “animals laying/hatching eggs”, and “deaths of domesticated animals”. Of the 14 question items, the six highest-ranking items all concerned animals, while the seventh-highest ranking item concerned “plant germination and growth”. For these items, over 80% of students replied that they “experience the sensation of life”.

The analysis about “experiences” and “view of life” are as follows: (1) Gender differences are perceived about “nature-based experiences”, “experiences capturing/ gathering animals”, and they are effective in developing view of life with regard to living things. (2) As female students’ view of life with regard to living things is higher than male students’, “experience raising/contact with animals” is effective in developing a view of life than “experiences capturing/ gathering animals”. (3) Nature-based experience, learning experience on living things and experiences of breeding or contact with animals can be an effective medium for developing view of life. (4) Students’ view of life with regard to plants is lower than animals, especially withering of wild plants.

We can conclude that sensing living things and developing view of life through experiences is important for science education. It is a future problem how to develop view of life with regard to plant on aspects of the view of biodiversity and environmental education.

TEACHING CHEMISTRY-RELATED PROFESSIONS IN THE FIELD OF ENVIRONMENTAL PROTECTION

Rabea Wirth and Verena Pietzner
Carl-von-Ossietzky University Oldenburg, Oldenburg, Germany

As a part of the PACE-Chem project (Professional Approaches to Career Education in Chemistry) we are developing materials for a School Lab as well as for a professional development courses for chemistry teachers that connect chemistry-related professions with an environmental protection context. The materials deal with environmental protection in the areas of economy, landscape projection/agriculture as well as public administration. In the School Lab, the students work on the analysis of different fertilizers that are embedded in different contexts of the professions considered, like Environmental Lab Technician, Agricultural Biologist or Environmental management officer. The concept of the School Lab, the professional development course for chemistry teachers as well as first results of the evaluation of the material will be presented.

Keywords: career education, environmental protection, chemistry school labs

THEORETICAL BACKGROUND

During their schooldays, students have to master the task of making a suitable career choice for themselves. The students have to align their interests, desires, knowledge and skills with the possibilities, needs and requirements of the professional world. Therefore, career education for young people is a complex task in which they need assistance (Taskinen, 2010; Krapp, 2006). The career choice of an individual is influenced by different stakeholders (see Figure 1), like family, personal interests, peer groups and school (Andre, Whigham, Hendrickson, Chambers, 1999, Bianchini, Cavazos, Helms, 2000, Kniveton, 2004; Bregnab, Killen, 1999, Pannizzon, 1997). All of them are important for young people, but school often does not take over responsibility, although it is an important mission. One important part of career education in the field of Science Education is Scientific Literacy.

![Figure 1. Stakeholders for career choice](image-url)
In the curriculum for natural sciences in Germany, scientific literacy is characterized as follows: it "provides an orientation for professional fields of science and technology [...] foundations for connection-oriented learning [creates] and [...] thus perspectives for the later career choice [opened]" (KMK 2007; OECD, 1999). The curriculum for natural sciences in Germany explicitly mentions that the students should be able to name and describe chemical professions (Niedersächsisches Kerncurriculum, 2007). This means that career education is an important task of the German education system that should be integrated into everyday teaching, in particular with respect to teaching scientific literacy. Therefore, teachers should address career education in their lessons; in chemistry class, students should learn about scientific and technical fields of work in order to get a better foundation for their career choice (Marks, Stuckey, Belova, and Eilks, 2014; Dedering, 2002, Curry, Belser, binns, 2013). In Germany, every school has to develop an own career education concept. However, these concepts mostly cover only general aspects of career education like the analysis of the personal interests and skills. The integration of career education into the respective school subjects, also the subject of chemistry, is still missing. Therefore, students know only little about typical activities of scientists or engineers (Frank, 2014). For this reason, it is important to develop teaching materials for chemistry-related career education that can easily be integrated into the chemistry curriculum.

There are two theories of particular interest for studies on career education. In his RIASEC model Holland postulates that each individual can be categorized into one of six different personality patterns: realistic, investigative, artist, social, enterprising, and conventional. The more an individual fits into a personality pattern, the more stable, for example, are professional and academic achievements (Holland, 1966, 1997). However, it is to classify most people in just one personality pattern. This is why Holland's theory was improved by Nauta, Kahn, Angell & Cantarelli (2002). They consider that an individual has a secondary and tertiary personality pattern in addition to his primary personality pattern, and developed the so-called Holland code. In the Holland code, three letters of the six personality traits describe the individual personality pattern. For example, a natural science scholar should have the following personality pattern: ISC (investigative, social, and conventional).

The second theory is the integration approach of Gottfredson (1981). According to Gottfredson, an individual develops his or her personal self-concept during childhood according gender, status/prestige of a profession and personal priorities. This process takes place in four phases: Orientation to size and power (3-5 years), orientation to gender role (6-8 years), orientation to prestige (9-13 years) and orientation on the inner self (14+ years).

![Figure 2. Phases of the theory of Gottfredson (1981)](image)
With these four phases, an individual develops a self- and professional concept, which leads to a career choice. According to Gottfredson, teenager from the age of 14th deals seriously with suitable professions. However, if a compromise between the self- and professional concept has to be found, the phases are traversed backwards and hierarchically, and no phase can be skipped. Therefore, previously developed aspects have a higher effect than later developed. This means that when choosing a profession, one might rather choose a career with less prestige that one that does not fit to his or her gender. This means that gender plays an essential role in the choice of a career (Gottfredson, 1981; Kristen, 2007).

The choice of a career is also influenced by a person’s self-efficacy. The concept of self-efficacy is based on Banduras (1994) assumption: “Perceived self-efficacy is defined as people’s beliefs about their capabilities to produce designated levels of performance [...].” The individual self-efficacy is influenced by actionability and objective performance. This means that to succeed in an action or performance, an individual has to be confident in his- or herself (Gebauer, 2013).

Within the PACE-Chem project, the institutional framework for career education in chemistry classes of secondary schools has been investigated (Haase, 2017). More than 1,000 students of grade 7-10 at secondary schools in Lower Saxony have been asked about their knowledge about chemical professions. German students of this age only have little knowledge about chemistry-related professions; the most known professions are chemistry teacher and chemist (unspecified). Therefore, the students do not know about the diversity of chemical professions. Keeping in mind that this also holds true for students of secondary schools that do not lead to Abitur (necessary to enter University), this is an alarming fact. These students might be sure that chemistry has no relevance for them because they might think that there is not chemistry profession that they can learn.

First concepts for the implementation of chemistry related career education in the form of career-oriented learning tasks were already developed and tested in chemistry class (Pietzner & Sokolowski 2014; Alberding, 2016). To integrate professions related to chemistry as well as environmental protection, we developed a School Lab activity for students of grade 7-10. This activity should give an insight into the diversity of chemical professions in this field. The tasks in the school lab deal with the context of the analysis of a fertilizer. The lab includes the following professions:

- Agricultural-technical assistant (apprenticeship)
- Environmental management officer (continuing education)
- Agri-biologist (University study programme)
- Environmental scientist (University study programme)

The materials contain various experiments for the analysis of a fertilizer, which are designed to detect different ions. At the beginning of the School Lab the students get an introduction into the topic. Here, the whole activity is contextualized. The students are set into the situation that a citizen comes to them to get a recommendation about a suitable fertilizer for potatoes. Afterwards, every group gets one of three different fertilizers and has to find out if this fertilizer
is suitable for the requested purpose. For this, they first do a sample preparation in the lab and then analyze the fertilizer.

In addition, we offer professional development courses for chemistry teachers to support them in implementing career education into their classes. Here, the teachers get an introduction into the basics of career education and work on the experiments of the School Lab. Afterwards, there is a reflection on the experiments and a discussion about possible settings in chemistry class.

With the accompanying evaluation, we would like to answer the following research questions:

1. What is the impact of the School Lab on the students’ self-efficacy?
2. What do the students learn about chemical professions within the Lab?
3. What differences regarding gender or age exist with regard to self-efficacy and occupational perceptions?

**METHOD**

To evaluate the school lab, the students filled out a questionnaire at the end of the lab time. In order to pilot the materials and the questionnaire for the students, both were carried out with 4 classes and a total of 96 students. Afterwards, the questionnaire and the material have been revised. The questionnaire for the students includes the following structure:

1. Career education at school from the student's view
2. Rating of activities of chemical professions with respect to self-efficacy
3. Evaluation of experimental handling with respect to self-efficacy
4. Rating of own chemistry lessons
5. Information about the visit of the school lab
6. Personal data

The questionnaire has 4 pages and the students have up to 30 minutes to answer the questions. The reliabilities for the questions about typical activities in chemical professions, experimentation in the school laboratory and chemistry classes in general and about chemical skills range between $\alpha = 0.557$ and $\alpha = 0.939$ and thus are acceptable (see Table 1). Date evaluation was done with the program SPSS 24. For the questions related to activity, experiments and chemistry lessons general and chemical skills a factor analysis was carried out. With this, different factors could be identified that were discussed in a panel of experts and the discussion revealed the following factors. The factors analysis of the activities resulted in two factors *affective aspects* as well as *performance*. In the experiments, the two factors arose *affective aspects* and *improvement of performance*. The item for chemistry education generally invite to a single factor, and the items for *chemistry lessons* in terms of chemical skills have resulted in the following four factors: *competence in chemistry, social aspects, self-efficacy in secondary subjects and everyday aspects of chemistry*. After that, the differences regarding gender, grade (7/8 and 9/10) and the type of school were evaluated with interference-statistical methods.

**RESULTS**

The sample comprises a total of 615 students of grade 7-10. The study was conducted in the Federal States Lower Saxony and Hesse. In total, 51 % of respondents were female and 49 % male. Almost 24 % of the respondents were learners from the grades 7/8 and 76 % of 9/10, respectively. The number of students from Realschule, Gymnasium (grammar school), Oberschule and Gesamtschule (comprehensive school) was fairly balanced, whereas only about 2 % of the 615 learners visit a Hauptschule (see Table 2).

The first question in the questionnaire was: “Do you already have a career aspiration?”. Of the 615 students, 608 responded this question. Only 158 (26.0 %) of the students have no career aspirations (see Table 3).

In addition, the students should specify their career aspiration. Of the 450 students that answered the first question with “yes”, 391 named a specific career aspiration (see Table 4). Only 59 of the students didn’t answer the question. To evaluate the answers, we have classified the professions into ten categories according to the German Federal Employment Agency. The categories are: Military; commercial services, trade, distribution, hotel and tourism; agriculture, forestry, animal husbandry and horticulture; raw material production, production and manufacturing; construction, architecture, surveying and building technology; organization, accounting, Law and administration; transport, logistics, protection and security; media, art, culture and design; natural sciences, geography and computer science and health, social, teaching and education.

</tbody>
</table>

Table 4 shows the results from the questionnaire, which shows the numbers of student responses in the field of profession. About 27 % of the students can imagine taking a job in the field of health, social affairs, teachers and education. Within this range, some students have indicated that they can imagine working as teachers in the field of natural sciences. Only three students have explicitly stated that they want to become chemistry teachers. This area is followed by the field of natural science, geography and computer science. However, most students have specified computer science as a career aspiration. Only 2 % of the students have indicated a chemical profession as a career aspiration.

The above factors are further investigated by the Mann-Whitney-U-Test (see Table 5, Table 6 and Table 7). Table 5 shows the factors that have ranked significantly higher by male students. The factors performance in activity (U = 32177.000, Z = -2.618 **), competence in chemistry (U = 28087.000, Z = -1.709, p = 0.087), and self-efficacy in secondary subjects (U = 14948.000, Z = -9.924 **) are considered to be more relevant for male students than for female students.

</tbody>
</table>

Table 6 shows the factors that are ranked higher by female students. What is interesting about the results is above all that for female students, chemical professions can be introduced by using social tasks. The factors affective aspect (activity) ($U = 29696.000$, $Z = -3.971^{**}$), both for activities and for chemical experimentation ($U = 27067.500$, $Z = -3.270^{**}$) and social aspects ($U = 23053.000$, $Z = -2.618^{**}$) are relevant for girls. To bring female students closer to chemistry and to inform them about the activities, the materials should consider affective and social aspects. For example, in our materials on environmental protection, we also address social issues in addition to the chemical background.

Table 7 shows the factors showing no significant difference between male and female students. These factors are improvement in performance, aspects of chemistry, and everyday aspects in the field of chemistry. Here, everyday aspects of chemistry is of particular interest since this aspect applies to both boys and girls. This implies that using everyday aspects of chemistry to implement career education within the chemistry curriculum might be a suitable strategy.

DISCUSSION AND CONCLUSIONS

The most students have a career aspirations, but chemistry related professions are less relevant. However, they showed much interest during the School Lab Activity what indicates that students might be more interested in chemistry-related professions if they knew more about it. For this reason, it is relevant to show the students as many different professions as possible and also to discuss the expertise required for these professions. Overall, it is important for young people to look up other professions in addition to the classical chemistry professions like Chemistry Lab Technician or Chemist. The students should have a good overview of the professional world in order to be able to find the best possible job after graduation.

The results show that is gives significant differences between boys and girls respect to activities of professions and chemical experiment. It is important that the career guidance materials are adapted to the needs of the students in order to reach as many students as possible. Currently, we develop a new school lab to cover more chemical professions in the field of environmental protection.

ACKNOWLEDGEMENT

We thank the Deutsche Bundesstiftung Umwelt for supporting our project.

INVESTIGATING TEACHER PLCS IN SUPPORT OF AN AFTER-SCHOOL STEM CLUB: A COMPARATIVE CASE STUDY

Kylie S. Hoyle¹ and Margaret R. Blanchard²
¹University of Colorado Colorado Springs, Colorado Springs, USA
²North Carolina State University, Raleigh, USA

Professional Learning Communities (PLCs) have been initiated in school systems and other educational settings with the goal of enhancing student outcomes. Studies focused on PLCs suggest that PLCs contribute to positive outcomes, not only for students, but also for teachers and can aid in supporting educational initiatives. However, the role of a PLC has yet to be investigated in connection to an after-school STEM program. In this comparative case study, Teacher-Coaches (T-Coaches) from two rural middle schools in the southeastern United States (U.S.) participated in a novel version of a PLC, in which teacher professional development sessions and pre-club (PLC) meetings prepared them to lead after-school STEM Club meetings. This study investigated how T-Coach teams interacted during PLCs to plan STEM Club activities, and then to implement them in after-school STEM Career Clubs at their middle school. The community of practice (CoP) social learning framework (enterprise, mutuality, and repertoire) was used to gain an understanding of how T-Coaches interacted in their PLCs, based on audio recordings of PLC planning meetings. Additionally, field notes taken during STEM Club meetings were used to code the Dimensions of Success (DoS) observation tool in order to document how STEM Clubs were carried out. Results indicate that in each case, the clubs’ teachers interacted positively during PLC meetings. However, in one of the club’s PLCs, Southern Middle School, the T-Coaches interacted in ways that demonstrated higher and more equivalent levels of enterprise, mutuality, and repertoire. The DoS ratings for the STEM Clubs at Southern Middle School were higher in nearly all twelve scored dimensions. These findings indicate that all aspects of the CoP social learning characteristics were important in supporting STEM Club implementation.

Keywords: plcs, teacher professional development, stem clubs

SUBJECT/PROBLEM

The implementations of Professional Learning Communities (PLCs) can lead to positive results for new initiatives (Park & So, 2014; Ronfeldt, Farmer, McQueen, & Grissom, 2015) and have resulted in benefits for teachers and students (Hardinger, 2013; Owen, 2015; Ronfeldt et al., 2015). This study investigated the role of a PLC, as a Community of Practice (CoP) in the context of an informal setting (i.e., after-school STEM Club), which has yet to be investigated. Drawing on previous literature, implementing a PLC can advance teachers' knowledge, efficacy, and beliefs (Miranda & Damico, 2015; Moirao, Morris, Klein, & Jackson, 2012; Owen, 2015; Park & So, 2014). In addition, research on effective PLCs have reported that encouraging more innovative teaching practices and communication between teachers positively impacts outcomes (Owen, 2015; Park & So, 2014; Vescio, Ross, & Adams, 2008). Research on Professional Learning Communities (PLCs) has provided evidence that PLCs have a higher success rate when interpersonal relationships are strong (Robertson & Jones, 2013). If relationships are lacking, this can lead to antisocial, non-collaborative environments, which
may result in feelings of isolation, resentment or tension (Morton, 2010). Investigating Teacher-Coach interactions can provide insight into how collaborative teams work with one another to prepare and achieve a common goal, such as a STEM after-school program. STEM programs can encourage K-12 students' engagement and stimulate interest in STEM fields and careers. Some schools have piqued student interest in STEM through STEM Clubs, Robotics clubs, Engineering clubs, or closely related subjects (ChanJin Chung, Cartwright, & Cole, 2014; Dabney et al., 2012; Dabney, Tai, & Scott, 2015; Kong, Dabney, & Tai, 2014). However, few researchers have studied the foundation and structure of these STEM programs (Franco, Patel, & Lindsey, 2012; Nikischer, 2013; Schneider, 2012; Walton, 2015; Ward, 2015). To date, no researchers have investigated how club leaders who implement STEM programs work together to achieve intended program and student outcomes.

**Theoretical Framework**

This study is informed by Wenger's (1998) Community of Practice (CoP). A CoP is defined as "groups of people who share a concern or a passion for something they do and learn how to do it better as they interact regularly" (p. 1). Snyder and Wenger (2010), Wenger (1998; 2000), and Wenger and Snyder (2000) describe three characteristics that define a CoP: domain, community, and practice. In this study, the **domain** is the STEM Career Club project, the **community** is the group of teachers from a single school who attend TPD meetings and PLC meetings, and the **practice** is teachers carrying out the STEM Club at their schools. The purpose of a CoP is to develop members' abilities and to share and build knowledge. Social learning takes place in a CoP when there is enterprise (learning energy), mutuality (interpersonal relationships), and repertoire (community norms and reflection) as referred to as 'Dimensions of Progress' (Wenger, 2000).

**Research Questions**

1) How do teachers interact and prepare for STEM Clubs during Teacher-Coach PLC meetings, and 2) Are there differences in STEM Club outcomes for the two clubs, and how do these relate to interactions during Teacher-Coach PLCs?

**DESIGN/PROCEDURE**

**Design**

This study uses a comparative, case study design (Creswell, 2014) to investigate how Teacher-Coaches (T-Coaches) who lead after-school STEM Career Clubs interact and collaborate to prepare for student club meetings. T-Coach teams from two STEM clubs that were a part of a larger-scale teacher professional development (TPD) project were purposely selected as separate cases. STEM clubs at these two schools were observed, and qualitative data was gathered during T-Coaches’ PLC meetings, and during STEM clubs.

**Context**

This investigation is part of a three-year National Science Foundation (NSF) ITEST grant serving four rural, high poverty, high minority population middle schools. The focus of the NSF grant was to increase the awareness of, interest in, preparation for, and intention of middle
school students to continue in STEM courses, major in STEM, and possibly pursue STEM careers. Each of the STEM Clubs at the four middle schools were led by a group of teachers from each school (T-Coaches), located in two middle schools in the southeastern United States (U.S.).

**Teacher-Coach Professional Development**

Teacher-Coaches received teacher professional development at one of the school locations. The TPD took place from nine am to four pm on four Saturdays spread throughout the school year, and rotated to a different middle school for each session. On each TPD Saturday, university staff modeled the procedures in the manner and design they intended for the next three STEM Clubs to be conducted, with the teachers participating (as a team) as the students would, then reflected on instructional considerations. All STEM activities highlighted at least one of the STEM content areas in each club and were explicitly linked to potential STEM careers. The T-Coaches were given all materials needed to reproduce the activities with their students at their schools, packaged for each club meeting. T-Coaches also received club agendas, and any packets or worksheets necessary for the meetings, to aid the T-Coaches in preparation and organization for their clubs. After the TPD, T-Coaches were encouraged (and paid) to have a one hour PLC meeting before each club meeting to prepare for the club, which they facilitated. Ideally, the T-Coaches would have twelve PLC meetings each year in preparation for the twelve STEM Clubs. T-Coaches received ongoing support between the TPD sessions through frequent communication with the research team members via email and periodic visits to school sites.

**Cases**

The researcher wanted to select two schools as cases that represented the diversity of the four clubs (Creswell, 2014). The preliminary Dimension of Success scores, Teacher Belief Interviews, degree of PLC meeting implementation, club structure, and attendance at Teacher Professional Development were used to select the two study schools, Northern MS and Southern MS. These individuals were expected to take part in the TPD, PLC meetings, and after-school activities. T-Coaches also completed a survey on demographic, educational, and career status that was self-reported. Data was collected during fall and spring of the study year.

**DATA SOURCES AND ANALYSIS**

Qualitative data was collected during the T-Coaches’ PLC meetings (up to six) as they planned for the club meetings and during the six STEM Clubs implemented during this study.

**PLC Meetings Audio Data and Analysis**

Prior to each club meeting, STEM Club T-Coaches met to review materials and to plan for the next student club meeting. STEM Club T-Coaches were strongly encouraged (and paid) to attend PLC meetings (the anticipated length was 60 minutes). The research team provided checklists matched to each of the STEM club meetings for the T-Coaches to use as a guide for their PLC work. During PLC meetings, T-Coaches were asked to audio record all of the planning meetings that were held, in order to capture the interactions they had as they worked
through the logistics of the club activities. Audio recording was done to capture the interactions taking place. The audio data was transcribed verbatim by a professional transcriptionist and open coded in Atlas.ti by the first author. Four PLC meetings (out of a possible five) from Northern MS were audio recorded, and three from Southern MS (out of a possible five), resulting in approximately three and a half hours of audio recordings and 200 double-spaced pages of transcription data. The first read-through of the transcripts was used to gain a general understanding of what was taking place (Creswell, 2014); then, a second pass was used to document the activities of each of the T-Coaches throughout the PLC. The third pass was to code for the frequency of the T-Coaches actions, and the fourth pass was to code the statements of the T-Coaches into one of the three a priori characteristics from the CoP: mutuality, repertoire, and enterprise. These were also frequency coded for each team, at each PLC meeting.

**Dimensions of Success Observation Tool and Analysis**

The researcher was present at all student club meetings at both schools during this study (twelve club meetings, total). The researcher recorded which T-Coaches were present, and how many students were present. Field notes were taken and used to score the DoS observation tool (see Figure 1) immediately following the club meetings. Each meeting for the two STEM Clubs was given a dimension score for each of the twelve DoS dimensions, which was also totaled for an overall score. The CoP analysis of the presence of mutuality, repertoire, and enterprise were then compared to the DoS scores, to analyze whether there was a relationship between the team’s quality of social learning in the CoP and the DoS scores.

![Figure 1. The DoS domains and dimensions (Based on Papazian et al., 2013)](image-url)
FINDINGS

Northern MS PLC

This T-Coach team spent a considerable amount of time attempting to teach one another what the club activities were about and the associated content, which was most likely due to the low attendance of the team members at the TPD (one of which was beyond their control). These absences resulted in gaps in the knowledge of team members, and they used PLC time to address these gaps, which showed that the Northern PLC members cared about the success of the club meetings. Another regular focus area of every PLC meeting was planning for STEM Club procedures, routines, supplies, club structure, and logistics. These interactions showed that the T-Coaches have a certain way of doing things within their PLC (i.e., roles and responsibilities) and trusted each other's ability to complete a task. Interactions also provided evidence that, when an issue or challenge arose, the team was willing to work together in a democratic way, in which each member's voice was valued. The focus of the interactions between team members also indicated a high priority on student interest, engagement, and comprehension. Typically only one or two members dominated the conversation during the meeting, which seemed to result from the fact that only two or more T-Coaches had attended the TPD.

![Activities Performed at Northern PLC Meetings](image)

Figure 2. Activities performed at Northern PLC meetings

Southern MS PLC Summary

This team was lively and often joking with each other during PLC meetings. They spent time reviewing the club activities and the associated content, as they put a high priority on student comprehension. Because all of the teachers had attended the TPD, they were able to focus a lot of the PLC time on procedures, routines, supplies, club structure, and logistics. These interactions showed that the T-Coaches had certain ways of doing things (norms, procedures) within their PLC, such as established roles and responsibilities (i.e., Rosa was the leader) and
trusted each other's ability to complete a task. Interactions also provided evidence that when an issue or challenge arose the team was willing to work together in a democratic way, in which each member's voice was valued. PLC meetings included interactions indicating that the T-Coaches felt comfortable and relaxed with one another (sharing details of their lives), had positive relationships between members, and clearly cared about each other as individuals.

![Activities Performed at Southern PLC Meetings](image)

**Figure 3. Activities performed at Southern PLC meetings**

**Dimensions of Success (DoS) Ratings**

DoS rating averages for both schools over six club meetings are used as descriptive outcomes. The ratings of club success were meant to better understand if certain T-Coach team interactions and higher functioning CoP within their PLC are related to more desirable DoS ratings (score of 3 or 4; 1-Evidence Absent; 2-Inconsisssitant Evidence; 3-Resonable Evidence; 4- Compelling Evidence). Table 1 displays the average DoS ratings for both Northern and Southern MS. The presence of a checkmark signifies a desirable for each domain and dimension.

Although both schools received identical TPD, club materials, and PLC checklists, the two schools differed in their club success, based on the DoS observation tool results. Northern MS met desirable rankings for seven out of twelve dimensions (58%), which translated into achieving desirable ratings for two out of the four domains. Southern MS proved more successful, achieving desirable DoS ratings in eleven out of twelve dimensions (92%), translating to all four domains (see Table 1).

**DISCUSSION & CONCLUSIONS**

Finding from this study reveal that Teacher-Coaches in both of the case study STEM Clubs had communities of practice, with evidence of social learning characteristics (enterprise, repertoire, and mutuality) during PLCs. However, one of the teams (Southern MS) achieved a higher and more equal level of all three characteristics than the other team (Northern MS). The findings from this study also suggests the following: 1) Implementing a PLC in the context of a STEM after-school program assisted T-Coaches in STEM Club facilitation; 2) Levels of social functioning could be examined through communication of the T-Coaches during pre-club PLC meetings; 3) T-Coach teams who exemplified higher levels of all of the social characteristics of a community of practice (enterprise, repertoire, and mutuality) also had higher ratings on dimensions of STEM Club success, based on the DoS ratings; 4) The personal relationships of the team members mattered in terms of more visibly positive STEM Club
experiences and more desirable team outcomes; 5) Attendance at TPD was a critical component to success of the PLC, and then the STEM Club; and 6) The CoP framework and the DoS tool were useful for examining how a STEM Club PLC was functioning, and the resulting success of the clubs.

CONTRIBUTION

From this study, it is recommended that when initiating a STEM after-school program a PLC could assist T-Coaches in preparing for the STEM Clubs. It is also suggested that all of the social characteristics of a community of practice (enterprise, repertoire, and mutuality) be stressed to the team members; as seen in this study, higher levels of these as well as an equal balance can positively impact program outcomes. It is also suggested that personal relationships of team members be encouraged during TPD, as these seemed to matter in terms of more visibly positive STEM Club experiences and more desirable team outcomes. It should be stressed to team members to attend TPD as it was seen as a critical component to success of the PLC, and then the STEM Club. If intending to assess how individuals collaborate to facilitate a STEM program, CoP framework and the DoS tool could both be useful for examining how a STEM program PLC was functioning, and the resulting success of the program.

GENERAL INTEREST

This research is likely to be of most interest to those who are involved in informal STEM education efforts for after school activities or in informal settings and research on the impacts of these experiences. This also informs the implementation of PLCs in education.

HEALTH & WELLBEING

– THE SCHOOL GARDEN, A PLACE TO FEEL GOOD

Susan Pollin and Carolin Retzlaff-Fürst
University of Rostock, Department of Didactics Biology, Rostock, Germany

The school gardens may take over a significant function as an educational resource. Practical and theoretical work in a school garden lets the place become a relevant point of physical activity, stress reduction, sustainable learning and social interactions. With the task, to investigate the design of the teaching environment “school garden”, especially current psychological well-being of pupils is examined. The study is based on the Self-Determination Theory of Deci and Ryan - as a hypothetical construct. By adopting the basic psychological needs of the Self-Determination Theory, the research questions arise in terms of health and personal skills. What effect of well-being and social-emotional competences has garden work on pupils of the sixth grade? The first results of the Mood Questionnaire show a higher value of good mood and observations indicate more social interactions compared to school lessons in the classroom.

Keywords: health, well-being, school garden

INTRODUCTION

Children and adolescents spend a large part of their day at school. Therefore, school has to fulfil further functions beyond education in the classical sense. Promotion of health is one of these tasks. As a science subject, biology lessons can make an important contribution in this context. Specifically working in the school garden could be a suitable way to achieve this.

Studies show that garden activities and exercise substantially contribute to personal well-being (Barton & Pretty, 2010; Retzlaff-Fürst, 2016). Here, well-being is considered a predictor for health. As early as 1984, Ulrich reported that encounters with nature promote health (Ulrich, 1984). Further positive effects are summarized by The Health Council of the Netherlands in it's metastudy („Nature_and_health.pdf“, 2004), such as stress relief, physical activity, social contacts, as well as childhood and personality development.

However, the school environment itself has hardly been studied to date. Blair (2009) and Williams and Dixon (Williams & Dixon, 2013) specifically emphasize the need for scientific data. The aim of our study is to fill this gap. The effects of work in the school garden on the health of children will be investigated on a broad empiric basis, especially against the background of the basic needs of the Self-Determination Theory (Deci & Ryan, 2004). The emphasis of our study will be on the mental state and the social-emotional aspects of health.

The research question is: “What effect does theoretical and practical work in the school garden have on pupils of the sixth grade in regards to

- their well-being (mental state)
- the development of social-emotional competences?”
THEORETICAL BACKGROUND

Referring to the WHO definition of 1946, “health” is to be measured by the degree of physical, mental and social well-being. Antonovsky’s salutogenic health model mentions the social support as an important resource for resistance or coping (Antônôvsqî & Franke, 1997). As well Schwarzer and Leppin (1994) address the effects of social integration in their causal model. They directly correlate social integration with stress relief and mental health. Well-being is a complex construct that is influenced by a variety of factors, such as: social, cognitive and affective-motivational dispositions and abilities. Analysis models, such as Becker's "demand-resource-model" (SAR model), also consider the interactions between personality traits and environmental traits (Becker, 2006). The environment of the individual (external demands and external resources), the psychophysical characteristics of the individual (internal demands and internal resources) as well as the behavior and experience of the individual influence the personal state of health. Peter Beckers structural model of well-being define “well-being” in more detail (Abele & Becker, 1991). Depending on development over time, Becker distinguishes between habitual well-being (which is relatively stable, based on experience) and current well-being. According to Becker, current well-being consists of positive feelings (joy, happiness…), positive moods (well-being, relaxation…) and current freedom of complaint, achievable through sensory experiences, successful actions, social benefits, happy circumstances and imagination. Moods and emotions are separate constructs of psychology, which are to be separated from each other. Emotions can be reactions to specific events or situations, as well as processes and states (Traue, 1998). But moods are not object-oriented or situation-dependent in comparison to feeling and can only be grasped by considering several dimensions (Schimmack, 1999; Steyer, Schwenkmezger, Notz, & Eid, 2003). The current mood is according to Steyer et al. (1997, p. 4) is described as being and "marks the current inner experience and feeling of an individual that has become conscious". It is not only composed of a good-bad mood, but also includes the dimensions alertness-tiredness and restlessness.

The structural model of well-being overlaps with the Self-Determination Theory (SDT) in social aspects and successful action. In the SDT of Deci and Ryan (Deci & Ryan, 2000, 2004; Ryan & Deci, 2001) autonomy, competence and social relatedness are define as basic needs. They are conditions for intrinsic motivation and well-being. The teaching design of the environment “school garden” bases on the SDT of Deci and Ryan (2000, 2004). Accordingly, these factors are taken into account in the design of the teaching unit. The pupils experience the basic needs - basic psychological needs in the school garden through the specific teaching organization: working in bed groups, making their own decisions regarding sowing and care of the plants and experiencing the work in the garden as successful (Figure 1).

Deci and Ryan (1993, p. 236) emphasize the pedagogical importance of self-directed learning in motivation and learning in particular: "Environments in which important caregivers participate, facilitate the satisfaction of psychological needs, support autonomy aspirations of learning, and facilitate the experiences of individual competence. promote the development of a motivation based on self-determination. "

1288
Figure 1. Fulfilment of psychological needs, a hypothetical model

**DESIGN AND METHODOLOGY**

The development of a good learning environment is and will be studied in the school garden, in application of the design-based research (DBR) method (inter alia Akker et al., 2013). The individual cycles of the DBR include a trial and analysis phase (Fig. 2) in which the work with school classes in the garden is examined and further developed on the basis of effectiveness in terms of well-being and on the practicability of school gardening. The methodical and didactic development of the teaching unit is and will be created in cooperation with teachers. After the formative evaluation (cycles - review and revision of lessons), a summative evaluation follows, in which the final version of the lesson design is assessed. This summative evaluation will be done in 2018 after the analysis and evaluation of the last cycle (Fig. 2).

Subject of the teaching unit are “plants and soil”. The contents of natural sciences correspond to the requirements of the curriculum that the German State of Mecklenburg-Hither Pomerania demands for the fifth and sixth grade (Ministerium für Bildung, „Naturwissenschaften_Orientierungsstufe_5-6_2010.pdf“, o. J.). Over a period of ten weeks, the 90-minute lessons for the pupils (half class) changed weekly between the garden and the classroom. The total number of trial participants in gardening season 2016 is n=124, 59 boys and 65 girls.

For the school garden intervention, the following questions arise with regard to the organization of teaching organization and the development of scientific experiments: In what way does the teaching in the school garden have to be organized and structured so that a scientific work is possible? Which task formats are feasible in the school garden for the subject of learning soil and plants?

The paper and pencil Multidimensional Mood State Questionnaire (MDMQ) by Steyer et al. (Steyer, Schwenkmezger, Notz, & Eid, 1997) is used to assess the current well-being/mood state. After each teaching unit, the pupils filled out the short form of the MDMQ with 12 items. The short version A of the MDMQ comprises three dimensions: good-bad mood, awake-tired and calm-nervous. This scale is standardized and takes only 4-5 minutes. The social and emotional interactions of the pupils in the school garden are directly observed and recorded. The evaluation tool is a standardized observation protocol. Primarily, empathy as well as the
abilities to communicate and to work in a team are documented. Via self-reports, the pupils further document the emotions they felt during the lessons: A predefined list of emotion terminology will be scored with regards to the subjective intensity. The triangulation method will be used to supplement and validate results.

Figure 2. Design based research of the study

FINDINGS

In the following, the results of the main study from the year 2016 of the comparative analysis of science education with and without use of a school garden are described. The analysis of the data from the third cycle 2017 has not yet been completed and will soon follow.

The results of the Multidimensional Mood Questionnaire (MDMQ) reveal a higher value of good mood and a lower one of awake and calm mood after practical garden work. Compared the school garden lessons to the school lessons in the classroom (Fig. 3), only the subscale 'good-bad mood' shows a significant value (p=0.001) with mean garden 16.9 to mean classroom 17.7 (standard deviation: garden 2.5 and classroom 2.0). The effect size by Cohen is moderate, $d_{\text{cohen}} = 0.2$. The pupils (n = 114) felt more comfortable, better and happier in the school garden than in the classroom.
The results regarding the observed social interactions show in eight indicators a significant value, in average pupils in the garden showed high social interaction (team work Fig. 4, and communication Fig. 5). In the summed averages the team work in the school garden is 4.8 points higher in comparison to the classroom. A similar result can be seen in the social interaction for communication (Fig. 5). Significant value given by indicators “able to defend own point”, “keeps eye contact” and “speaks clearly”. The comparison of school garden and classroom shows, that the garden is a place of social interaction, the pupils communicate more and work more often in the team.

Figure 3. Multidimensional Mood Questionnaire, graded in the three dimensions, n=114

Figure 4. Social interaction, team work, school garden n=115, classroom n=45
The evaluation of the emotional diary shows that pupils in the school garden perceive each emotion more often than in the classroom (Fig. 6). In particular, the feelings pride (20%), happiness (13%) and surprise/wonder (16%) are positive feelings, which are mentioned more often in the school garden (in sum 49%). Also the negative feelings (e.g. disgust 11% and anger 8%) more often (in sum all emotions 32%) in the school garden lessons via classroom. In sum up to 80% emotions were more often perceived by the pupils in the garden.

Results of the perceived intensity of the feelings show generally higher levels in the school garden (Fig. 7). The feelings of joy, pride, amazement, anger and disgust are perceived more intensively by pupils in the garden via classroom. (significantly according Wilcoxon-Test).

---

**Figure 5. Social interaction, communication, school garden n=115, classroom n=45**

**Figure 6. Frequency of emotions (garden n=133. Classroom n=123)**
Figure 7. Intensity Emotions (1 low, 2 moderate, 3 high), school garden n=118, classroom n=45

CONCLUSIONS

Against the background that the garden design fulfills the psychological needs of SDT, the results of the study can discuss. A comparison between the settings school garden and classroom should be made, although different variables (different social form, teacher attitude and other influences like the weather) may have influenced the result of well-being. The results of the MDMQ and the emotional diary show positive effects during and after work in the school garden. A clear, if only a moderate effect, in good mood is determined after school garden work in comparison to school lessons in the classroom. However, pupils feel less awake and calm after working in the school garden (not significant) - these results can be explained by the physical work and the hot days in the summer 2016. The frequent of social interactions in the garden show in comparison to the results in the classroom a clear picture, significantly more social interactions can be seen in the garden, more communication and team work. This result can be explained by the cooperation of the pupils on the plant beds. Even the perceived feelings in the garden are more frequent and intense over the classroom results. The classroom seems to be charmless. The results of the Multidimensional Mood Questionnaire and the Emotion Diary seems to support the theory of the SDT. The findings of the study also clarify the importance of the experiencing nature. Pupils statements continue to show that more than 80% of pride, happiness and surprise/wonder are caused by working with plants in the garden. In the classroom, the positive feelings to 59% are based on the tasks and methods. Negative feelings (anger, fear) were often triggered by classmates in the garden. Further studies are necessary in order to evaluate the correlation between school-garden work and the mental well-being in detail. Unfortunately, the pupils did not do enough statements, so that only a few findings are given. The research question “What effect of well-being has garden work on pupils of the sixth grade?” could final answered with the following statement.
The pupils of the sixth degree have expressed a better, good mood after working in the school garden. This shows that school garden work can promote the mental well-being.

The pupils of the sixth degree have shown a better social and emotional interaction when working in the school garden. This shows that garden work can improve the social and emotional competencies.

THE COGNITIVE AND NON-COGNITIVE EFFECTS OF OUT-OF-SCHOOL LEARNING

Nóra Fűz and Erzsébet Korom
Institute of Education University of Szeged, Hungary
MTA-SZTE Science Education Research Group

The effectiveness of out-of-school learning (OSL) programmes has been shown by several studies with special reference to its beneficial role in raising students’ interest in a particular topic, increasing learning motivation and providing a special personal and social experience. In addition, it may also have a significant positive effect on cognitive processes of learning depending on the nature and method of the out-of-school programme. An OSL activity linked to the subject matter, for instance, could encourage a deeper understanding of the topic, help to put the acquired knowledge to practical use and contribute to the long-term storage and easy recall of the studied information thanks to the experience-rich environment. The study discusses the results of one component of a complex online survey (The Effect of the Specific OSL Programmes, Cronbach α=0.94), in which primary school students, teachers and principals were asked about their opinions on the usefulness of OSL activities in the achievement of certain cognitive and non-cognitive learning outcomes.

Keywords: outdoor education; education outside the classroom; out-of-school learning

THEORETICAL BACKGROUND

While the tools and methods of public education are often left out-dated and artificial (Braund & Reiss, 2006; Duran, Ballone-Duran, Haney & Beltyukova, 2009; Eshach, 2007; Hofstein and Rosenfeld, 1996), informal learning spaces just as science centres, open laboratories and museums, for instance, tend to display scientific and technological innovations in line with the expectations of modern audiences in order to fulfil their function of representing science and offering entertainment at the same time. These spaces can be used to pique students’ curiosity for science and help them understand abstract concepts that are difficult for them to grasp while at the same time developing individual responsibility for their further studies and academic progress (Gardner, 1991, cited in Eshach, 2007. pp. 171).

Dimension of out-of-school learning

The usefulness of out-of-school learning is affected by several factors such as students’ prior knowledge, the physical properties of the environment, the teaching and learning methods employed, the students’ social relationships or, for an outdoor programme, even the weather. Each of these factors includes a number of critical features that have a decisive effect on the added pedagogical value of out-of-school classes and programmes.

Combining Orion and Hofstein’s (1994) three-factor model of fieldtrip learning with Falk and Dierking’s (2000) contextual model of museum learning, Eshach (2007) suggests a model of the effects of out-of-school learning comprising four factors. The four factors may comprise both cognitive and affective components and they are all believed to affect the cognitive and affective aspects of learning processes. The four critical factors identified by Eshach are the following:
1. Physical: e.g., the environment and furnishings of the learning space;

2. Personal: e.g., the student’s prior knowledge about the subject matter (cognitive) and the student’s attitude towards the subject (affective);

3. Social: e.g., interpersonal interactions between the students (cognitive) and the students’ perception of the instructor’s personality (affective);

4. Instructional: introduction to the scene and topic of the out-of-school activity (cognitive) and the concluding discussion of the experiences of the programme (affective).

This aspect does not, however, comprise the “teaching factors” mentioned by Orion and Hofstein (1994), which include the embeddedness of the activity in the subject matter, the instruction methods employed, the educational objectives, etc. These factors of learning organisation may, however, have a substantial effect on learning outcomes, therefore a fifth factor containing teaching and learning methods and objectives should be added to the out-of-school learning model: the didactical factor. Our extended model is shown in Figure 1.

Although the instructional and the didactical factors may seem to overlap to some extent and instructional features could be assigned to the didactical factor, it is still reasonable to separate the two because the appropriate introduction to and conclusion of an OSL activity is at least as important for the outcome as the other factors mentioned here (Rickinson et al., 2004; Fiennes et al., 2015; James and Williams, 2017; Orion, 1993; Orion and Hofstein, 1994).

![Figure 1. Factors affecting out-of-school learning (based on Eshach’s model, 2007)](image)

Most studies on OSL fit this model since they tend to investigate outcomes along at least one of these dimensions. Systematic surveys and meta-analyses of the OSL literature (Becker, Lauterbach, Spengler, Dettweiler & Mess, 2017; Fiennes et al., 2015; Hattie, Marsch, Neill & Richards, 1994; Rickinson et al., 2004; Scrutton and Beames, 2015; Waite, Bolling & Bentsen, 2015) typically also use this system of categorisation or one corresponding to this system to organise their results on the effects of OSL, that is, they look at cognitive, affective, social, or personal factors.
THE SURVEY

Aims

The present study discusses the results of a selected questionnaire (The Effect of the Specific OSL Programmes) of a large-scale online survey with the aim of identifying the educational goals with regard to which primary school principals, teachers and students found OSL activities useful. The study focuses on the added educational value of OSL activities in participating students’ learning processes, both in cognitive and in non-cognitive aspects. Further results of the survey have been discussed in other publications (Fűz & Korom, 2017; Fűz, in press).

Sample

Data collection was carried out in May and June 2016. Participants included students in Grades 3 to 8 (N=4680), their class teachers (N=112) and principals (N=69). The sample came from the partner institutions of the Szeged Centre for Research on Learning and Instruction. Participation was voluntary with the condition that at least one class in the school participated in at least one out-of-school activity during the school term preceding data collection.

Ninety-six primary schools participated in the survey, 44 per cent of which were located in villages, 25 per cent in towns, 19 per cent in county seats, 9 per cent in townships, 2 per cent in municipalities and 1 per cent in the capital. Schools located in the capital city are underrepresented in the sample: t(3880)= -8.29; p<0.001. Our sample is representative of the country for the remaining settlement types and a set of independent t-tests show no significant difference between the country and the sample distributions.

Looking at the distribution of genders, they were virtually equally distributed among students: of the total of 4,680 students, 2,202 were boys and 2,221 girls. Two-hundred and fourteen students did not specify their gender and 43 students gave an uninterpretable response (marked both options). The different grades are also distributed evenly in the sample: the frequencies and percentages are shown in Table 1.

Method

A complex self-developed online questionnaire entitled Educational Use of Out-of-School Learning Places Questionnaire was administered through our Electronic Diagnostic System (eDia, Molnár & Čsapó, 2013; Molnár, 2015) in the ICT labs of participating schools.

The survey consists of 5 sub-questionnaires: (1) The Administrative Structure of the School, (2) Characteristics of the Specific OSL Programmes, (3) The Effect of the Specific OSL
Programmes, (4) General Attitudes toward OSL Programmes (adapted from Orion & Hofstein, 1991) and (5) Conditions of Organizing OSL Programmes.

This study discusses the second sub-questionnaire: *The Effect of the Specific OSL Programmes*, which included statements regarding both cognitive and non-cognitive components of OSL. The lists of considerations in the teacher and principal versions were modified and turned into first-person statements in student version as shown in Table 2 in order to assist comprehension. The letters assigned to the statements in the Table will be used in further analyses to help interpret the results. Respondents were asked to rate the statements on a four-point Likert scale, where the level of agreement was: 1 – Strongly Disagree; 2 – Disagree; 3 – Agree; and 4 – Strongly Agree.

*: A: affective, C: cognitive, S: social learning factor

The items of the questionnaire can be divided into two groups: cognitive aspects and non-cognitive aspects of learning. The Kaiser-Meyer-Olkin test for sampling adequacy was used to test the suitability of the theoretical model for principal component analysis, and the resulting value (0.963) proved to be decidedly high indicating that our data were indeed suitable for
factor analysis. The factor analysis created three factors with 66.63% of the total variance explained by the three together. Table 2 shows the factor structure after a varimax rotation with only values above a factor loading of 0.4 included.

The factors were assigned the following labels: cognitive (C), affective (A) and social learning (S). The reliability of the 8 statements belonging to the cognitive factor measured by Cronbach’s α was 0.91, the 3 statements in the affective factor showed a reliability value of 0.87 and the corresponding value for the 4 statements in the social learning factor was 0.78. The combined reliability of the three scales for the whole sample was 0.94. The factors that emerged therefore allow us to group the aspects of learning into cognitive versus non-cognitive categories as suggested in the introduction, and further allow us to distinguish cognitive, affective and social components of the learning taking place during OSL programmes.

SELECTED RESULTS
Criteria for assessing OSL programmes

No significant differences were found between the answers of principals and those of teachers. Since their questionnaires used the same format, their responses were combined for the purposes of the analyses reported here (see Figure 2).

![Figure 2. Mean ratings of the usefulness of OSL programmes for the teacher/principal and student subsamples by statement](image)

As we can see in the Figure, teachers and principals gave more positive ratings for almost all statements than students; the pattern was reversed for only one statement: foundations of lifelong learning (teacher version) – the realisation that things can be learnt outside the classroom (student version), where students rated OSL more useful than teachers/principals. For the use of instruments and empirical methods and for the improvement of dexterity, t-tests showed no significant differences between the two subsamples. For the remaining features, however, teachers and principals gave significantly more positive answers than students at the 99 per cent probability level.
Both students and their teachers and principals thought that the social experience \( (M_{\text{student}}=3.36, \ SD=.67; \ M_{\text{teacher/principal}}=3.77, \ SD=.34) \) and the acquisition of new information \( (M_{\text{student}}=3.25, \ SD=.68; \ M_{\text{teacher/principal}}=3.77, \ SD=.33) \) were the learning aspects that benefitted most from OSL. For students, the programmes were also highly appreciated for the opportunity to learn things outside the classroom with a mean rating of 3.23 (SD=.67), while for teachers and principals, the increased interest in the subject matter \( (M=3.54, \ SD=.46) \) and the deepening of school knowledge \( (M=3.51, \ SD=.5) \) ranked next.

Looking at all the out-of-school learning spaces combined, the OSL programmes proved to be least effective in enhancing manual skills \( (M_{\text{student}}=2.7, \ SD=.95; \ M_{\text{teacher/principal}}=2.62, \ SD=.83) \). This is understandable since the educational goal of improving manual skills is typically limited to activities involving arts and crafts. What is a lot more interesting is that the greatest difference between the teachers’ and the students’ ratings appears for the effects of increasing learning motivation \( (M_{\text{student}}=2.65, \ SD=.89; \ M_{\text{teacher/principal}}=3.45, \ SD=.51) \) and arousing interest in the subject matter \( (M_{\text{student}}=2.8, \ SD=.82; \ M_{\text{teacher/principal}}=3.54, \ SD=.46) \): for both of these features, teachers and principals rated the contribution of OSL programmes substantially higher. In fact, students ranked the usefulness of OSL in increasing learning motivation lowest of all aspects, which is unexpected given that several research studies highlight increased learning motivation as a crucial benefit of OSL activities. We should note, however, that our students’ ratings fall into a considerably smaller range of values than the teachers’ ratings, where the difference between the highest and the lowest average usefulness rating is more than one point on the four-point scale. Also, the average ratings of teachers and principals are greater than 3.00 for 13 statements while the students rated only 3 statements higher than that value. Thus, although the effect on learning motivation was rated lowest, it did not lag far behind the remaining aspects.

No major differences were found between boys and girls in the ratings of the statements either in terms of ranking or in terms of rating values. Only two of the aspects showed significant gender differences: two-sample t-tests \( (p<.01) \) revealed that girls rated OSL activities as more useful than did boys with respect to social experience \( (M_{\text{girls}}=3.41, \ SD=.64; \ M_{\text{boys}}=3.33, \ SD=.68) \) and the acquisition of new information outside the classroom \( (M_{\text{girls}}=3.27, \ SD=.67; \ M_{\text{boys}}=3.2, \ SD=.72) \).

**Assessing OSL programmes by school grade**

Looking at the average ratings of the programmes by school grade, they showed a monotone decreasing trend with an increase in grade (see Table 3).

If we group the statements into the three factors, the monotone decreasing trend remains: the ratings of cognitive, affective and social learning factors negatively correlate with the number of years spent at school.

An analysis of the individual statements of the questionnaire reveals that students in every school grade without exception gave the highest rating to the social experience accompanying OSL programmes. The lowest ranking statement varied by school grade. It was learning about their national heritage for third graders \( (M=2.95) \), improved dexterity for fourth graders \( (M=2.81) \), help with the organisation of studying for fifth graders \( (M=2.81) \) and increased...
learning motivation for sixth, seventh and eighth graders (M=2.51, 2.42 and 2.3 respectively). The highest average rating was therefore given by third grade students for the social experience offered by OSL programmes (M=3.58) and the lowest average rating by eighth grade students (M=2.3), who did not think that OSL activities made them feel like learning.

The three dimensions of the usefulness of OSL programmes

Looking at the learning aspects benefiting from OSL activities grouped into the three factors discussed above, for the student subsample OSL appears to have the greatest effect on social learning with a mean rating of 3.2 (SD=.56). This is followed by the cognitive dimension (M=2.82, SD=.66), and the affective aspects come last (M=2.77, SD=.76).

An analysis of gender differences reveals a similar pattern to that observed before: boys and girls do not differ in their ratings of the cognitive and the affective dimensions but there is a small but statistically significant difference between their ratings of the social learning dimension with girls giving higher values than boys (see Table 4).

The teachers’ and principals’ answers also suggested that the social learning aspects are the greatest benefit of OSL programmes with an outstanding average rating of 3.52 (SD=.38). In contrast with the students, however, they found its role in achieving affective goals almost as important (M=3.45, SD=.48). Teachers and principals thought OSL programmes had the weakest effect on the cognitive aspects of learning, but their mean rating remained above 3 even for this dimension (M=3.18, SD=.47).

CONCLUSION AND DISCUSSION

Our empirical study looked at the effects of out-of-school learning programmes organised by the school with respect to both cognitive and non-cognitive aspects. We conducted a survey with a sample of 4,681 people from primary schools throughout Hungary. The sample
comprised teachers, principals and students in grades 3 to 8. The survey instrument was a complex online set of questionnaires, of which the results of a four-point Likert scale questionnaire developed by our research group were discussed in the present paper. The questionnaire comprised 15 items, which were grouped into three factors by factor analysis: an affective, a cognitive and a social learning factor. The questionnaire was designed to map students’ and teachers’ experiences and views on the educational usefulness of OSL programmes.

The results of the study provide further support for the conclusions of meta-analyses and research surveys (Becker et al., 2017; Hattie, Marsh, Neill & Richards, 1994; Rickinson et al., 2004; etc.) indicating that OSL activities can become effective additions to classroom instruction in several areas of learning including its social, affective and cognitive aspects as shown in our study. Of the 15 educational objectives included in the questionnaire, both teachers/principals and students found that the greatest benefit of the OSL programmes in which they participated during the six months preceding data collection was the social experience they provided and the new knowledge they helped to acquire. This result confirms the dual function of OSL spaces: learning as entertainment (Eshach, 2007; Hofstein & Rosenfeld, 1996).

Since learning that takes place in the usual classroom environment tends to become boring to students, it would certainly be worth making efforts to integrate informal learning spaces into formal education since this would help curb the decline in their learning motivation and school subject attitudes. A great number of studies have found that OSL has a positive effect on students’ intrinsic motivation and their attitudes towards a school subject or topic (Dettweiler, Ünlü, Lauterbach, Becker & Gschrey, 2015; Fägerstam & Blom, 2013; etc.) This conclusion is also supported by the answers of the teachers in our survey, who thought that OSL programmes played an especially important role in arousing students’ interest in the subject matter and enhancing their learning motivation and subject attitudes. The students’ answers, however, appear to contradict this result: they rated an increase in learning motivation as the least likely effect of OSL activities. This may be unexpected given the wide range of studies suggesting the opposite, but we should note that students gave lower ratings than their teachers or principals to almost all aspects included in the questionnaire. Not only did they give lower ratings but the range of ratings they used was also considerably smaller for students than for teachers: the mean student rating for learning motivation, which they found the least noteworthy aspect, did not lag far behind the others. On average, students only rated three statements higher than 3.00, while for teachers 13 aspects crossed this threshold. Furthermore, it is well known that students’ learning motivation and subject attitudes linearly and steeply decline with an increase in the number of years spent at school (Braud & Reiss, 2006; Csapó, 2000; Józsa and Fejes, 2012; Holmes, 2011). This decreasing trend also surfaces in our cross-sectional study since the students’ attitudes towards OSL programmes negatively correlated with their school years. The last place of learning motivation in the ranking seems justified under these circumstances. Although students rated their learning motivation following an OSL programme rather low, it is quite possible that their attitudes would be even more negative if the same activities had taken place in their usual classroom environments. Most studies arguing
for the positive effects of OSL programmes in the affective dimension provided evidence either by using a control group for comparison or based on a longitudinal study, where the effects of the programme can be clearly isolated. Our large-scale online study did not allow us to exercise that level of control, but our next, smaller-scale, paper and pencil longitudinal study will provide an opportunity to isolate the effects of OSL programmes.

Our analysis of the three factors emerging from the study revealed that both students and teachers/principals found that the greatest contribution of OSL activities was the opportunity it provided for social learning. For students, this was followed by the cognitive dimension with a considerable gap between the two, and the affective factor came last with no lag this time. For teachers, the three factors received similarly high ratings closely following one another in the following order: social learning, affective aspects and cognitive aspects.

On the whole, both students and teachers/principals showed a positive attitude towards the out-of-school programmes in which they had participated during the six-month period preceding data collection. This positive attitude applied to several different aspects of these programmes such as the social experience they provided, their contribution to the acquisition of new knowledge, the deepening of school knowledge, practice in filtering information and cooperation with peers, etc. These results suggest that it is well worth the effort to enrich classroom instruction with the numerous opportunities provided by OSL. Integrating OSL into the school curriculum and educational practice would go a long way in making the learning environment more varied and true to life and thus alleviating the difficulties of public education.

FIELDWORK-ORIENTATED BIOLOGY TEACHERS’ VIEWS ON OUTDOOR EDUCATION

Anttoni Kervinen, Anna Uitto and Kalle Juuti

University of Helsinki, Helsinki, Finland

Outdoor environments are considered as important learning environments in biology education. Previous studies on outdoor education and fieldwork indicate many positive impacts on students’ cognitive and affective achievements. However, the amount of fieldwork in biology education has declined during the past decades and is considered to be low in many countries. Outdoor education often consists of single fieldtrips guided by outdoor educators, and little research has been done on fieldwork as a regular part of formal science education. In this paper, we focus on three secondary school biology teachers who use fieldwork extensively. Based on semi-structured interviews and qualitative data analysis, we studied their views on and arguments for fieldwork as part of regular biology teaching. According to the results, the teachers considered fieldwork as a meaningful alternative for teaching many contents and skills included in the curriculum. The teachers emphasized students’ authentic nature experiences and the importance of affective and cognitive experiences as the main arguments for fieldwork. Besides the curricular learning goals, they placed at least equally important emphasis on students’ experiences as part of their comprehensive wellbeing and the development of positive relationship with nature. Knowledge on goals behind extensive outdoor education practices will help focus further studies about the role of fieldwork in biology education.

Keywords: outdoor education, fieldwork, biology education

INTRODUCTION

Activities outside the classroom are considered valuable part of teaching in general as well as in science education (Rennie, 2014; Resnick, 1987). Out-of-classroom environments can be argued to offer opportunities for authentic practical work and improved development and integration of concepts as well as positive social outcomes and promoted attitudes to school science (Braund & Reiss, 2006a). As one of out-of-classroom teaching, outdoor environments and fieldtrips allow students to engage in authentic science learning especially related to biological and ecological the themes (Braund & Reiss, 2006b).

There is considerable evidence that fieldwork and outdoor learning can result in higher levels of cognitive achievement compared to solely classroom teaching (Ghent et al., 2014; Nundy, 1999; Randler et al., 2005; Scott & Boyd, 2016). Also, outdoor learning has been shown to increase student’s personal interest and motivation towards learning (Drissner et al., 2010; Fägerstam & Blom, 2013; Randler et al., 2005; Stokes & Boyle, 2009) as well as improve environmental attitudes (Ballantyne & Packer, 2002; Carrier et al., 2014; Drissner et al., 2010).

It has been argued that as the ecological understanding of scientists develop progressively from observations and fieldwork, the science teaching should likewise follow a ‘bottom up’ approach giving more emphasis on observing and inquiring nature instead of just conceptual approach (Barker & Slingsby, 1998; Magro et al., 2001). Magntorn and Helldén (2007) discuss the importance of outdoor environments in science teaching as learning to ‘read nature’ and
develop ecological understanding from taxonomy to system ecology. Waite (2007) and Farmer et al. (2007) suggest that positive effects may relate to student’s long-lasting memories from authentic outdoor experiences and efficient recall of the learned material. It has also been suggested that students’ personal familiarity with the natural world outdoors allows them to apply informal prior learning in a way that benefits academic outcomes (Scott & Boyd, 2014).

Although outdoor environments are considered as important learning environments in science there have long been a concern of the declining amount of outdoor education and fieldwork in schools as a part of biology education (e.g. Lock, 2010). The latest Finnish national core curriculum emphasizes varied learning environments including the outdoors as well as on inquiry skills and nature values (FNBE, 2014). However, in the Finnish formal education, outdoor environments are averagely rarely used, which is a likely reason to finding that students’ biology-related attitudes and performance are not related to outdoor learning (Uitto & Kärnä, 2014). Yet, there are teachers who apply fieldwork intensively (Uitto & Kärnä, 2014). In order to understand how to promote fieldwork, we analyzed three teachers’ views on fieldwork in secondary school biology. Teachers were experienced in extensive use of fieldwork.

Our research question is: How do teachers who use fieldwork intensively argue for fieldwork in biology education?

**METHODS**

**Description of the cases**

The multi-case study (Bogdan & Biklen, 2006, p. 69) focused on three secondary-school biology teachers who were selected for their experience in using fieldwork extensively in secondary-school biology teaching. By studying a known untypical example, it is possible to produce new specific knowledge that cannot be acquired by studying average cases, but that also allows the theoretical understanding of the phenomenon also in a broader and more general level (Flyvbjerg, 2006). Three teachers, Krista, Joel and Laura (teacher and school names are all pseudonyms), were selected. All three were subject teachers in biology education and qualified to teach in Finnish secondary school. They were working in two public middle schools (for students ages 13 to 15) in an urban area of southern Finland. At the time of the interview, Krista had been teaching biology for 30 years, Joel for 6 years and Laura for 8 years. For decades, Krista had been developing a biology curriculum that emphasises outdoor learning at the Kuusela school, but at the time of the interview she had been working in a school in Koivula for three years, using the same outdoor-intensive model. Joel and Laura were working in Kuusela and had adopted an outdoor emphasis in their teaching. In both schools, the biology course on the forest ecosystem included fieldwork in a majority of the lessons. The educational goals of the teaching were consistent with the Finnish national core curriculum (FNBE, 2014).

All three teachers used outdoor teaching as a major part of their biology teaching in two courses, one focussing on water ecosystems and another focussing on forest ecosystems. In the forest ecosystem course, outdoor teaching accounted for 60 to 80 per cent of the lessons; in the water ecosystem course it made up about 30 per cent of the lessons. The teachers had many
similar practices in organizing their teaching. This was partly because of their common history in the Kuusela school, which has a long tradition of outdoor teaching.

The learning activities in the forest were diversified and included short-term activities as well as longer-lasting inquiries. The short-time activities were, for example, observing and discussing different types of forests, identifying abiotic and biotic factors, observing different biotopes and layers of vegetation, and collecting and identifying invertebrates, mushrooms, tree leaves and plants.

**Data collection and analysis**

Research data was collected as a part of larger research project focusing on the outdoor education and learning in the nature. For the purpose of this study, the first author interviewed the teachers. The interviews were semi-structured and open-ended and took about an hour each. Teachers were asked about 1) their experiences and how they used fieldwork in their teaching, 2) their views on and justification for fieldwork as part of biology education, and 3) the challenges related to fieldwork.

The interviews were audio recorded and transcribed. We analysed the data through thematic analysis by identifying, analysing and reporting patterns within the material (Boyatzis, 1998; Braun & Clarke, 2006). The unit of analysis was a sequence of talk consisting of one or several sentences that formed a coherent expression or idea. The analysis focused on the semantic content of the data, that is, the experiences of and meanings given to outdoor learning by the teachers, regarded as the reality for the participants. However, in addition to the explicit meanings, we also sought to identify and interpret underlying ideas, assumptions and conceptualizations in the participants’ speech, which Boyatzis (1998) refers to as analysing themes at a latent level.

**RESULTS**

Applying thematic analysis, we identified two themes from the teachers’ argumentation for using regular and extensive fieldwork in their teaching. In the following, we present teachers views through these two themes. We support our findings with representative samples of the teachers’ answers.

**Promoting students’ authentic experience in nature**

When arguing for their pedagogical choices, all three teachers made several references to what we identified as authentic experience in nature. The teachers viewed that learning biological knowledge about forest ecosystem is most authentic in forest or forest-like habitat, and thus the most appropriate learning environment for biology lessons is in nature. The authenticity of the learning in the nature was considered to be somehow obvious, but still needed to be expressed to and justified for the students.

*Well, if we are studying forest, the forest is in the forest of course. (Laura)*

*I say to the students - then they always say that why don’t we use the textbook with you – so I say, look out the window. It is there for real. That everything on these pages is less than what is out there, because it is there for real. (Krista)*
All teachers mentioned the Finnish national curriculum that requires use of diversified learning environments including also outdoor activities as part of biology teaching. With the curriculum, it is possible to justify also the large amount of outdoor activities to children, parents, and school management, and have them regarded as normal schooling. In general, all three teachers pointed out that the contents and goals for learning outdoors are similar to those in classroom teaching, or that outdoor teaching even fulfil better the requirements of the national core curriculum than text-book based classroom teaching.

Well, I think the goals are the same as in the classroom. [...] We do have textbooks too. But often when students say that, hey, we haven’t done anything from the textbook, when we start to look together at those chapters in the book... we actually have done, like, everything. So, we have the goals from the curriculum when we go into the forest. [...] (Laura)

The core of the argument for the benefits of the authentic experience in nature was that because forest ecosystem is authentic outdoors, students more easily engage in thinking and activities that promote relevant understanding of forest ecosystem. All teachers considered that learning situations in classroom do not manage enough to promote understanding of nature and skills to observe and inquire things related to forest ecosystem. Using invertebrates as an example, Laura and Joel claimed that even if the students learn names of the species and their habitat from the textbooks, they still have difficulties in using that knowledge in authentic environment to find and observe the invertebrates.

But then [in the forest] the students need to think that where to find them [invertebrates] and what kind of places they live in. And when put them in jars, it usually always happens that one eats another. So, it turns out that they’re predators. And that’s the logic I like, that the same topic will come through the concreteness. (Joel)

The authenticity of the learning experience was considered to be produced by students’ ability to use various senses and have tangible interaction with the nature.

But of course, when you smell and hear, when you observe the forest with every sense, then it is of course better than just to look at a picture. [...] And if I show a picture, then the nature is somewhere over there but not quite present. [...] So, when we quite concretely look that how this is like, if it this is moist or dry and what is the soil like, it indeed matters. (Laura)

This was considered to support students’ observation skills and ability to make relevant questions about nature.

And they learn more to observe the nature. They really don’t learn it by reading the textbook. And when reading the textbook, you don’t, in a way, come up with questions like why is this or that like it is. (Laura)

Krista and Laura considered that the main goals for teaching are the ability to make and understand biological observation, or "read the book of nature", and understand the process of acquiring biological information. The teachers argued that one benefit of outdoor learning
comes from the fact that the activities outdoors require more work and processing from the students than textbook-based or teacher-led learning.

*I think the main thing is that they learn to see what’s around them. That they simply learn to observe. [...] And I want that they would know how to read the book of nature. [...] You see this means after all more work for them. Since they already know how to scan some text and copy the keywords just like that. [Krista]*

Joel reflected on the risk of students not learning as much detailed knowledge and biological contents during outdoor activities as they would during textbook-based classroom teaching. Even if he seemed to agree with the issue of less-detailed learning, he regarded the knowledge and skills learned through the authentic experience to be more relevant. Moreover, Joel acknowledged that although the outdoor activities can sometimes appear inefficient, the same may apply to classroom teaching.

*Like the logic I like myself is quite clear, that the concreteness would achieve the same thing. [...] Is there sometimes a kind of risk for fiddling around or it remains a little cursory. But then I always come back to the idea that it would remain cursory in the classroom as well. (Joel)*

One aspect that make the authentic environment beneficial was related to students remembering well the things they encounter in nature and regarding outdoor learning affectively engaging.

*Well, perhaps the experiential aspect is even the first thing, that the memory traces are stronger. [...] I firmly believe that when thy [students] are older they will remember those things. No necessarily all those details that what we actually learned there, but they will remember that they have been outdoors during the biology lessons. And I believe that it enables quite different learning for many students. (Joel)*

The teacher’s told about noticing students’ engagement and interest during many of the outdoor activities. The teachers appreciated the connections that were made to student's everyday life during the outdoor activities. The connections occurred during the informal conversations and through spontaneous observations, such as seeing animals. Krista described how the childhood experiences of students are turned in to biological competence during a spontaneous encounter with frogs when visiting a nearby pond.

*There were quite many frogs there. Then, you see, and it is always so nice, the boys say that ‘as little kids we were like every day [with the frogs] and I know for sure where to find the frogs. They are inside those little ditch pipes.’ And then they look for the frogs, and something that they have done as kids turns into know-how. [Krista]*

The freedom related to outdoor learning were also seen to have positive impact on the teacher-student relationship. This, in turn, was considered to benefit both dealing behavioural challenges and learning.

*You’ve got time for unofficial discussions with the students and kind of things you aren’t usually able to in the classroom. So, the teacher-student relationship develops to quite many-sided and is different. (Joel)*
And those who are terribly restless, they keep running around. But they always come across me from time to time. And they always have something like, ‘look what I found’. And you can have a kind of small positive moment, something which is difficult to have in the classroom with such a lively student. (Krista)

In general, all the teachers perceived that the group management problems and behavioural issues could be more easily dealt with in outdoor settings than in classrooms.

Of course, they can get in a little bit of running there and consume their energy, but they will then calm down and get excited about the activity. Whereas if we were in the classroom, then they would just, like, spin in their chairs, and they couldn’t manage it. (Laura)

Developing positive relationship with nature

In addition to promoting the understanding of biological content and skills, the teachers described making students’ interested in nature and developing positive relationship with nature as well as improving environmental responsibility as major goals in outdoor teaching. Especially Krista regarded the possibility for students to have a pleasant experience of being in nature as key goal in the teaching.

And then they have kind of a little fun when they don’t have to be under my watch all the time. They get kind of a tiny nature experience. That you can have a nice time in nature with your friends, I think that it kind of carriers them. [...] I think that’s perhaps the most important thing. (Krista)

She argued that nature experiences in biology lessons may serve as counterbalance for students’ everyday life filled with virtual reality and alienation from nature.

You see, this virtual reality is so heady. So, I really think that it needs really much kind of real thing for counterbalance. And just touching. For example, I prefer that the plants are collected by hand rather than digitally [the Finnish curriculum includes preparation of a collection of species, usually plants]. [...] I want that hands get into soil. (Krista)

Krista considered also that having such experiences, the students would learn important skills for life and for example would be able and motivated in the future to “unfold the nature a bit for their children” and have picnics in the forest, for example. Also, Joel and Laura regarded the experiential aspect of outdoor activities important. Laura considered that outdoor teaching can bring balance student’s everyday life and mentioned the potential health benefits of being outdoors.

But there has also been research evidence that being in the forest lowers blood pressure and so on. So, you can tell it from the students. They lead such busy lives and now when they... like the hurry ends when you get there, even if you had only an hour of time. And somehow, they calm down in there. (Minna)

Joel reflected the possible contradiction between effectively learning the biological knowledge and having an authentic experience of nature. He seems to give at least equal importance on
the authentic experience in nature than the actual learning.

And it is really hard to determine if it is more valuable that they are at the cliff and kind of experience it or that whether they learn to identify that kelp or not. Of course, it is also a goal, though [to learn to identify]. (Joel)

Joel teacher also emphasized that “getting students inspired about things” is more essential object in secondary school biology (grades 7-9) rather than “learning everything by heart”. He considered, that “things related to sexuality and reproduction and evolution should be learned for example, but not like everything”.

DISCUSSION

In this article, we have sought to contribute to the research on the outdoor education practices and teacher’s argumentation for using outdoor education. Combining outdoor teaching in the nearby nature with the ordinary school work has been considered both desirable and challenging (Ayotte-Beaudet et al., 2017; Glackin, 2016; Lavie Alon & Tal, 2017). Fägerstam and Blom (2013) concluded, that still only few studies focus on outdoor learning as part of ordinary school work. In this study, we explored the views on and arguments for outdoor teaching from three teachers who use outdoor environments extensively in their everyday biology teaching.

This study focused on three teachers who were using outdoor teaching in nearby nature exceptionally much during their biology courses. Whilst the findings are not representative of all science or biology teachers, they allow us to interpret many important aspects that need to be considered if intensive outdoor teaching in schools is to be promoted. Knowledge on goals that are perceived as preconditions for successful fieldwork will help to focus further studies about fieldwork and the role of nature environments in biology education.

Concerning the reasons of using outdoor teaching, the fieldwork-oriented biology teachers seem to have many similar arguments than biology teachers in previous studies (cf. Rickinson et al., 2004). The teachers emphasized the authenticity and the tangibility of the outdoor experience, something which has been argued as the main justification (Braund & Reiss, 2006a). Also scientific skills such as making observations and “reading nature” were emphasised by the teachers, similarly to previous research (Magntorn & Helldén, 2007; Magro et al., 2001).

What comes to the reasons for why authentic experiences would promote learning, the teachers in this study mentioned students’ improved memories from the learning situations. Previous studies have also implied to the positive effect of long lasting memories from the outdoors (Farmer et al., 2007; Waite, 2007). Krista and Laura also considered that studying outdoors would demand more cognitive activity and responsibility from the students than the textbook and lecture-based learning they are more used to. Similar implications have been found out by Lavie Alon and Tal (2017) who suggest that student-led learning in the outdoor environment would promote learning outcomes compared to teacher-led practices. We suggest that more studies should focus on the actual learning situation outdoors in order to find out how the outdoor environment can contribute to students active learning.
The fieldwork-oriented teachers regarded outdoor learning to have other benefits beside the authenticity of the scientific phenomena and the learning outcomes. All of the teachers who regarded the experience of being in the nature as having close to an intrinsic value for students. Krista emphasised the experimental aspect of having good times in the forest as “perhaps the most important thing”. Laura considered outdoor learning as counterbalance for alienated from the nature or feeling busy and stressed during the school days. Joel reflected on the possible contradiction of learning details and learning in the nature and concluded that the affective aspects in the outdoor learning are at least as important as the cognitive learning achievements. Improved environmental attitudes have been noted as an important aspect in outdoor education (Ballantyne & Packer, 2002; Carrier et al., 2014; Drissner et al., 2010). That the fieldwork-oriented teachers emphasized the experiential aspects and development of students’ positive relationship with nature as evenly important as the cognitive learning goals is, however, particularly interesting. The teachers in this study did not found insurmountable contradiction of combining the cognitive learning objectives of the Finnish curriculum and the emphasis on nature experiences. If we aiming to increase the amount of outdoor education, as suggested recently (Lock, 2010; Uitto & Kärnä, 2014), we may need to consider if the emphasis on cognitive learning benefits alone is sufficient. Instead, we should ask whether the value of outdoor education is more prominent in affective, social, environmental educational, and experiential aspects, and how we can achieve these goals without compromising the learning of the ecologogical fundamentals. Again, more research should focus on the students’ experiences of learning in the nature and how different cognitive and affective aspects are manifested during the learning situations.

In conclusion, the results of this study imply that regular and extensive outdoor education can be implemented as part of formal biology teaching. The fieldwork-oriented teachers have diverse arguments for they pedagogical choices. They prioritize providing students with nature experiences that, according to their experience, result in authentic learning at least equally importantly benefit students’ comprehensive well-being and positive relationship with nature.

INQUIRY IN OUTDOOR EDUCATION - A CASE STUDY IN PRIMARY SCHOOL SCIENCE

Anna Uitto and Tuija Nordström
University of Helsinki, Faculty of Educational Sciences, Helsinki, Finland

Inquiry and learning outside the classroom are important approaches in biology education. Constructivist inquiry-based models of learning and instruction have been used in science education, but there is no empirical research on the use of instructional models in outdoor nature environments. This study investigates third-grade pupils’ learning process during the outdoor inquiry carried out in the sea shore environment. The data was collected by means of video recordings focusing on activities and discussions of a group of five pupils. A stimulated recall was carried out after one week in the school. The transcribed data of pupils’ talk and activities were coded using the inquiry-oriented BSCS 5E model of instruction as a reference. The activities relating to exploring, explaining and elaborating could be found in the video episodes, but they did not appear in the sequential order as in the instructional model. The concepts used by the pupils were relevant to the topics of learning. The pupils talked much about their sense perceptions when studying the properties of the water and identifying water invertebrates. Occasionally pupils’ discussion deepened to explanation, elaboration and evaluation. The pupils elaborated the learned issues with their prior knowledge and experiences in lake and sea water environments. The results showed that although the inquiry was structured and guided by the teacher, lot of learner-centered activities and discussions took place in the experiential and situated activities of the field work. It is suggested that in outdoor science education, video research is able to reveal valuable information on educational practices and pupils’ learning in authentic environments.

Keywords: inquiry approach, outdoor education, experience

INTRODUCTION

According to the constructivist learning theories learning is social activity in which pupils are engaged to construct their own knowledge and skills (Palincsar, 1998). Thus, the use of teacher- or student-centered approaches are key questions in teaching and learning science (Furtak, Seidel, Iverson & Briggs, 2012). Inquiry-based learning (IBL) is currently highlighted approach in the curriculum of science education (Abd-El-Khalick et al., 2004). To help teacher to plan their teaching, several constructivist instructional models have been developed. According to the inquiry-based instructional model of Bybee et al. (2006) and Bybee (2014), the teacher helps the pupils to challenge their conceptions, engage them to explore an interesting phenomenon collaboratively, explain their findings, elaborate their new knowledge and evaluate the learning process, understanding and skills. The original learning cycle (Bybee et al. 2006) is formed of five different phases: Engage, Explore, Explain, Elaborate and Evaluate, including the guidance for the teacher and pupils, so that the teacher can flexible provide scaffolding to the pupils. Depending on the teacher- or student-centered approach, Banchi and Bell (2008) have categorized the different inquiry types to Confirmation, Structured, Guided and Open. However, in their meta-analysis Furtak, Seidel, Iverson and Briggs (2012) showed that the types of instruction varies, with only few focusing on the extent
to which activities are led by the teacher or the student. Thus, more research on the details of the inquiry process is needed.

Learning in outdoor environments are included to formal science education (Rickinson et al., 2004). Fieldwork is important to learn for instance knowledge on ecological phenomena and the skills to make observations and studies in the outdoor nature environment. Nature experiences are important, because for instance pupils’ out-of-school nature experiences are related with their interest in living nature and ecology-related phenomena (Uitto, Juuti, Lavonen, & Meisalo, 2006). According to the objectives of the national curriculum for basic education, in environmental studies primary school pupils learn to make small-scale inquiries in different learning environments, including fieldwork (Finnish National Board of Education, 2015). Research on primary school outdoor education is mainly focused on the goals of environmental education (Palmberg & Kuru, 2000; Rickinson et al. 2004; Dillon et al. 2006), and there are only few studies focusing on more detailed characteristics and implementation of inquiry approach in the nature outdoor environment. Thus, it is important to know more for instance about pupils’ experiences and perceptions on fieldwork, how they learn to make field observations, use simple tools to study the environment and learn to use basic ecology-related concepts during the inquiry activities. Also, it is important to know what kind of interests and emotions outdoor science education awakes in pupils’ minds.

Video research is a suitable approach to investigate learning (Derry et al., 2010). Video-recordings are considered to be an excellent source of data that can be used to assess relationships between behaviors that occur in close temporal proximity to one another. Because the data can be played and replayed; sped up, slowed or paused; discussed, analyzed, and reanalyzed, the analyses of videotaped data provides rich data to investigate human behaviour (Morse & Pooler, 2002). A group of pupils have many types of social interactions and interaction with their physical environment, which can be systemically observed, analysed, and interpreted with the help of video recordings.

To study primary school pupils’ outdoor learning we stated the research question: What are the characteristics of inquiry-based learning in the fieldwork, when primary school pupils’ activities and discussions are categorized using the BSCS model of instruction?

**MATERIAL AND METHODS**

Primary school third grade pupils and their teachers participated a two week research and development project of the LUMA Centre Finland (Kervinen, Uitto, Kaasinen et al., 2016). As a part of the project, primary school pupils studied the water environment in park near their school. The pupils were engaged to the inquiry in the classroom prior the fieldwork, and they were prepared and interested to come to the sea shore and start the studies. A group of five pupils, three girls and two boys, were videotaped. The video-recording was carried out on a shore of a bay, where the pupils studied the brackish water environment. The group of pupils was guided by the teacher and the pupils used a worksheet that was prepared by the teacher. The worksheet included activities such as using inquiry equipment, taking water samples, searching and identifying aquatic invertebrates, studying properties of the water, making sensory observations of the water and assessing the quality of the water.
A 19 minute period of the fieldwork was video-recorded. The episodes of pupils’ talk and behavior were transcribed. In the stimulated recall of nine minutes, carried out in a week, the pupils looked and commented the video. The interview was audio recorded and transcribed. A deductive approach (Neuendorf, 2011) was used in the thematic analysis when the appearance of the sequential activities of the field study was categorized using the instructional model (Bybee, 2014). The content analysis was used to categorize pupils’ and teacher’s talk and activities and the transcribed data of pupils’ talk and behavior were coded using a modified inquiry-based model of instruction as a reference. The pupils were guided by the teacher and they carried out the inquiry using the structured worksheet.

The unit of analysis was defined to be a meaningful mention of an inquiry-related concept or activity, occurring mostly within a sentence or couple of sentences in the content analysis. For instance, the meaning of a sentence “I suppose it [the water] is very cold” was coded and categorized to belong to Exploring (making assumptions, see Bybee et al. 2006).

RESULTS

Field activities

The videotape was analysed in one minute’s episodes. The meanings of the sentences were classified according to the instructional model (Bybee et al. 2006). The pupils talked almost continuously during the video-recorded fieldwork activities, either by commenting their own or other pupils’ observations, actions, conceptions, memories etc. The talk and behavior did not directly follow the characteristics of different phases of the original instructional model, but occurred occasionally, triggered by various observations and comments of the pupils or the teacher. The exchange of ideas awoke rabidly, and for instance an observation was followed by intensive explanation and elaboration (Figure 1).

Two main different type of episodes were found. In the first episode lasting about 7 minutes (Figure 1), the pupils took water samples and talked about the properties of the water. The discussions initiated spontaneously among the pupils or by the teacher, or when a pupil read the questions from the worksheet. The second activity of about 11 minutes was invertebrate sampling and species recognition. In this section there was not so much talk, because the pupils tried to find the invertebrates by ladling and filtering the sandy bottom substrate in sea line. Only in one occasion the talk was intensive, when the pupils tried to identify small larvae using species identification cards. Also in this case, within a minute, the exploration comments rapidly changed to explanation and elaboration.

Excepting the phase Engaging, the characteristics of other types of phases of the instructional model were found in pupils’ comments and activities in the sea shore. The number of mentions linked with different types of activities are shown in the Figure 1.

Pupils talk was mostly categorized to belong to the phase Exploring, when they commented their immediate observations on the studied phenomena:

- This [the water in the test tube] is really a bit yellowish.  B2
- It is a bit brown.  B1
- It is when you look at it against the paper.  G1
Exploring was soon followed by Explaining that occurred in the discussion on the same topic (properties of the water). When Explaining the pupils tried to answer their own questions, made assumptions and used their learning and prior knowledge in answering:

*Do think that the water is clean?* \( G_2 \)

*No, no at all, once a guy had shown that he had found a couple of dustbins there, terrible amount of bottles, some stones and everything was rusty and there was all kind of metal things ... so it is dirty!* \( B_2 \)

*It may not be so dirty, but you should not drink sea water* \( G_2 \)

*I have been drinking lake water in our summer cottage.* \( B_1 \)

*Yes, lake water in different, it is not so salty at all.* \( T \)

In Elaborating the pupils applied their learning to their experiences and in new contexts:

*I have tasted the water of the Dead Sea. It is really very much salt in it.* \( B_2 \)

*It must be at least five times more salt in it when compared to the ordinary sea water.* \( B_1 \)

In Evaluating one pupil evaluated the goals of the study:

*Why not to use tap water to study these kind of issues?* \( B_1 \)

*Well, we just want to study sea water now.* \( T \)

*It would be better to study tap water, because it is really clean. But you could still swim in this [sea]water, and there is nothing [bad] in it.* \( B_1 \)
In summary, the pupils talked most in the episodes that reflected exploring, when they talked about their observations and emotions the sensory perceptions awoke. They also talked much about their own prior experiences in similar contexts (e.g. in the sea or lake environments), stated hypotheses about the phenomena to be studied, and explored and explained the phenomena. The pupils applied their knowledge by comparing for instance water temperature and salinity in different contexts, places and environments.

**Stimulated recall**

During the stimulated recall, Exploring (commenting field observations) and Evaluating were almost the only inquiry-related topics in pupils’ talk. In the beginning the pupils were very engaged to see the video and they were most interested to recognize themselves in the video. They also asked teacher the questions on the content of the video, but moved soon to comment and evaluate the fieldwork activities.

In the stimulated recall the focus of the discussion followed slightly the sequences of the field study activities. The discussion was triggered by the most interesting features of the video following the pattern: pupils themselves – the video watching – the interestingness of different field activities – evaluation of circumstances (cold weather) – sensory observations and temperature measurements (Figure 2). Only in few comments the pupils elaborated some field experiences to everyday life, and in some cases they tried to memorize the meaning of different activities in the sea shore. The most frequent comments were related to Evaluation, when the pupils discussed their field activities. In the stimulated recall the pupils talked much about their emotions and the interestingness of different activities of the study.

![Figure 2. Total number of the units of analysis (mentions) in pupils’ talk concerning the outdoor inquiry activities.](image-url)
DISCUSSION

The result of this study showed that by applying the instructional model of Bybee et al. (2006) as a deductive framework, the structured outdoor inquiry carried out by the primary school pupils could be categorized to different types of inquiry activities. The activities typical to the phases of Exploring, Explaining, Elaborating and Evaluating could be found when analyzing the transcribed data of the video. However, the activities did not appear in the sequential order as in the instructional model, but occasionally, initiated suddenly by a specific event or discussion, and deepened quickly to pupil-centered discussion that was related to Elaboration and Evaluation. The pupils made observations, stated hypotheses and applied their knowledge to every-day situations autonomously, and sometimes the discussion was initiated or guided by the teacher. Interestingly, the teacher did not have to make much effort to motivate and guide the activities, because the sea shore, the investigations and the collaboration with other pupils and the teacher were engaging. The outdoor inquiry included the aspects of the structured and guided inquiry. However, there was much student-centered activities and discussions (c.f. Banchi & Bell, 2008). The pupils could work autonomously, collaborate with each other and interact with the physical environment, which is suggested to make outdoor learning more experiential when compared to class room learning (c.f. Kolb & Kolb, 2009).

The stimulated recall showed that the pupils were very interest to see themselves in the video, but they also discussed and evaluated the fieldwork. The results showed that sensory observations and emotions were important for the pupils, but they also discussed and evaluated their field observations and studies, the focus of the IBL.

Our results agree with the reviews of Rickinson et al. (2004) and Behrendt & Franklin (2014) in that outdoor is an effective experiential learning environment, because pupils are in direct sensory-based contact with the learning environment, the content and context of the instructional topics of learning. Outdoor inquiry provided pupils an opportunity to learn to make field observations, carry out inquiry, and apply learned concepts and skills in their experiences of real-life situations. The results suggest that classroom learning prior the fieldwork and teacher’s guidance is needed to facilitate pupils to use their knowledge and skills outdoor (Behrendt & Franklin, 2014).

We suggest that the video-based research (Derry et al., 2010) provides valuable information on pupils’ experiences, perceptions, emotions, interactions and collaboration, as well as on conceptual and procedural learning in outdoor environments. In a science lesson the teacher may not have possibilities to follow pupils’ discussions, and much of the learning process remains hidden. Also, the video research provided information on the influence of pupils’ personalities in different learning situations. The pupils had different roles, but for instance the number of mentions among the pupils varied similar ways both in the field study and the stimulated recall, suggesting that pupils had strong personal influence in collaborative learning.

This study showed that although the field activities were basically structured (Banchi & Bell, 2008), the characteristics of the student-centered inquiry could be found: The pupils were autonomous and collaborative, they made observations, used simple tools to carry out field studies, stated hypotheses for the water properties measurements and applied their learning to every-day life situations. Thus, to understand the outdoor learning process, it is important to
study more closely how pupils talk, behavior and collaboration in the authentic outdoor learning situations.

ACKNOWLEDGEMENT

LumaMessenger research and development project of the LUMA Centre Finland and the coordinator Anttoni Kervinen are acknowledged from providing the video data.

STRAIGHT 10: INTRODUCTION

SCIENCE CURRICULUM AND EDUCATIONAL POLICY

Science education policy reform is an enduring topic of interest for researchers. The impetus partly comes from a continual desire to improve the outcomes of science teaching in schools and universities. It also arises from a perceived failure of current educational systems to respond to the needs of modern societies, leading to calls for the reform of educational systems (Fullan, 2007; Tytler, 2007). One long-standing problem is the artificial distinction between learning in school and out-of-school. This often inhibits the development of knowledge and skills, and creates unwanted obstacles for re-instituting learning as a powerful motivator of human innovation and problem-solving capacity. The promotion of the latter has been at the core of what has been called a framework for 21st Century Skills, which despite the criticism, is an attempt to conceptualize how “learning” should be operationalized anew to meet current needs (Dede, 2010).

International studies such as TIMSS and PISA have given policy-makers grounds to compare performance of countries’ educational systems across the world. In parallel to this there are ongoing efforts to increase possibilities for all students to reach levels of scientific literacy that are beneficial to all citizens in modern societies. This has promoted an evolution of science curricula towards supporting the development of positive attitudes, and skills such as scientific problem solving and evidence-based argumentation. Future citizens are expected to recognise science in society and use technology and scientific theories in discussions and decision making in their daily lives. These two lines of development have been discussed by Roberts (2007, 2011) through idealized extremes called vision I and II. In a recent review Ryder discusses implications of this complex development for teachers and their possibilities to adapt policies to suit their local context (Ryder, 2015).

Research on science teaching and learning are constantly growing and the field of research presented in this strand explores numerous aspects and perspectives. The strand covers:

- Curriculum development. Reform implementation, dissemination and evaluation.
- International comparison studies such as TIMSS and PISA. Evaluation of schools and institutions. Policy and Practice issues: local, regional, national, or international issues of policy related to science education

The papers published in this section are diverse in terms of geographical context (Africa, Europe, South America), projects within and between countries, subject matter (specific science subjects, integrated science and STEM), research subjects (books, teachers and policy makers) and methodologies employed.

Mnguni discusses an analysis of curriculum ideologies in the official curricula for the two subjects Natural Sciences and Life Sciences in South Africa. Results suggest that all four ideologies, namely discipline-centred ideology, service-centred ideology, student-centred ideology and citizenship-centred ideology, are reflected in these subjects, but to a varying degree. Strikingly, the citizenship-centred ideology was the least represented.
Nielsen presents an analysis of the key changes between the new and the preceding curriculum for compulsory education in Denmark. The new science curriculum has an emphasis on modeling. The dataset includes audio-recordings of groups of teachers talking about their planning in relation to the curriculum. The paper discusses prospects and challenges the implementation of the new curriculum may lead to when teachers enact it in their local context.

Chaiklin gives a distinctive account of the process by which the most recent science lower-secondary school curriculum was formed in Denmark. The analysis rests on interviews with five key persons involved in producing the curriculum. The paper points to the need to acknowledge discrepancies within official curriculum documents as one way of improving the realisation of their intentions.

Maceno et al. explores the teaching practices of sixty-five secondary chemistry teachers from the state of Santa Catarina (Brazil) using two written surveys. They discuss profiles of teachers’ expressed educational needs in relation to future in-service training. Important building blocks are structural support for long-term development and collaboration, permanent contracts, teaching projects and pedagogical alternatives.

Krumbacher et al. present an exploratory comparative analysis of Swedish, Finnish, and German compulsory school curricula related to structural implementation of integrative instruction with a main focus on STEM subjects. They demonstrate that ideas of integrated instruction differ between the aforementioned countries, and problematize to what extent integrative instruction is an addition to, or a replacement of, traditional subjects.

Sheeran et al. presents an overview of findings from the evaluation of the STEM Learning Facilitator Programme in Ireland. They highlight the complexity of the development of practice, and how impacts are softly couched within everyday teaching and difficult to describe. They conclude that the programme has had an impact on teachers’ confidence and pedagogical knowledge of inquiry teaching.

These contributions demonstrate a commitment within ESERA to researching curriculum and policy using a range of methodologies and including international and comparative studies. We hope that you will enjoy reading the papers and that they provide models for related studies in other policy areas across Europe and beyond.

“IDEOLOGICAL WARS” IN THE SOUTH AFRICAN NATURAL SCIENCES AND LIFE SCIENCES CURRICULA

Lindelani Mnguni
Department of Science and Technology Education, College of Education, University of South Africa, Pretoria, South Africa

Curriculum reforms aimed at redressing the inequalities and injustices of the apartheid regime by introducing citizenship education have been implemented in South Africa by the democratic government. In the current research, the researcher investigated the curriculum ideology of two biology subjects, namely, Natural Sciences and Life Sciences. Natural Sciences is taught at Grades 7-9 and Life Sciences is taught in Grades 10-12. Document analysis using a previously validated standardized document analysis instrument was used to analyse the curriculum documents of these subjects to determine their curriculum ideology. Results suggest that all four ideologies, namely discipline-centred ideology, service-centred ideology, student-centred ideology and citizenship-centred ideology, are reflected in these subjects, albeit in varying extents. Both subjects reflected aspects of the student-centered ideology the most. The citizenship-centered ideology was the least supported. The absence of a single explicit curriculum ideology may lead to an ‘ideological war’ between stakeholders who may interpret and use the curriculum differently. Citizenship education may also not be achieved through these two subjects given the apparent lack of focus on the citizenship-centred ideology.

Keywords: Life Sciences; Natural Sciences; Citizenship education; Curriculum ideologies.

INTRODUCTION
Students in South Africa have recently participated in the #FeesMustFall protests demanding a decolonization of the curriculum in order to introduce free, and context-specific quality education for all. This is in spite of several curriculum reforms that have been implemented since 1994 (Jansen, 1998). To this end, Nelson Mandela argued that “education is the most powerful weapon you can use to change the world” (Mandela, 2003). At the core of these curriculum reforms therefore has been the introduction of citizenship education which is aimed at ensuring that students, and the society, become clear-thinking and enlightened citizens who participate in the reconstruction and empowerment of the society (Waghid, 2002). The effectiveness of these reforms, within the context of citizenship education, however remains to be investigated. Goodlad and associates (1979) suggest that there are at least five different levels of a curriculum, namely, the ideological, formal, perceived, operational and the experienced levels of the curriculum. As such, curriculum reforms at any one level are not guaranteed to be transferred to another. Previous research has also shown that misinterpretations and alternative interpretations occur during the translation of the curriculum through the different levels (Bantwini, 2010).

Theoretical framework
Mnguni (2013) suggests that the curriculum ideology of a curriculum can be used to determine the effectiveness of curriculum reform in relation to social transformation. A curriculum ideology refers to “the overarching aims or purposes of education, the nature of the child or student, the way learning must take place, the role of the teacher during instruction, the most
important kind of knowledge that the curriculum is concerned with and the nature of this kind of knowledge, and the nature of assessment” (Schiro, 2008: 7). There are at least four curriculum ideologies, namely, discipline-centred ideology, service-centred ideology, student-centred ideology and citizenship-centred ideology (Mnguni, 2013; Schiro, 2008).

In the last few decades, most curricula globally have adopted the student-centred ideology (Hannafin, Hill, Land & Lee, 2014). These curricula claim to promote, support and facilitate the development of the students’ interests and abilities (Hannafin et al., 2014). As such, students are supported in using their cognitive, affective and psychomotor domains to construct knowledge and develop skills. Teaching in this regard is therefore a function that focuses on nurturing and facilitating the student-development process. Alanazi (2016) suggests that in the student-centred ideology, the goal of education is helping students to develop their innate abilities which can be used in future endeavours. Those who support the student-centred ideology argue that school curricula should be designed in a manner that caters for what interests the students in order to facilitate healthy, virtuous, and beneficial growth (Mnguni, 2013).

The discipline-centred ideology on the other hands tends to focus on supporting the growth of the discipline by transmitting discipline-specific cultural knowledge, skills and values (Cotti and Schiro, 2004). This ensures the plurality and autonomy of academic disciplines and the associated knowledge (Schiro, 2008). In the curriculum, therefore students are taught discipline-specific epistemology and ontology (Schiro, 2008; Ravitch, 2000). Teachers in this regard view education as a way of helping students to learn accumulated knowledge of the specific academic discipline (Farahani & Maleki, 2014).

The service-centred ideology focuses on ensuring that students are trained to do specific functions required in the society (Schiro, 2008). As such, service-centred ideology is focused on preparing students for their active roles in ‘service delivery’. Authorities and curriculum developers in this instance are tasked with identifying social needs, and develop strategies for integrating related skills and knowledge in to the curriculum, to ensure that the curriculum prepares students to perform specific tasks when rendering social services. Service-centred ideology is based on Bobbitt’s (Bobbit, 1918: 42) argument that “education that prepares for life is one that prepares for the specific activities. However numerous and diverse they may be, they can be discovered. This requires only that one go out into the world of affairs and discover the particulars of which these affairs consist. These will show the abilities, attitudes, habits, appreciations, and forms of knowledge that men need. These will be the objectives of the curriculum. The curriculum will then be that series of experiences which children and youth must have by way of attaining those objectives…that series of things which children and youths must do and experience by way of developing abilities to do the things well that make up the affairs of adult life; and to be in all respects what adults should be.”

In the citizenship-centred ideology students are viewed as members of the society, who must be trained to identify and solve emerging social challenges. Teachers therefore expose students to knowledge and skills that will enable them to identify social ills and be able to reconstruct social norms, values and practices. Students in this ideology are therefore viewed as change
agents. In essence, citizenship-centred ideology is related to citizenship education in that teaching and learning are integral to community settings and everyday dynamics of the society.

**Aim of the research**

Based on the above framework, the aim of the current research was to determine the curriculum ideology of two South African biology-related school subjects (i.e. Natural Sciences and Life Sciences) by analysing their formal curriculum documents known as Curriculum and Assessment Policy Standards (CAPS). Findings would then be used to make inferences about the social transformation goals of the South African education system.

**RESEARCH METHODS**

Scholars (e.g. Houang & Schmidt, 2009; Martone & Sireci, 2009) suggest a number of approaches to curriculum analysis. The current research relied on the methodology used by Mnguni (2013) in analysing a school curriculum to determine its ideology. In this regard, two school curricula were the subject of interest. These are locally known as Natural Sciences and Life Sciences. Natural Sciences is a multi-disciplinary subject taught in Grades 7-9, which covers foundational knowledge of physics, chemistry, biology, and geography. It is a prerequisite for Life Sciences, which is taught in Grades 10-12 and covers biology content knowledge, including molecular biology, zoology and botany. Document analysis therefore was performed on the curriculum documents CAPS Life Sciences (Department of Basic Education 2011a) and CAPS Natural Sciences (Department of Basic Education 2011b). The first step in this regard was close reading of the CAPS documents to ensure that the researcher is familiar with their contents and structure. This was followed with curriculum mapping as suggested by Nieuwenhuis (2007). Curriculum mapping in this regard refers to the use of an instrument (Table 1) that was developed by Mnguni (2013) to examine sections of the CAPS documents in order to identify specific emerging themes and subthemes which are characteristic of the four curriculum ideologies. These emerging themes and subthemes were then quantified and classified into specific curriculum ideologies as guided by Mnguni (2013) and Schiro (2008). The instrument used comprised of six open-ended questions. These were adopted from Schiro’s (2008) standard inventory for curriculum analysis aimed at determining a curriculum ideology. Scholars (e.g. Nicholls, 2003; Evans & Davies, 2000) suggest that using a standardized instrument improves validity and credibility of the analysis. To further improve validity and credibility however the instrument used in this research was validated through a panel of experts who were tasked with determining its content and face validity with regard to its suitability for the intended purpose. Having satisfied the validity requirements the researcher then identified sections in the CAPS documents, which best provided responses to the questions in the document analysis instrument. These are presented in the results section as verbatim and narrated extract from the two CAPS documents. The researcher subsequently, used these responses to qualitatively and quantitatively make inferences regarding the curriculum ideologies of Natural Sciences and Life Sciences that are best represented in the CAPS documents.
Table 1. The standardized data collection instrument used for reviewing components of the CAPS documents (Adapted from Mnguni, 2013 and Schiro, 2008).

RESULTS

Purpose of the subject

The purpose of Natural Sciences was found to reflect both the student-centered ideology and service-centered ideology. According to Schiro (2008), ‘self-fulfillment’ is characteristic of a student-centered ideology. He further contends that participating in society in relation to specific tasks is a characteristic of a service-centered ideology. These characteristics were found in the Natural Sciences curriculum. For instance, the CAPS document (Department of Basic Education 2011b: 4) suggests that:

“Natural Sciences serves the purposes of equipping learners, irrespective of their socio-economic background, race, gender, physical ability or intellectual ability, with the knowledge, skills and values necessary for self-fulfilment, and meaningful participation in society as citizens of a free country providing access to higher education; facilitating the transition of learners from education institutions to the workplace; and providing employers with a sufficient profile of a learner’s competences”.

Life sciences on the other hand was found to lean towards a discipline-centred ideology. For example, the CAPS document (Department of Basic Education 2011a: 12) suggests that Life Sciences aims to provide students with opportunities to make sense of ideas they have about nature. It also encourages students to ask questions that could lead to further research and investigation. This focus on ‘understanding the natural world’ as defined in the biological sciences is typical of a discipline-centred ideology (Mnguni, 2013). This was also evident in that the CAPS states that Life Sciences “involves knowing, understanding, and making meaning of sciences...in the process of acquiring a deep understanding of science” (Department of Basic Education 2011a: 13).
**Nature of Knowledge**

With regards to the nature of knowledge, Natural Sciences was found to adopt the discipline-centered, service-centered and citizenship-centered ideologies. Here the CAPS document states that “Natural Sciences at the Senior Phase level lays the basis of further studies in more specific Science disciplines. It prepares students for *active participation in a democratic society* that values human rights and promotes responsibility towards the environment. Natural Sciences can also *prepare students for economic activity and self-expression*” (Department of Basic Education 2011b: 9). Here the classification of science discipline, focus on capabilities of action and reference to democratic societies are typical characteristics of discipline-centered, service-centered and citizenship-centered ideologies respectively. Similarly, Life Sciences also was found to adopt all four ideologies in as far as the nature and purpose of knowledge is concerned. For instance, the CAPS document (Department of Basic Education 2011a: 9) states that “*all of the sub-disciplines* (of biology) are introduced, to varying degrees, to provide a broad overview of the subject, Life Sciences. The three main reasons for taking Life Sciences are to *expose students to the scope of biological studies* (characteristic of discipline-centred ideology) to *stimulate interest studies* (characteristic of student-centred ideology) in and create awareness of possible specialisations (characteristic of service-centred ideology); and to provide a sufficient background for further studies in one or more of the biological sub-disciplines.”

**Instructional process**

Evidence of service-centered and student-centered ideologies was found in natural Sciences where the primary actor during learning is the student rather than the teacher, discipline or society. Here the CAPS document states that it follows “active and critical learning, encouraging an active and critical approach to learning” (Department of Basic Education 2011b: 4). The student-centred ideology was also implied in that Natural Sciences “facilitates the transition of students from education institutions to the workplace” (Department of Basic Education 2011b: 4). In Life Sciences there was evidence of a student-centred ideology where “teaching and learning of science involves the development of a range of process skills that may be used in everyday life, in the community and in the workplace. Students can gain these skills in an environment that supports creativity, responsibility and growing confidence. Students develop the ability to think objectively and use different types of reasoning while they use process skills to investigate, reflect, synthesise and communicate” (Department of Basic Education 2011a: 12).

**Roles of the student and the teacher**

Both the subjects support active learning as implied in the student-centred ideology. Natural Sciences also facilitates the development of “skills that may be used in everyday life, in the community and in the workplace” (Department of Basic Education 2011b: 4), a typical feature of both service-centred and student-centred ideologies where students are developed to become active change agents in their communities. Teachers in natural sciences are also expected to manage their classrooms, and other resources such as lab equipment and other learning materials. This managerial role is typically found in the service-centred ideology. Teachers in
Natural Sciences also play a facilitator role, which is characteristic of the student-centred ideology. For example, CAPS states that “When teaching Natural Sciences, it is important to emphasise the links students need to make with related topics to help them achieve a thorough understanding of the nature of and the connectedness in Natural Sciences. Students need regular opportunities to read and write a range of genres in order to improve their reading and writing skills.”

In Life Sciences, students are actively involved in the assessment process, which includes self-assessment and peer-assessment. This active participation in the learning is typical for the student-centred ideology. Life Sciences was also found to prescribe skills and content that must be presented to students, as recommended in the discipline-centred ideology. Here teachers are given a list of verbs that must be used in assessment, as well as a range of skills that students must acquire during practical work. The prescription of knowledge, skills, teaching and assessment approaches is characteristic of the discipline-centred ideology (Mnguni, 2013).

**Assessment**

Natural Sciences defines assessment as “a process that measures individual students’ attainment of knowledge (content, concepts and skills) in a subject by collecting, analysing and interpreting the data and information obtained from this process” (Department of Basic Education 2011b: 85). Schiro (2008) suggests that using assessment to certify attainment of knowledge and skills is a characteristic of a service-centred ideology. However, the use of informal and subjective assessment, which was found in Natural Sciences, is a feature of student-centred and citizenship-centred ideologies. In Life Sciences, assessment is used to diagnose abilities and facilitate growth, a characteristic of a student-centred ideology. For example, the CAPS document (Department of Basic Education 2011a: 66) states that ‘Self-assessment and peer assessment must actively involve the students being assessed. This is important as it allows students to learn from and reflect on their own performance. The results of the informal daily assessment tasks are not formally recorded unless the teacher wishes to do so.”

**Overall ideology of the subjects**

Results showed that the four curriculum ideologies are all reflected, to varying extents, in both Natural Sciences and Life Sciences curricula. In this instance evidence obtained related to six themes, namely, the aim of the subject, the nature of knowledge taught in the subject, the instructional process recommended and/or prescribed, the roles of the students and teachers during teaching and learning as well as assessment methods recommended and/or prescribed. The researcher found that in Natural Sciences the student-centered ideology was most dominant (i.e. 31%), followed by service-centered ideology (30%), then discipline-centered ideology (24%) whereas citizenship-centered ideology was least supported (15%). Life Sciences on the other hand reflected student-centered ideology the most (45%), followed by discipline-centered ideology (38%), service-centered ideology (14%) and then citizenship-centered ideology (3%). In both subjects, a contradiction was also observed where one ideology is preferred for one theme of the curriculum and a different ideology for another theme.
DISCUSSION

This research has demonstrated that the citizenship-centred ideology is least supported by both subjects even though the curriculum reforms were aimed at introducing citizenship education. Mnguni (2013) argued that the citizenship-centred ideology is best suited for the development of skills and knowledge related to citizenship education. Furthermore, this research has also shown that both Natural Sciences and Life Sciences lack a single explicit curriculum ideology. Instead, they adopt all four ideologies to varying extents. The consequence of this mélange of ideologies is not clear. However, given Goodlad and Associates (1979) assertion about the different levels of the curriculum, the current researcher believes that the absence of a single explicit curriculum ideology may lead to an ‘ideological war’ where politicians, curriculum experts, the society, teachers and students interpret the curriculum differently. For example, Bantwini (2010) argues that what is intended in the formal curricula is not always what students receive. As such, a lack of a single explicit curriculum ideology means stakeholders, particularly teachers, students and curriculum designers, may not have a common understanding of “the overarching aims or purposes of education, the nature of the child or student, the way learning must take place, the role of the teacher during instruction, the most important kind of knowledge that the curriculum is concerned with and the nature of this kind of knowledge, and the nature of assessment” (Schiro, 2008: 7). Further research is being done to determine the curriculum ideology of the two subjects based on the teachers and students views in order to determine whether the ideologies reflected in the curriculum are similar to those held and/or preferred by stakeholders. Further research is required to determine, empirically, the effect of the multiple ideologies in a subject. Moreover, research is necessary to determine the overall curriculum ideology of the South African curriculum as reflected collectively in all the subject. Findings thereof could be compared with similar studies in other countries.

PROSPECTS AND CHALLENGES IN TEACHERS’ ADOPTION OF A NEW MODELING-ORIENTED SCIENCE CURRICULUM IN LOWER SECONDARY SCHOOL IN DENMARK

Sanne Schnell Nielsen
Department of Science Education, University of Copenhagen, Denmark, and University College UCC, Copenhagen, Denmark

A new science curriculum with a significant emphasis on modeling has recently been adopted in Danish compulsory education. The purpose of this paper is to identify the key changes between the new and previous curriculum, and analyze what kind of prospects and challenges this may lead to when teachers adopt this new curriculum. The data sources include audio recordings of three teacher-teams’ talk-in-interaction during their instruction planning. In addition, science teachers completed an electronic questionnaire (n=227). Significant changes were identified between the new and previous curriculum in relation to: (i) The characteristics of what and how to address models and modeling in the teaching, (ii) Assessment requirements, (iii) Teaching approaches, (iv) Subject-specific versus interdisciplinary teaching, and (v) The prioritizing of different inquiry practices. The analysis suggests that teachers have a positive attitude towards the modeling emphasis in the new curriculum, and models play an important and valued role as a learning tool. In addition, teachers have a tendency to see models as a product of content knowledge and concepts to be learned. Teachers raised concerns in adopting the new curriculum due to: (i) Lack of time for preparation, teamwork and teaching, (ii) Shortage of clarifications and examples in the curriculum materials, (iii) Shortage of teacher education and in-service training how to adopt modeling in practice, (iv) Overcrowded curriculum and fragmented teaching time with students, and (v) Lack of alignment with a national test and an exam. The findings will have implications for teacher education, professional development and curriculum development.

Keywords: Modeling competence, Science curriculum reform, Teachers’ practice.

INTRODUCTION

A new school reform has recently been adopted in Danish compulsory education, commencing in the school year 2015-2016 (Ministry of Education, 2014a). This reform includes changes to the national science curriculum for lower secondary education (grades 7 to 9). One significant change relates to an enhanced focus on models and modeling in teaching and assessment. This study examines the prospects and challenges for teachers in adopting the new modeling-oriented curriculum. The focus is on the tension and gap between theoretical educational intentions and arguments for integrating models and modeling into science education, on the one hand, and teachers’ practices, rationales and conditions for integrating models and modeling into their teaching and assessment practice, on the other (Figure 1). In this study, the modeling aspects of the new curriculum and the key purposes of science education represent the theoretical intentions and arguments.

The assumption for this study is that the degree of alignment between theoretical intentions and teachers’ rationales, practices and conditions significantly affects the prospects and challenges for adopting the new curriculum. This assumption is aligned with former studies.
showing that science teachers’ rationales, conditions, and practices challenge the prospects for adopting the intentions reflected in competence and goal-targeted curricula (e.g. Sølberg, Bundsgaard & Højgaard, 2015).

Figure 1. Two perspectives on integrating models and modeling into science education. Illustrated as tensions between theoretical educational intentions and arguments and teachers’ practices, rationales, and conditions on integrating models and modeling into their teaching.

However, as emphasized by Kenn and Osborne (2017), these challenges and prospects are also directly related to the prioritization, volume and descriptions of the content in the curriculum. This also includes how the curriculum elaborates on why and how the content could contribute to accomplishing key purposes of science education (Osborne, 2014).

The Danish school context

In Denmark, science is taught as an integrated subject from grades 1-6 (age 7-13). From grades 7-9 it is taught as three separate subjects: biology, geography, and integrated chemistry/physics. There is no national standard on how to structure science lessons during the school year. However, each science subject is typically distributed equally across the school year with 1-3 lessons (of 45 minutes) per week (Table 1). This study only considers grades 7-9. Science teachers most frequently teach 6-10 science lessons per week with a range of 2 to more than 17. Most teachers teach two different science subjects.

Table 1. Number and distribution of science lessons (of 45 minutes) per week by subject and grade in Danish compulsory education.

THEORETICAL BACKGROUND

Models and modeling offer prospects for accomplishing some of the key purposes of science education

Models and modeling are central for teaching and learning science and are seen as a core practice in science and scientific literacy (Lehrer & Schauble, 2015). The term ‘model’ can be perceived as a product of science whereas the term ‘scientific modeling’ refers to a process or practice used in science that involves: developing models by embodying key aspects of theory and data into a model; evaluating models; revising models to accommodate new theoretical ideas or empirical findings; and using scientific models to predict and explain the world (Schwarz & White, 2005). Since modeling involves repeated cycles of developing, representing and testing knowledge, modeling is an important part of scientific inquiry (Lehrer, Schauble, Lucas, 2008). Lehrer and Schauble (2015) have suggested that science is primarily a ‘modeling enterprise’. They have argued for a broad perspective on modeling as a core scientific practice with prospects for incorporating other science practices (investigation, communication, argumentation, questioning, etc.) when constructing, revising, critiquing and contesting models of aspects of the natural world.

Several scholars have pointed to the affordances of modeling in facilitating students’ learning of science concepts, scientific reasoning processes and awareness of how science works (Campbell & Oh, 2015; Nicolaou & Constantinou, 2014; Schwarz et al., 2009). These affordances of modeling in facilitating students’ learning conform to three of Hodson’s (2014) purposes for science education: learning science, learning about science, and doing science.

The above mentioned learning prospects for modeling, is also aligned with the purpose of science education as reflected in the PISA 2015 framework (OECD, 2017). The framework highlights three distinguishable but related elements of knowledge that are required to accomplish science literacy. The first is “content knowledge”, corresponding to Hudson’s (2014) “learning science”. The second, is “procedural knowledge”. Finally, the third is “epistemic knowledge”. Note that Hudson’s (2014) “knowledge about science” is made more specific in the PISA document by splitting it into the two components – procedural knowledge and epistemic knowledge.

In sum, integrating models and modeling as a core scientific teaching practice offers prospects for accomplishing some of the key, internationally-agreed purposes of science education.

A competence-based approach to models and modeling

In Denmark and internationally, there has been a strong educational effort to engage students in scientific practices such that the key purposes of science education shifts from students knowing scientific and epistemic ideas to students developing and using these understandings as tools to make sense of the world (Berland et al., 2016; Ministry of Education, 2014a; OECD, 2017).

In science education, the concept of competence is still the subject of ongoing debate. In this paper, the concept of competence is framed in an educational context and considered to be subject-specific. This framing is inspired by the definition proposed by Busch, Elf & Horst
In their definition, they describe a subject-specific competence as: a domain-specific insightful readiness to successfully act in a way that meets the challenges of a given situation which contains a particular domain-specific problem (slightly modified by the author during translation to fit English). In other words, a subject-specific competence approach to science education implies that students should apply their scientific knowledge to different situations or tasks related to science-correlated issues.

The strong reference to application of scientific knowledge aligns well with the above mentioned effort to shift the key purposes of science education from students who have scientific content knowledge, procedural knowledge, and epistemic knowledge, to students who apply these different elements of knowledge.

 Former approaches to science education focused predominantly on the content knowledge of the models – *the product of science* - without developing an understanding of the processes that led to the knowledge embedded in the model or the purposes, value and utilizations of models in science (Kind & Osborne, 2017; OECD, 2017). In this kind of *product-oriented approach* to modeling, teaching will focus on the use of established models to describe and explain scientific concepts and their relations, while the modeling process leading to this knowledge attainment will play a minor role. In addition, a *product-oriented* teaching approach to models will merely focus on models as representations of already well-established knowledge and how this knowledge is represented in the models. This approach aligns well with what Gouvea & Passmore (2017) define as *models of something*. According to Kind & Osborne (2017), a *product-oriented* approach will mainly provide students with lower-order cognitive challenges of recall, comprehension and application. In addition, if models are solely introduced in the classroom as representations of what is known and not as tools for inquiring, students’ prospects for engagement in applied scientific practice will be reduced (Passmore et al. 2014).

In contrast, in a competence-based practice, the starting point for integrating models into teaching should be “what should students be able to do with models – and what kind of knowledge do they need to know to do it?” This kind of teaching entails a *process-oriented* approach to models. In process-oriented teaching, the focus will be on models as tools for dealing with scientific tasks, for example, models’ nature and use for predicting, knowledge-generating, problem-solving, discussion and sharing of data. This applied view to models shares features with Gouvea & Passmores’ (2017) *models for* teaching approach, with a strong reference to the epistemic functions of models (what they are for). They advocate an approach aimed at facilitating students’ development, understanding and valuing of the *processes of science* that led to the knowledge embedded in the models, e.g. a teaching that emphasizes students’ engagement with designing and using models as tools for supporting inquiry and exploration. In the same vein, Nicolaou & Constantinou (2014) emphasize the affordance of including students’ meta-knowledge on the nature, use and purpose of models, and criteria for evaluating them in competence-based teaching.

In this way, integrating a competence-based approach to models and modeling as a core scientific teaching practice can facilitate the efforts to shift the key purposes of science education away from students knowing scientific and epistemic ideas, to students developing
and using these understandings as tools to different situations or tasks related to science-correlated issues.

The way in which these prospects are used, however, depends on the assumption, prioritization and description in the curriculum of how and what kind of knowledge and practice teachers are supposed to integrate into their teaching and assessment.

THE NEW REFORM INCLUDES CHANGES IN THE CURRICULUM’S HOW AND WHAT TO TEACH AND ASSESS

The new reform includes a significant change to the national science curriculum. In the previous curriculum, each of the three science subjects was taught separately. In addition, there was a strong focus on field and laboratory investigations as the main inquiry practice in science. Furthermore, the knowledge and skills to be taught held a dominant position, and were to a large extent approached as two different aspects of learning (Ministry of Education, 2009). Another major change in relation to the former curriculum is the introduction of a requirement for teachers to integrate the three separate science subjects into six different interdisciplinary units from grades 7 to 9.

Another significant change for all the science subjects involves a statement of what students should learn in terms of four main competences: investigation, modeling, contextualization, and communication (Ministry of Education, 2014a). For each of the four competences, there is a related competence goal and three pairs of related skills and knowledge goals (Table 2).

Table 2. The new science curriculum describes what students should learn in terms of knowledge, skills and competence goals. Here exemplified by modeling for biology (Ministry of Education, 2014b)

<table>
<thead>

</tr>
<tr>
<td></td>
<td></td>
<td>Student can evaluate models</td>
<td>Student has knowledge about evaluation criteria for models in science</td>
</tr>
</tbody>
</table>

The competences are intended to play a significant role in school science instruction and assessment in Denmark. This intention is reflected in a legal requirement for teachers to assess students’ learning of the competences in their day-to-day assessment, and to use the competences as a starting point for instructional planning (Ministry of Education, 2014a).

Compared to the pre-2014 curriculum, the focus on models and modeling is particularly novel (Ministry of Education, 2009, 2014b). This focus is reflected in the frequency of the term “model” and “modeling” in the curriculum requirements. In the pre-2014 biology curriculum,
"model" is mentioned twice and modeling not mentioned, whereas model is mentioned 44 times and modeling 25 times in the new biology curriculum (Ministry of Education, 2009, 2014b). It is not only the frequency of terms that is used differently, however, but also the way in which the role of models is described. In the former curriculum, the description only relates to the nature of models to visualize something abstract; students’ practice with models is related to description and explanation, and students’ evaluation of a given model is related to its explanatory power (Ministry of Education, 2009). The new curriculum has a more elaborated description. For instance, students’ evaluation of a given model is related both to its explanatory and to its representational power. Furthermore, the nature of models is related to their adjustability to fit different purposes, simplification, accessibility, and visualization. In addition, modeling is (but only to some extent) perceived as an inquiry practice. For example, the description of students’ use of models is not limited to their explanation of scientific phenomena but also includes a requirement to evaluate models, compare and select between multiple models, and design and revise models (Ministry of Education, 2014b). In sum, the new curriculum contains significant changes to the characteristics of what and how to address models and modeling in teachers’ science teaching. The description in the new curriculum (although not very detailed) seems to share many characteristics with a competence-oriented approach to models and modeling.

In addition, from 2017, a new final interdisciplinary oral science exam has been introduced at Grade 9 to test students’ learning within the competences (Ministry of Education, 2015). In addition to this exam, students are assessed by external national tests and an additional subject-specific final exam. The additional exam is randomly selected between the three separate science subjects. In contrast to the competence-based exam, the external national tests and the additional exam are individual, digital and composed of multiple-choice questions. In sum, the new curriculum includes changes to the characteristics of what and how to address models and modeling, teaching approaches, new prioritizing and more variation in the use of scientific practices, new interdisciplinary teaching units, and new format and criteria for assessment (Table 3).

RESEARCH QUESTION

What kind of prospects and challenges do teachers perceive when adopting a new curriculum based on a competence-oriented approach to models and modeling to accomplish key purposes of science education?

METHODS

To answer the RQs, an electronic survey questionnaire with a five-point Likert Scale rating and boxes for additional comments was distributed via email. The survey questions were challenges, prospects and motivations with respect to adopting the new modeling-oriented curriculum in their teaching and assessment practices. With one survey reminder, 227 teachers responded (31.6% response rate). To obtain a more in-depth explanation of the issues raised in the questionnaire, and to elaborate on some of the responses, a more detailed and qualitative study was conducted. The participants in this part of the study were six voluntary science teachers with different teaching experiences (2-20 years), employed at three schools each
representing different academic achievement groups of students. The data from this part of the study consist of audio recordings of teachers’ talk-in-interaction during their instruction planning of a teaching unit focused on models and modeling. The planning was part of a larger action research project. The researcher took an active part in the planning by raising reflective questions related to the teachers’ rationale and practice with respect to models and modeling. To facilitate the talk-in-interaction and teachers’ reflection, labels with pre-formulated statements were regularly presented by the researcher during the planning session. The discussions were conducted with one teacher-pair at each school. All audio recordings were transcribed. The preliminary data analysis was guided by the research questions and focused on two overarching themes: teachers’ perceptions of the prospects and challenges for adopting the new modeling-oriented curriculum, and teachers’ practices, rationales and conditions with respect to models and modeling.

PRELIMINARY RESULTS

Teachers’ practices and rationales for integrating models and modeling into their teaching

Teachers’ responses to the questionnaire show that they have a diverse understanding and use of models. This diversity was particularly reflected in the free text boxes, with teachers’ examples of physical forms of models used in their teaching. In general, the teachers acknowledged the numerous examples of model types that they used in their teaching. For example, one teacher wrote: “No [science] teaching without models” and another wrote: “My daily teaching varies greatly and is inquiry based [...] so many different models are used [...] it is not possible to avoid the periodic system; we have a new interactive one [periodic system] in the passage so that all students can be inspired and be curious”. The need as well as the value of models in teaching was frequently reflected in the teacher-teams’ talk-in-interaction during their teaching planning as well, as exemplified by this quotation: “It [models] permeates the way we explain [scientific] stuff. In the communication of science you can neither avoid nor do without models.” In addition, during the teaching planning, the teachers often emphasized and exemplified how students’ understanding of models forms part of the reading and understanding of science. In sum, the analysis of the questionnaire, as well as the talk-in-interaction, demonstrated that models were already an integral and valued part of teachers’ existing practice, and perceived as a needed and central part of science teaching.

Teachers’ precipitation of the affordance of models was closely linked to students’ learning of science concepts (i.e. Hudson’s about science). As reported in the questionnaire, the most common model practice was “Students’ explanations of scientific phenomena”, while more process-oriented practices were used to a lesser extent, i.e. predicting, revising and designing. The least used practice was “Students’ revisions of models”. Although the different teachers used models in a diverse way, the teacher-teams’ talk-in-interaction generally reflected a more product-oriented approach to modeling as opposed to a more process-oriented one. This is exemplified by this quote:” I think the overall purpose [for using the model] is that I want them [the students] to understand the protein synthesis and you [the other teacher] want them to understand the nitrogen cycle”. In sum, most (but not all) teachers had a tendency to see and use models as a product of content knowledge and concepts to be learned. Aspects of meta-knowledge seemed to play a minor role in teachers’ practice. However, when addressed in the teaching planning, it was mainly related to the existence of multiple models designed for different purposes or limitations in representing the target. The nature of models was mostly related to simplification and visualization. However, the tentative and progressive nature of models was emphasized when related to specific topics (e.g. evolution and structure of atoms).

Teachers’ school-specific conditions

Many of the school-specific conditions affecting how teachers were able to adopt the new curriculum were directly or indirectly related to time. For instance, teachers struggled with engaging students’ in more time-consuming practical and process-oriented modeling activities due to limited and fragmented teaching time per class (see Table 1). In addition, with few teaching lessons per class, teachers found it hard to change the class culture from a more
knowledge-based to a more competence-based approach. This point was especially highlighted by teachers who only taught one or two of the science-specific subjects and particularly biology and geography teachers.

Another issue related to time was the relationship between teaching lessons in science and other school subjects. Teachers with few science lessons reported a very restricted time allocated for in-service training, teamwork, preparation, and meetings related to science. Teachers perceived this as a limiting factor for their possibilities of prioritizing and adopting the new curriculum in the day-to-day teaching. Furthermore, teachers found it difficult to find time to develop and share new teaching and assessment approaches. The completed questionnaires showed that less than 30% of the teachers thought they “had time to meet with science colleagues to develop how to realize the intentions of the new curriculum.”

**Support for teachers in terms of how and why to adopt the theoretical intentions of the new curriculum**

Another issue raised by teachers was related to how models and modeling are addressed in the curriculum and teaching materials. Teachers described how the following aspects challenge their efforts to adopt the curriculum: lack of clarifications and examples in the curriculum materials; insufficient explanation as to why and how models and modeling can accomplish the key purposes of science education; lack of teaching material and/or the existing material did not fit into teachers’ valued teaching approach; a central part of the curriculum format signals a “skill and knowledge check list” compared to requests for a more competence-based approach to the interdisciplinary units described in the curriculum; overcrowded curriculum; and a mismatch between curriculum requests and students’ abilities. Teachers particularly called for guidance and support in assessing students’ models and modeling progress and achievements.

**Lack of alignment between central assessment requests and a competence-based approach to models and modeling**

In Denmark, there is a strong tradition of collaborative and practical work that is well suited to a competence-based approach to models (i.e. student sharing, discussing and designing models). Teachers note that this kind of approach was aligned with the interdisciplinary exam. In contrast, the subject-specific multiple-choice national test and the randomly-selected exam is individual and mainly assesses content and “variable control” knowledge. Some teachers expressed how this kind of assessment shifts their teaching towards a more knowledge-based approach to models and modeling, with less time allocated for discussion and practical work. The process of evaluating and revising models was found to be rather time consuming and therefore rarely used.

**An overcrowded curriculum means limited time for students to engage in practical and process-oriented modeling activities**

A repeated issue raised during teachers’ preparation work was a mismatch between teaching time and an overcrowded curriculum. Teachers stated that the introduction of the six interdisciplinary units had increased this mismatch.
Teachers’ knowledge and experience of models and modeling

From the time the new curriculum was implemented, and over the next three years, 80% of the teachers who answered the questionnaire said they had participated in less than 20 hours of in-service training related to science. In the same vein, less than 20% of the teachers agreed or highly agreed that they had participated in sufficient in-service training to integrate modeling into their teaching as a competence-based practice. In addition, 15% agreed or highly agreed that they had obtained sufficient knowledge during their teacher training on how to integrate models into their teaching.

DISCUSSION AND CONCLUSIONS

Significant changes were identified between the previous and new curriculum in relation to the characteristics of what to address and how to address models in the teaching. The pre-2014 curriculum took a knowledge- and product-oriented approach to models. The new curriculum has a more competence- and process-oriented approach. Teaching guided by the new curriculum will mainly focus on students applying and integrating content, procedural and epistemic knowledge to different modeling-oriented tasks, tasks where students are using models as tools for revising ideas, discussion etc. Theoretical intentions in the curriculum do however not in itself transform into changes in the classroom.

Nevertheless, and in line with other countries (Kind & Osborne, 2017), the official curriculum documents in Denmark provide only limited support for teachers in terms of how to adopt the curriculum in practice. The description of the modeling competence is formulated in general, unspecific terms in the curriculum, and not based on a systematic theoretical framework (Nielsen, 2015). In addition, the curriculum includes neither the intentions nor arguments for how modeling as a competence can accomplish the key purposes of science education. Moreover, there is no tradition among Danish government institutions of developing or approving teaching materials targeted at the curriculum or of including guidelines for instruction in the curriculum.

Before modeling can be adopted as a competence-based practice in the classroom, teachers must first interpret and unpack what the different aspects of modeling as a competence-based practice are, based on their own perception of relevance with respect to the key purposes of science education. Secondly, teachers must identify what form of knowledge is required for students to undertake aspects of the modeling practice. In addition, teachers need to identify the potential challenges of the different aspects of the modeling practices. Finally, they must suggest what kind of performance is indicative when assessing students learning in the different aspects of modeling practice. None of these tasks is particularly easy and nor have teachers received much training in how to carry them out (Osborne, 2014). In addition, it is a rather time-consuming teaching preparation process for the teacher to undertake.

In addition, the new reform also includes changes to teaching approaches, new priorities and more variation in the use of scientific practices, new interdisciplinary teaching units, and a new format and criteria for assessment. The introduction of so many major changes is quite a demanding task for Danish science teachers as demonstrated in this study. The analysis suggests that teachers have a positive attitude towards the modeling emphasis in the new
curriculum, and models play an important and valued role as a learning tool. Even though the teachers thus really would like to base their teaching on the new curriculum, it remains a tall order. Teachers particularly raised concerns in adopting the new curriculum with regard to: (i) Lack of time for preparation, teamwork and teaching, (ii) Shortage of clarifications and examples in the curriculum materials, (iii) Shortage of teacher education and in-service training how to adopt modeling in practice, (iv) Overcrowded curriculum and fragmented teaching time with students, and (v) Lack of alignment with a national test and an exam.

The assumption of this study is that the degree of alignment between theoretical intentions and arguments for integrating models and modeling into science education, on the one hand, and teachers’ practices, rationales and conditions, on the other, significantly affects the prospects of and challenges for teachers in adopting a competence-based modeling teaching practice.

This study indicates a “gap” in this alignment. If we want to narrow this gap, we have to consider the challenges and prospects on each side. This study highlights the following areas for consideration: take advantage of and extend teachers’ valued and already well-established modeling practice to make it more process-oriented; ensure better alignment between assessment and teaching approaches, and between the different assessment tests and exams; change the current capacity at school level e.g. to enable science team meetings; rework the existing curriculum to match the number of teaching hours; reconsider how to support teachers in the process from understanding to adopting the curriculum, and reconsider how teacher education and professional development can contribute to this process.

SCIENCE CURRICULUM FORMATION IN DENMARK: CHALLENGES IN INTRODUCING A NEW CURRICULUM

Seth Chaiklin
University College UCC, Copenhagen, Denmark

The focus of this paper is to give an account of the process by which the most recent physics/chemistry lower-secondary school curriculum was formed in Denmark. The main empirical source is interviews with five key persons involved in producing the curriculum. New features were introduced into the curriculum for the first time, including competence goals and a special matrix structure for describing the entire curriculum in terms of learning goals. The specific concern of this investigation was that apparent discrepancies between the actual curriculum document, and the ways in which it was being presented would serve to create unnecessary difficulties for teachers. This issue is particularly salient in relation to the Danish curriculum, because teachers are expected to interpret specific curriculum requirements in relation to the general purpose of subject, and then form teaching units that often must integrate different points within these requirements. Rather than speculate about the validity of these discrepancies, the aim was to reveal the actual process by which the curriculum was formed, in order to give an empirical underpinning for a sharper interpretation of the actual document. The expectation is that more insight into the actual construction of the curriculum will help teachers and researchers better understand how to approach using an official curriculum. The interviews revealed several critical points where the actual document produced did not actually reflect the general characteristics that were used to describe the curriculum. While these mismatches do not make the new curriculum unusable, the lack of documentation and public acknowledgement of these discrepancies serve to hinder productive use of the curriculum. The paper concludes with a reflection about the need for acknowledging discrepancies in the communication of official curriculum documents, as a way to improve the realisation of their intentions.

Keywords: curriculum-making, curriculum reform, physics/chemistry curriculum

INTRODUCTION

In many countries around the world, the national government takes responsibility for forming the curriculum document. An important set of relationships are established with the production of this document. Presumably the relevant authorities are expecting that the curriculum documents are adequate for their intentions to be realised, and in turn, that teachers are acting in their classrooms in ways that realise these intentions. This simple relation between curriculum document and classroom teaching is a critical and necessary part of the process by which educational authorities seek to influence teachers’ actions in their classroom. However, there are many practical challenges involved in realising this simple relation. For example, at first glance, one might expect that (a) the curriculum designers are able to formulate and express their intentions or expectations clearly in the curriculum document, (b) that teachers are able to understand or interpret those intentions, and (c) that teachers are able to formulate plans for teaching activities that are likely to realise those intentions. One reason for explicitly enumerating these logical expectations (or assumptions) is to raise the possibility that none of them are easily or readily satisfied in practice. A second reason is to highlight the point that if these minimal conditions are not satisfied, then it seems unlikely that educational authorities...
can rely on curriculum reform alone as a method or mechanism for making changes in schooling practice. This singular set of relationships is the background interest of the present study. The assumption is that educational authorities and school professionals have to address these points if there is going to be a genuine relationship between curricular documents and classroom teaching practice. To make this problem more concrete, the underlying problem is formulated as follows: How to form a curriculum document, so that teachers can use the document in a way that reflects the intentions of the curriculum designers? The ultimate aim behind this question is to understand possibilities, barriers, and remedies in using a national curriculum document as part of a school system.

Before going further with this analysis, it is necessary to highlight that this question must be approached in a historically-located way. In contrast, it is also useful to approach the question in an abstracted manner. Both of these points are relevant to the ultimate aim. After these three points are explained, the logic of the concrete study can be introduced.

**Historically-located study**

The meaning of the term *curriculum or curriculum document* often reflects a national tradition of practice. Some countries have detailed documents, or even required methods of teaching, seeking to control teachers’ actions closely. Other countries have slender, open-ended documents, that expect teachers to interpret or elaborate. There are large variations in the form and degree of specificity with which curriculum documents are formed. In a review of school science curricula in eleven high-achieving jurisdictions, Hollins and Reiss (2016) comment on these differences.

Comparisons of the scope, progression, levels of demand and key competences are often difficult to make due to the different ways that these are presented. For example, in the specification of the primary stage … the number of objectives listed ranges from 24 for Finland to 350 for Ontario. This does not relate to the extent of the science curriculum, rather to the specificity of the statements. (p. 83)

In light of these variations, it should be apparent that the meaning (or concretisation) of the question depends critically on the tradition of the educational system under consideration. Furthermore, to study this question empirically, it is necessary to work with actually existing national systems. For example, it is unlikely that it would be possible to conduct a randomized control experiment where different teachers were assigned to use different forms of curriculum documents in their daily professional work. In the present study, the focus is on the lower-secondary school science curriculum in Denmark.

In 2013, a new lower-secondary science curriculum was introduced into Denmark, as part of a general reform of the primary and lower-secondary curriculum for all subject-matter areas. The main interest of the current study is to understand the construction and intention of the actual curriculum document, which has gotten a dramatically new form and introduced competence goals for the first time. In other words, the focus is primarily on the first link in the chain by which curricular intentions come to expression in the classroom. As will be explained, a complicated process was involved in the production of the Danish curriculum document, which
makes it unlikely that any singular or coordinated intention was sought to be expressed in the curriculum document.

**Abstracted study**

The previous section highlights the need to study the use of curriculum in concrete, historical situations. This section highlights a contrasting point – that it is also useful to abstract from other historical aspects involved in the use of curriculum documents. Actual curriculum practice is a complex process. Goodlad (1979) suggests that inquiry into curriculum practice should consider at least three kinds of phenomena: substantive (e.g., goals, content), political-social (e.g., values about ends and means are preferred), and technical-professional (i.e., processes by which curricula are improved). He acknowledges that each of these areas can be conceptualised and studied separately, even though they are inseparable (p. 17).

The present study can be characterised as focusing on the technical-professional area, abstracting from the substantive and the political-social. That is, it studies the actually developed curriculum, without analysing or arguing what should be included in the curriculum. The main abstraction is to restrict focus primarily to the three “minimal conditions” enumerated in the opening paragraph. This abstraction is motivated by the interest to understand how to support teachers in working with curriculum documents, and to understand how to support the production of useful curriculum documents. In other words, the focus is on the curriculum from the point of view of the primary user, the classroom teacher, without engaging in a critical analysis of the meaning or significance of the curriculum content in relation to the pupils or the society.

Paradoxes and moral contradictions arise here; a spectre of a technocratic understanding of the relation between the curriculum document and the teaching practice, where the task is to find ways to realise any curriculum document with no normative evaluation of its contents. At the same time, it seems meaningful and productive to restrict attention primarily to the technical-professional aspect, while addressing possible paradoxes or moral contradictions that arise. The important point is that although it is necessary to investigate technical-professional problems in a historically-located manner, it does not then imply that all historical aspects (i.e., substantive and political) must also be included.

At the same time, the abstraction from substantive and political issues is not meant to imply that it is possible to address the technical-professional aspect alone. For example, the new national curriculum document is accepted without discussion. However, there are many reasonable and attractive ideas in the new Danish science curriculum, it seems meaningful to study, even if it is not ideal. In Denmark, it is a necessary but not sufficient component in the development of school teaching practice.

Another paradox that arises from the aim to improve the formation and use of curriculum documents is the implication that one is expecting a unidirectional technocratic process in which curricular reforms are to be transmitted and implemented faithfully. However, there is no reason to believe that such a “technocratic” process could ever exist, especially in light of Ryder’s (2015) review of 34 studies of externally-driven school science curriculum reform, in which he identified a wide variety of factors that influenced teachers’ responses to new
curriculum (e.g., whether the teacher accepted or agreed with new requirements). This review highlights that a simple technocratic expectation (i.e., educational authorities can formulate curricular visions or reforms, which will become actual in a schooling practice) is not likely to be achieved.

Despite the empirical evidence against a technocratic approach, one can see – in practice – that this approach has some kind of appeal – perhaps because it provides a rational model of organizational behaviour. Cuban (1990) speculated that the adoption of this model by reformers may explain why the same (inadequate) reform attempts have been used in the history of education, again and again (p. 5). The present focus on the three minimal conditions could appear as adopting or being oriented to a technocratic approach. The situation is characterised by a set of paradoxes: curricular documents are being put forward as an instrument for use in school practice – including development and reform. At the same time, it is not sufficient – by itself – for curricular documents to be adequate for achieving expected rational goals – yet it seems worthwhile to continue to engage with understanding, conceptualising, and improving this technical aspect, in part because it seems unlikely that educational authorities in many countries will drop the use of curricular documents.

By confronting or engaging with these paradoxes, it is expected that improvements can be made in ways of forming and using a curriculum document, without gliding over into an expectation that it will be ultimately be sufficient (as a technocratic or rational model would expect). At the same time, by engaging directly with this technocratic aspect, it becomes possible to problematise enabling assumptions for a technocratic perspective. For example, an assumption (or hypothesis) that has emerged in this investigation is that it is impossible to make an unambiguous, self-sufficient curriculum document. If this premise is accepted, then the rational basis for a technocratic approach disappears – because there is not a clearly-defined ideal that is available. Another implication of this “impossibility” hypothesis is that the idea of "faithful implementation" of a curricular document becomes meaningless – again because there is not a clearly-formed ideal to be implemented. However, if one unconsciously maintains the belief that the curriculum document contains a well-defined idea to be implemented, then one is inclined to consider the discrepancy between the intentions and the actually achieved classroom teaching. By problematising the relation between curriculum document and practice, we can come out of the uncritical acceptance of a technocratic perspective. The concern is that by persisting to maintain the technocratic perspective implicitly in the framing of research questions, then one risks reproducing this perspective – even while consciously rejecting it explicitly.

The paradoxical nature of this problem can be illustrated with the following example. Goodlad, Klein, and Tye (1979) frame the gap between an educational ideal and the actual practice as implemented in the classroom as “slippage” (p. 59). Recently Westbroek, Janssen, & Doyle (2017) reported a study in which they investigated possible factors that influence “slippage” between the curriculum. There can be good reasons to look at these discrepancies between curricular intentions and actual practice – but if “slippage” (from an unclear ideal) becomes reified, then the technocratic perspective gets a kind of legitimization that it may not deserve. That is, the notion of “slippage” implies that the curricular ideal is always correct (rather than
underspecified, for example), and inclines one to locate the problem with the “reception” or “capability” of the teacher, rather than considering that the impossibility of forming an unambiguous curricular ideal may require other framing assumptions in this technical process. In other words, there can be good reasons to investigate the technical aspects as a necessary part of the professional process of teaching practice, and even seek to improve the possibility for a rational approach. But when it is presupposed that the curricular ideal is always well-formed, then it directs attention away from other ways of conceptualising the situation – where the notion of “slippage” would become meaningless.

**Aim to have a useful curriculum document**

The underlying interest in the present project is motivated by a simple assumption: the national curriculum document in Denmark is a necessary part of the daily professional practice of school teachers. The question of whether or not a curriculum document is actually needed for a successful school system is enticing to consider, but for the present study, the starting point is that teachers in Denmark are legally required to work in relation to the demands in the curriculum documents.

The necessity of this component justifies closer attention, especially if the interest is to support the professional development of in-service and pre-service teachers in using a new curriculum document. From that point of view, it is worthwhile to understand what intentions are sought to be introduced into the curriculum through the existing curriculum document, for the purpose of helping teachers to work more effectively with the document, to help the educational authorities realise the intentions that are pursued in the document, and through these efforts to seek ways to improve the formation of this document. While it is recognized that this improvement alone is not likely be sufficient to realise the intentions of the curriculum document or develop school teaching practice, it will necessarily be difficult or impossible to realise curricular intentions if teachers cannot understand how to use the curricular documents, or the documents do not express intentions adequately.

**EMPIRICAL STUDY OF CURRICULUM FORMATION IN DENMARK**

The basic focus of this paper is to provide an account of the process by which the most recent physics/chemistry curriculum for lower-secondary education (year 7 to year 9) in Denmark was formed. A first step in the investigation is to understand how the intentions of the curriculum designer are expressed in the curriculum document. The basic strategy was to analyse the actual process that generated the curriculum document, as a starting point for interpreting the document in relation to expected teacher practice. This paper is a preliminary report of the research strategy used to investigate this problem, and some initial observations in relation to the question of expressing clear curricular intentions.

**Background**

In 2013, the entire school curriculum in Denmark was revised. For a variety of reasons, a need arose to investigate the process by which the new structure of the curriculum was produced. One set of reasons concerned the introduction of some new features that had not previously been used in the Danish curriculum. In particular, the entire curriculum was formulated in terms
of knowledge, skill, and competence goals, which was inspired by the European Qualification Framework for Lifelong Learning (2008). Furthermore, a special matrix structure was developed to express the relationship between knowledge, skill, and competence goals (see Figure 1). For present purposes, the main thing to recognize in the Figure is that it is supposed to express hierarchical relations between competences and specific knowledge and skill, and to show learning progressions for the development of competence. In principle, the basic content in this new curriculum was familiar to the teachers because the revision started with the existing curriculum from 2009, but with the requirement to remove some of the content, without adding any new content. On the other hand, the new curriculum was radically different from the 2009 curriculum, because of the introduction of this matrix structure, along with a focus on competences as the main educational goals.

![Figure 1. Denmark: Physics/Chemistry Curriculum for Years 7-9](image)

A second set of reasons revolved around the lack of clarity about how to understand this new structure.

a. The new features introduce radical new challenges for school teachers, because they have not previously worked with a curriculum formulated in terms of learning goals, and they have not worked with competence goals for pupils’ achievement.

b. While the Ministry provided a guidance document which explained how to use the new curriculum structure, there were no background documents available from the Ministry of Education, which explained systematically the logic of or motivation for this new matrix structure, and it has not been possible to find examples of this kind of structure elsewhere in the academic research literature.
c. Most importantly, it appeared that there were discrepancies between the logical structure of the matrix used to present the curriculum, and what appeared in the actual document.

A third set of reasons concerned the fact that this new curriculum revision is considered an important part of a larger school reform, which is part of a broad political agreement. Part of the agreement was that the curriculum should be simplified to support raising the academic level of pupils’ achievement, and to make it easier both for teachers’ daily work with planning, implementing, and evaluating teaching, and for leaders and parents to understand the curriculum, so that they could be actively involved in supporting pupils learning (Aftale, 2013, p. 9). This simplification effort was motivated largely because of an evaluation report that documented a variety of reasons for why teachers were not using the existing curriculum (Danmarks Evalueringsinstitut, 2012). However, if the new curriculum structure is not easy to understand, as noted in the previous point, then there is a present danger that the good intentions of the curriculum reform will be lost (despite the good intention to clarify and simplify the curriculum). There are already many well-documented examples of the failure of school reforms to achieve their purposes because the key actors (e.g., teachers) do not understand adequately what is being requested (e.g., Spillane, 2004).

A fourth set of reasons arose from criticisms and concerns raised in academic and professional publications about the new focus on learning goals as a way to describe the curriculum. Some of these debates were heated, at times it seemed that criticisms were based on a misunderstanding of the new curriculum and how it was supposed to be used.

A fifth set of reasons arose from my practical experience with teachers, where many seemed to be interpreting the new curriculum as defining the limits of what could be permitted in their teaching, rather than appreciating the need to work constructively and integrative in relation to the curriculum.

And a final set of reasons arose because of a need to overcome some structural barriers for communicating about the new curriculum. The formal legal status of the curriculum (e.g., the matrix in Figure 1) is such that the Ministry of Education is responsible for the formulation of the curriculum, which is then formally approved by an act of Parliament. In practice, the new curriculum is made by working groups, which the Ministry has commissioned. From this point of view, it seemed difficult for members of the working groups to make public statements about the curriculum, including how to interpret or understand then new, unfamiliar structures.

In light of this situation, I decided to make interviews with persons who were involved in the process of producing the new curriculum. Rather than speculate about the intentions and characteristics of the new curriculum, it seems appropriate to get an empirically-grounded understanding of the origins of the curriculum structure, which could be used to give a more justified interpretation of the curriculum and how to use it. A special feature of the investigation is that the analysis is based on interviews were five persons who were centrally involved in the process.
Method

The curriculum revision for the physics/chemistry curriculum occurred in two phases. In the first phase, a so-called "master" group was commissioned by the Ministry of Education to develop a general template by which learning goals should be described. The same template was to be used for all subject-matter areas. Thereafter a workgroup for physics/chemistry was commissioned to use the general structure to guide their formulation of the new curriculum.

The "master" group had 11 members, where three of them were ministry officials, and three others were appointed from school unions and the regional government association. The remaining five members had either an academic (3) or professional (2) background. Interviews were conducted with two of the academic members and one of the professional members. The physics/chemistry workgroup had five members plus a ministry liaison. Two members of the workgroup were interviewed.

Prior to the interviews, I obtained documents that described the commission of the master group and the workgroup in physics/chemistry, as well as the instructions that were given to the workgroup. I also obtained the timeplan and meeting schedules for both the master and workgroup. Semi-structured interviews were used. The informants were asked to give a chronological account of the process by which they conducted their work with the master template or with the physics/chemistry curriculum. Informants were asked to focus only on describing the process, and not to give their opinions about the process. The intent was to obtain a reasonably descriptive account of what happened, rather than presuppose a particular interpretation in advance. The master group interviews were completed prior to the interviews with the workgroup, so that it was possible to understand the intentions of the master group, when interviewing the physics/chemistry workgroup.

The first column in Figure 2 provides an overview of the main actors in the process by which the Danish physics/chemistry curriculum document was formed. The second column indicates the "products" (in the form of written documents) that were produced by these actors. The rows are a chronological sequence in the sense that the product of one row became the starting point for the work on the actors in the next row.

Figure 2. Analytic strategy
The last two columns show the focus of the current analysis. The idea is to formulate the intentions that appeared in each stage of the investigations, and then compare the actual product that was produced, compared to the intentions.

**Preliminary results**

The main result that appears to be emerging is that no one is actually responsible for the final curriculum document, in the sense that they have a particular vision or intention that they tried to achieve in the actual product. The political agreement is formulated in global terms, which the Ministry had to interpret and concretise in their kommisiorium. However, the mastergroup had to do additional concretisation, which was constrained by requirements from the kommisiorium. For example, the mastergroup introduced the relations between competence, knowledge and skill, which resulted in the matrix structure shown in Figure 1. There was no indications in the intentions of the politicians or the Ministry that this was expected or required.

The interviews with the members of the physics/chemistry workgroup revealed that they had difficulties in following the template of the matrix structure provided by the mastergroup. The process can be characterized as a dialectical interaction, in which the workgroup attempted to fit the content to the constraints and requirements in the matrix structure. They then evaluated their attempt, making adjustments, which often broke with the template structure, so that they could preserve coherence, or be sure to include topics that have been historically important in the curriculum. Rather than a simple process of “filling in the blanks” of a generic template, the final product emerged out of repeated efforts to create a coherent structure, without the workgroup ever having a predetermined plan that they were trying to implement. As a result, the final product, the curriculum document did not reflect the specific intention of any of the actors in the process of its production.

Furthermore, the curriculum document (i.e., the matrix in Figure 1) had many inadequacies, relative to its intentions. The Ministry communicated the ideal intention of the matrix (from the point of view of the mastergroup). However, interviews with the workgroup members (as well as my own inspection of the matrix) revealed that there were several aspects in the actual content in the matrix that did not correspond to the official description from the Ministry.

**Discussion**

The opening discussion in this paper raised the question about whether curriculum designers are able to express their intentions in their curriculum document. In the present case, the distributed nature of the process by which the curriculum document was formed makes it impossible to identify a singular, stable intention that was sought to be embedded into the curriculum document. At the same time the actual document that was produced does not correspond to how it is being presented. There is no indication in the Ministry’s presentation about these discrepancies.

It is now possible to return to the hypothesis that it is impossible to make an unambiguous, self-sufficient curriculum document. The actual case here has shown some of the ways in which good, but underspecified, intentions (from the political and Ministry level) become concretised in ways that introduce new aspects, including some which are not clearly identified.
The importance of the “impossibility” hypothesis is that these “inadequacies” are perceived as "normal" or "expected", because there was never an expectation that it would be possible to achieve a coherent expression of the curricular intentions. This result has important and interesting consequences in relation to a technocratic conception of curriculum development. Rather than act as though the curriculum product has realised its intentions, it could be productive for the Ministry to include meta-communication about their curriculum documents, particularly to identify areas where the existing documents do not actually meet the intended characteristics. These honest communications of “failure” may prove to be an effective way to help teachers and others gain better insight into the intentions and characteristics of the curriculum documents.

CHARACTERIZATION OF PREFERENCES AND PRACTICES OF TEACHING OF CHEMISTRY TEACHERS OF THE STATE OF SANTA CATARINA FROM SURVEY TALIS

Nicole Glock Maceno¹, Moisés da Silva Lara² and Marcelo Giordan¹
¹ Laboratory of Research in Chemistry Teaching and Educational Technology, Faculty of Education, University of Sao Paulo, Brazil
² Faculty of Education, University of Sao Paulo, Brazil

This work explores the characteristics and teaching practices of sixty-five secondary chemistry teachers from the state of Santa Catarina (Brazil) starting from two surveys based on instrument MS-12-01 of 2008 from the Teaching and Learning International Research (TALIS). The research problem was to understand the profile of teachers regarding different educational needs to organize two continuing training courses, and it was found that they want to develop a better collaborative culture in the schools, rise the impact from formal and informal activities to professional development, the negotiation of the control of activities in the class and more scholar productions of students.

Keywords: Teaching practices, TALIS, chemistry.

INTRODUCTION

Surveys have been used in research for macro level data production, on various educational aspects, besides the characterization, preferences and practices of teachers. Sondergeld and Johnson (2014) endorse the use of surveys in the study of scientific conceptions, which can be done by analyzing the degree of agreement or disagreement, according to the Likert scale, in relation to the assertions. A surveys allow to interpret several factors and from its use it is possible to obtain satisfactory data on a range of situations and when there are diverse subjects, it allows the quantification of the data and establishment of an overview of aspects considered important.

This text presents the validation process and results of two surveys and one instrument about personal data completed by chemistry teachers of the State of Santa Catarina (Brazil) to obtain information about development and supporting teachers, professional needs, job satisfaction and teacher practices in public schools. The State surveyed belongs to the southern region of the country, with one of the best social indexes in Brazil and Latin America. The colonial origin was settled by Germanic, Italian, Portuguese, Swiss and Norwegian immigrants, and currently it stands out in the sectors of industry, agriculture, extractivism and tourism. The main reasons for the interest in the production of empirical data on Chemistry teachers of the State are: to know better their characteristics and specificities in order to subsidize the planning and development of continuing education courses and research on education; to be representative of the educational landscape of the southern region of the country; to possess intense industrial activity; and need professionals who work in industries and schools. The information was used to organize and apply two continuing training courses.

First, we present the processes of selection of questions and validation of the surveys and instrument used in this study. After that, we present the results of characteristics and
preferences of 75 Chemistry teachers of the state of Santa Catarina about their professional development, school climate, appraisal and feedback about their work, practices and believes about teaching. Finally, we present the conclusions about the educational landscape of the State under study.

**Preparation and validation of the surveys**

To understand the characteristics and preferences of professionals, we invited all the Chemistry teachers of Santa Catarina by e-mail and a website of the University between May to October in 2016 to answer three instruments previously selected and validated.

The first instrument used called “Personal Information” (Instrument I) shows information about name, age, genre, academic formation, neighborhood, local of work, use of social networks (*Facebook* and *WhatsApp*), number of schools work and weekly workload of those teachers. To produce this instrument, we used one of the surveys applied and validated first in a course called “Specialization course in science education of the network Sao Paulo network of teacher training” (Redefor), that was developed by Sao Paulo University. This instrument was complemented with information about telephone number, weekly workload and use of social networks and was available in an app *Google Drive* called *Zoho Survey®* with two other surveys and the “Free and Informed Consent Form”. This app helped teachers to answer the instruments online and to produce the data faster.

In the next phase of the research, for the elaboration of the surveys, questions 11, 17, 18, 21, 22, 29, 30, 31 and 42 of the teacher questionnaire instrument of the 2008 Teaching and Learning International Survey (TALIS) were selected, which, in addition to being translated and adapted, were grouped into two themes: “Teacher Formations” and "Teacher Practices, Conceptions and Attitudes". TALIS has been applied by the Organization for Economic Cooperation and Development (OECD) acquiring international relevance to analyze education and teaching. Created in 2008, it was recently applied in 2013, with more than 25% of the responses of Brazilian teachers from the 6th to 9th year of primary education (Canada, 2014), but until then, it had not been applied to secondary level professionals.

The instrument originally contained 43 questions, being chosen only nine that contained the Likert scale. They also had assertions grouped into different categories as Freeman, O'Malley & Eveleigh (2010) states. After the selected questions had been translated and adapted, they were examined by a group of experts who answered, discussed and critically analyzed their forms and contents.

Some of the issues presented in TALIS study version number MS-12-01 (Freeman, O'Malley & Eveleigh, 2010) have been translated from the English language into Portuguese and have been corrected, with grammatical adequacy and the correct terms used. Few assertions of the original surveys were removed because they were repeated or the translation and appropriateness of the sentence were insufficient to understand the meaning of the linguistic expression presented. There were also cases of need to include or adapt the options presented in the Likert scale of the original questions.

For the first survey, we used questions 11, 17, 18, 21 and 22 of the original instrument, while questions 29, 30, 31 and 42 were used for the second survey. After editing the surveys in the
Zoho Survey®, the same ones were answered by the pairs of the Laboratory of Research in Teaching of Chemistry (USP), totaling ten pre-tests for each one. In this way, the validation by peers and specialists, who verified each assertion, the time taken to respond, and suggested corrective corrections were made with caution to qualify the instruments and, at the same time, guarantee the originality of the same, since already were validated. The Personal Instrument was validated by the same research group.

**Results**

The instruments were answered by teachers from Santa Catarina, yielding 75 responses to Instrument I (100%); 72 for the first survey (96.0%) and 64 for the second (85.3%). Table 1 summarizes the results of teachers. The teachers who participated in the research were not selected previously.

**Table 1. General information from Instrument I.**

<td>76.0% have a temporary contract. 62.7% work from Mondays to Fridays in the morning from 30 to 50 hours a week. 12.0% work in more than one school.</td>
</tr>
</tbody>
</table>

For responses, we see that two-thirds are women, which indicates a female profile for this career, which is repeated for the overall TALIS 2013 result (Canada, 2014). Teachers presented between 20 and 49 years of age, with a greater number of professionals between 31 and 40 years old, which is the opposite of the TALIS participating countries (Canada, 2014), where teachers are better known as 49 years old. In this way, these are professionals at the beginning of their careers.

Two-thirds of workers have temporary contracts. In the participating countries of TALIS 2013 (Canada, 2014), average professional experience when responding for a 16-year age, being 3 years, with other educational functions and 4 years for another type of work. In the case of Santa Catarina State, a presence of many professionals with temporary contract is not positive, since it constantly changes the school staff, which compromised the continuity of the work developed throughout the school year. There is also a need to carry out contests for an effective training of professionals and courses for the improvement of knowledge and practices.

More than 93% of professionals have undergraduate or specialization degrees. Those with masters or doctorates are rare, totaling 6.66%. Although they indicate that one of their greatest training needs is the use of Information and Communication Technologies, many are open to
using Facebook and Whatsapp for communication purposes. In terms of housing town, the professionals reside primarily in the Northeast.

In terms of training, less than half have a Degree in Chemistry (45.3%), and the qualifications in other courses are common. We also observed that 66.66% of them graduated from some University of Santa Catarina. Even with many temporary contracts, less than half have the required degree and 24% did not report their undergraduate course. In terms of institutions studied, they are quite varied, both from the south as well as from the southeast. Of those who answered the question, 48.00% graduated from private institutions and 48.00% from public institutions. According to Table 1, most of them work Monday through Friday on the morning shift. Already in the afternoon, some work mainly on Mondays and Thursdays. Less than the number of teachers who work at night and most when doing so mainly on Mondays and Thursdays. Most work from six to eight shifts per week (48.27%).

Table 2 shows the amount and percent of teachers by age, which shows the need for higher qualification of teachers. Table 3 shows the questions used in the surveys.

<tr>
<td>3. For each item below, indicate how much you agree or disagree.</td>
</tr>
<tr>
<td>4. We would like to know how many times each of the following activities are done in the classroom during the school year.</td>
</tr>
</tbody>
</table>
The results of the surveys show that most of the teachers have already participated in some kind of informal activity, such as a reading of the professional literature and the dialogue with coworkers. In the last 18 months they participated in courses and workshops (68.0%), conferences or seminars on education (47.2%), but they have many training needs (Table 4), especially on special education and evaluation.

Regarding professional development for TALIS 2013 (Canada, 2014), 88% of teachers reported that they participated in some type of activity in the last year, which is convergent in relation to the results of Santa Catarina. The lowest participation in professional development activities for the 32 countries occurs among men, especially those of temporary contact. It has also been noted for the State that teachers with temporary contract have less participation in formal development activities, but mainly among the women who constitute the majority.

The level and intensity of participation in professional development activities are influenced by the types of supports teachers receive. In general, for TALIS 2013 (Canada, 2014), teachers report great participation in the activities listed in the poll. The formal activities carried out by the teachers included courses and workshops (71.0%), conferences and seminars (44.0%), work in training networks (37.0%) and collaborative or individual research (31.0%). In Santa Catarina, the similarity of result occurs only for the formal activity of courses and workshop (68.05%), considered the most accomplished by teachers. For all other formal activities, the number of teachers who did not participate was higher than those who participated.

About the training needs presented in question 2 (Table 3 and 4), the teachers responded that the most urgent are the teaching of students with special learning needs ("diversity" category) together with evaluation practices ("pedagogical" category) and standards of content and performance required in the respective field of activity ("pedagogical" category). The disciplinary issues ("pedagogical" category) and the ICT use skills ("diversity" category) were also indicated. For a significant number of teachers, there is little training need regarding management, student counseling and multicultural education. In general, the percentage of professionals who indicated little or no training needs for all aspects mentioned in question 2 was lower than the percentage of those who indicated moderate to high need, that is, they have many training demands.

</tbody>
</table>

Teachers claim to use different instructional strategies in the classroom and propose practical problems to be solved by students, but schools lack a collaborative culture that has a significant impact on professional development despite of the many teaching needs indicated.

Regarding the formative need for TALIS 2013 (Canada, 2014), special education (category "diversity") was highlighted in descending order; ICT skills ("diversity" category); student
behavior and class management ("pedagogical" category); and multicultural education (category "diversity"). The least needful ones reported were the knowledge and understanding of the field of action and the curriculum (both of the "pedagogical" category). In the case of Santa Catarina, special education (category "diversity") and evaluative practices ("pedagogical" category) were highlighted in descending order; content standards and student discipline (both in the "pedagogic" category). Minor needs reported were school management and management ("pedagogical" category), student counseling ("diversity" category) and multicultural education ("diversity" category). Thus, there is convergence in results only for special education, in both cases indicated as greater need in terms of education. While three of the four major teaching needs for TALIS 2013 teachers (Canada, 2014) were in the "diversity" category, for Santa Catarina, three of the four major teaching needs belong to the "pedagogic" category. This result probably arises from the relevance of greater training and study of teachers on issues related to teaching given the little experience and age they present.

About the school's appreciation of the teacher's work every fortnight (Figure 1), the pedagogical team and peers are the ones who carry it out most, and few are evaluated by members outside the school or by the principal. In contrast, most teachers report never being evaluated either by external members (55.55%) or by peers (38.88%). The evaluation by the directors and the pedagogical team, although it is more expressive than the other subjects, is also not so frequent: only 31.94%, 29.16% and 18.05% are evaluated fortnightly by the pedagogical team, by the peers and by the director respectively about the development demonstrated in the classroom and the relationship with the students.

![Figure 1. Frequency of appraisal and feedback of teacher's work.](image-url)

In general terms for TALIS 2013 (CANADA, 2014), a unique trend is noted: there is more appreciation of the work by principals followed by other members of the school team. In terms of all countries, the best known as job evaluations are direct leaders (54%), other members of the school administration (49%), other teachers (42%) and people outside the school (29%). Such information converges to what can be verified for Santa Catarina.

The most important aspects in the evaluation of teachers' work were demonstrated professional development ("individual" category) and relationship with students ("collective" category). Several other individual and collective aspects were emphasized, alternating these categories,
but two of them of the collective scope were considered of less importance in Santa Catarina: the relation of the professor with the director and colleagues and the return of the pairs. Regarding the results of TALIS 2013 (Canada, 2014), teachers receive assessments about their work from various sources: about 80% of the observations of what occurs in the classroom and 66% after the students’ analysis in function of the results obtained in the tests. With this, what happens in the classroom and the appreciation of the students have great importance in the evaluation of the work of the teacher. Teachers reported at TALIS 2013 (Canada, 2014) that the return they receive in their schools has scope in several aspects of their teaching, and highlights the three main ones: student performance (1st), student behavior (2nd) and the knowledge for the field of action (3rd). In Santa Catarina, the development of the teacher (1st), the relationship with the students (2nd) and the behavior of the students (3rd) are the most important factors, i.e. both for the outcome of TALIS 2013 (Canada, 2014) as well as of Santa Catarina two of the three main aspects reported depend strongly on the students.

The second survey was answered by 64 teachers and in general lines for question 1 (Table 3) a high degree of disagreement of the respondents was observed in relation to assertions of teaching concepts centered on the direct transmission and greater agreement of the respondents in relation to teaching based on problems to be solved by students (Table 5). Although assertive 1 is part of the first category (“direct transmission”) according to Freeman, O’Malley & Eveleigh (2010), it was the one most agreed upon by professionals, that is, they consider that good teachers should indicate the correct way to solve a problem. However, once they have a high degree of agreement with problem-oriented teaching, and we disagree with the categorization of this assertive as belonging to "direct transmission", since it is the responsibility of teachers regardless of the conception of teaching that presents.

Teachers agree that their responsibility is to facilitate the student’s research process and that it is more important to think of students’ reasoning processes than specific content, which highlights attention to how students are learning. They also agree that students should be allowed to think of solutions to practical problems before they show how they should be resolved and that the class should find the solutions on their own. Teachers disagree with the idea that they should not let the students present incorrect answers, that in order to have effective learning the room should be silent, that the problems presented in the room should be of quick resolution and easy pickup or that they should choose what activity the students should do.

In general terms, chemistry teachers in Santa Catarina are more inclined to have teaching based on problem-solving and to allow students to solve them before exposure by the teacher. They therefore have preference for assertions that highlight problem solving by the class. With the exception of the first assertive in question 1 of the second survey, the other four that the teachers most agree converges with the preferences of those who participated in the TALIS 2013 (Canada, 2014) in relation to the items on problem solving, reversing only the order (94.2% in TALIS in 2013 and 90.62% in Santa Catarina); "Students should be allowed to think of solutions to practical problems before the teacher shows them how they are solved" (92.8% in TALIS 2013 and 79.68% in Santa Catarina); "Thinking about students' reasoning processes is more important than thinking about specific content" (83.4% in TALIS 2013 and 62.50% in
Santa Catarina); "Students learn best when they find solutions to problems on their own" (83.2% in TALIS 2013 and 76.56% in Santa Catarina).

</tbody>
</table>

For a question 2 from second survey (Table 3), teachers were asked to attend eleven listed actions and, in general terms, it can be observed that teachers do not perform all of them so frequently, mainly as professional collaboration and that they consider the development (Table 6). The most frequently performed activities (monthly or weekly) are: establishing minimum standards in assessments to assess student progress; participation of team meetings to discuss a vision and mission of the school and discuss issues about discussions about the development of learning for a specific student. The three less practiced actions are respectively teaching together with a team in the same class, attending conferences that thematicizes an age group that the teacher teaches and an observation of the class of other teachers for a return. Although it is observed that some of the teachers have a possibility of exchanges and collaboration of the other teachers, for a great majority they are not. In this case, work environments disfavor as shared training actions among peers and we can say that teachers were not used as behavior.

The degree of satisfaction of teachers is high, and they consider that they make a significant difference in the education of students who are successful with the classes they teach and who can progress even with the most unmotivated or difficult students. Regarding the climate of the school, most agree that the professionals of the institution are interested in what the students have to say, that they are respected, with good relation with the students and interested in the well-being of the classes. They also agree that if one of the students needs extra assistance, the school provides. The only assertion in which there was a greater degree of disagreement among the respondents was that it is not the principal who has the initiative to discuss an issue with
the whole school when a teacher has problems in the classroom. There was also greater
agreement over the more discussed issues at school meetings.

They replied that they are satisfied with their work and that they are successful in the classroom,
however, the most frequent weekly activities are developed exclusively by them (Table 7), with
little space for individual or collective productions of students.

| Table 6. Performed activities of Chemistry teachers. |
| Assertives                                                                 | Frequent Monthly or semiannually |
| Observe other teachers' class and give them a return.                      | 3 |
| Attend conferences that thematize the age range that I teach.              | 9 |
| Teach together with a team in the same class.                              | 13 |
| Development of the school curriculum or part of it.                       | 16 |
| Discussion and selection of the instructional means (books, exercises,     | 18 |
| handouts, computers, among others).                                        |
| Engage in joint activities with different classes and age groups (eg projects). | 21 |
| Exchange of materials with other teachers.                                | 23 |
| Discuss and coordinate homework practices among peers.                    | 23 |
| Participation in discussions about the development of learning for a specific student. | 28 |
| Participation of team meetings to discuss the vision and mission of the school. | 30 |
| Establish minimum standards in assessments to assess student progress.     | 36 |

| Table 7. Frequency of classes activities. |
| Classes activities                                                                 | Always performed (%) |
| I review the homework the students are doing.                                   | 64.5 |
| I present a new topic to the class.                                             | 61.3 |
| At the beginning of the lesson I give a brief summary of the previous lesson.   | 54.8 |
| I ask my students to remember each step in a procedure.                         | 48.4 |

There are activities that are done, but more often in half of the school year classes, such as
group activities. Activities that are almost never practiced by most teachers are, respectively,
student-led discussions, asking students to suggest or help plan classroom activities or topics,
and have them design a product that can be used by someone else. In general, the practices
organized and executed exclusively by the teacher are the most frequent; the practices
performed by students for reinforcement, improvement and improvement (third category) are
carried out, but less frequently compared to those made by the teacher. The activities performed
by the students (second category) are less usual than those carried out by teachers, but are more
frequent than those that require improvement and group work.
For TALIS 2013 (Canada, 2014), the most frequent and "always" activities were: the revision of lesson and home exercises (26%), the presentation of a brief summary of the previous class (22%), work in groups to present the solution of a problem (14%), the proposition of exercises for students that solve more quickly (9%) and problems that resolve a week to solve (6%). The two assertions of greater agreement among Santa Catarina teachers coincide with the results of TALIS 2013 (Canada, 2014), but although they are more attuned to the conceptions of teaching based on the problems as we discussed earlier, the classroom practices are quite focused on the teacher, which constitutes an aspect to be analyzed in the school context.

We conclude that there is a feminization among the professionals, who have temporary contracts, were graduated, little experience in the classroom and a considerable weekly workload. Despite participation in activities, many educational aspects need to be discussed. The lack of collaborative actions further jeopardizes work in schools coupled with the high turnover of teachers and their centralization of classroom practices. TALIS results can be useful to identify the educational problems to be faced and the priority public policies regarding teacher training (Freeman, O’Malley & Eveleigh, 2010). The instrument has transcultural validity for the possibility of comparison between several cities and countries. The analysis indicates the extent of the formative gaps in the state of Santa Catarina, which may be common to other localities.

CONCLUSION

In this state, the situation of secondary education shows many professional necessities. Despite of higher levels of self-efficacy and job satisfaction in the schools, teachers don’t promoted the collaborative relationships. First, the relations are important to formation. Second, teachers need to have permanent contract and increase their knowledge about many educational factors. The practices of teaching need more alternatives to grow up the participation and production of students. It’s indispensable researches on effective professional development and impact in a school collaborative culture in specifics situations of teaching. And finally, to understand the particular necessities, it’s necessary to invested in formative program about many scholar processes, teaching projects and pedagogical alternatives (GIORDAN, 2006, p.9) and invest in the interactions processes in the classes and the quality of communication between all school attendees to have more impact in the teaching.

INTEGRATIVE INSTRUCTION IN GERMAN, FINNISH, AND SWEDISH CURricula

Christina Krumbacher¹, Lea Ahrens¹ and Risto Leinonen²
¹Department of Education, University of Osnabruck, Osnabruck, Germany
²Department of Physics and Mathematics, University of Eastern Finland, Joensuu, Finland

In this study the curricula of Swedish, Finnish, and German compulsory schools are analyzed referring to the structural implementation of integrative instruction with a main focus on STEM subjects. Therefore, structural and organizational aspects of integrative instruction as well as skills, knowledge and aims are compared in the different curricula. In an explorative approach, different aspects oriented on previous research are analyzed in a criteria based assessment. The results show that – on the structural level – the underlying concepts and ideas of integrated instruction differ between the aforementioned countries in the level of aims and competences, context and others. However, all analyzed curricula are mostly normatively oriented instead of being developed on an empirical proven base. As a next step, variables have to be elaborated from the different concepts of integrative instruction on a theoretical base to evaluate to what extent integrative instruction is a meaningful addition, if not a replacement, to traditional subjects.

Keywords: integrative instruction, curriculum

INTRODUCTION

This study concentrates on analyzing how integrative instruction in STEM subjects is approached in the curricula in Germany, Finland, and Sweden. These three countries differ in their history of integrative instruction in the compulsory education. In German primary schools, natural sciences, social sciences, and technology have been taught in one subject called “Sachunterricht” since the early 1980s (Köhnelin, 2011). In the Swedish and Finnish school system, there are subjects which combine different disciplines. Hence, the background of educational policies differs in those countries, as the latest curriculum reform in Finland (Opetushallitus, 2014) has highlighted the role of integrative instruction in Finnish schools in a top down process.

Hence, our research question is formulated as follows: How is integrative instruction addressed structurally in German, Finnish, and Swedish curricula for compulsory education?

Despite the emphasis and popularity of integrative instruction amongst educators and researchers, the meaning of the concept and terminology do not seem to be established. There are a multitude of different terms, which some authors use as synonyms, whilst some others are well aware of the different concepts that are expressed by the terms, such as integrative instruction, multidisciplinary learning, interdisciplinary learning etc. (Chettiparamb, 2007; Czerniak, 2007). For this study, we use the term integrative instruction (InI) and define it in accordance with Hooper, Green, and Sample (2014), as teaching and learning processes that are created for linking different phenomena to each other.

In order to elaborate this definition, we rely on the following explanations of the German concept of “Vielperspektivität” which is strongly related to InI and means that “rich topics are not one-dimensionally related to a specific subject but multi-dimensionally examined, i.e.,
potentially regarding all aspects relevant for learning and making them fruitful for the classroom [...]” (Köhnein, Marquardt-Mau & Duncker, 2013, p. 1, translated by the authors). This idea includes different subjects as well as discipline related and general skills and attitudes of thinking (e.g., epistemological ideas). One important linguistic issue should be kept in mind, though. In international context, the same terminology might reflect different approaches and is difficult to translate or use interchangeably.

Literature of integrated instruction and integrated curricula mentions a multitude of theoretical advantages the concept is supposed to offer. For the longest time, a desideratum of empirical research supporting these claims could be detected. In a literature review, Czerniak (2007) sums up evidence that integrated instruction does positively influence student performance, motivation, problem-solving competence and other soft skills, even though those findings are restricted to (natural) sciences and mathematics. At the same time, critics of InI determine lack of teacher knowledge, existing school structures and the assessment of performance as problems connected to InI (Mason, 1996). Moreover, a “forced” integration of mathematics and (natural) sciences can lead to confusion amongst the students as well as a trivialization of respective discipline related concepts (Mason, 1996; Czerniak, 2007). Putting this into an example, Mason (1996) uses a somewhat exaggerated analogy: “a poem about photosynthesis may not help one understand photosynthesis as a process, or poetry as a genre” (p. 266).

Bocoş and Chiş (2013) sum up ten different InI models in primary school curricula ranging from fragmentation to “real” integration of disciplines, respectively subjects. These approaches and their descriptions are introduced in Table 1. The table shows that integration can take place in different dimensions, for example in content, skill and subject dimension. Bocoş and Chiş’ (2013) summary of models takes these dimensions into account.

An idea of the underlying concept referring to integrative instruction can be found in actual, legal curricula. Even though curricula and standards do not necessarily reflect the actual learning processes in school classes, they set the guidelines for schools and teachers.

METHOD

The analysis is based on the national curricula of Finland and Sweden (Opetushallitus, 2014; Skolverket, 2016). Due to the political system of Germany, every German federal state has its own curriculum for every school form. Hence, the analysis is based on the “Perspektivrahmen Sachunterricht” (Gesellschaft für Didaktik des Sachunterrichts, 2013), which forms the base for all German primary school science curricula, and on the standards of the ministry of education for all secondary school curricula (Ständige Konferenz der Kultusminister der Länder in der Bundesrepublik Deutschland, 2005a-c). The English versions of the Finnish and Swedish curricula are analyzed whilst the German documents are analyzed in their original language, as they do not exist in English. These choices enable two or three researchers to cross-check the documents in ambiguous cases. The documents are analyzed at primary and secondary levels, and these levels are distinguished in results when possible.
Table 1. Ten models of curricula and examples as presented by Bocoş and Chiş (2013, p. 35-53). Generally, the level of integration increases downwards.

<table>
<thead>
<tr>
<th>Model Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>The Model of Fragmented Curriculum</td>
<td>In this traditional approach, subjects are taught separately.</td>
</tr>
<tr>
<td>The Model of Connected Curriculum</td>
<td>Topics are studied in their traditional disciplines but connections between the topics and concepts are made. This model is usually implemented within a certain time frame (day, week, ...).</td>
</tr>
<tr>
<td>The Model of Nested/cone Curriculum</td>
<td>The focus is on skills that can be used in more than one subject (e.g., producing a brochure).</td>
</tr>
<tr>
<td>The Model of Sequential Curriculum</td>
<td>Subjects are taught separately but the themes are synchronized (e.g., sentence structure discussed both in the classes of mother tongue and foreign language).</td>
</tr>
<tr>
<td>The Model of Shared/common Curriculum</td>
<td>Two subjects are partially connected to one based on determination of aspects in common (e.g., mathematics and natural sciences)</td>
</tr>
<tr>
<td>The Branched Model of Integrated Curriculum</td>
<td>One topic is the focus of various subjects. The topic is being examined from the different discipline perspectives (e.g., change: biological, historical, chemical, ...).</td>
</tr>
<tr>
<td>The Model of Interlinked (Linear) Curriculum</td>
<td>Transversal competences are focused in various subjects (e.g., “How do we communicate?”). These competences are examined from the different discipline perspectives either sequentially or in parallel.</td>
</tr>
<tr>
<td>The Model of Integrated Curriculum</td>
<td>Overlapping study areas are examined from various discipline viewpoints in parallel, and discipline borders are eliminated. Developing knowledge, competence, and abilities takes place by means of holistic view instead of individual subjects.</td>
</tr>
<tr>
<td>The Immersion Curriculum Model</td>
<td>The content of curriculum is adjusted based on pupils’ interests and expertise, and the content is assimilated to their previous learning experiences.</td>
</tr>
<tr>
<td>The Model of Web Curriculum</td>
<td>This exclusively pupil-centered model starts with pupils choosing a network of topics and learning resources linked to the central topic to be studied. These connected topics are approached as transdisciplinary topics with the aid of experts, namely teachers.</td>
</tr>
</tbody>
</table>

The method for analysis is a comparative curriculum analysis in which the afore-mentioned documents are evaluated with the aim of finding how different aspects of InI are addressed in the documents. These aspects are adapted from Klein (2002, p. 217), and evaluated at two levels, namely organisational and conceptual levels; this division is conducted for the sake of clarity for presenting our results. The organizational level here refers to “hard facts” that do not enable interpretation but can be stated rather declaratively. These include but are not limited...
to descriptive numbers, explicit mentions about certain essential terms, etc. The conceptual level, then again, refers to certain aspects that can be expected in terms of teaching and learning from InI or that are related to actual implementation of InI. Typically, the latter ones are vaguer by nature and they cannot be measured as easily as the organizational ones so they are more sensitive for interpretations.

At organizational level, the following aspects are elaborated in the course of this study (Klein, 2002, p. 217). After each aspect, a succinct description about it and the criteria utilized in the analysis is provided.

1. **School forms and grades:**
   This aspect refers to introducing the limits of primary and secondary level for the three countries evaluated. These are introduced to put the following results into wider context of educational systems.

2. **Implicit or explicit interdisciplinarity:**
   This aspect is evaluated by means of evaluating if InI (or other similar concepts) is introduced explicitly as a distinguishable concept in the curricula, or if addressing it and its features is merely implicit.

3. **Structural addressing of InI:**
   This aspect refers to how and to what extent InI is addressed in the curricula. In practice, it is evaluated if it is addressed solely in general parts of the documents or also under certain subjects, and how many pages these parts cover.

4. **Quantitative extent of InI in school schedules:**
   The extent of structural scheduling refers to possible curriculum guidelines for how to implement InI in teaching: permanently, as separate learning modules, etc. In practice, it is evaluated which types of orders or suggestions related to this were presented in the curricula.

5. **Subjects as part of InI:**
   For this aspect, both the general and subject-specific parts of the curricula are analyzed in order to see which individual subjects were mentioned in the context of InI.

The conceptual aspects (Klein, 2002, p. 217) evaluated are introduced below. Besides, succinct descriptions and criteria for each aspect are provided.

6. **Expected skills related to InI (integrative skills)**
   This aspect addresses the integrative skills expected from pupils at curriculum level. This means that the curricula were analyzed to see if any specific skills related to InI were introduced in them. These can include mentioning skills like observing, measuring, evaluating, just to name but a few.

7. **Expected content knowledge related to InI (integrative content knowledge)**
   This aspect refers to evaluating if the curricula analyzed provide any practical examples about content knowledge or themes that should be addressed by means of InI. Besides, it
was analyzed if teaching content knowledge with the aid of InI is addressed at all in the curricula.

8. Suggestions for implementation

As there are numerous ways to implement InI in teaching, this aspect concentrates on analyzing that what types of pragmatic suggestions the curricula provide for this issue. This aspect can include both general suggestions, such as “holistic instruction” and specific items or tasks to be utilized.

9. Aims of InI

This aspect was approached by means of analyzing the aims presented in the curricula and evaluating if they are related to InI or to single subjects. This, as most of the conceptual aspects, were mostly analyzed from the general parts of the curricula as the parts related to individual subjects rarely exceed discipline subjects in these aspects.

RESULTS

An overview of the results concerning the five organizational aspects addressed is presented in Table 2 and the results concerning the four conceptual aspects are presented in Table 3. The results are distinguished for primary and secondary school levels when possible. All the aspects are elaborated with examples or further descriptions after the tables.

The results related to the first aspect show that structurally the division between primary and secondary level is similar for all three countries. However, these minor differences should be kept in my mind whilst evaluating the following results as they are an important context in specific situations.

Regarding the second aspect concerning the explicit or implicit nature of InI in the curricula, it was revealed that German primary and Finnish curricula address InI explicitly whilst the other ones have merely implicit, if that, focus in them. The German primary curriculum introduces a “competence model” where the concept is addressed explicitly for competences, skills, and content knowledge. Then again, the Finnish curriculum introduces the requirements and aims for InI explicitly but does not address any competences etc. like the German one.

The third aspect concerning the structural addressing of InI revealed significant differences between the countries. In Germany, InI is emphasized greatly for primary level but it proves to be practically absent at secondary level. In Finland, InI is introduced as a general idea in numerous parts but it is not introduced as one underlying concept for instruction like at German primary level. The Swedish curriculum makes implicit references to InI sporadically but the concept is not introduced or addressed explicitly.

The fourth aspect shows great differences in the quantitative extent of InI between different curricula. In German primary schools InI should be implemented permanently as one integrated subject but for secondary level there are no guidelines or suggestions provided. The Finnish curriculum sets a minimal requirement for the quantitative extent of learning modules related to InI but also other forms, such as permanent implementation, is supported by the document. The Swedish curriculum does not provide any guidelines or suggestions for this aspect.

</tr>
</tbody>
</table>

With respect to the subjects that should be a part of InI as evaluated in the fifth aspect, the curricula at primary level appear rather similar. However, there are some differences related to the subjects that are included in the integrated subjects taught (e.g. the integrated subject in Germany includes social sciences and in Sweden there are two integrated subjects for the first
three grades). At secondary level, none of the curricula emphasize InI greatly for any subjects but the Finnish one has some explicit but vague mentions about it under certain subjects.

When it comes to the expected integrative skills seen in the sixth aspect, each curriculum has a bit different approach. The German curriculum for primary level introduces certain skills, e.g., observing and evaluating, explicitly. The secondary level curriculum, however, just states certain competence categories expected for natural sciences but does not name any particular skills. The Finnish curriculum mentions that working methods should be examined in InI but does not provide any concrete suggestions for skills directly, similarly to the Swedish curriculum that merely mentions interdisciplinary working methods.

The seventh aspect related to the expected integrative skills has similar characteristics as the previous aspect related to skills. This means that for German primary level, the curriculum provides concrete examples (e.g., mobility, sustainability, and nutrition) for InI but for the secondary level this aspect is practically absent. The Finnish and Swedish curricula acknowledge this aspect at a general level but do not provide any suggestions or requirement for topics or content knowledge to be addressed by means of InI.

The suggestions for implementation of InI seen in the eighth aspect show some significant differences between the curricula. When the German primary curriculum provides concrete suggestions and materials to be utilized as a part of instruction with certain topics, the Finnish one provides six example how a teacher could implement InI in one’s teaching but do not connect them to any concrete topics or tasks. The German secondary and Swedish curricula do not provide any suggestions for InI implementation.

Concerning the ninth aspect about the aims presented for InI, the results support the trend seen in preceding results; the German primary curriculum addresses the aspect with concrete examples related to different types of aims, such as attitudes and skills. The Finnish curriculum states seven general explicit aims that are rather diverse in nature as seen in the examples in Table 2. The German secondary and Swedish curricula do not provide any general or specific aims related directly to InI.

DISCUSSION AND CONCLUSIONS

An answer to our research question “How is integrative instruction addressed structurally in German, Finnish, and Swedish curricula for compulsory education?” is descriptive rather than declaratory at this stage.

On the structural level basic differences can be found in the curricula of the three countries. While the Finnish curriculum has one consequently underlying concept of integrative instruction, and the Swedish one addresses the concept implicitly, the German curricula/standards for compulsory schools differ greatly between primary school and secondary school. This “gap” cannot be explained by findings of developmental psychology or empirical studies.

Another difference can be seen on the level of implementation. While the Finnish curriculum focuses on the general attitude of InI, the German primary school “Perspektivrahmen” provides practical topics and suggestions. InI is almost absent in the Swedish curriculum which,
naturally, does not mean that InI does not take place in Swedish schools but evidently that it is not guided by their national curriculum. The curricula of Finnish compulsory and German primary school present normatively oriented aims or competences of InI, since neither the competences nor the aims are empirically proven results of InI.

Regarding the curricula analyzed here, it was revealed that different countries follow different models presented by Bocoș and Chiș (2013). The German primary school curriculum can be categorized as “The Model of Interlinked (Linear) Curriculum” as the expected competences are focused in the competence model. The German secondary school curriculum, on the other hand, is a “Model of Fragmented Curriculum” due to its traditional approach with separated subjects. The Finnish curriculum does not give strict guidelines for implementing InI but some decisions are left to be decided locally. However, at primary level natural sciences are taught as one subject which suggests that Finland partially follows “Model of Connected Curriculum” at primary level but at secondary level the balance is more on “Model of Fragmented Curriculum” as subjects are taught separately. However, there are certain requirements (e.g., minimally one multi-disciplinary learning module per school year), suggestions for implementing InI, and skills, content, and aims related to InI explicitly addressed in the curriculum. This means that even if the Finnish curriculum is not tightly connected to or does not apply any particular model by Bocoș and Chiș (2013), it includes certain characteristics of most of these models. The Swedish curriculum mostly follows “Model of Fragmented Curriculum” as InI does not get much attention in the document. Then again, combined subjects for primary level indicate that it has some characteristics of “Model of Connected Curriculum” for primary level, as has the Finnish curriculum. References to content and skills related to InI can be seen as characteristics of the models of “Sequential” and “Nested/cone Curriculum” but they have only a minor role in the document.

The results of this study show the differences in the curricula cannot be explained by language-dependent terminology, but rather seem to be caused by different underlying concepts, which are not clearly defined. Additionally, there is some evidence that the ideas underlying InI as seen in the curricula are based on normative understanding, not on empirical data. That seems surprising in this context, because InI is of importance in the curricula, especially in the German primary school curriculum. Even if there is an insufficient amount of empirical data, the literature review of Czerniak (2007) shows that certain data is available, e.g., empirical evidence that student performance and problem-solving skills can be enhanced with the aid of InI. Which variables exactly influence the learning outcomes and to what extent, is still vague, though. As a next step, further variables have to be elaborated from the different concepts of integrative instruction on a theoretical base to evaluate empirically how integrative instruction can be a meaningful addition, if not a replacement, to traditional subjects.

The RDS STEM Learning Programme is an initiative of the Royal Dublin Society (RDS), the first phase of which was developed in partnership with the former St Patrick’s College and Centre for the Advancement of STEM Teaching and Learning (CASTeL) - a multidisciplinary research team from Dublin City University (DCU). The pilot Programme proposed a model of professional development for in-service primary school teachers which has had positive impacts in the teaching and learning of Science in Irish primary classrooms. The model provided participants with opportunities to explore, engage with and reflect on, a range of pedagogies and methodologies for teaching science though inquiry. The specific goals of the Programme were to: i) to support and challenge primary school (principals, teachers and students) to engage with and understand science, technology, engineering and mathematics, and to demonstrate the relevance of STEM (science, technology, engineering, mathematics) subjects in the primary curriculum; ii) to support teachers in developing their Pedagogical Content Knowledge (PCK) in teaching STEM through inquiry iii) to develop a community of practice by providing participants with a forum to reflect on and share their experiences of teaching science. In the first pilot phase (2012 – 2015) there were two sub-programmes to the overall Programme - a) the RDS STEM Learning Facilitator Programme – aimed at teachers with good competence and confidence in teaching science and mathematics who want to take their learning further, becoming peer leaders in STEM education and b) RDS STEM Learning Teacher Education Programme – aimed at teachers keen to increase their confidence and competence in STEM education. In the case of the individual teacher, the teacher became the facilitator in implementation of the Teacher Education Programme. The overall Programme operated with a strong emphasis on hands-on inquiry-based approaches to teaching and learning science. This paper presents an overview of some of the findings from the evaluation of the pilot programme of the RDS STEM Learning Facilitator Programme, highlighting the complexity of the development of practice, and how impacts are subtly couched within everyday teaching and difficult to isolate. We will nonetheless note the positive impact that the Programme has had on participants’ confidence and pedagogical knowledge of teaching through inquiry, particularly with regard to their confidence in teaching science and technology and establishing a reflective community of practitioners among the participants.

Keywords: primary science teacher, professional development

INTRODUCTION

It is well-documented that there is a need to systematically support teachers and children in developing higher-order thinking skills in Science across primary, secondary and tertiary education in Ireland. In particular, within primary school science and mathematics education in Ireland ‘the teaching approaches used in many classrooms are not conducive to skills development; levels of child-led investigation and ‘design & make’ undertaken by students are relatively low and primary school children are not relating their school science experiences to the wider world or to future aspirations’ (Varley, Murphy & Veale, 2008).
It is further highlighted in the research literature that in comparison to their peers in other countries primary teachers in Ireland demonstrate ‘below average levels of participation in continuous professional development, particularly where related to maths or science’ and report ‘average confidence levels for maths and below average confidence for science’ (Eivers & Clerkin, 2013). It would also appear from data gathered from PIRLS and TIMSS (2011) that primary teachers in Ireland display a low level of professional collaboration for example, ‘27% of Irish fourth class pupils were taught by teachers who never or almost never collaborated in planning and preparing instructional materials with other teachers’ (Varley, Murphy & Veale, 2008).

To address the above challenges in primary education and to support existing initiatives in Ireland such as the National Literacy and Numeracy Strategy (DES, 2011), the RDS brought together strategic partners in education to develop an innovative and collaborative professional development programme. With a core focus on pupils’ skills development, the RDS STEM Learning Programme aims to develop primary school teachers’ pedagogical knowledge of, and confidence in, teaching science through inquiry while also developing a reflective professional learning community among primary school teachers. At the time that this Programme was initiated the existing models of science provision in Ireland emphasized the implementation of science as a prescribed activity and focused on providing teachers with an introduction to teaching the curriculum using a thematic approach. The RDS STEM Learning Programme therefore aimed to move beyond implementation and look deeper into the skills aspect and the process of teaching and learning science in conjunction with mathematics, technology, design and engineering.

The RDS STEM Learning Programme is informed by national and international research, by those with research expertise in science, education and pedagogy and importantly by the needs of primary school teachers. The development and delivery of the Programme was based on the learning outcomes of successful CPD programmes for teachers which identified several factors that could impact on the success of such programmes – such as length and duration (Timperley et al, 2007), focus on pedagogical improvement versus content knowledge (Coe et al, 2014), opportunities for trialing, implementation and reflection and ongoing support following such programmes (Joyce & Showers, 2002). Of emphasis within the literature is the importance of providing opportunities for teachers to trial approaches and pedagogies directly, to allow them to see that changes in their classroom practices can benefit student learning, as this will change their attitudes and beliefs towards particular pedagogy (Guskey, 2000).

RDS STEM Learning recognises that children’s natural curiosity, creativity and critical questioning can be nurtured through inquiry-based science education (IBSE). Therefore participants engaged in scientific inquiry using pedagogies from the perspectives of Nature of Science (NoS) (Mc Comas, 2012) and CASE (Cognitive Acceleration through Science Education) (Adye & Shayer, 1993). The Programme supported teachers to help children develop ‘working scientifically’, and ‘design & make’ skills as outlined in the curriculum and

to integrate numeracy and literacy as integral components of a scientific investigation in the classroom.

Many teachers who are fearful of science or who have had limited education themselves in science may experience science as a set of activities to be completed in a prescribed manner with pre-determined results. Many feel that this is an active, hands-on approach to science teaching (Murphy et al, 2015; Smith, 2013); however, in the RDS STEM Learning Programme, the focus was on developing a competence in the teaching and learning of science. That is, where both teacher and student are active in the process of thinking about the science. This became the focus of the Programme - how to move teachers, and their students, from the practices of ‘doing science activities’ to becoming competent teachers of science where thinking was an integral part of the process.

DEVELOPMENT AND ROLLOUT OF THE RDS STEM LEARNING PROGRAMME

In setting up the RDS STEM Learning Programme, focus group discussions with over 60 teachers identified their vision for science in primary school classrooms. Teachers summarised why they wanted to improve science education in the primary classroom: ‘To take Science beyond the 'wham, bang, whoosh' of activities, so that science will be alive in the classroom and will become an integral part of student’s lives, and so that student-led problem solving, lateral thinking and confidence will be given importance’. Additionally, the teachers themselves wished to be part of a group of teachers to exchange ideas and experience. The two core strands to the initial pilot phase of the RDS STEM Learning Programme were a) the STEM Facilitator Programme and b) the STEM Teacher Education Programme.

The STEM Facilitator Programme involved 30 contact hours of workshops where participants worked collaboratively to explore ways of:

- Encouraging Creativity in Science;
- Developing students’ dialogical and thinking skills through Science;
- Integrating Science and Mathematics in the Classroom;
- Using Design and Technology in the Classroom;
- Guiding Child-led Investigation;
- Exploring Children’s Ideas of Science;

Participants in the Facilitator Programme were primary school teachers who had a strong interest in science education and a proven commitment to develop and implement their own knowledge of teaching and learning. On completion of the first programme phase, the participants were instrumental in developing the goals, objectives, framework and content for the STEM Teacher Education Programme which they delivered to their peers. Delivery used a form of co-teaching for eight workshops across 20 hours to ensure that the Facilitators continued their own professional development and reflective practice.

The STEM Teacher Education Programme aimed to introduce new and innovative techniques to support primary school teachers to integrate open ended, problem solving activity within the classroom, allowing students to explore the primary science curriculum through
child-led inquiry. This was a shorter course than the **STEM Facilitator Programme** delivered over 20 contact hours but was based on many of the same overarching principles. The **STEM Teacher Education Programme** focused on how innovative approaches to teaching could be applied to the wide range of primary science initiatives and resource material already available. Using the question ‘What will a teacher learn/experience from this workshop?’ as a framework, the workshops within the **STEM Teacher Education Programme** also allowed time for reflection, discussion and sharing of experience from previous weeks’ sessions.

**STEM Teacher Education Participants** were primary school teachers who had some previous experience of participating in science activity but who wanted to further develop their teaching skills and knowledge in this area. Where possible, two teachers from a school participated in the Programme to allow sharing of experience as this provided a good foundation for the school community to build upon - especially as the planned future progression of **RDS STEM Learning** included the development of a whole school programme.

Participants of both Programmes were required to have the support of their Principal to participate in the course as they would put their learning into action in class and reflect on their classwork as part of the evaluation of the pilot Programme. Participation in the Programme was fully funded by the RDS and was delivered outside of school hours, every 2-3 weeks, allowing time for classroom practice and reflection between sessions. During this first phase 12 Facilitators and 38 teachers engaged with the pilot Programme.

**METHODOLOGY**

A two-phase approach was taken to measure the impact and effectiveness of the Programme through a structure of continuous feedback and reflection. The data which were collected throughout the pilot was subject to review by the authors of this paper, in addition to being used within the independent external evaluation two - the key outcomes will be included in this paper.

Data Collection and Review

1. **Surveys** - Baseline surveys of teachers’ attitudes, perceptions and experiences were captured at the beginning, middle and end of the Programme participation.

2. **Reflection Sheets** - Teachers completed Reflection Sheets after implementing workshop ideas and approaches in the classroom. This captured their change in emphasis from activity focus to looking in greater depth at the children’s engagement and thinking process.

3. **Reaction Sheets** - Teachers’ engagement with and reflection on the content and implementation of each workshop of the Facilitator Programme was captured through written feedback on Reaction Sheets - this contributed to the refinement and development of the pilot Programme week to week.

4. **Discussion and Focus Groups** - Group discussion sessions focused on development of the **RDS STEM Learning** Teacher Education Programme workshops were recorded to

---

determine the key aspects that the teachers felt were important to bring into the second phase of the Programme.

5. Qualitative interviews - These were undertaken as part of the external evaluation

6. International literature review - In addition to the data collection across Programme delivery the independent evaluation set out to benchmark RDS STEM Learning against national and international primary teacher CPD programmes.

7. The external evaluation also reviewed the Programme objectives in accordance with the five OECD evaluation dimensions of relevance, effectiveness, efficiency, impact and sustainability to draw evidence-based conclusions as to the achievements and impact of the pilot, and recommendations about its continuation and future development.

RESULTS

It is apparent from the data that participation in the RDS STEM Learning Facilitator Programme greatly increased participants’ confidence and competence in teaching science through inquiry. It was also apparent that participation in the programme was particularly effective in establishing a community of reflective practitioners - participants reported that the Programme involved and encouraged peer learning and collaboration, one participant reporting that ‘I cannot overemphasise the importance of the collaborative nature of the Programme. I really found this most beneficial’. The data also indicated that the generation of an atmosphere where teachers felt comfortable to openly share their experiences and vulnerabilities was instrumental to this outcome; ‘The culture and tone of the Programme very much supported engagement in reflective practice. The discussions every week with teachers and the open and friendly atmosphere in the face to face sessions and on the online forum helped make it a place where I felt comfortable in saying when things I tried went well and when they were disasters’.

It is interesting to note that participants’ experience of RDS STEM Learning was different, and more positive, than their experiences of other CPD initiatives. On reflection within a focus group discussion participants agreed the following elements as the key differentiators between RDS STEM Learning and other CPD initiatives, reflecting that RDS STEM Learning has:

1. Encouraged a different approach to teaching, (participants are) now teaching in a different way, asking different questions. Children are going home and talking about science;
2. Focused on the process and skills, not just recipe-style activity;
3. Been a kinaesthetic experience, learning by doing and not hand-out based;
4. Been sustained - course taking place over long period was more beneficial than short course;
5. Homework (for participants) and opportunity for trialling activities during STEM workshops was of benefit – feedback was shared in the group, from colleagues and children;
6. Been interactive - Reflections at the start of each session, good for sharing ideas and experience, feeling of being in a club;
7. Provided (participants) an opportunity to input into the development and direction of CPD programme.

What was notable at this juncture was that, despite highlighting these as key elements which they themselves had found most beneficial, in the process of preparation for Teacher Education Programme these same teachers first thought of the ‘what’ - suitable activities, before setting out the ‘why’ – ie what was to be achieved within the Teacher Education Programme and why it was important. This emphasises the importance of a sustained intervention to support teachers to deepen their understanding and to reflect on their practice over time on their journey to becoming peer leaders in education.

Analysis of teachers’ reflections captured within the Reflection and Reaction Sheets across the duration of the Programme shows the development in process from simply ‘doing science activities’ to thinking through science for example, ‘The past fortnight has shown me that science has many different facades and sometimes it may be good to lead the children in scientific discussion...its ok for them not to be doing hands on activities all of the time.’

There was an emerging change in teachers’ thinking, with the majority reporting an increase in their awareness of the importance of thinking about science as well as about their students’ experience of science ‘It showed me that I find some of the reasoning and thinking skills necessary for the activities quite challenging. It was good to feel a bit of what the children might feel in my classes when trying to come up with a solution to a problem’. In addition the notion of achieving the ‘right answer’ dissipated over the course of the Programme from an ‘initial wariness’ to a confidence that ‘There was a definite positive impact on the children’s learning due to the classroom practice as a result of the STEM workshops. The children became more confident that they did not have to know the right answer when setting out on an investigation.’

What has come through overall is that Facilitator participants have begun to use scientific investigations as a vehicle to develop literacy and oral language skills in their students, while an increase in child-led classwork is encouraging children to collaborate and solve problems together. There is some evidence - stronger in some areas than others - of a greater use of inquiry skills, open-ended questions and Design and Make techniques; and a deeper emphasis on skills development among teachers. In addition, the nature of the feedback from teachers changed from a focus on an activity where ‘children stayed on task’ to observing their students’ learning ‘I would now put more emphasis on encouraging children to think more about why they are doing what they do in science investigations - to communicate their thoughts aloud, as well as devising tasks that would challenge their thinking’.

Overall it can be observed that participation in RDS STEM Learning has supported teachers to create a classroom environment where students are encouraged to question, reason and explain their thinking process, and that teachers have a greater awareness of the importance of focusing on skills development in the children. However, the Programme also highlights the complexity of the development of practice, and how impacts are subtly couched within everyday teaching and difficult to isolate, for example in one reflection. Sometimes I don’t spend enough time actually teaching skills, showing children the difference between observations and inferences. I get frustrated when trying to get children to talk about what’s going on in an investigation.
and they are mixing up what they saw and what they think is happening or why – but of course I have never taken the time, or knew how to help them develop those key skills’. This reflection is a first step to moving from a change in thinking about their science teaching leading to a longer-term change in their teaching practice.

**KEY LEARNINGS AND NEXT STEPS**

On review of the first phase of the pilot Programme it is clear that the Programme has impacted on an individual teacher level and that at a Programme level it has been a departure from existing models of CPD in Ireland.

On an individual teacher level:

- The pilot Programme has delivered significant measurable impact in the areas of teacher confidence and ability, and student engagement.
- Participants in the pilot Programme began to shift from measuring success in teaching in terms of ‘what a child knows’ to the way in which a child can think.
- Teachers are now much more reflective of how lessons are going and how they can be improved.
- An additional impact for students was also noted; that they observed that ‘their teachers’ education was continuous and not static’.

At a Programme level:

- International benchmarking and literature review has shown that a balance between pedagogical improvement and the provision of subject specific knowledge is imperative in effective CPD programmes; the pilot Programme has demonstrated effective practice in these areas.
- STEM CPD programmes of longer duration tend to have better outcomes for students and teachers; while not reaching the internationally recommended length, the pilot RDS STEM Learning Programme has demonstrated a positive departure from existing CPD offerings in Ireland.
- The engagement of external academic experts in pedagogy and CPD, and the collaborative delivery model of the pilot Programme has yielded positive outcomes.
- There is no international consensus on benchmarking effective CPD; the pilot RDS STEM Learning Programme has the potential to demonstrate innovative practice in this area.

The RDS STEM Learning Programme has clear strategic development goals and the capacity to develop over 5-year timeframe, with substantial increased impact and scale. The strive to achieve a change in thinking among participants, to then lead to a change in classroom practice requires a sustained and deep intervention over time. As a model of professional development RDS STEM Learning has been ambitious and highlights the importance of evidence based programme development, linking best practice in educational research with the reality of everyday classroom practice to support participants in a continuum of learning across their career.

Strand 11 focused on a wide range of issues related to the evaluation and assessment of student learning and development, both on an individual and classroom level and on a national and international level.

The use of assessment instruments (like tests, questionnaires etc.), as tools for exploring and answering other research questions of interest, is not part of the strand mission. In Strand 11 the focus is primarily on the instrument itself, the emphasis is on the development, implementation, validation and use of assessment instruments – and on the consequences of the use of the instruments. These can include standardized tests, achievement tests, high stakes tests, and instruments for measuring attitudes, interests, beliefs, self-efficacy, science process skills and competences, conceptual understandings, and so on. They may be developed with a view to making assessment more ‘authentic’ in some sense, to facilitate formative use of assessment, or to improve summative assessment of student learning.

USE OF CASE STUDY TO DEVELOP AND EXEMPLIFY OF A MODEL OF TEACHER ASSESSMENT

Sarah Earle
Bath Spa University, England

The Teacher Assessment in Primary Science (TAPS) project is based at Bath Spa University and funded by the Primary Science Teaching Trust. Using a Design-Based Research (DBR) approach it has worked collaboratively with schools to operationalize a model of teacher assessment put forward by the Nuffield Foundation (2012) whereby formative classroom assessment information is summarized for summative purposes (Davies, Earle, McMahon, Howe & Collier, 2017). This paper presents a case study of one of the TAPS project schools utilizing data from school visits and TAPS development days, collected between June 2013 and June 2015. The case study addresses research questions around the nature of formative and summative assessment, and the relationship between the two within the school. In discussion of the case, the aim is to explore the enactment of a ‘formative to summative’ approach to assessment in primary science, as proposed by the Nuffield Foundation (2012) and TAPS (Davies et al. 2016). Key features of practice drawn from the case include the use of: pupil self and peer assessment; explicit criteria; and whole school moderation meetings. Questions are raised for the DBR approach regarding benefits of the partnership for the school, since little change in primary science practice was seen during the case study period; whilst the school has supported development of the TAPS pyramid model, for example, with the inclusion of a ‘shared understanding’ criterion in response to practice seen in schools.

Keywords: formative assessment, design-based research, primary school

INTRODUCTION

Assessment is fundamental to the practice of education, yet it is not neutral, it is value-laden; assessment processes determine what is valuable to learn and what success will look like, it: “creates and shapes what is measured” (Stobart, 2008: 1). Since assessment shapes the curriculum as experienced by children; it is essential for such assessment practices to be well understood by teachers. The functions and effect of assessment have received much attention, with some arguing (Black & Wiliam, 1998) that assessment should have an impact on learning otherwise there is little point in conducting the assessment in the first place. Research into formative assessment champions the use of assessment to support learners with their next steps (Gardner, Harlen, Hayward, Stobart & Montgomery, 2010); whilst summative assessment became viewed in a negative light because of suggestions that it was the cause of curriculum narrowing and teaching to the test (Harlen, 2013). However, education systems require both purposes to be fulfilled, with assessment information used to support learning and to summarise achievements. Such a clash between a positive view of formative assessment and a negative view of summative assessment may be counter-productive, leading teachers to run separate, and consequently unmanageable, assessment systems (Earle, 2014).

A closer relationship between formative and summative assessment is seen by some as crucial to effective teacher assessment (Harlen, 2013; Hodgson & Pyle, 2010; Nuffield Foundation, 2012; Wiliam & Black, 1996). An expert group convened by the Nuffield Foundation (2012) proposed that assessment information gathered for the purposes of formative assessment during
the course of typical classroom activities could also be used to serve summative purposes by informing summaries of pupil performance when reporting for different purposes. Their pyramid-shaped model of teacher assessment, in which information flows from the classroom base to the reporting tip, was developed in response to growing concerns for the negative impact of external summative testing, skewing the taught curriculum to that which was easily tested (Gardner et al., 2010). Whilst the Nuffield model was welcomed by the primary science community, it contained little detail of how to implement its proposals.

The Teacher Assessment in Primary Science (TAPS) project, based at Bath Spa University and funded by the Primary Science Teaching Trust (PSTT), set out to operationalize the Nuffield proposals using a Design-Based Research (DBR) approach to work collaboratively with project schools to translate research into practice (Anderson & Shattuck, 2012). During iterative cycles the TAPS school self-evaluation model was developed, containing criteria and examples to support schools to develop their assessment processes (Earle, McMahon, Howe, Collier & Davies, 2016). This paper presents a case study of one of the TAPS project schools, with the aims of testing and exemplifying the model of ‘formative to summative’ assessment.

METHODS

The case was selected as a ‘critical’ or ‘instrumental’ case (Stake, 2006), to provide a test case for the ‘formative to summative’ model, since School A was an award-winning PSTT school who asserted that they used formative classroom assessments to make summative judgements. In this paper, the following research questions are addressed:

RQ1. What are the characteristics of formative teacher assessment in science in School A?
RQ2. What are the characteristics of summative teacher assessment in science in School A?
RQ3. What is the relationship between formative and summative assessment in School A?

The data for School A was collected, with ethical agreement from school and participants, between June 2013 and June 2015 and consisted of: non-participant lesson observations (N=3) and interviews (N=3) from six school visits; school documentation including policies, lesson plans and assessment records; and activities from six TAPS development days. On many occasions the school was represented by the science subject leader, the class teacher responsible for leading the development of science across the school, thus much of the data was from her perspective. In order to triangulate the reported practice, classroom observations and documentation from across the school were included in the data. Particular attention was paid to the research questions in order that the analysis should remain focused on the relationship between formative and summative assessment, whilst placing this within the rich context of the school. Qualitative data analysis was supported by ATLAS.ti software, with codes developed deductively from the research questions and the TAPS pyramid (Earle et al., 2016), and inductively from the data itself. ‘Higher order codes’, those which were both frequently represented in the data-set and pertinent to the research questions (Bryman, 2016), have been selected as examples for discussion in this brief paper.
RESULTS

Formative teacher assessment

Formative assessment at School A was built into lesson planning, for example in the form of key questions for teachers to ask their pupils. Classroom discussion was a prominent feature in all three of the observed lessons (see Table 1), with each teacher used strategies like talk partners to increase participation and wait time. For example, in the Year 6 lesson, pair talk dominated with the teacher ‘listening in’ to discussions to support her formative assessment, then asking probing questions to stimulate further discussion. In the Year 5 lesson, it was noted that the teacher was ‘withholding judgement’ (Table 1, row 4) during the class discussion. The teacher questioning focused on explanations and use of vocabulary, but the teacher did not say ‘that’s right’ and move on. This could support a more dialogic (Alexander, 2008) approach to discussion, moving beyond the mere ‘call and response’ of interactive-authoritative dialogue (Mortimer & Scott, 2003). By withholding summative judgement of pupils’ answers, the children were prompted to explain further and the teacher received richer formative assessment information, from a greater number of children.

Teachers use assessment to advance students’ learning by adapting the pace, challenge and content of activities

Teachers use assessment to advance students’ learning by giving feedback

Teachers use assessment to advance students’ learning by providing time for students to reflect on and assess their own work

---

Pupil self and peer assessment was supported by explicit success criteria, with stages of scientific inquiry displayed on the wall and referred to in lessons. For example, the subject leader’s Year 5 lesson (January 2014) began with a whole class carpet discussion about the Earth and sun. In the main part of the lesson the pupils worked in pairs or threes to physically model the orbit of the Earth around the sun using different sized balls. As the children moved the ‘Earth ball’ they gave a commentary on what was happening, which was then peer-assessed for clarity and accuracy, with the groups giving advice to each other for how to improve their explanations. The teacher emphasized the accurate use of scientific vocabulary, pointing to the success criteria on the wall, leading the pupils to listen out for the word ‘orbit’ or ‘axis’ in the explanations. The use of explicit success criteria, a key feature of formative assessment (Wiliam, 2011), supported both teacher and pupil assessment in the observed lessons.

Pupil recording included ‘floor books’ for younger children in the school (a large-format, ‘home-made’ book), where an adult scribed their responses verbatim, whilst older children made focused recordings in their science books. The subject leader stated that:

“Marking is used to feed judgements back to children. Children are given the opportunity to respond to marking at the beginning of sessions”

(Subject leader interview, November 2013).

Evidence of both teacher marking and pupil responses was seen in children’s science books. Some of the teacher marking included numerical scores, which Butler (1988) had found
cancelled out the positive effect of feedback via comment-only marking. Black and Harrison (2010) also argue that the score signifies that the process is complete; the judgement has already been made. They recommend that comment-only marking is used, with any scores recorded for the teacher tracking only.

**Summative teacher assessment**

When asked how she made a summative judgement, the Year 6 teacher replied:

> “It’s best fit, look at child’s work over term, teacher judgement about where work fits and give sublevel. Sometimes do end of term something which can be part of information, but does not ‘give’ you a level, it informs. There is no set model”

(Year 6 teacher interview, January 2014).

The ‘best fit’ teacher assessment is described as drawing on a range of information which may include a ‘child’s work’ in normal lessons or an end of term task or question. The Y6 teacher emphasised that the ‘end of term something’ does not ‘give you a level’. This is perhaps highlighting the difference between end of Key Stage assessment procedures for different subjects, for example, when the pupils sit a reading test and the score would be converted, by a pre-defined formula, into a level; the test would ‘give’ the level. In contrast, for a teacher assessment in science, there is no calculation or pre-defined formula, ‘no set model’, to provide a ‘best fit’ judgement.

For ‘best fit’ summative assessment, the teacher aims to find the closest match between pupil outcomes and National Curriculum criteria. Such an assessment could enhance validity by reducing the construct under-representation inherent in testing (Gardner et al., 2010) and enhance reliability since teacher assessment can utilise more evidence than is available through external assessment instruments (Mansell, James & the Assessment Reform Group, 2009). However, the lack of transparent processes for collating a term’s work into a summative judgement, both opens teacher assessment up to criticisms of bias, especially if the judgements form part of the school’s accountability measures (Green & Oates, 2009), together with making it very difficult to explain the processes to others in the community. It also requires a large amount of knowledge of the subject on the part of the teacher, the teacher being entirely responsible for judging whether the pupil’s answers are consistent with the teacher’s ‘model’ or expectation of how the pupil can demonstrate understanding (Black & Wiliam, 1998). Connelly, Klenowski and Wyatt-Smith (2012) note that teacher judgements do more than match evidence to criteria, they draw on multiple sources of knowledge, of pupils and previous experience. Without guidance and exemplification, an inexperienced teacher may struggle to make a ‘best fit’ teacher assessment because they lack a clear expectation of what it would look like for pupils to demonstrate understanding in a topic, and there is a lack of transparent processes for combining such assessments into a ‘best fit’ judgement.

In addition to concerns regarding the amount of subject-specific knowledge needed to make ‘best fit’ judgements, another criticism of such an approach is the way that a ‘best fit’ model produces an overall judgement which could mask gaps in understanding. This was one of the reasons behind the removal of levels in the English National Curriculum, changing to an ‘age-related expectations’ model whereby pupils would need to meet all criteria (Department for
Education, 2013). The language of summative assessment at School A followed the statutory change from ‘levels’ at the beginning of the case study period, to ‘meeting expectations’ by the end of the case study period, but the process for making the summative assessment judgements appeared to continue to be one of ‘best fit’. The school’s progression grids which were used as criterion scales, were also used throughout the case study period, with only minor alterations to remove the levelling vocabulary for scientific inquiry. Thus it appeared that school processes were resistant to change during the case study period.

The relationship between formative and summative assessment

The science subject leader at School A defined the key purpose of assessment as formative, as Assessment for Learning (AfL):

“The purpose of assessment is to develop learning, to identify where children are, and to plan next steps. Assessment should involve children (AfL) and include some success criteria. It should also involve listening and questioning.”

(Subject leader interview, November 2013)

She goes on to state that this formative classroom assessment is utilized when making summative judgements:

“The summative judgement arises from formative assessment... a whole school decision was made that summative would be informed by formative leading to a best fit model.”

(Subject leader interview, November 2013)

The use of such a ‘formative to summative’ model was the reason for choosing this school as a case study, to explore such practice in action, but as noted above, it appears that the notion of ‘best fit’ summative judgements require a lot of knowledge on the part of the teacher. Underlying the ‘formative to summative’ model represented by Nuffield (2012) and TAPS (Earle et al., 2016) and enacted in School A, is a shared understanding of progression in science, with explicit criteria or curricular expectations which are, for example, recorded in planning and shared in lessons.

In order to build such a shared understanding of progression and criterion-referenced assessment, a key feature of practice at School A was the allocation of staff development time to science. During regular whole school staff meetings the subject leader introduced new strategies for formative assessment and led the staff in moderation discussions to support summative judgements. As Deputy Head, she would also support staff with planning and teaching using the school’s planning and criteria structures.

Harlen (2007) argues that whilst teacher assessment is often perceived as having low reliability, with effective moderation procedures, the reliability of teacher assessment can be as high as it needs to be, in the ‘trade off’ between reliability and validity (Wiliam 2003). School A appear to be using moderation staff meeting discussions to serve multiple purposes, more than a checking of judgements, it was also a means of staff development (Green & Oates, 2009), supporting both teacher ‘assessment literacy’ and teacher understanding of progression in science.
DISCUSSION AND CONCLUSIONS

Active pupil involvement in assessment during lessons became the base layer of the TAPS pyramid model (Earle et al., 2016), with many of the examples being provided by School A, including those for self and peer assessment. The school’s structures, for example, their progression grids for scientific inquiry, provided explicit criteria for both pupils and teachers to use in their judgements, which together with the moderation discussions, appeared to build a shared understanding of progression in science across the school. This shared understanding was found to be a key feature in other PSTT award-winning schools (Earle, 2015) and became a central addition to the TAPS pyramid model at the monitoring layer (Davies et al., 2017).

The explicit criteria within the school planning structures were used to support both formative and summative assessment, providing success criteria within the lesson and criteria for summative judgements. It is perhaps these common criteria which provide a bridge between formative and summative assessment, providing opportunities for the same classroom activities to be used to inform both formative next steps and summaries of learning.

The case study of School A supported the development of the TAPS pyramid model, both in the addition of new criteria and the provision of exemplification materials. Nevertheless, many of its structures were based on a previous version of the English National Curriculum, when summative assessments used a system of levelling. Unlike other TAPS project schools, little change was seen in assessment practices, perhaps suggesting a one-sidedness in the DBR collaboration. Perhaps School A and its subject leader viewed their role as a provider of examples, rather than as a co-researcher, since they felt that they had already found a way to use formative assessment to inform summative judgements. The lack of change over time in School A is impossible to reduce to the influence of one factor, but recognition of the potential effect of stagnation from over-exemplification is useful to be aware of for future iterations of DBR.

The aim of the TAPS pyramid model is to present assessment principles, supported by a range of exemplification from different contexts, to enable the user to self-evaluate their individual context. This case study of assessment practice at School A has provided some examples for the use of formative assessment in primary science, and the way this information can be summarized to provide a summative judgement.

However, questions have been raised about the school’s use of ‘best fit’ and it is not assumed that this is the only way to implement a ‘formative to summative’ model of teacher assessment. Additional research is needed to explore practice in other schools and contexts to further test, develop and exemplify the model of teacher assessment, an ongoing focus for the next phases of the TAPS project.

COMPLEXITY OF PRACTICAL WORK IN SCIENCE CURRICULA AND NATIONAL EXAMS: ANALYSIS OF RECONTEXTUALISING PROCESSES

Sílvia Ferreira and Ana M. Morais
UIDEF, Instituto de Educação, Universidade de Lisboa, Portugal

The study is focused on the level of complexity of practical work in science curricula and national external assessment with regard to the secondary school discipline of Biology and Geology in Portugal. This level of complexity is appreciated through the conceptual demand of practical work as given by the complexity of scientific knowledge and cognitive skills and the relation between theory and practice. The recontextualising processes that may have occurred in the exams were analysed by studying the relation between curriculum and exams. The study makes use of theories and concepts of the areas of psychology and sociology, particularly Bernstein’s theory of pedagogic discourse. The results show that the level of conceptual demand of practical work varies according to the specific curricular text under analysis, i.e. Biology or Geology. Practical work as assessed in the exams recontextualises the curriculum in the direction of lowering its level of conceptual demand. In methodological terms, the article explores assumptions used in the analysis and presents innovative instruments.

Keywords: practical work; science process skills; conceptual demand

INTRODUCTION

The role of practical work in offering students the opportunity to experience the process of scientific investigation is one of the arguments for practical work in science education (Hofstein & Kind, 2012; Lunetta et al., 2007; Osborne, 2015). Students are expected to both learn scientific knowledge and mobilize science process skills whenever they are doing investigative practical activities. The nature and complexity of practical work in science curricula and national exams and the recontextualising processes that may have occurred between them should be analysed and discussed because these are aspects that broadly guide textbook authors and teachers’ practices.

In science education, as well in other areas of knowledge, it is essential that there are no discontinuities between curriculum, pedagogical practice and assessment (e.g. Britton & Schneider, 2007; Duschl, Schweingruber & Shouse, 2007). For that reason these different texts and contexts “should be conceived of, designed, and implemented as a coordinated system” (Duschl et al., 2007, p. 347). In the specific case of external assessment, evidence from several studies indicates that national exams limit the teaching and learning process and also the classroom assessment tools (Hamilton, 2003). If exams and curriculum are inconsistent, teachers tend to focus on what is assessed in the exams rather than on what is presented in the curriculum and in this way the content that is not tested tends to be ignored in pedagogical practice (Britton & Schneider, 2007). The external assessment can push “teaching and learning in undesirable directions that are counterproductive to the goals of scientific literacy” (p. 1009). However specific types of assessment have the potential to promote particular forms of effective teaching.
The study is focused on the analysis of both the Portuguese curriculum and the national exams for secondary school biannual discipline of Biology and Geology (ages 16-17). In Portugal likewise many Latin countries, Biology and Geology, although epistemologically distinct, have traditionally been part of the same discipline (often but not always called Natural Sciences). Theoretically, the study is multidisciplinary, making use of theories and concepts of the areas of psychology and sociology, particularly Bernstein’s theory of pedagogic discourse (1990, 2000).

Bernstein develops a theory about the production and reproduction of pedagogic discourse, in which he considers the complex set of relations between various fields and contexts of what he calls pedagogic device. Throughout this process, recontextualisations at the various levels of the pedagogic device can take place and for that reason the pedagogic discourse is not the mechanical result of the dominant principles of society, which constitute the general regulative discourse (GRD). As a result of the official recontextualisation of the GRD, namely at the level of the Ministry of Education and its agencies, the official pedagogic discourse (OPD) is produced. This discourse is expressed, for example, in curricula and in national exams.

Bernstein’s model also evidences that the official recontextualisation field is influenced by the fields of economy and symbolic control and defines the what and the how of the pedagogic discourse. The what refers to the knowledge and skills that are the object of the teaching and learning process and the how is related to the way in which the teaching and learning process occurs.

In particular the relation between curricula and national exams was analysed in this study to explore recontextualisation processes that may have occurred between the message conveyed in these official documents, with regard to different dimensions of the what and the how of pedagogic discourse related to practical work. The study addresses the following research problem: What are the messages transmitted by the official pedagogic discourse (OPD) expressed in both the curriculum and the national exams of Biology and Geology of secondary school, with regard to their level of complexity of practical work, and what is the extent to which recontextualising processes do occur?

Varying with authors, practical work can have different meanings. Hodson (1993) considers practical work as a broad concept which includes any activity that requires students to be active. Millar, Maréchal e Tiberghien (1999) limit the definition presented by Hodson (1993) to consider that practical work is ‘all those kinds of learning activities in science which involve students at some point handling or observing real objects or materials (or direct representations of these, in a simulation or video-recording)’ (p. 36). In the same line, Lunetta, Hofstein and Clough (2007) give the following definition of practical work: ‘learning experiences in which students interact with materials or with secondary sources of data to observe and understand the natural world’ (p. 394).

The meaning of practical work in the present study is made more precise in that considers that it must mobilize science processes skills. These skills were considered as ways of thinking more directly involved in scientific research, such as observing, formulating problems and hypotheses, controlling variables and predicting (Duschl, Schweingruber and Shouse, 2007). Thus, practical work is defined as: all teaching and learning activities in the sciences in which
the student is actively involved and that allow the mobilization of science processes skills and scientific knowledge and that may be materialized by paper and pencil activities or observing and/or manipulating materials.

The level of complexity of practical work can be appreciated by its level of conceptual demand. In the context of the research that has been carried out by the ESSA Group (Sociological Studies in the Classroom, Institute of Education, University of Lisbon) within Bernstein’s theory, the concept of conceptual demand is defined as the level of complexity of science education as given by the complexity of scientific knowledge and the strength of intradisciplinary relations between distinct knowledge and also by the complexity of cognitive skills (Morais & Neves, 2016).

**METHOD**

The analysis of the Biology and Geology secondary school curriculum was focused on two official documents which contain directions for the teacher: 10th Biology and Geology syllabus and 11th Biology and Geology syllabus (in force since 2002 and 2003, respectively). Although part of the same discipline and of the same curriculum, Biology and Geology come in the curriculum as two distinct subjects, with strong boundaries between them. The analysis of the national exams involved 26 exams, from 2006 to 2011.

The whole curriculum was segmented into units of analysis but the units of analysis with a specific reference to practical work (requiring the mobilization of science process skills) were the only ones considered in this study. For the same reason, the analysis of national exams considered only the questions which focused on practical work, i.e., questions that mobilised science process skills. Each question was taken as a unit of analysis.

The level of conceptual demand was determined through the analysis of specific dimensions of the what and of the how of the OPD (Figure 1). The first corresponds to the level of complexity of scientific knowledge and cognitive skills and the second to the strength of intradisciplinary relations between theory and practice. The discontinuities between the curriculum and the national exams were studied through the recontextualising processes that may have occurred between the messages of these official documents.

Three instruments were constructed in order to characterise the message underlying each one of the units of analysis, and consequently the OPD transmitted by both the science curriculum and the national exams, with regard to the conceptual demand of practical work. The construction of the instruments followed a mixed methodology (Creswell & Clark, 2011; Morais & Neves, 2010; Teddlie & Tashakkori, 2009), using qualitative and quantitative approaches. The text that follows contains a brief description of the instruments constructed and how they were used, and gives also some examples to show how analyses were made.
The instrument for analysing the complexity of scientific knowledge was based on the distinction between facts, generalized facts, simple concepts, complex concepts and unifying themes/theories, following several authors (e.g. Brandwein et al., 1980; Cantu & Herron, 1978; Duschl et al., 2007; Pella & Voelker, 1968). For instance, simple concepts have a low level of abstraction, defining attributes and examples that are observable (Cantu & Herron, 1978). Complex concepts correspond to abstract concepts proposed by Cantu and Herron (1978) and “are those that do not have perceptible instances or have relevant or defining attributes that are not perceptible” (p.135). Table 1 presents an excerpt of this instrument and examples of units of analysis which illustrate different degrees of complexity.

Table 1. Excerpt of the instrument to characterise the complexity of scientific knowledge.

Units of analysis:

Degree 1: [1] Search for information on the internet, in newspapers and magazines about the consequences of such situations [anthropic occupation of floodplains and coastal zones, and construction in slope zones] for populations. *(11th Geology syllabus)*.

Degree 2: [2] [...] 6. When exposed to the sun, the surface of the coat of *C. dromedarius* can reach temperatures above 70 °C, while at the skin level the body temperature does not exceed 40 °C. Explain, from the data provided, how the research carried out allowed to relate the adaptation to high temperatures to the levels of transpiration presented by *C. dromedarius*. [...] *(National Exam of 2009, 1st phase)*

Degree 3: [3] [...] 6. Genetic studies in *Coccomyxa* suggest that as soon as the endosymbiotic relation with *Ginkgo biloba* was established the algae was transmitted from generation to generation. Explain how the results of those studies may relate the transmission of the endosymbiotic relation from generation to generation to the way such relation was initiated. [...] *(National Exam of 2009, 2nd phase)*.

Degree 4: [4] Collect, organize and interpret data of a different nature related to evolutionism and to arguments that support it by opposition to fixism. *(11th Biology syllabus)*.

Adapted from Ferreira & Morais (2013, 2014)
Excerpt [1] emphasises facts related to the consequences for populations of the anthropic occupation of floodplains and coastal zones and construction in slope zones, and for that reason it was classified with the degree 1. In excerpt [2], the national exam question and respective recommended correction involve simple concepts related to thermoregulation. In the question presented in excerpt [3] and in the given respective correction are involved complex concepts related to the genetic transmission of an endosymbiotic relation between a plant and a green algae. If the question appealed to a relation to the model of endosymbiosis, the degree of complexity would increase to degree 4. The excerpt [4] focuses knowledge of a very high degree of complexity related to the theory of evolution.

A second instrument, for analysing the complexity of cognitive skills, was based on the taxonomy created by Marzano and Kendall (2007, 2008) with four levels for the cognitive system: retrieval, comprehension, analysis and knowledge utilization. Retrieval, the first level of the cognitive system, involves the activation and transfer of knowledge from permanent memory to working memory. “The process of comprehension within the cognitive system is responsible for translating knowledge into a form appropriate for storage in permanent memory” (2007, p.40). The third level, analysis, involves the production of new information that the individual can elaborate on the basis of the knowledge s/he has comprehended. The fourth and more complex level of the cognitive system implies the knowledge utilization in concrete situations. Table 2 presents an excerpt of this instrument.

Table 2. Excerpt of the instrument to characterise the complexity of cognitive skills.

Units of analysis:
Degree 1: No units of analysis were found.
Degree 2: [5] [...] 3.2. Select the alternative that completes the following statement correctly. For the results of Büchner’s experiment prove that the occurrence of fermentation is in some way related to the intervention of living beings (or their derivatives), it would be necessary to introduce in the procedure a device containing ...
(A) ... yeast in a sugar solution.
(B) ... yeast extract in a sugar solution.
(C) ... only a sugar solution.
(D) ... exclusively yeasts. (National Exam of 2007, 2nd phase)
Degree 3: [6] Classify rocks based on genetic and textural criteria. (11th Geology syllabus)
Degree 4: [7] [...] 6. Some authors consider Giardia as a missing link in the evolution between prokaryotic cells and eukaryotic cells, while others authors argue that it has evolved from more complex eukaryotic cells by the loss of certain organelles. Present a possible path of investigation that would allow one of the hypotheses mentioned to be proved and the other to be rejected. [...] (National Exam of 2006, 1st phase)

Adapted from Ferreira & Morais (2013, 2014)

In excerpt [5] the national exam question implies the mobilization of science process skills related to the identification of the control group characteristics, which is associated with the
process of comprehension. The syllabus aim presented in excerpt [6] involves the mental process of classification, associated with the cognitive process of analysis. The excerpt [7] focuses the planning of investigative laboratory activities, which is related to the cognitive process of knowledge utilization.

The analysis of the relation between theory and practice was characterized through Bernstein’s concept of classification (1990, 2000), to indicate the strength of boundaries between various types of knowledge. This instrument contained a four degree scale of classification (C++, C+, C−, C++). The weakest classification (C−) corresponds to an integration of theory and practice where both have equal status and the strongest classification (C++) corresponds to an insulation between theory and practice. The empirical descriptors for each degree translate the relation between declarative knowledge (theory) and procedural knowledge (practice) (Roberts, Gott & Glaesser, 2010). Table 3 presents an excerpt of this instrument, followed by examples of units of analysis which illustrate different levels of classification.

Table 3. Excerpt of the instrument to characterise the relation between theory (declarative knowledge) and practice (procedural knowledge).

<table>
<thead>
<tr>
<th>C++</th>
<th>C+</th>
<th>C−</th>
<th>C++</th>
</tr>
</thead>
<tbody>
<tr>
<td>The focus is either on declarative knowledge only or on procedural knowledge only.</td>
<td>Declarative knowledge and procedural knowledge are focused, but not the relation between them.</td>
<td>The relation between declarative and procedural knowledge is focused, giving higher status to declarative knowledge.</td>
<td>The relation between declarative and procedural knowledge is focused, giving equal status to both types of knowledge.</td>
</tr>
</tbody>
</table>

Units of analysis:

C++: [8] [...] 3. Select the alternative that fills the spaces in the following sentence, in order to get a correct statement. The study II allows to conclude, through the quantification of the seeds produced, that the _____ space selected plants with _____ dispersion capacity.

(A) urban (...) greater
(B) country (...) greater
(C) urban (...) minor
(D) country (...) minor (National Exam of 2008, 1st phase)

C+: No units of analysis were found.

C−: [9] The cell: The laboratory observation of uni and multicellular living beings, collected in the field, will enable the understanding of the cell as a structural and functional unit of living beings and facilitate the approach to its basic constituents. (10th Biology syllabus)

C++: [10] Create models and simulate laboratory situations of landslide, trying to identify the factors that contribute to their occurrence. The teacher should draw attention to the analogies between the model and the geological process, stressing, however, the variables involved and the different scales of time and space in which phenomena occur. (10th Geology syllabus)

Adapted from Ferreira & Morais (2013, 2014)

The national exam question presented in excerpt [8] focuses on procedural knowledge only, associated with the knowledge of the scientific process of interpretation of simple experimental data, explored in the introductory text of this question. The excerpts [9] and [10] involve a relation between declarative and procedural knowledge, but in the former the higher status is given to declarative knowledge about the cell, and in the latter both types of knowledge have equal status.
In order to clarify how the same unit of analysis was classified in the study in terms of the dimensions related to the what and the how of pedagogic discourse, an illustrative example of the analysis that was made is presented:

[11] Setting experimental devices with simple aerobic facultative living beings (e.g. Saccharomyces cerevisae) in nutritive media (e.g. “bread dough”, grape juice, aqueous solution of glucose…) with different degrees of aerobiosis. Identification with the students of the variables to be controlled and the indicators of the process under study (e.g. presence/ absence of ethanol). (10th Biology syllabus)

Excerpt [11] presents a methodological guideline of the 10th Biology syllabus. With regard to the what of the OPD, this unit is focused on a laboratory activity, which appeals to simple concepts, related to glucose degradation in the presence and in the absence of oxygen (degree 2), and to cognitive skills involving the cognitive process of analysis, since it implicates the control of variables (degree 3). With regard to the how of the OPD, this unit of analysis involves a relation between declarative and procedural scientific knowledge, where equal status is given to these two types of knowledge (C−).

RESULTS

Figure 2 gives a synthesis of results of the conceptual demand of practical work of both science curriculum and national exams for the three dimensions studied. These results refer to the Biology and Geology curriculum specific guidelines only and to the national exams from 2006 to 2011.

When Biology and Geology curricular subjects are compared, Biology shows more complex concepts and unifying themes (degrees 3 and 4) than Geology. The higher knowledge complexity in Biology practical work is especially given by the focus on cell theory and on evolution theory. In the case of Geology there are no units classified with degree 4 and there are units classified with degree 1. Simple concepts prevail in exams (degree 2). Degrees 1 and 4 (facts and unifying themes/theories, respectively) are absent in exams questions about practical work.
When the focus is the complexity of cognitive skills, it is Geology that places greater emphasis on complex cognitive skills of a high level (cognitive process of knowledge utilization – degree 4) when compared with Biology. The highest complexity of cognitive skills in Geology practical work is particularly related to the formulation of hypotheses, decision making, construction of models and research, organization and processing of information. Exams questions that mobilised science process skills were focused on the cognitive process of comprehension (degree 2).

With regard to the relation between theory and practice, most units were classified with $C^-$ in Biology which correspond to the units that reflect a relation between the two types of knowledge with a focus on declarative knowledge. The data of Figure 2 also shows that $C^-$ prevails in Geology syllabus which means that most units suggest a relation between declarative and procedural scientific knowledge, equal status being given to these two types of knowledge. In the exams half of the questions were classified with $C^{++}$. This classification refers to the second part of the respective instrument descriptor (Table 3), that is these questions only present procedural knowledge.

**DISCUSSION AND CONCLUSIONS**

The present study intended to appreciate the recontextualising processes that may have occurred between the messages expressed in the curriculum and the national exams of the Biology and Geology discipline in relation to the complexity of practical work. The results show the occurrence of discontinuities between the messages of the curriculum and the external assessment. Although the analysis is focused on the Portuguese educational system, the findings and methodologies of this study may be extended to other studies and may give a contribution to raising the level of conceptual demand of practical work in science education.

Through the analysis of the complexity of scientific knowledge and cognitive skills and the relation between theory and practice, it was possible to appreciate the level of conceptual demand of practical work expressed in the Official Pedagogic Discourse. When the discipline is taken as a whole (Biology and Geology together), the results evidence a considerable level of conceptual demand of practical work. However the separate analysis of the two subjects shows that Biology has a generally higher level of conceptual demand when compared with Geology. Practical work assessment in the national exams has a low level of conceptual demand, showing recontextualisation processes in the direction of lowering the level of the curriculum.

Within the curriculum have also occurred recontextualisation processes between the messages of practical work in Biology and Geology, considered as two separate components of the same discipline. One possible explanation for these discontinuities is related to the Ministry of Education selection of two different teams of authors to construct the curriculum of each one of the curricular areas. Each team of authors seemed to value different dimensions of *the what* and *the how* of pedagogic discourse. Some of these differences may also be related to the fact that Biology and Geology, although in Portugal are part of the same discipline, are epistemologically distinct curricular areas. In the case of the external assessment, the level of conceptual demand of practical work is lower than the level of the curriculum, namely in the
case of the Biology syllabuses (the area most valued in the exams questions about practical work).

With regard to the complexity of scientific knowledge, the external assessment of practical work mainly values simple concepts. There is therefore a discontinuity between assessment and the curriculum practical work messages, where the Biology syllabuses give more emphasis to complex scientific knowledge (complex concepts and unifying themes/theories). If science education is to reflect the structure of scientific knowledge then it should lead to the understanding of concepts and big ideas, although that understanding requires a balance between knowledge of distinct levels of complexity (Morais & Neves, 2016). Bybee and Scotter (2007) also present this aspect as a principle for the development of an effective science curriculum.

When the focus is the complexity of cognitive skills, the external assessment gives greater emphasis to simple skills, especially those involving the cognitive processes of comprehension. Similarly to scientific knowledge, in this case there is also a discontinuity in relation to the message of the Biology syllabuses in which complex skills prevail, particularly those associated with the cognitive process of analysis. The situation that better represents an efficient scientific learning, when practical work is implemented, is a situation where there is a balance between complex and simple cognitive skills. In this way, only when students develop simple skills, such as the memorization of certain facts and concepts, can they develop complex skills, such as applying these concepts to new situations (Geake, 2009).

In the case of the relation between theory and practice, there is also a devaluing of this relation when passing from the Biology and Geology curriculum to the national exams. For example while in the Biology syllabuses there is a relation between theory and practice, in the external assessment half of the practical work questions only focused procedural knowledge without relating it to declarative knowledge. The results of external assessment reinforces the results of other studies (e.g., Abrahams & Millar, 2008) that point out to the existence of a separation between theory and practice when teachers implement practical activities, particularly laboratory work.

In this study it was considered that the desirable situation with respect to the relation between theory and practice is a situation in which relations between declarative and procedural knowledge predominate, with more status being given to declarative knowledge in the relation. This is the situation that best represents an efficient scientific learning that is learning that is supported by the understanding and applying of science processes knowledge. The Biology syllabuses are closer to that situation.

The results of this study show that the external assessment presents a low level of conceptual demand, evidencing recontextualisation processes that reduce the level of the Biology and Geology curriculum. These are results of particular concern because external assessment tends globally to influence the curriculum in practice and specifically to condition textbook authors and teachers’ practices. All knowledge and skills that are not the subject of external assessment tends to be ignored in pedagogic practice (e.g., Britton & Schneider, 2007).
The study highlights a major issue of educational systems that are not horizontally coherent i.e. systems where assessment is not aligned with the curriculum. As Wilson and Bertenthal (2006) refer, “to serve its function well, assessment must be tightly linked to curriculum and instruction so that all three elements are directed toward the same goals” (p. 4).

ACKNOWLEDGEMENT

The authors acknowledge to Isabel Neves for her contribution in the analysis of the curriculum and national exams and in the manuscript revision. This research was partially financed by the Foundation for Science and Technology (SFRH/BD/68346/2010).

PEER-ASSESSMENT AS A LEARNING ACTIVITY FOR SECONDARY SCHOOL STUDENTS IN MODELING-BASED LEARNING

Olia Tsivitanidou¹, Costas P. Constantinou¹ and Peter Labudde²
¹ University of Cyprus, Nicosia, Cyprus
² University of Applied Sciences and Arts, Northwestern Switzerland

The aim of this study was to investigate how reciprocal peer assessment in modeling-based learning can serve as a learning activity for secondary school learners in a physics course. The participants were twenty-two upper secondary school students from a Gymnasium in Switzerland. They were asked to model additive and subtractive color mixing in groups of two, after having completed hands-on experiments in the laboratory. Then, they submitted their models and anonymously assessed the model of another peer group. The students were given a 4-point rating scale with pre-specified assessment criteria, while enacting the peer-assessor role. After implementation of the peer assessment, students, as peer assesses, were allowed to revise their models. They were also asked to complete a short questionnaire, reflecting on their revisions. Data were collected by: (i) peer-feedback reports, (ii) students’ initial and revised models, (iii) post-instructional interviews with students, and (iv) students’ responses to open-ended questions. The data were analyzed qualitatively and then quantitatively. The results revealed that, after enactment of the peer assessment, students’ revisions of their models reflected a higher level of attainment toward their model-construction practices and a better conceptual understanding of additive and subtractive color mixing. The findings of this study suggest that reciprocal peer assessment, in which students experience both the role of assessor and assessee, facilitates students’ learning in science.

Keywords: reciprocal peer assessment; modeling competence, physics instruction.

INTRODUCTION

Recent developments in the field of assessment stress the importance of formative approaches, in which assessment is realized as part of the learning process to support the improvement of learning outcomes (Bell & Cowie, 2001). Formative assessment has also received emphasis as a mechanism for scaffolding learning in science. Peer assessment, when employed formatively, can improve students’ learning accomplishment and their overall performance (e.g., specific skills and practices) in various domains including in Science Education (Grob, 2017; Tsivitanidou & Constantinou, 2016; Tsivitanidou, Zacharias, & Hovardas, 2011; Chen, Wie, Wu & Uden, 2009). Reflection processes can be enhanced in the context of reciprocal peer assessment, in which students can benefit from the enactment of the role of both the assessor and the assessee (Tsivitanidou et al., 2011). Learning gains can emerge when students receive feedback from their peers, but also when they provide feedback to their peers, because they might be introduced to alternative examples and approaches and can also attain significant cognitive progression (Hwang, Hung & Chen, 2014). This renders peer assessment not only an innovative assessment method (Cestone, Levine & Lane, 2008), but also a learning activity (Orsmond, Merry & Reiling, 1996), in the sense of co-construction of knowledge, that is, constructing new knowledge by the exchange of pre-conceptions, questions, and hypotheses (Labudde, 2000). Despite those benefits, few studies have focused on peer assessment in
modeling-based learning (Chang & Chang, 2013). As a result, there is a need to further examine what students are able to do in modeling-based learning, especially in terms of whether the experience of peer assessment could be useful for them and their peers with respect to the enhancement of their learning.

THEORETICAL FRAMEWORK

Reciprocal peer assessment and peer feedback

Peer assessment can be characterized as one-way or two-way / reciprocal / mutual, depending on the particular roles that students enact while implementing it (Hovardas, Tsivitanidou, & Zacharia, 2014). This study focuses on reciprocal peer assessment, that is the type of formative assessment in which students are given the opportunity to assess each other’s work, thus enacting both roles of the assessor and the assessee. While enacting the peer-assessor role, students are required to assess peer work and to provide peer feedback for guiding their peers in improving their work (Topping, 2003). In the peer-assessee role, students receive peer feedback and they can further use it for revising their artefacts and ultimately enhance their future learning accomplishments (Tsivitanidou & Constantinou, 2016).

Research findings have shown that, when learners are engaged in both roles of the assessor and the assessee, in the context of reciprocal peer assessment, certain assessment skills are required (Gielen & de Wever, 2015). When enacting the peer-assessor role, students need to be able to assess their peers’ work with particular assessment criteria (Sluijsmans, 2002), judge the performance of a peer, and eventually provide peer feedback. Apart from assessment skills (Sluijsmans 2002), peer assessment also requires a shared understanding of the learning objectives and content knowledge among students in order to review, clarify, and correct peers’ work (Ballantyne, Hughes & Mylonas, 2002). In the role of the peer assessee, students traditionally need to review in a critical manner the peer feedback and decide on whether and how to further utilize it for improving their own work (Hovardas et al., 2014, p. 135). In both cases, reciprocal peer assessment engages students in cognitive activities such as summarizing, explaining, providing feedback and identifying mistakes and gaps, which are dissimilar from the expected performance (Van Lehn, Chi, Baggett, & Murray, 1995).

The provision of peer feedback is also intended to involve students in learning by providing to and receiving from their peers’ opinions, ideas, and suggestions for improvement (Hovardas et al., 2014; Black & William, 1998; Kim, 2005). In the context of peer assessment, students receive feedback from peers who share a similar language level/code as their own, which may result in the feedback being more comprehensible (student-speak) compared to a feedback received from the teacher (teacher-speak) or an expert (science-speak). The peers, as assessors, have also had to perform the same task themselves, so might have a good sense of where potential problems/difficulties in executing the task could lie. Their language could speak more directly to the actual features of task performance (than that of an assessor standing outside). In fact, previous studies have revealed that peer feedback might bare more learning benefits to students than expert feedback (Frost & Turner, 2005; Yang, Badger & Yu, 2006).

Although feedback has proven to be advantageous for both learning and performance (e.g., Nelson & Schunn, 2008), it appears that not all types of feedback automatically result in
performance improvement (Kluger & DeNisi, 1996). For example, it has been shown that peer feedback comments including explanatory statements and justification are associated with the effectiveness in enhancing the performance of asessees (Narciss & Huth, 2006). Apart from that, there are certain conditions under which feedback can lead to learning benefits for students. According to Nicol and Macfarlane-Dick (2006) external feedback might be provided to a student by the teacher, by a peer or by other means (e.g. a placement supervisor, a computer). This additional information might augment, concur or conflict with the student’s interpretation of the task and the path of learning (Nicol & Macfarlane-Dick, 2006). However, to produce an effect on internal processes or external outcomes the student must actively engage with these external inputs. In effect, any kind of external feedback (provided either by peers or the teacher) has to be interpreted, constructed and internalized by the student if they were to have a significant influence on subsequent learning. Apart from the effect that feedback may entail in students’ learning, previous studies, have also revealed that providing feedback may be more beneficial for the assessor's future performance than that of asessees who simply receive feedback (Cho & Cho, 2011; Hwang et al., 2014; Kim, 2009; Nicol, Thomson & Breslin, 2014), since giving feedback is related mainly to critical thinking whereas receiving feedback is related mainly to addressing subject content that needs clarification or other improvement (Hwang et al., 2014; Nicol, et al., 2014). For these reasons, researchers argue that further research on the impact of peer feedback on students’ learning and performance is needed (e.g., Tsivitanidou & Constantinou, 2016; Evans, 2013; Hattie & Timperley, 2007).

The modeling competence in science learning

Research focusing on the modeling competence contributed significantly to the overall growth and development of research in science education (Gilbert & Justi, 2016) and that is because scientific models and modeling play an important role in the teaching and learning of science (Acher, Arcà, & Sanmartí, 2007; Hodson, 1993) by introducing learners to scientific ways of reasoning and by linking the worlds of observations and theory (Schwarz, et al., 2009). The modeling competence can be fostered in the context of modeling-based learning (Nicolaou 2010; Papaevripidou 2012), which refers to “learning through construction and refinement of scientific models by students” (Nicolaou, & Constantinou, 2014, p. 55). Papaevripidou, Nicolaou, and Constantinou (2014) proposed the Modeling Competence Framework (MCF) which suggests the breakdown of modeling competence into two categories: modeling practices and meta-knowledge about modeling and models (Papaevripidou et al., 2014; Nicolaou & Constantinou, 2014). It emerged from a synthesis of the research literature on learning and teaching science through modeling (Papaevripidou et al., 2014). Within this framework, it is suggested that learners’ modeling competence emerges as a result of their participation within specific modeling practices, and is shaped by meta-knowledge about models and modeling (Schwarz et al., 2009). In this study, we focused on students’ modeling practices of model construction and evaluation, because these are essential processes that lead to successful and complete acquisition of the modeling competence (Chang & Chang, 2013; NRC, 2007; NRC, 2012). In addition, in the context of modeling-based learning, a few studies (e.g., Chang & Chang, 2013; Pluta, Chinn, & Duncan, 2011; Tsivitanidou, Constantinou, Labudde, Rönnebeck, & Ropohl, 2017) have provided evidence specific to the educational
value of teaching-learning activities that involve the evaluation of models by students themselves. The evaluation of models as a process involves engaging students in discussing the quality of models for further improvement and revision (Chang, Quintana, & Krajcik, 2010; Schwarz & Gwekwerere, 2006; Schwarz & White, 2005; Schwarz et al., 2009). Considering that previous research in this direction is scarce (Tsivitanidou, et al., 2017) there is a need to further investigate what students can do when assessing peers’ models and how peer assessment, in modeling-based learning, can foster students’ model-construction practices, as well as their conceptual understanding of scientific phenomena (Chang & Chang 2013; Pluta et al., 2011).

Objectives of this study

In this study, we aimed to examine whether reciprocal peer assessment, when employed formatively, can facilitate students’ learning in science. In particular, we sought to examine how the enactment of the peer-assessor and peer-assessee roles is associated with students’ improvements on their own constructed models, after enacting reciprocal peer assessment. In this study, we focused on students’ modeling practices of model construction and evaluation (Schwarz & White, 2005). The research question that we sought to address was: Is there any evidence suggesting that the enactment of reciprocal peer assessment is related to secondary school students’ learning benefits in modeling-based learning in the context of Light and Color?

METHODOLOGY

Participants

The sample consisted by N = 22 upper-secondary school students coming from a Gymnasium, in Northwestern Switzerland. Overall, there were almost equal numbers of girls and boys (12 girls and 10 boys). Students worked in randomized pairs in most activities and the pairs remained unchanged throughout the intervention. There were eleven groups of two students (home groups). The home groups were coded with numbers (1 to 11), and within each group, the students were also coded (as Student A and Student B). As confirmed from the post-instructional interviews with eleven participants, most of them (n = 8) had experienced oral and / or written peer assessment in the past in different subjects.

Teaching material

The sequence was grounded in collaborative modeling-based learning, during which students were asked to work in their groups and collaboratively construct their model. The students worked through the learning material on the topic of light and color in the context of their physics course. The curriculum material required the students to work, in groups of twos (home groups), with a list of hands-on experiments on additive and subtractive color mixing. Those activities lasted four meetings of 45 minutes each (week 1 and 2). In the meeting that followed (week 3), and after having completed the experiments, students in each group were instructed to draw inferences relying on their observations and the gathered data. Their inferences were explicitly expected to lead to a scientific model which can be used to represent, interpret, and predict the additive and subtractive color mixing of light. For doing so, students were provided
with a sheet of paper, color pencils, and a list of specifications that they were asked to consider when developing their model. Finally, in the last meeting (week 4), the students implemented the peer-assessment activity (models exchange, peer review, revision of models). Overall, it took the student groups six meetings (lessons) of 45 minutes to complete this sequence, in a total period of four weeks.

**Peer-Assessment Procedure**

As soon as the students had finalized their models in their home groups, they exchanged their models with other groups, that is, two groups reciprocally assessed their models (e.g. home group 3 exchanged its model with the model of home group 4). The pairs of groups involved in the exchanges were randomly assigned by the teacher. Peer assessors used a 4-point Likert rating scale with eight pre-specified assessment criteria for accomplishing the assessment task. The assessment criteria were addressing the Representational Power (PP), Interpretive Power (IP) and Predictive Power (PP) of the model and thus they were in line with the list of specifications that was given to the students prior to the model-construction phase. Assessors rated their peers’ models on all criteria in accordance with the 4-point Likert scale. Along with the ratings, assessors were instructed to provide assessee groups with written feedback (for each criterion separately), in which they were to explain the reasoning behind their ratings, and provide judgments and suggestions for revisions. On average, it took each peer assessor 15 minutes to complete the assessment (SD = 2.0). Once the students had completed the assessment of their fellow students’ models on an individual basis, they provided the feedback that they had produced to the corresponding assessee group. Therefore, each home group received two sets of peer feedback from another peer group. During the revision phase, students in their home groups collaboratively reviewed the two peer-feedback sets received from the corresponding assessor group. Students were free to decide on whether to make any revisions to their model. By the end of the revision phase, students responded, in collaboration with their group mate in their home groups, to two open-ended questions which were given to them for reflection purposes (Question A: “Did you use your peer’s feedback to revise your model? Explain your reasoning.” Question B: “Did you revise your model after enacting peer assessment? Explain your reasoning.”). By the end of this intervention, eleven students (each from a different home group) were interviewed individually about their experience with the peer-assessment method. Each interview lasted approximately 15 to 20 minutes. Students were first asked about any previous experience in peer assessment; then they were asked whether they found peer assessment, as experienced in this study, useful assuming the role of the peer assessor and peer assessee respectively. Interview and post-instructional questionnaire data were used for triangulation purposes.

**Data sources**

At the beginning of the intervention, a consent form was signed by the students’ parents for allowing us to use the collected data anonymously for research purposes. The following data were collected: (i) students’ initial models; (ii) peer-feedback reports; (iii) students’ revised models; (iv) post-instructional interviews with eleven students, and (v) home-groups’ responses to the two open-ended questions at the end of the intervention.

1409
Data analysis

We used a mixed-methods approach that involved both qualitative and quantitative analyses of the data. In particular, the data were first analyzed qualitatively and then also quantitatively with the use of the SPSS™ software, except for the interviews and students’ responses to the two open-ended questions which were only qualitatively analyzed. We examined each student’s learning progression as reflected in the quality of their initial and revised models, with respect to the intended learning objectives. In case of revisions applied by students, we further examined possible parameters which might have let the students proceed with the revisions in their models. Inter-rater reliability data were also collected [Krippendorff’s Alpha coefficient > 0.79 for the coding of peer-feedback data and initial and revised models; Cohen’s Kappa > 0.80 for qualitative (categorical) items].

RESULTS

The data analysis revealed that ten, out of eleven home groups, revised their models, after the enactment of peer assessment. All revisions applied by assessees were found to improve the quality of their initial models; in other words, no case was identified in which assessees proceeded to revisions that undermined the quality of their initial model. This implies that students, as assessees, were able to filter invalid comments included in the peer feedback received.

We first analyzed students’ initial models (before the enactment of peer assessment). The data analysis revealed different levels of increasing sophistication displayed by the students for each component, which align to some of the levels suggested by Papaevripidou et al. (2014). Table 1 shows six levels of increasing sophistication that illuminate the degree of development of the learners’ model construction practices, along with the coded student groups assigned to each level. We further analyzed the students’ models with respect to the extent to which they drew on the relevant specifications in a valid manner while constructing their models (see table 2).

We then analyzed students’ revised models (after the enactment of peer assessment). The revised models of most of the student groups indicated that the students switched to a higher level of attainment in terms of all relevant aspects of their models, including the validity of those aspects (see Tables 1 and 2).

The revised models of most of the student groups indicated that those students switched to a higher level of attainment in terms of all relevant specifications of their models (Representational Power: PP; Interpretational Power: IP; and Predictive Power: PP), including the validity of those aspects. A Wilcoxon rank test showed statistical significant differences between the quality of initial and revised models with respect to the degree to which students had thoroughly addressed the three specifications (RP, IP, and PP) in their models ($Z = -3.270; p < .01$). Likewise, statistical significant differences were found between the validity of initial and revised models with respect to the RP ($Z = -2.0; p < .05$) and PP ($Z = -3.376; p < .01$).

The type of peer-feedback comments received by assessees was found to be related with the quality of the initial models of the assessees. In particular, negative comments (i.e., references in the peer-feedback comments to what the assessees had not yet achieved) (Kendall’s $T_b = -$
0.373, p < .05) and also justified negative comments (Kendall’s $T_b = -0.348, p < .05$) were related with the quality of assessees’ initial models. The data analysis revealed that all revisions (in terms of the student group’s attainment of the modeling competence) identified in the revised models of three groups (Groups 3, 8 and 10) were suggested in the peer feedback received, whereas in the revised models of seven groups (Groups 1, 2, 4, 5, 6, 7, and 9) only some revisions were suggested in the peer feedback received. In other words, we identified revisions in the models of seven groups, which were not suggested in the peer feedback comments received from peer assessors. For example, students from Group 1 added an explanation (i.e., “if green and red coincide, yellow is formed”) in their revised model which was not included in the peer-feedback comments offered by their peer-assessors (students from Group 2). When examining the initial model of Group 2 (peer-assessors), we detected a sentence resembling the revision of assessesee Group 1 (i.e., “We have 3 sources of light: blue, red and green. If they coincide, one of the colors shown on the figure is formed”). This is an indication that students from Group 1 might have borrowed this idea while they were assessing the model of Group 2. Triangulation—with data from the post-instructional reflective questionnaire and the interviews with the students—revealed that students proceeded to revising their models, not merely due to the reception of peer feedback comments, but also due to the enactment of the peer assessor role (e.g., engagement to self-reflection processes; exposure to alternative examples while assessing peers’ models).

**DISCUSSION**

This study focused on examining how reciprocal peer assessment in modeling-based learning can serve as a learning tool for learners in a secondary school physics course, in the context of light and color. The findings of this study show that reciprocal peer-assessment—experienced by the students in the roles of assessor and assesse—enhanced their learning in the selected topic, as inferred by the quality of their revised models. It is vital to consider that between the model construction and the model revision phase, no instruction or any other kind of intervention took place; therefore, any possible improvements identified in students’ revised models arose due to the enactment of peer assessment and in particular either due to the experience that students gained while acting as peer assessors or due to the exploitation of peer feedback received in the peer-assessee role or both.

Students, as assessees, acted on most or all suggestions provided by their peers for revising their models. Students in this study were not reluctant to accept their peers as legitimate assessors, contradicting findings from previous studies (e.g. Tsivitanidou, et al., 2011; Van Gennip, Segers, & Tillema, 2010). They used the peer feedback received from their peer assessors for revising their models and those revisions improved the quality of their models in terms of their RP, IP and PP, as well as in terms of the scientific accuracy of their models. They were able to wisely use the peer feedback received, by filtering peer-feedback comments and finally proceeding with revisions that improved the quality of their initial model with respect to the intended specifications. Students did not proceed with revisions which could potentially undermine the quality of their model. Hence, we have indications of the participants’ skills to interpret feedback in a meaningful way and to use to wisely for improving their models. In fact, the analysis revealed that even in cases of receiving invalid feedback comments assessees were
able to filter such invalid comments, as already suggested in previous studies (Hovardas et al., 2014). However, not all revisions detected in assessees’ revised models, were explicitly or implicitly suggested in the peer-feedback comments received. We searched for evidence about the possible reasons which might have led assessees to applying those revisions in their models.

The data analysis indicated that assessees revised their models also due to the opportunity which they were offered to act as assessors. In particular, the findings of this study suggest that when students enact the peer-assessor role, they are exposed to alternative examples (i.e., their peers’ artefacts) (Tsivitanidou & Constantinou, 2016) which might inspire students to further revise their own artifacts. Also, while enacting the peer-assessor role, the students reconsider the learning objectives that should have been addressed and therefore better appreciate what is required to achieve a particular standard (Brindley & Scoffield, 1998). Moreover, the findings of this study suggest that when students enact the peer-assessor role, they are also engaged in self-reflection processes. Peer assessment, as a process itself, requires self-reflection and in-depth thinking (Cheng, Liang, & Tsai, 2015) and this process bares learning benefits for students. Indeed, students in this study claimed in the post-instructional interviews that while assessing their peers’ models, they were engaged in self-reflection processes. They also reported that the opportunity which was given to them to compare—at least implicitly—their own model with that of another peer group while assessing, made them realize what they had interpreted wrongly or not on the basis of their experimental results. This comparison strategy applied by assessors in this study resembles the comparative judgment approach which has been reported as a method that assessors may endorse when offering peer feedback, even if not instructed to do so (Tsivitanidou & Constantinou, 2016).

In this vein, receiving peer feedback while also providing peer feedback was beneficial for students’ learning progress. Previous studies in science education have shown that students can benefit from the enactment of peer assessment in terms of their learning (e.g., Prins, Sluijsmans, Kirschner & Strijbos, 2005; Tsai, Lin & Yuan, 2002). The findings of this study suggest that those benefits can also arise in modeling-based learning. We can argue that reciprocal peer assessment can serve as a learning method, confirming findings of previous studies in other contexts and teaching approaches (Orsmond et al., 1996), since students in this study benefited from the reciprocal peer-assessment method, not merely because of receiving peer feedback, but also because they were given the opportunity to act as assessors. The fact that reciprocal peer assessment in modeling-based learning can facilitate students’ learning in science, needs to be considered, first, by policy makers and second, by educators, for integrating peer assessment and modeling-based learning in the curriculum and in the everyday teaching practice, respectively.

A TEACHER PERSPECTIVE ON BENEFITS AND CHALLENGES OF PEER-ASSESSMENT

Regula Grob¹,², Monika Holmeier¹ and Peter Labudde¹
¹Center for Science and Technology Education, University of Applied Sciences and Arts Northwestern Switzerland, Basel, Switzerland
²University of Teacher Education, Fribourg, Switzerland

Formative assessment has been suggested as a means to support student learning in inquiry-based science education. However, teachers need support in implementing formative assessment practices, such as peer-assessment, in their daily teaching. As a prerequisite for shaping suitable means of support, primary and upper secondary teachers’ perspectives on benefits and challenges of peer-assessment in inquiry learning have been explored. Data was collected from 7 primary and 10 upper secondary school teachers from Switzerland who implemented peer-assessment in their science classes. The data included teaching plans, evaluation forms, individual interviews, and group interviews. Inductive coding of the data revealed that the teachers perceived challenges of peer-assessment at the level of teaching practice but also at the level of educational policy. These results suggest that different measures of support such as professional development programmes, but also concrete examples and tools as well as guidelines from educational policy are needed. Considering the benefits of peer-assessment, the teachers from both school levels did not only believe that peer-assessment enhances student learning but also anticipated social and motivational effects. This result implies that formative assessment theories should be more closely connected to learning theories in which student motivation has been identified as a main contributor to learning.

Keywords: formative assessment, peer-assessment, inquiry-based science education

INTRODUCTION

Problem statement

Inquiry and other competence-oriented approaches have become important parts of science education in the recent decades. One issue, however, has been how to support students in their inquiry learning and how to assess respective student competences (e.g. Harlen, 2013). A possible answer to this is the promotion of formative assessment at an international (e.g. OECD, 2005; 2013), but also at a national level (e.g. in the curriculum for the compulsory school levels for the case of Switzerland, D-EDK, 2014). But as a number of studies show, the use of formative assessment in teaching practice varies greatly between teachers (Black, 1993; Bell & Cowie, 2001; Heritage, 2010; Herman, Osmundson & Silver, 2010; Stiggins, Griswold & Wikeland, 1989). The quality of formative assessment rests to a high degree on the strategies teachers use to elicit evidence of student learning and on the use of this evidence to shape subsequent instruction and learning (Bell & Cowie, 2001; Ruiz-Primo, Furtak, Ayala, Yin, & Shavelson, 2010). Subsequently, the need of help for the teachers is stated: “Simply embedding assessments in curriculum does not guarantee improved learning and teaching. Teachers need tremendous support using assessment in their teaching practice” (Yin, et al., 2008, p. 356). The focus of this study will therefore be on science teacher perspectives on peer-assessment, a formative assessment method relatively well-described in the literature (e.g. Topping, 2003), in the context of inquiry learning.
Literature review

Formative assessment has the purpose of assisting learning and for that reason is also called ‘assessment for learning’. It involves processes of “seeking and interpreting evidence for use by learners and their teachers to decide where the learners are in their learning and where they need to go and how best to get there” (Assessment Reform Group ARG, 2002, p. 2). The following four characteristic features for an operationalisation of ‘formative assessment’ were found: (1) Clarity in expectations (e.g. Black, Harrison, Lee, Marshall & Wiliam, 2004); (2) Diagnosis of student level with respect to expectations (Ruiz-Primo et al., 2010); (3) Presence of feedback (Furtak & Ruiz-Primo, 2008) (4) Opportunity to use this feedback (e.g. Andrade, 2010).

For the context of inquiry-based science education, a number of concrete methods of formative assessment have been suggested (e.g. Barron & Darling-Hammond, 2008). The focus of this study will be on peer-assessment which is defined as a process in which students assess their peers’ work and provide feedback on it (e.g. Topping, 2003). Peer-assessment follows the idea of "activating students as instructional resources for one another" (Leahy, Lyon, Thompson & Wiliam, 2005, p. 21): Students take both the role of the assessor and the asessees by assessing each other’s work. The aim of peer-assessment is to assist peers in identifying the strengths and weakness of their work and to provide suggestions for improving it (Dochy, Segers & Sluijsmans, 1999; Topping, 2003).

A number of advantages and challenges that are associated with peer-assessment have been identified in the literature. The advantages of peer-assessment are, firstly, that feedback from peers who had the same difficulties in the learning progress might suggest direct ways to overcome those difficulties, and formulate them in a language that is naturally used by the students (Black et al., 2004). Secondly, students who assess their peers’ work engage in cognitively demanding activities, such as critical thinking (Hanrahan & Isaacs, 2001; Harlen, 2007; Lin, Liu & Yuan, 2001; Lindsay & Clarke, 2001; Topping, 2003; Tsivitanidou, Zacharia & Hovardas, 2011). Thirdly, students get the opportunity to see examples of other students’ work. This can potentially lead to self-assessment: By comparing their own work to that of their peers, students can be prompted to reflect on their own learning achievements (Hanrahan & Isaacs, 2001; Lin et al., 2001; Topping, 1998; 2010). Fourthly, peer-assessment may be easier to accept since it is perceived less authoritative than feedback from adults and therefore open to negotiation (Cole, 1991; Topping, 2010). Fifthly, feedback from peers can be more immediate, timely, and individualized than feedback from the teacher (Topping, 2010) simply because there are many more students than teachers in a classroom. Lastly, providing feedback to peers develops the social, communicative, meta-cognitive and other personal and professional skills on the way (Topping, 2010).

Beside the aforementioned advantages, a number of challenges of peer-assessment have also been identified in the literature: When doing peer-assessment, students need to judge the performance of a peer. This needs a certain degree of knowledge in the field that is assessed (Topping, Smith, Swanson & Elliot, 2000). Furthermore, students need to communicate the judgments to their peers and need to provide constructive feedback about their learning process for which communication skills are necessary (Black, Harrison, Lee, Marshall & Wiliam
Thirdly, the recipients need to critically review the feedback and decide on the actions to be taken: Since peer-feedback might include flaws, the recipients need to filter it and then decide whether there is a need to adopt the peers’ suggestions and to revise their work (Sluijsmans, 2002). Fourthly, peer-assessment costs lesson time for organization, training and monitoring, particularly in the beginning, if it should be provided at a good level of quality (Topping, 2010). Lastly, social processes influence and contaminate the validity and reliability of assessment provided by peers (Topping, 2010).

**Statement of intentions**

Following the problem statement, the exploration of the teacher perspective on formative assessment methods such as peer-assessment is considered relevant for a successful implementation of respective approaches. Teachers’ perceptions of the benefits and challenges of peer-assessment will therefore be investigated and the implications for supportive measures for the implementation of peer-assessment in inquiry-based science education will be discussed. Furthermore, a widening of the conceptual framework for formative assessment is suggested based on the results.

**METHODS**

For this study, a 3-semester cooperation with 20 science teachers in Switzerland (9 primary, 11 upper secondary) was established. In every semester, the teachers incorporated a formative assessment method from a pre-defined list (including peer-assessment) in one of their normal inquiry units. The methods were used to assess one or several student competences from another pre-defined list (including, for example, investigation competence, argumentation competence, and modelling competence). The cooperation also included regular meetings with all the teachers, and a teacher manual on the assessment methods which also included illustrative examples.

**Data collection**

The teachers provided their teaching plans and -materials (student worksheet etc.) from their trials and filled out an evaluation form in which they reflected upon the benefits and challenges of the assessment method. No more than ten days after the trials, individual interviews were held with a sub-group of the teachers (consisting of n=8 teachers from both school levels) in order to speak about the trials and about general issues related to assessment in more detail.

**Data analysis**

Based on the teaching plans and the teaching materials, it was decided whether the trials included a formative assessment activity. This was evaluated with the four characterizing features of formative assessment as introduced in the literature review. Afterwards, it was decided whether the formative assessment activity was peer-assessment. The respective criterion was whether the students diagnosed and provided feedback on their peers’ work. This resulted in 7 primary and 10 upper secondary school cases.

For the analysis of the benefits and the challenges of peer-assessment, the evaluation forms (n=17 evaluation forms) and the transcripts from the individual interviews (n=8 interviews)
were inductively coded. This led to a coding frame with 8 categories for the challenges and 5 categories for the benefits which will be presented in the results part. 18% of the data was double-coded ($\kappa = 0.89$).

RESULTS

Looking at the challenges, the teachers mentioned difficulties related to the planning of peer-assessment activities (challenge 1). Furthermore, the teachers expressed their doubts about the quality of the diagnosis done by peers (challenge 2), about the quality of the feedback provided by peers (challenge 3), and their uncertainty about their own role (challenge 4). The teachers also anticipated that some of the students might not consider the feedback received from peers to revise their work (challenge 5) or that assessing peers could be boring for students (challenge 6). Another aspect was the role of peer-assessment within the assessment framework, for example the relation between peer-assessment and grading from the teacher (challenge 7). Peer-assessment was also considered rather time-intensive and dependent on a good training of the students (challenge 8).

Considering the benefits, the teachers mentioned that the feedback is provided in a language that is naturally used by the students and it is accepted because the assessor is a peer (benefit 1). Furthermore, the responsibility for the learning in a peer-assessment setting lies with the students, resulting in a lower workload for the teachers and a higher capacity for individual support (benefit 2). The teachers anticipated learning effects in inquiry-specific but also in transversal competences (benefit 3) as well as effects on the classroom climate and the students’ motivation (benefit 4). Lastly, the low preparation time for the teacher (benefit 5) was mentioned.

One of the emerging results from the benefits of peer-assessment as mentioned by the teachers is that the teachers from both school levels did not only perceive learning effects (see benefit 3) from peer-assessment but also social and motivational effects (see benefit 4; illustrative quotes: “Peer-assessment enhances the relation between the students”; “Peer-assessment is a way to take students serious and to give value to what they say. This motivates them in their work”). This aspect will be discussed in more detail in the next section of the paper.

DISCUSSION AND CONCLUSIONS

Comparison of the results to the literature

Comparing the benefits and challenges of peer-assessment as mentioned by the teachers in the study to the results found in the literature, a number of aspects are similar. The specific language characteristics of feedback formulated by peers and the responsibility for learning have been previously reported in Black et al. (2004). No references on the resulting capacities of the teachers were found in the research literature, however. The effects of peer-assessment on the students’ transversal competences (Topping, 2010) and on self-regulated learning (Hanrahan & Isaacs, 2001; Lin et al., 2001; Topping, 1998; Topping, 2010) have also been previously mentioned but not the effects on the classroom climate and on the students’ motivation as anticipated by the teachers in this study. The preparation time was not covered in the literature either.
Considering the challenges, the planning issues as brought up by the teachers in this study are not mentioned in the literature. The quality of the diagnosis (Topping et al., 2000; Topping, 2010) and the quality of the feedback (Black et al., 2003) have been previously discussed. The uncertainty about the own role that resulted, according to the teachers in this study, from the questionable quality of the diagnosis and the feedback, was not found in the literature. The lesson time and the training needed were recognized by Topping (2010), too. None of the teachers in the study spoke about the difficulties in what feedback to use for revision as reported in Sluijsmans (2002).

Overall, the benefits of peer-assessment perceived by the teachers in this study are similar to what is mentioned in the research literature. These effects appear to be independent of the school level and the country-specific context. The social and motivational benefits from peer-assessment have not been found in the literature, though. This will be discussed in more detail in the paragraph ‘widening of the theoretical concept needed’ below.

The challenges of peer-assessment in the literature were not specifically focussed on the perspective of the teachers nor on organisational issues, resulting in a smaller congruence between the results of this study and the research literature. However, it becomes apparent that the challenges of peer-assessment cannot be neglected.

**Support needed**

The challenges of peer-assessment appear to need support at different levels to be overcome: Professional development as well as concrete teaching resources could help teachers to enhance their own assessment literacy (see challenges 1, 4) but also to let the students improve their abilities in diagnosing, providing and using peer-feedback (see challenges 2, 3, 5, 6, 8). The role of peer-assessment in the assessment framework (see challenge 7) was the only challenge mentioned that is not situated at the level of teaching and learning practice. Rather, it refers to a more strategic level, with teachers needing help in understanding the relation between formative assessment methods and summative as well as evaluative methods. Guidelines from educational policy representatives could help to clarify the relation between formative and summative assessment.

**Widening of theoretical concept needed**

Regarding the benefits of peer-assessment, the teachers did not only perceive learning effects but also social and motivational effects. This is not aligned with formative assessment theory which focusses on the former by conveying the idea that formative assessment supports student learning (Black & Wiliam, 1998; Natriello, 1987). Interdependencies between formative assessment and student motivation (Black & Wiliam, 1998) and a relation between formative assessment and student confidence (Smit, 2009) have been suggested, but literature on these effects is generally scarce. The result suggests that the formative assessment theory should be widened towards learning theories in which student motivation has been identified as a main contributor to student learning.
Retrospects and prospects

The aim of this study was to explore teachers’ perceptions on benefits and challenges of peer-assessment in order to shape suitable means of support for teachers. The study was conducted with a small number of participants and in an open setting where the teachers designed the inquiry units themselves. It is therefore hard to decide on the specificity of the results (e.g. to what extent the challenges refer to peer-assessment specifically rather than to formative assessment methods in general). Nevertheless, the participating group of teachers included different school levels, subjects, years of teaching experience and gender. Furthermore, the rich data on the teachers’ trials and their reflections upon them provide a dense picture of the teachers’ perspectives on peer-assessment in the context of inquiry.

The study results in two main outcomes: Firstly, it offers first ideas on how to support the uptake of more peer-assessment in daily teaching practice. Secondly, it provides implications on how to further develop formative assessment theories.

ACKNOWLEDGEMENT

DEVELOPMENT AND VALIDATION OF LEARNING PROGRESSIONS ON CHEMICAL CONCEPTS

Kübra Nur Celik and Maik Walpuski
University of Duisburg-Essen, Essen, Germany

The development of scientific literacy is very important for lifelong learning and the understanding of core concepts in science (AAAS, 2007). At the same time, a study conducted in North Rhine-Westfalia in Germany as a national assessment (Pant et al., 2013) shows that a lot of students perform only poorly in standardized assessment tests in chemistry and do not even reach the necessary basic skills. These students often lose track in chemistry instruction because of their early knowledge deficits and inability to catch up accordingly. To support these low-achievers it is important to investigate how essential ideas and concepts are related to each other and how they contribute to the logical (in large parts hierarchical) structure of chemical knowledge. For the German context learning progressions for the chemical concepts “Structure of Matter”, “Chemical Reaction” and “Energy” (c.f. MSW, 2011) for the first two learning years in chemistry instruction have been developed, with several core ideas and their specific requirements. The first aim of the presented project is to evaluate these learning progressions empirically. In addition, it focuses on defining achievable minimal knowledge levels that guide all students to gain scientific proficiency in the long run. On the basis of performance tests specific to the assumed learning progressions it is possible to identify interdependencies between the core ideas and evaluate the progressions’ validity. The pilot study reported here primarily describes the test instrument, its test parameters and possible methodological considerations for analyzing the main study data, which is not yet complete.

Keywords: learning progressions, competencies, chemical concepts

INTRODUCTION AND THEORETICAL FRAMEWORK

Problem and initial situation

Similar to other nations, Germany has introduced educational standards, which describe competencies the students should have acquired by the end of a particular grade (KMK, 2005). These educational standards are formulated as general standards addressing the average performance level (Klieme et al., 2007). However, the 2012 IQB national assessment study (Pant et al., 2013) revealed that German students, particularly in North Rhine-Westphalia, perform lowly on these standardized assessment tests in chemistry. With regard to an US study (Alonzo & Gotwals, 2012) it can be assumed that low test results may be related to unfocused and disconnected science education. The reason for this could lie in the largely hierarchical structure of chemistry knowledge. The hierarchical structure might put students, particularly low-achieving ones, who lost track at some point during chemistry instruction, at a disadvantage, where they are unable to catch up on the content. In order to support these students it is necessary to investigate the relationship between essential ideas and concepts in chemistry and their contribution to meaningful learning and knowledge structures. One possible approach is to map the interdependencies as learning progressions and use them as a guiding framework for structuring chemistry instruction within the first two learning years in chemistry. Teachers might also use the learning progressions to identify difficulties...
understanding concepts and ideas on an individual basis and derive according supporting measures.

**Theoretical framework**

This study uses the concept of learning progressions as a way of describing the structure of chemical content knowledge. Learning progressions propose the development of essential core ideas that support cross-linked knowledge and can be read as possible learning pathways to develop professional competencies. They also postulate a particular sequence of abilities and core concepts, which students have to acquire over time (e.g. Corcoran, Mosher, & Rogat, 2009; Duschl, Schweingruber, & Shouse, 2007; Duncan & Hmelo-Silver, 2009; Stevens, Delgado, & Krajcik, 2009).

Learning progressions consist of several core ideas the students have to understand. Students enter the progression with their prior knowledge and abilities (lower anchor). They proceed through predetermined learning pathways successively to achieve the learning targets which describe skills and knowledge for end of the progression (upper anchor) (Corcoran, Mosher, & Rogat, 2009). The levels between the lower and upper anchor are defined by the learning performances which set the level of understanding and competencies students would be able to perform (Corcoran, Mosher, & Rogat, 2009; Duncan & Hmelo-Silver, 2009).

Other studies have already used learning progressions successfully. The American Association for the Advancement of Science (AAAS, 2007), for instance, aspires in “Project 2061” the idea of developing scientific literacy for all students and developed learning progressions for various domains in science education, such as Physical Science and Earth Science. They used strand maps to visualize the development of students’ understanding of core ideas at different stages of progress and represent the link between core ideas and learning targets to diagnose students’ conceptual abilities (AAAS, 2007). There have also been first attempts at developing and validating a learning progression via strand maps for the concept of energy in physics in the German context (Neumann, Viering, Boone, & Fischer, 2013). In addition, first investigations of core ideas related to the basic concept “Structure of Matter” and “Chemical Reaction” in chemistry have already been conducted, as well (Weber, Emden, & Sumfleth, 2016). However, rare attention has been paid to a learning progression for all three basic concepts in chemistry and the interdependencies of their core ideas.

**PROCEDURE AND DESIGN**

**Research questions**

The following research questions are addressed by this study:

1. Can the developed Learning Progression be validated empirically?
2. Is there an interdependency between the chemical concepts? Are requirements from one chemical concept necessary to achieve requirements from a different chemical concept?
Study context and preliminary work

In a quasi-longitudinal study, students in the first two learning years in chemistry instruction at comprehensive schools in North Rhine-Westphalia are tested. Prior to testing, a working group consisting of science education researchers, school teachers and educational administration stakeholders has developed a preliminary strand map and its core ideas as anchors. On the basis of educational standards for chemical education (KMK, 2005), school books and school curricula this team has identified 57 core ideas for the three chemical concepts “Structure of Matter”, “Chemical Reaction” and “Energy” (c.f. MSW, 2011) for the first two learning years in chemistry (Table 1). This is the equivalent of grades 8 and 9 at the lower secondary level in Germany.

Table 1. Distribution of the developed 57 core ideas across the three chemical basic concepts for the first two learning years in chemistry.

<table>
<thead>
<tr>
<th></th>
<th>1st learning year</th>
<th>2nd learning year</th>
</tr>
</thead>
<tbody>

<td>19</td>
</tr>
<tr>
<td>Chemical Reaction</td>
<td>6</td>
<td>7</td>
</tr>
<tr>
<td>Energy</td>
<td>7</td>
<td>5</td>
</tr>
</tbody>
</table>

Each core idea is framed by a description of what students are expected to know and be able to do if they have fully understood the core idea. Additionally, boundaries were formulated describing what students are not expected to know at this point. Usually these boundaries are defined by content of another core idea or the complexity of the content idea for this level). Typical misconceptions of students are also related to the core ideas and can be used as distractors in the assessment test (Figure 1).

These chemical core ideas were then brought into a logical sequence and were connected via stand maps (analogous to the project of AAAS (2007)) (Figure 2).

The strand map considers the hierarchical arrangement of the core ideas over the first two learning years and differentiates between necessary and sufficient requirements for a meaningful construction of knowledge. Requirements, which are assumed to be necessary for the understanding of the hierarchically higher core idea are represented with red arrows and the requirements, which are not assumed to be necessarily relevant for the hierarchically higher core idea are represented with black arrows (Figure 2).
Basic concept: Structure of Matter

Core idea: Protons and neutrons can be found in the atomic nucleus and constitute almost the whole mass of an atom, while electrons are located in the electron shell and determine the size of an atom (Rutherford).

Expectations: Students are expected to know that ...
- forces act between the elementary particles of an atom.
- the electrons build the atomic shell.
- the protons and neutrons build the atomic nucleus.
- the mass of an atom is almost completely determined by the atomic nucleus.
- the size of an atom is determined by the atomic shell.
- an atom predominantly is void.
- proton and neutron each have a mass of one u.

Boundaries: Students do not have to know (for this core idea) ...
- that the mass of proton and neutron are marginally different.
- which influence the electron has on the mass of an atom.

Typical misconceptions:
- The atomic shell contains air.
- The atomic shell is an actual shell.

Figure 1. Description of a core idea.

Figure 2. Exemplary part of the strand map for the chemical basic concepts “Structure of Matter” and “Chemical Reaction” for the first two learning years.
Test items and test design

In order to test the validity of this purposed strand map as well as to assess students’ abilities it was necessary to develop suitable test items. The test items reflect each core idea and its according expectations which the students are expected to know. For a sufficiently large item pool at least five test items have been developed for each of the core ideas (Table 1). This resulted in a total of 329 items in a multiple-choice single-select format. In the pilot study this item pool was used to identify problematic items which should be removed for a final test instrument. Due to the large number of items, a multi-matrix design was realized, where the test items were distributed among 25 different test booklets. The test booklets were constructed by considering the relations between the core ideas in the strand map (Table 2).

<table>
<thead>
<tr>
<th>Test booklet</th>
<th>Items for the main core idea</th>
<th>Items for the directly connected core ideas</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Structure of Matter 7.6</td>
<td>Structure of Matter 7.11, 7.12, 7.13;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Chemical Reaction 7.2, 7.4</td>
</tr>
</tbody>
</table>

Note: The core ideas Structure of Matter 7.13 and Chemical Reaction 7.2 are also represented as main core ideas because all items of the directly connected core ideas are in this test booklet.

In consequence, not all the 25 test booklets contain the same amount of items because of the differing number of relations in the strand map between core ideas. While constructing the test booklets it was also necessary to pay attention to items giving the answer to succeeding ones. In order to achieve a true multi-matrix design, each test booklet was anchored via overlapping items of at least one core idea so that an overall analysis of all test items was ensured. The test items were administered to 787 students from grades 8 to 10. In the German school system these grades typically correspond to the first three learning years in chemistry. Grade 10 (third learning year) students were tested additionally by intention to obtain data from students who are expected to know all core ideas and to generate sufficient variance in the performance of the students.

Methods

The basis for the following analyses are unidimensional Rasch models from item response theory as it is expected that items are not equally difficult to solve. To make valid statements about the quality and reliability of the test items, they were analyzed with regard to their test parameters and model fit parameters. These items were also ordered with increasing item difficulty on a Wright Map to get a first rough estimation of whether the whole item difficulty spectrum is covered for all three basic concepts and items for hierarchically higher core ideas (second learning year) are more difficult than lower ones (first learning year). All analyses were conducted using ConQuest® software (Wu, Adams, & Wilson, 2007).
Results of the pilot study

The following results refer to the pilot study data of $N = 787$ students (50.3 % female). Of this sample, 33.7 % are from the first learning year, 53.1 % from the second learning year and 13.2 % from the third learning year. The students should work on items whose item solution they know. So that all of the crude and wrong answered items were assessed as false. Besides, the items would not be answered in the same number so that in an incomplete block design for the core ideas each item reached 32 responses in average. The following table (Table 3) presents the model fit parameters of all 329 multiple-choice single-select items. All, but are within the weighted-Mean-Square threshold value between 0.80 and 1.20. In addition, the $t$-statistics for all but three fall within the tolerable range of $-1.98 < t < 1.98$. The item reliability is excellent so that the item difficulties are estimated accurately. The EAP/PV reliability is also satisfying (0.828), which means the estimated person abilities are accurate, as well.

Table 3. Fit statistics of the 329 test items.

<table>
<thead>

<td>0.913</td>
<td>-1.936 - 3.954</td>
<td>0.8 - 1.22</td>
<td>-3.4 – 3.3</td>
</tr>
</tbody>
</table>

Items with problematic fit measures were analyzed in more detail via distractor analyses. An observation of the according item characteristic curves and their item discrimination values revealed that they had anomalous curve patterns and therefore should be revised or removed from the test instrument.

The item difficulty varies between $M = 0.6169$ ($SD = 0.0779$) logits for the first and $M = 1.3096$ ($SD = 0.0613$) logits for the second learning year. A paired $t$-test reveals a significant difference between them with a medium-sized effect ($t(297.841) = -6.981$, $p < .001$, $d = 0.77$). Hence, items for the second learning year are significantly more difficult than items for the first year.

In the strand map the core ideas are hierarchically arranged. Therefore, the item difficulties are expected to be different for the first two learning years. As can be seen in the Wright Map (Figure 3) the item difficulties and person abilities are normally distributed. However, the difficulty of the items is above average for the students. The three basic concepts consist of difficult items as well as easy items, but easy items for low-ability persons are missing. It is assumed that the mismatch between person ability and item difficulty is due to fact that some of the content has not been covered by the teacher or that the low-achieving students are left behind at some point and are not able to follow anymore.
The mean value for the items of the core ideas from Chemical Reaction is $M = 1.0890$ (SD = 0.1033), for the items of Energy $M = 0.9732$ (SD = 0.1485) and for the items of Structure of Matter $M = 0.9619$ (SD = 0.0638) (Figure 4).

An ANOVA revealed that the item difficulties of items for the three basic concepts are not significantly different from one another ($F(2, 326) = 0.454$, $p = .636$, $\eta^2 = .003$). All of these analyses show that the test items are suitable for our investigations and can be used in the main study.

All of these analyses show that the test items are suitable for our investigations and can be used in the main study.
OUTLOOK FOR THE MAIN STUDY

In the main study the revised performance test will be administered at two points of measurement (in the middle and at the end of a school year) to investigate the hypothetical interdependencies between the core ideas. For each interdependency between two core ideas, approximately 50 answers per item and point of measurement are needed.

The following example shall illustrate the methodological approach to verify or falsify the interdependencies between core ideas (Figure 5): Core idea A is (hypothetically) the requirement for understanding core idea B. The items for both core ideas (A and B) will be administered to the same students. As a consequence, the dependency between the core ideas A and B can be tested by analyzing solution probabilities. Ideally, all students who answer the items for the core idea B correctly also answered the items for idea A correctly, so that the dependency between the two core ideas is verified. In the other extreme case all B-solvers did not answer the items for the core idea A correctly, in which case the dependency is disproven. Certainly mixed cases are also possible, which have to be determined by a quantitative threshold.

There is no standardized procedure to test learning progressions. Therefore statistical methods with a different focus (time, person, items) like the cross-lagged panel analysis, the McNemar test, the Guttman scale, and the Bayesian network will be used as possible methodical ways to test the hypothetical assumptions made in the strand map.
Figure 5. Example for the methodological approach.

The cross-lagged panel analysis enables to predict the performance during later points of measurement on the basis of the first performance data at the first points of measurement (Kenny, 1975; Döring & Bortz, 2016). The McNemar-test examines whether the item for core idea B are more difficult to solve than items for core idea A at several measurement points and allows to divide the students into the groups “solved the item” and “did not solve the item” (Eid, Gollwitzer, & Schmitt, 2013; Field, 2014). The Guttman scale ranks test items as indicated by their solution probability and shows which students are able to solve the items in the basis of their ability. The students who solve the more difficult items also solve the easier items for the same content (Döring & Bortz, 2016). The Bayesian networks investigate the overall hierarchical structure of several interdependencies between the connected core ideas in the strand map because it focuses on conditional probabilities to evaluate if one core idea is conditional on the probability of the other core ideas (Mislevy & Gitomer, 1996 in West et al., 2012).

The results of the main study can be used as evidence about the necessity of one chemical core idea to understand the next one or whether knowledge in one idea is just beneficial for the understanding of the others. Therefore, the results of the study should enable to diagnose students’ deficits so that teachers can explicitly support particularly low-achieving students to reprocess their deficits by working off the relevant chemical core ideas, which are based on each other and are indispensable for the construction of systematic knowledge. Learning progressions promise to build a better connecting point between standards, curriculum, instruction and assessment to improve science education and to promote scientific literacy (Alonzo & Gotwals, 2012; Duncan & Hmelo-Silver, 2009). So instruction can be better coordinated and student learning can be supported target-oriented.

ACKNOWLEDGEMENT

Many thanks to the SINUS working group and QUA-LiS who support the project and also the students who participated in the performance tests.

INCLUSION IN CHEMISTRY EDUCATION
IN SECONDARY SCHOOL

Dagmar Michna and Insa Melle
TU Dortmund University, Chair of chemical education, Dortmund, Germany

The UN-Convention on the Rights of Persons with Disabilities (CRPD) from 2009 requires the right of equal participation in schools for students with and without special educational needs (CRPD, 2006). In accordance with this convention, the school law act of North Rhine-Westphalia was amended in 2013 (NRW, 2013). The demand for inclusion does not mean that the curriculum has to be designed entirely unique, but that the students work on the same content individually (Kullmann, Lütje-Klose & Textor, 2014). The implementation of inclusive teaching is difficult, as there are very few and insufficient learning environments, especially in the field of science. In order to find a more efficient method of implementing inclusive teaching, we developed a concept that combines instructive as well as constructive elements, and the Universal Design for Learning (UDL, CAST, 2011). The main idea is to involve all students in the learning process by offering varied ways to access a certain content. The aim of this study is to develop and evaluate an inclusive teaching unit in chemistry (Michna, Melle & Wember, 2016). On the one hand, it contains a lecture given by the teacher and on the other hand, the learners use a self-evaluation sheet in order to identify their own learning abilities and their aspired proficiency levels. Learners first assess themselves on a four-point Likert scale to illustrate what they have already learned from the lecture. Afterwards, the students decide what knowledge they want to achieve. Then, they work with material that is based on the UDL. The study is carried out with two different groups of secondary education students (Grade 8, n = 172). Both groups deal with the same material in a 225-minute inclusive teaching unit. The difference between the groups is their composition: The intervention group is an inclusive learning group, while there are no students with disabilities in the control group.

Keywords: inclusion, universal design for learning, chemistry education

MOTIVATION

In June 1994 representatives of 92 governments and 25 international organizations formed the World Conference on Special Needs Education, held in Salamanca, Spain (United Nations Educational, Scientific and Cultural Organization, 1994). The conference established a new framework, approving that ordinary schools should accommodate all students regardless of their physical, intellectual, or social background. Germany ratified the Convention on the Rights of Persons with Disabilities in 2009. But even today, there are still few and insufficient learning environments, especially in the field of science. As a consequence, the goal of the study presented in this paper is to develop and evaluate an inclusive learning unit in chemistry for secondary schools. Therefore, this project combines instructive elements, constructive learning phases, and the UDL.

THEORETICAL BACKGROUND

Instruction and construction

An example of instruction is the direct instruction (Engelmann, 1980), which is based on the assumption that every student can do well, if he receives proper instructions. Direct instruction
implies a teaching concept that serves to learn basic knowledge in which teaching is intended teacher-centered (Grell, 1999; Gruehn, 2000, pp. 42; Hasselhorn & Gold, 2009, pp. 241; Quitoenbaum, 2016). Furthermore, an example of construction is the self-regulated learning (Zimmerman & Martinez-Pons, 1988). This method includes the use of self-regulated learning strategies, students’ responsiveness for self-oriented feedback, and the motivation to achieve academic goals which are personally intended by the students. Evidence shows that self-regulated learning can lead to greater success in learning (Pintrich & De Groot, 1990) and that accurate instruction has positive effects on learning outcomes (Touvinen & Sweller, 1999; Klahr & Nigam, 2004).

**Universal Design for Learning**

As a result of the heterogeneity in classes, the design of learning environments has to be changed, as different aspects have to be taken into account regarding planning, implementation and analysis of lessons. The Universal Design for Learning (UDL) is a framework for the design of inclusive learning environments that has been proposed in the US as being an evidence-based approach to make schools and learning accessible for all learners. The leading idea is that successful learning for all may only be possible if all students have access to the learning content. (Center for Applied Special Technology [CAST], 2011; Meyer, Rose, & Gordon, 2014). In detail, the framework of UDL consists of instructional approaches that provide students choices and alternatives concerning the materials, contexts, contents etc. A successful learning environment supports and challenges students while minimizing barriers. Minimizing barriers requires flexible teaching methods and materials. Accordingly, the UDL framework consists of three overarching principles (CAST, 2011):

1. “Principle I: Provide Multiple Means of Representation (the “what” of learning)"
2. Principle II: Provide Multiple Means of Action and Expression (the “how” of learning)"
3. Principle III: Provide Multiple Means of Engagement (the “why” of learning)"

To go more into detail, the principles are broken down into guidelines and checkpoints. The UDL can be summarised in a table, where the guidelines, the three principles and the checkpoints are given (Table 1). Guideline 2, for example, deals with options for language or symbols. A picture or image that carries a specific meaning for some learners may carry a very different meaning for other learners from different cultural backgrounds. As a result, inequalities can arise when information is presented through a single form of representation.

By implementing the UDL it should be possible to reduce barriers in methods and materials, and to provide access to information and learning, ideally for all students.

**RESEARCH QUESTIONS**

Based on the theoretical background, the question arises whether a learning environment, which consists of instructive and constructive elements and which is designed by using the UDL, leads to a comparable knowledge growth of all learners in inclusive and non-inclusive classrooms.
Thus, this study addressed the following research questions:

1. Is the increase in knowledge of both groups comparable?
2. Is the increase in knowledge of both groups comparable in the long term?
3. Is the teaching unit rated as equally well by both groups?

**DESIGN**

The procedure of the main study is based on the results of a pilot study. The following illustrations only refer to the main study.

The learning unit deals with the topic “chemical reaction” which consists of five 45-minutes lessons and is a new topic for all of the students. To answer the research questions, two experimental groups were created. Both groups work with the same materials during the whole time. The major difference between the groups is their composition: The intervention group 1 (WithinSEN) is an inclusive learning group, while there are no students with special needs in the intervention group 2 (WithoutSEN). One week before the learning unit, chemistry performance, intellectual performance and academic self-concept are assessed. Furthermore, the student skill assessment is compiled by using a rating by the teacher (pre-test, 60 minutes). The first lesson starts with a 10-minute lecture given by the teacher. After the lecture, the students work with the self-evaluation sheets and the learning materials. These two lessons are followed by an experiment-based lesson. At the beginning of the experimental phase, a short safety briefing is conducted, as most students of the participating classes have no experience in experimenting. Finally, the last two lessons contain the combination of a lecture given by the teacher and also of self-regulated work again. One week after the learning unit, the chemistry performance is measured again and the additionally, students’ feedback is assessed (post-test, 45 minutes). Four weeks after the second measure-point the chemistry performance is collected for the third time (follow-up-test, 30 minutes).
METHODS AND MATERIAL

Lecture

The lectures are supported by power-point-presentations and provide first information about the topic. Both lectures have a timeframe of approximately 10 minutes and are given by the teacher at the beginning of the self-regulated workphases. Both lectures include three subtopics on the topic of chemical reaction. In total, the first power-point-based lecture consists of 24 slides, which also contain explanations on the work with the self-evaluation sheets. In comparison, the second lecture contains only 19 slides.

Each subtopic is discussed in a similar way within each lecture as each of them consists a start-up slide illustrating the focused question, followed by the explanation of the content and ending with a summary.

Self-evaluation-sheet

The self-evaluation-sheets are structured in a tabular format and are presented in a A3 format. All in all, six statements about the students’ abilities are listed, written in the first person singular (“I can…”). Each statement covers one subtopic of the chemical reaction. The subtopics “chemical reaction”, “difference between chemical and physical reaction” and “chemical equation” are arranged together and the remaining subtopics “oxidation”, “conservation of mass” and “chemical reaction with particles” are listed on the second self-evaluation-sheet. In order to identify what the students have learnt, the students assess themselves on a four-point Likert scale going from “I am very confident” to “I am not confident at all”. After that they decide which proficiency levels they want to reach by using another four-point Likert Scale. Both, the assessment of their distinct achievement and the setting of a personal goal define the individual learning path, which the students pass independently. On the self-evaluation sheets the students find direct links to exercises in different levels of complexity and further informational texts. After completing an exercise, a feedback can be obtained by using sample solutions. Once students have finished a task, they document what material has been used.

Learning material

The learning material consists of informational texts, exercises and sample solutions which are used by the students during the self-regulated working phase. Between the two self-regulated working phases, the experimentation takes place. As additional guidance, the learners receive experimental instructions.

Informational texts

For each of the six subtopics, the learners are provided with informational texts on one A4 page, so that three explanations can be read during each of the self-regulated phases (90 minutes). Because of the fact that the lessons are an introduction to the topic of chemical reaction, it appeared reasonable to provide texts that summarized what previously was part of the presented short lectures. With regard to the UDL, especially the principles of the first guideline are implemented here since it focuses on the perceptual aspect of collecting
information. On this basis, important information is emphasized and information-supporting images are implemented. In addition to the visual perception, meaning independent reading, the following corresponding auditory variant of information is offered to the students: The learners have the option to read the informational texts by using a lecture-pen. The pen used in this intervention is the AnyBook reader from Franklin Discover. Informational texts were recorded by the researchers on the lecture pens prior to the lessons. Each class had five pens available during the intervention. For the preparation of the informational texts, the texts were laminated and customized according to the recordings on the memory sticks of the AnyBook reader. Short passages were chosen so that the students could read individual passages of the informational texts aloud. As the pen can recognise a specific code on stickers, these are put next to the written equivalent of the recorded auditory information linked to this code and to which the learners can listen to with head phones. Of course, in addition to the laminated explanations, informational texts in the usual paper format are provided. Thus, each learner is able to decide for himself how he wants to access information.

Learning material

The six subtopics are represented by a three-stage differentiation. Thus, each subtopic includes three worksheets with different tasks. The cognitive demands on task management increase from simple to mediocre to challenging. Depending on the assessment and learning goal of the learners, the individual learning path is determined. For fast learners, there is an additional task at the end of a 90-minute lesson phase, which links content from three main areas. In total, nine worksheets of different difficulty level are made available to the students in each self-regulated learning phase, as well as a worksheet with linking tasks. In addition to the design aspects already described in relation to the informational texts, the differentiation into levels of complexity is another special factor of the UDL and is especially addressed within the third guideline regarding the promotion of persistent learning as this can be supported by different levels of challenge. It was particularly crucial in the chosen differentiation that there were three different worksheets with different types of tasks, each of which focus a common theme. A differentiation only in terms of the task seemed unsuitable for preventing the learners from working only on the quite simple exercise sheets.

Sample Solution

Especially when working independently, the feedback aspect of an activity should be given as much attention as possible which is why sample solutions are used to implement this element. Within the framework of the teaching unit, a sample solution is thus available to the learners for each worksheet which makes a total of nine sample solutions per 90-minute phase. Like all other developed materials, the sample solutions are based on the principles of the UDL which was especially taken into account in the design aspect. For example, the sample solutions also include pictures. In addition, the solutions are highlighted in different colours in order to make it easier for learners to see what the correct answer is. Furthermore, the use of sample solutions promotes self-regulated learning which is also part of the UDL. The sample solutions differed from the corresponding task sheets in their laminated form. The students are encouraged to use a red fibre pen when checking their results. In this way, we can later analyse later to what degree the students use the sample solution during the intervention.
Experimental Sheet

Altogether, five experiments were available for the pupils, which could be worked on independently by the learners with corresponding experimental instructions. This is because the experimental phase should also follow the principles of self-directed learning in order to satisfy the widest possible range of learners. At the beginning of the experimental phase, a short safety briefing covering the use of gas burners for example, was given. Since the pupils had little experience in experimenting, a special selection of experiments was required. In addition to the oral safety instruction, a poster in A0 format was also placed in the classroom, which presented all important safety-relevant aspects in text and pictorial form. As with the other materials of unity, the principles and guidelines of the UDL were also used in designing the experimental sheets to give as many learners as possible access to it. The presentation of the required materials as well as the execution steps were supported by photographs of the objects and actions. In addition, the students had the choice between recording their observation as a drawing or writing it on the experimental instructions. Common technical terms such as “execution” were supplemented by linguistically simplified descriptions such as “That's how you do it”. As with the learning materials used in the self-regulated work phase, learners were able to control and correct their results with the help of sample solutions, using a red fibre pen again.

PARTICIPANTS

The participants in the main study were eighth-graders attending five secondary schools (Gesamtschule) in Germany (N = 224). Due to sickness related absences, the sample was reduced to n = 172 subjects (pre/post). Furthermore, data sets of 158 students could be used in the pre/follow-up data analysis.

MEASURING INSTRUMENTS

- Intellectual performance test: This instrument measures students’ intellectual performance by doing one scale of the CFT 20 (Weiß, 1998) before the lessons.
- Self-concept scale: The second instrument assesses students’ self-concept and is done before the lessons. It is adapted from DISK (Rost et al., 2007).
- Chemistry performance test: For this instrument, we developed a multiple-choice test consisting of 24 items with one correct answer out of five possible options. The test is done once before and twice after the lesson. The Cronbach alpha measure of internal consistency reliability for this test was .80.
- Feedback questionnaire: The fourth instrument was used after the lessons. It measures students’ feelings towards the lessons. It contains 24 items. The five rating scale options range from totally agree to totally disagree. The Cronbach alpha measure of internal consistency reliability for this test was .89.
- Student skill assessment: The fifth instrument was used before the intervention. It measures students’ skills using a rating by the teacher. It contains 16 items and a five-point Likert scale from very good to not good at all. The Cronbach alpha measure of internal consistency reliability for this sheet was .97.
RESULTS

We used data from the multiple-choice tests and the feedback questionnaire to find out whether there were differences regarding the learning progress among the groups.

Learning outcome

Due to the limited extend of this article, only those participants who have taken part in all three measurement periods of the study are taken into account below.

To determine possible differences, a residual analysis was done. Our results indicate significant learning outcomes in both groups from pre to post (Pre-Post: WithoutSEN $n = 87$, $p = .001$, $\varphi = .84$; WithinSEN $n = 71$, $p = .001$, $\varphi = .84$). The residual analysis shows no indication of a difference between the groups ($n = 158$, $p = .849$, $\varphi = .01$). Considering the long-term-effect, the learning outcomes also increased significantly from pre to follow-up (Pre-Follow-up: WithoutSEN: $n = 87$, $p = .001$, $\varphi = .84$; WithinSEN: $n = 71$, $p = .001$, $\varphi = .81$). A group comparison (pre-follow up) shows an almost significant difference in favour of the WithoutSEN Group ($n = 158$, $p = .053$, $\varphi = .15$). Since there has been no controlled intervention between the time of the post-measurement and the time of the follow-up, it is not possible to say which contents were dealt with after the intervention in the classroom.

Feedback

The students’ feedback on the inclusive learning unit was positive ((Five-point Likert scale from 1 = totally agree to 5 = totally disagree) WithoutSEN $M = 2.25$; WithinSEN $M = 2.14$). There is no statistical difference between the groups ($n = 172$; $p = .253$; $\delta = 0.15$).

DISCUSSION AND CONCLUSION

The present study examines the question of whether the increase in learning in inclusive classes differs from that of non-inclusive classes. In a first step, a method containing both instructive and constructive elements was developed. The instructive part is represented by teacher presentations, while elements of the construction are covered by self-regulated learning. In order to ensure the best possible access to the content of the unit, the Universal Design for Learning was also implemented and especially taken into account when designing the learning materials.

The initial results show that there is no significant difference between the inclusive learning group (WithinSEN) and the non-inclusive learning group (WithoutSEN) groups in terms of both immediate and sustained knowledge growth. In addition, it can also be noted that both groups are equally positive about the teaching unit.

Since the intervention consists of three main elements, namely the instructive and constructive elements as well as the UDL, it cannot exactly be explained why the learners of both groups generate knowledge since the effect of the teacher's lecture or the self-evaluation sheet was not tested separately. This is due to the fact that there should be too much testing within the unit. Furthermore, it is also not clear in how far UDL lessons are more effective in comparison to conventional lessons. Overall, it can be assumed that the intervention has led to an increase in learning by combining the three central elements.
The study presented here was conducted under research conditions. It remains an open question to what extent the elements used can be transferred to teaching practices at schools. All in all, it must be taken into account that designing learning material based on the UDL is time-consuming. On the other hand, however, UDL lessons carry extra value for the students. Lastly, having appropriate materials for inclusive teaching can contribute to reduce the overall burden on teachers in schools.

ACKNOWLEDGEMENT

Finally, I would like to thank my entire working group and all students and teachers, who participated in the project, for their cooperation.

REPRESENTATIONS OF THE PCK BEFORE AND AFTER THE SUMMIT

Brunno Carvalho Gastaldo¹; Pablo Micael Castro²; Paula Homem-de-Mello¹ and Sérgio Henrique Leal
¹Federal University of ABC, Brazil
²University of São Paulo, Brazil

Pedagogical Content Knowledge (PCK), proposed by Shulman, has occupied the centre of effort to capture teachers’ expertise. Since Shulman’s work, several models have been developed, in order to better define the PCK. However, some of these derivations have diminished the strengths of the construct, because they can disagree in important aspects. To resolve this, a congress called PCK Summit was held, wherein the PCK Consensus Model was developed. To analyse if PCK Summit influences PCK research, this paper focuses on understating PCK Summit’s effect on PCK representations using a lexicometric exploratory, descriptive, and comparative analysis. We employedDescending Hierarchical Classification (DHC) and Factorial Analysis of Correspondence (FAC) of text segments, extracted from the corpus composed of papers containing the acronym “PCK”, published before (α), during (ε) and after (β) the PCK Summit. Our results show that the papers published during and after PCK Summit have a more mature view of the PCK than the α papers, and are about quantitative methods and curricula modifications to PCK development. Moreover, the representations found in β papers have an intense relation with the PCK Summit’s work groups, and that the topic-specificity of the PCK, has gained more attention in β works, appearing in two discourses. Therefore, it is possible to conclude that the PCK Summit has influenced PCK representation.

Keywords: descending hierarchical classification (DHC); factorial analysis of correspondence (FAC); PCK summit

INTRODUCTION

The desire to capture teacher’s expertise is ancient, and there is no final agreement on the qualities of a good teacher (Barnhart & van Es, 2015). However, since Shulman’s work (Shulman, 1986), the Pedagogical Content Knowledge (PCK) has occupied the centre of such effort, as it is said to comprehend the body of knowledge needed for teaching. From then on, several models were developed trying to better define the PCK. This rich effusion of propositions allowed a vast array of research covering different aspects and contexts. On the other hand, it diminished the strengths of the construct, once researchers diverged on what is exactly the PCK and its components, leading to the participants noticing an increased difficulty in publishing PCK articles (Borowski et al., 2011).

To mitigate the existing disagreement on the used vocabulary and the nature of the PCK (personal or canonical), ways to assess / measure it and its topic or domain specificity, a “congress like event” (Helms & Stokes, 2013) was held in Colorado Springs in 2012, gathering researchers from 13 research groups (Table 1) with the objective of exploring “the potential of a consensus model of PCK to guide science education research [and the] identification of
specific next steps [to] move the field forward” (Carlson, Stokes, Helms, Gess-Newsome, & Gardner, 2015, p. 16).

In preparation to the event, the organizers took some precautions in order to enrich the debate. The most important, according to the participants, was writing a conference paper detailing their PCK research program (e.g. their definition of PCK, model used, assessment tools, etc.) and also reading thoroughly theirs peer papers (Helms & Stokes, 2013).

Through the days of the event, forums (Table 2) were held allowing them to share their different views in small groups to solve discrepancies, and then in large ones to share the conclusions. At the final days participants were encouraged to form Work Groups (WG) according to the emerging interests (BSCS, 2012) Table 3).

In the last day of the event, a model was developed and named Consensus Model of PCK, and both Canonical and Personal PCK were defined. The former is the one that can be shared and is substantiated by systematic research (Rollnick & Mavhunga, 2015), whereas the latter is “the knowledge of, reasoning behind, and enactment of the teaching of particular topics in a particular way with particular students for particular reasons for enhanced student outcomes” (Garritz, 2015; Helms & Stokes, 2013).

Conversely, five years have passed, the participants seem to keep investigating in their specific fields of interest, and above all, not using the Consensus Model of PCK.

In this work, we aim to evaluate whether the Summit has affected or not the participants research, and if so, how those changes appear in their representation of the PCK in their latter papers. To do so, an optimal way is performing a lexicometric analysis as it “enables extracting the pattern of social representations of an object from corpora in natural language” (Lahlou, 1996, p. 279), and especially using Computer Assisted Qualitative Data Analysis (CAQDA) as it enables mining information from large corpora (Costa, Reis, Sousa, Moreira, & Lamas, 2017). It is also vastly used in the educational research field, above all to understand the interactions between students and teacher (e.g. Lewins & Silver, 2007; Mortimer & Scott, 2002; Sickel, Witzig, Vanmali, & Abell, 2013), nonetheless, is has a scarce usage in scientific texts (Atanassova, Marc, & Mayr, 2015; Bertin & Atanassova, 2015).

The lexicometric analysis, first proposed by Lebart & Salem(1988), was formalized in a software (Alceste®) by Reinert (Reinert, 1990), allowing an increase in the corpus size. In this paper, an open code version of the software developed by Ratinauld was used (Lowen, Peres, Crozeta, Bernardino, & Beck, 2015; Ratinauld & Marchand, 2012). The software divides the corpus in text segments and compares the frequency of their words in each segment, and then classifies the text segments with similar words together using a chi-squared ($\chi^2$) test (Camargo, 2005). Those classes show the different types of discourse present in the text, as “meaning may be studied through the way people use words in combination with other words” (Chartier & Meuneier, 2011, p. 8; Garnier & Guérin-Pace, 2010; Lahlou, 1996; Sommer Harrits, 2011).

Therefore, this paper focused on understanding if, and how, the representations of PCK changed after the Summit, and also to establish if the Summit can be inferred an INUS condition (insufficient but non-redundant parts of a condition which is itself unnecessary but sufficient for the occurrence of the effect)(Mackie, 1965).

**METHODS**

In order to understand the changes in representations of PCK, if any, in the production of the participants before and after the PCK Summit, a lexicometric exploratory, descriptive, and comparative analysis was performed.

First, the papers from 5 years before ($\alpha$), the conference papers ($\epsilon$), and 5 years after ($\beta$) the Summit were collected from the data bases: Google Scholar, Research Gate, ERIC and Directory of Open Access Journals (Harzing & van der Wal, 2008; Meho & Yang, 2007) and used in full to form a corpus. Other restrictions were: being written in English, being peer-reviewed, and having at least one author attending the Summit. They were normalized from
idiot variances and terminology used, and then, for this analysis, a sub-corpus was created with the text segments containing the acronym “PCK” originating the text segments $\pi_a$, $\pi_e$ and $\pi_B$, respectively.

The analysis was performed in the software IRAMUTEQ®, and the text segments contained 40 words and 12 tokens text segments vs. 14 tokens, with a maximum of 10 classes (standard parameter) (Gobbo & Same, 2016) and with lemmatization (Sarrica, Mingo, Mazzara, & Leone, 2016). Utilizing that sub-corpus, a Descending Hierarchical Classification (DHC) was developed and Factorial Analysis of Correspondence (FAC) was performed (Chartier & Meuneier, 2011; Costa et al., 2017; Lahlou, 1996). The DHC analysis was made regarding the 10 words with higher chi² ($\chi^2$) in the class, which enables the recognition of the typical features tagging it by its synthase semantic content, in an hermeneutical analysis (Chartier & Meuneier, 2011; Lahlou, 1996, 2012); and also looking at the most significant text segments (containing a higher sum ($\Sigma$) of $\chi^2$ from the its’ words).

To increase trustworthiness, all data was analysed by two independent researchers and the methods and data were deposited in the Center for Open Science’s Open Science Framework to assure transparency (Gastaldo & Castro, 2017).

RESULTS AND DISCUSSION

The analysis has shown that, the papers published before the Summit ($\alpha$) showed two different representations about the PCK, the first ($\alpha - 1/2$) was named PCK Model and focused on understanding how the PCK is constructed. Almost all groups who were related to any specific discourse fit into this class: they were groups 5, 8, 10, 13 (Figure 1). The words with a higher $\chi^2$ were: component, model, knowledge, Magnusson, SMK, orientation, Shulman, belief, include and category. As for the second discourse ($\alpha - 2/2$), which was named Development of PCK and CoRe, there is a marked presence of the CoRe instrument, both as a mean to assess the PCK and develop it. Although it has more than half of the text segments from the papers before the Summit, only one group contributed to it, group 4. The words with a higher $\chi^2$ were: CoRe, student, development, participants, PaP-eRs, learn, preservice, practice, construct and educator.

It is important to acknowledge that this was the group that developed this instrument, but, despite it being vastly used throughout literature, its presence is such that it establishes a distinct discourse.

The almost homogeneity of the discourses amongst those researchers can be justified by their interest in understanding the nature of the PCK and its’ origins in the teacher formation. Many papers discuss how the PCK is originated and what are its components (e.g. Berry, Loughran, & van Driel, 2008; Garritz, 2010; Henze, van Driel, & Verloop, 2008; Nilsson & van Driel, 2011).

This homogeneity is broken in $\pi_e$, where it is possible to see five different discourses. They show that researchers wandered in many directions trying to characterize the PCK, and it reflected in the way that PCK is represented.
The first distinct discourse is $\pi e - 1$ which was named Quantitative analysis of PCK. It inaugurates not the usage of quantitative methodologies to investigate the PCK, but a quantitative discourse to represent the PCK, having as responsible for it groups 12 & 13. The words with a higher $\chi^2$ were: CK, PK, dimension, physic, validity, professional knowledge, distinct, test, correlation, and task.

The second discourse found ($\pi e - 2$) was related to the Relation between PCK and students, being interested in teachers’ knowledge of students understanding of Subject Matter and their way of thinking. In this discourse class, text segments from a wide number of groups can be found, being G1 the only one who was statistically related to it. The words with a higher $\chi^2$ were: student, learn, specific, SMK, concept, notion, relate, understand, content, and lead.

Discourse number 3 ($\pi e - 3$) was named Teacher profession development research context as it has a marked desire to understand the researches related context in which the teachers develop their PCK. The groups and words more strongly associated to this discourse are: G4, 5 & 7 and preservice, investigate, in service, context, science, group, study, instance, validation, and educational.

As for the fourth discourse found ($\pi e - 4$), the main idea behind its text segments was the Teacher profession development programs. As it can be seen on Figure 1, $\pi e - 4$ and $\pi e - 3$ are closely related, and both are dedicated to the representation of the environment of PCK development. However, in this case, the representation is not focused on the researches but on the development of programs itself. The main groups that produced this discourse were G3 & G8 whose main words were program, design, support, professional development, research, education preparation, year, educative, and course.

The last discourse ($\pi e - 5$) opposes the 3 predecessors ($\pi e - 2$, $\pi e - 3$ & $\pi e - 4$) as, alongside with $\pi e - 1$, it does not represent the PCK development, but the PCK Models & components. Nonetheless, it shares similarities with the same 3 as they are all related to theoretical aspects of the construct, in contraposition to $\pi e - 1$ which representation, as already discussed, is dedicated to methodological aspects. The groups and words with higher $\chi^2$ were: G8 & G13 and component, Borko, description, distinct, Mulhall, Berry, KISR (Knowledge of Instruction Strategies and Representations), Krajcik, pentagon, and Grossman.
Regarding the papers published after the Summit (πβ), a wider matrix can be observed as six different discourses were found (Figure 1).

The first discourse (πβ – 1) follows the tendency of πε – 1 and is concerned with the Quantitative theory of PCK. That being said, in this class, PCK representations are particularly connected with specificities of the quantitative analysis and methodology, which can be seen in the words with higher $\chi^2$: Content Knowledge, Pedagogical Knowledge, dimension, physic, validity, professional knowledge, distinct, test, correlation, and task. As for the most important groups of this class, G12 and G2 can be pointed out.

The second discourse (πβ – 2) was named Topic specific level of PCK & SMK transformation, and a has a direct relationship with the Summit. It can be said that the topic specificity of PCK is not a new idea. However, the Summit grants a validation that makes it possible for G5 to create a body of text segments explicitly related to it, and by that means, allowing it to be identified as a distinct discourse. Such analysis is strengthened by the excerpt

Like our models the version of the model emerging from the summit separates teacher knowledge domains from a construct referred to as topic specific professional knowledge which aligns to our TSPCK (Rollnick & Mavhunga, 2015)

Amongst others which even evoke Shulman as an argumentum ad antiquitatem (e.g. Mavhunga, Ibrahim, Qhobela, & Rollnick, 2016; Mavhunga & Rollnick, 2013). The words with high $\chi^2$ that were used in this analysis alongside with the text segments (not shown) were Makinster, level, Veal, Shulman, transformation, equilibrium, specific, chemical, programe, and context.

The third discourse (πβ – 3) focuses on the Prospective curricular changes to increase the PCK and corresponds to the still existing gaps within the PCK field and points to ways to amend them. The groups that produced the text segments creating this PCK representation were G8 & G10, and they used as main words: evolution, curriculum, rich, kind, program, science, SMK, teacher, education, and understanding.

The topic specific level of PCK & PCK components were the subjects addressed by the forth discourse (πβ – 4). The PCK components theme returns in this discourse yet as a consolidated feature of PCK, not in the exploratory version as before. Groups G8 & G9 are the ones with significant relations to this discourse, and the main words are: component, topic, purpose, orientation, Magnusson, specific, Friedrischen, Science Teaching Orientations, and compare.

In the same cluster as πβ – 1, πβ – 5 represents PCK by means of quantitative measurements, and as the former addresses epistemological aspects, the latter deals with more practical characteristics. With group 7 as the characteristic one, the most relevant words were: item, test, sample, score, biology, scale, objective, evaluation, open, and main.

The last discourse from πβ (πβ – 6 – CoRe use for portraying PCK) is the most diverse, apart from the quantitative super-class (classes 1 & 5). As before with πα – 2 & πε – 4, this class is highly associated with Loughran’s research, that continued producing a PCK representation that relates to the CoRe instrument to assess and develop the PCK, at a point which this last type of discourse is exclusively produced by his group 4 (as is in its’ origins in πα – 2). The
main words were: CoRe, associate, student, phase, practicum, process, interview, Hume, source, and prompt.

Reckoning this data, is possible to affirm that the PCK representation matrix has a crescent complexity and that, after the Summit, there are more different and vast topics related to PCK representation, as Friedrichsen affirms: “questions have increased in number and […] in refinement” (2015, p. 159).

One of the changes observed was the rise of the quantitative representation after its first appearance during the Summit, and even the groups that do not present a quantitative representation use quantitative methodology.

On the other side of the scale, a decrease of papers regarding the PCK models is evident. As the forums’ themes had the goal of solving issues intriguing the researchers until that time, one could predict that those themes would disappear from the PCK representation, reaching a more mature version. This predicable phenomenon, in truth, happened in πβ particularly with the themes motivating the forums 2 – Beliefs, Teaching Orientation, and PCK & 3 – Nature of PCK, which do not relate to any πβ representation.

Finally, the representations of PCK gain a new feature in πβ. Those representations have a strong relation with the work groups (WG) held in the Summit. There is a clear semantical relation between WG1 – Refining the PCK model and representations πβ – 1 – Quantitative theory of PCK & πβ – 5 – Quantitative measurement of PCK, which expand the way to represent the PCK particularly as they present themselves as new representations and thus in more need to be expanded.

Close relations are also found between WG2 and πβ – 2 – Topic specific level of PCK & SMK transformation, πβ – 3 – Prospective curricular changes to increase the PCK, and πβ – 4 – Topic specific level of PCK & PCK components. Even more direct is the relation of the third WG – Connecting PCK to policy and πβ – 3- Prospective curricular changes to increase the PCK.

CONCLUSION

Our results show that the PCK Summit had a noticeable impact in PCK representations on the attending authors, even though they still do not use the Consensus Model, nor do they officially employ the new PCK definition. The papers presented at such encounter have a more mature view of PCK, and, after it, they showed the discussions made in it. The quantitative discourse appears on πε and pervades πβ, refining PCK representations and establishing a temporal precedence.

The Work Groups held at the end of the Summit have a close semantic relation with the PCK representations of the papers published after the Summit, indicating that, although the Consensus Model is not being adopted as a heuristic tool, the cognitive work developed at such event influenced the way the PCK is addressed.

By this effect, it is possible to affirm that the Summit constitutes an INUS condition, as it contributed non redundantly to what those researchers produced after it.

A COMPARISON OF STUDENT RESPONSES TO PICTORIAL AND VERBAL ITEMS FOCUSING ON CONCEPTUAL UNDERSTANDING OF THE PARTICLE MODEL OF MATTER

Elon Langbeheim¹, Emine Adadan², Sevil Akaygun², Manzini Hlatswayo³ and Umesh Ramnarain³

¹Department of Science Teaching, Weizmann Institute of Science, Rehovot, Israel
²Bogazici University, Istanbul, Turkey
³University of Johannesburg, Johannesburg, South Africa

We show that student reasoning about the particle model of matter is sensitive to pictorial and verbal formats of conceptual questions. This phenomenon is consistent across ages and curricula although the magnitude of the differences varies. We used a randomized trial in which a pictorial and verbal format of the same questions were assigned to students in the same classrooms. We administered the same questionnaire to three groups of secondary school students in three countries and found a significant difference in student response patterns between questions formats across all three groups. We suggest a more nuanced approach to the analysis of student ideas about matter that combines verbal and pictorial cues. Such an approach might have important implications on the design of curricula and learning progressions concerning the particle model of matter.

Keywords: mental models, visualizations, misconceptions

INTRODUCTION

The literature concerning student ideas about matter is dominated by Piagetian approaches that assign students to “stages” based on their responses to survey or interview questions (e.g. Johnson, 1998; Merrit & Krajcik, 2013; Hadenfeldt et al., 2016). For example, Johnson (1998) suggested that students’ ideas about matter may be characterized along four general mental models and that student understanding can be described as progressing from one model to the other. According to Johnson (1998), students holding naïve models of matter do not think of matter in terms of particles at all, students with a slightly more developed mental model, know that matter contains particles, but view particles as additional to the substance that comprises matter. Students at yet a higher level, think of matter as made of particles, but imagine these particles as having the same appearance and characteristics as the observable, macroscopic piece of matter. Students that acquire the “scientifically accurate” model, think of matter as comprised of particles, and understand that the properties of matter are collective, and that often, macroscopic observations of matter do not resemble the particle level behavior and appearance.

Developing such taxonomies of student ideas is important for science education, because it gives educators tools to identify the thinking of their students and to address it. However, such simplified categorizations of “flawed” understanding, may also overlook the important intuitive ideas that students use when learning these topics. Studies that challenge the mental models approach have shown that students’ misconceived reasoning encompasses the
activation of many fruitful knowledge pieces (e.g. Smith, et al., 1993). The activation of certain ideas depends on how students frame the problem (Hammer, Elby, Scherr & Redish, 2005) and how they interpret the information embedded in it (Langbeheim, 2015). For example, a problem entailing a familiar context such as a person driving in a car, may be framed by the student as one that calls for “everyday” reasoning, and not the Newtonian principles of force diagrams and equations that were discussed in the classroom context. In the case of the particle model of matter, problems that contain illustrations may be elicit different sets of ideas than verbal information and direct students towards different conceptualizations.

The current study re-examines the use of “reasoning levels” or mental model levels to characterize students’ conceptions of matter (Merrit & Krajcik, 2013; Hadenfeldt, et al., 2016). We explore whether information presented in a picture rather than in a written text, primes different patterns of reasoning about the structure of matter and physical processes in matter. Although researchers have recommended using both drawings and written text for eliciting student ideas about matter (Nussbaum & Novick, 1982), studies of student-made drawings of models (Nyachwaya et al., 2011) vis-à-vis student-made written descriptions of the same process are scarce. One such pioneering study (Akaygun & Jones, 2014) compared the prominence of structural and dynamic features in student self-generated particle models in drawings and in written explanations. In order to examine how does the presentation of information affect students’ reasoning patterns, we compared the reactions to pictorial and verbal survey items in three groups of learners of different age levels, who are exposed to different curricula.

**METHOD**

Two forms of a questionnaire containing eleven equivalent pictorial and verbal questions adapted from a prior study (Hadenfeldt et al., 2016) were randomly administered to secondary school students in South Africa (10th grade, N=126), Israel (7th grade, N=90), and Turkey (7th grade and 10th grade, N=90). The schools in Turkey and Israel were semi-private schools with enrollment of students above the national average, whereas the South-African school was a public school with student level reflecting the national average. Three sample items from these questionnaires are shown in Figures 1-3. The item in Figure 1 elicits student ideas about the structure of water, and the item in Figure 2 elicits ideas about the configuration of gas particles and the item in Figure 3 elicits ideas about the process of dissolving sugar.

In all three items, some of the choices where designed to represent the less “sophisticated” reasoning levels or mental models. For example, in item 1, options A and C, represent water particles as resembling the shape of the macroscopic water droplets, and thus a flawed or incomplete model in which the molecular-level entities maintain the form of the macroscopic liquid. Option A and D illustrate a "hybrid" conceptualization of matter, in which particles are perceived as embedded in the macroscopic liquid, but not as the building blocks of liquid itself.

Similarly, in item 5 shown in Figure 2, air is released from a balloon. In this case students might think that the lower part of the balloon would be empty and choose "The remaining air particles stay at the top of the balloon" (option C), whereas the appropriate response would be "The remaining air particles scatter evenly throughout the balloon" (option D).
Item 1. Julie wants to sleep but the dripping faucet in the bathroom in the room next door keeps her up. While she lies in her bed, she imagines how water is composed. How do you think the particles of which water is composed look like?

<td>E. The remaining air fills the entire balloon.</td>
</tr>
</tbody>
</table>

Figure 2. Spreading of air in a balloon eliciting ideas about the spatial configuration of gas particles

A final example is shown in Figure 3. The macroscopic disappearance of the sugar in the water, corresponds to answers such as “the sugar turns into water” (option C), or “the sugar particles disappear but leave a sweet taste behind” (option D).

The questionnaire was designed as a two-tier questionnaire, in which students first answered the multiple-choice item, and were then asked to explain their choices. The required explanation in the second tier was verbal if the item choices were pictorial, or pictorial if the item choices were verbal. Students’ drawings and written explanations were analyzed in order to compare their self-produced representations and the equivalent verbal/pictorial representation that was used in the multiple-choice options.
Item 8: When we add a sugar cube to hot water and stir, the sugar cube is no longer seen. Which of the following explains what happens to the sugar when it is added to the hot water?

Pictorial format: [Diagram of sugar dissolving in hot water]

Verbal Format:

A. The sugar scatters to the bottom of the cup
B. The sugar dissolves, and the sugar particles mix with the water particles
C. The sugar particles became water particles
D. The sugar disappears, and only the sweet taste is transferred to the water
E. The sugar particles become air particles that form bubbles at the surface of the water and then escape from the water

Figure 3. Sugar dissolved in hot water - eliciting ideas about the process of mixing

FINDINGS

An item-by-item comparison of student responses revealed differences in the response patterns, which were consistent across all three groups. In six out of the eleven items, the proportions of responses to the pictorial and verbal items were similar, whereas in five of the eleven items we found significant differences in the response patterns to the verbal and pictorial formats. Such significant differences are illustrated in the response patterns illustrated in Figures 4 & 6, similar response rates are illustrated in Figure 5.

Figure 4. Response rates to item 1 - Water Droplet. Note the higher proportion of correct responses in the pictorial format in all three groups (left), and the lower percentage of the most common inappropriate idea (B) in which water is represented as balls immersed in a liquid in the pictorial format (right).

Figure 4 shows that a majority of students from all three groups chose response “E” representing the normative scientific model of water in the pictorial form, but a much smaller proportion chose the equivalent verbal response as shown in Figure 4. Conversely, Figure 6 shows that in item 8, addressing the apparent “disappearance” of sugar upon dissolving in water - the appropriate pictorial option was chosen by a significantly smaller proportion of students than the verbal one. Figure 5 shows the proportion of students who chose the correct description of the configuration of the remaining air particles in the balloon. This proportion was similar in the pictorial and verbal formats, except in the Israeli group.
Figure 5. Response rates for item 5 – arrangement of remaining air particles in a balloon. In this item, there were no significant differences in the proportion of students who chose the correct response in the verbal and pictorial formats, except in the Israeli sample, which performed significantly better in the pictorial format, and did not choose the "stay at the top" option in the pictorial format.

Figure 6. Response rates for item 8 – sugar in water. Note the higher proportion of students who chose the correct verbal response than those who chose the pictorial one (left). Many of those who did not choose the correct picture, chose option “D” in which only water molecules are present (right). Fewer students chose the equivalent verbal response.

The proportions of correct responses in each format of the survey are summarized in Table 1 with a chi-square analysis of the significance of the differences in proportions between formats. Note the significantly higher proportion of students who chose the correct pictorial response in item 1 and the correct verbal response in item 8. The differences in item 5 are not significant, except in the Israeli group.

Between-country differences

In addition to comparing the verbal and pictorial formats, we examined also the between-country differences within each format (Table 2). Interestingly, we found significant differences between the countries within the pictorial format questions: In item 1 – the Turkish group performed significantly higher than the Israeli and South African samples, and in items 5 and 8, the South African group performed significantly lower than the Israeli and Turkish groups. In the verbal format, the only significant difference was found in item 5, in which the South African group performed significantly lower than the Israeli and Turkish groups.

Analysis of the second tier

Students were asked to explain their pictorial choice verbally, or vice-versa. For example, a student chose the pictorial option D for item 8 (dissolving sugar) and explained: “The sugar cube dissolved in the hot water to form a solution, which is why it is not seen”. This student seemed to understand the term “dissolving” as “disappearing in water”, which reflects her observation at the macro level. Note that the scientifically appropriate verbal response to this question “The sugar dissolves, and the sugar particles mix with the water particles” is the only
one that contains the term “dissolving”. It might be that many students chose this response because this word served as a verbal cue which signified a scientific term they heard in class. These students were not necessarily familiar with the underlying molecular level model of the mixture.

The drawings made by the students in response to item 1 reveal that many of them were familiar with the molecular representation of water molecules. Figure 7 (left) shows a drawing by South African student who chose option E (“There are many tiny water particles in a drop of water that do not look like droplets”). Conversely, the drawing in Figure 7 (right) represents an incomplete model of a student who chose the correct verbal option B. In this drawing of the dissolved sugar, one of the components – either water molecules or sugar molecules – is missing. This again illustrates that students who chose the correct verbal response, used the verbal cue in the question although their molecular-level model of the structure of a mixture – was lacking.

**Figure 7. Students’ drawings that explain their choices to item 1 (left), and to item 8 (right)**

**DISCUSSION**

We developed two formats of the same conceptual questionnaire about the particle model of matter. We randomly assigned questionnaire format to students in three countries and found significantly different response patterns in the verbal and pictorial format of half of the questionnaire items. Thus, what seems to be equivalent verbal and pictorial representations, failed to capture the same “reasoning levels” or mental models among students. This phenomenon is consistent across three groups of students from three countries, although some differences occur due to differences in curriculum and student populations.

On average, the between-country differences in the verbal format were smaller than the pictorial format. This might indicate that the questions in the pictorial format were less reliable. However, the significant differences between the South African group and the other two groups in interpreting the pictorial format might stem from the difference in curricular activities. For example, only 13% of the South African students reported that their teachers used particle simulations, whereas in Israel and Turkey the vast majority of the students reported using simulations (96% and 88% respectively).

In order to examine the origin of the difference between formats, we triangulated the findings from the multiple choice questions with the students’ own drawings and written explanations. We suggest that differences between the pictorial and verbal formats stem from molecular-level cues that were apparent in the pictorial format and missing from the verbal one or vice-versa. The pictorial format in item 1 (see Figure 1) elicited a familiar representation - the molecular structure of water - while the verbal response did not. The structure of the water
molecule was familiar to many students – especially in Turkey – where the molecular structure is part of the curriculum already in 7th grade. Conversely, the pictorial format in item 8 (see Figure 3) contained unfamiliar information (the hexagonal sugar molecule in option B) that deterred students from choosing this option – and led many of them to choose option D.

CONCLUSION

Our study shows that descriptions of students’ levels of reasoning based on their responses to multiple-choice items in studies such as Hadenfeldt et al., (2016) should be taken with caution. We suggest that in order to make more substantiated inferences, studies should rely more on sets of two or more items that examine the same concepts using verbal and pictorial information. Only respondents who use the same reasoning level in the pictorial item and the verbal item, can be considered as using a coherent and stable “mental model”.

DEVELOPMENT OF A TOOL TO ASSESS SECONDARY SCHOOL STUDENTS’ UNDERSTANDING OF MEASUREMENT UNCERTAINTIES

Johannes Schulz1, Burkhard Priemer1 and Amy Masnick2

1 Humboldt-Universität zu Berlin, Berlin, Germany
2 Hofstra University, Hempstead NY, U.S.A.

Estimating the quality of evidence is a core competence in science and science education. Applying this to quantitative observations means, for example, to judge the uncertainties in measurements. In order to do this systematically, a reference frame is needed. Hellwig (2012) and Priemer and Hellwig (2016) present a model that describes and structures content about measurement uncertainties relevant for the secondary school level. With a reference to this model, we are developing an assessment tool to probe students’ understanding of measurement uncertainties. This is done by formulating competencies and interpreting these as latent constructs. For these constructs, scales were developed based on Item Response Theory. This paper describes the general approach to the development of the tool and illustrates it with the two example scales: “Reliability of a Measurement Result” and “Comparison of a Result with other Values”.

Keywords: measurement, assessment of competence, secondary Education

INTRODUCTION

Competencies in identifying and handling measurement uncertainties are necessary to understand and perform scientific work like analyzing empirical data from experiments. The related activities can be identified in models that describe inquiry processes (e.g. the phase of data interpretation; Pedaste, Mäeots, Siiman, De Jong, Van Riesen, Kamp et al., 2015), or experimental work (e.g. “evidence evaluation” in the Scientific Discovery as Dual Search (SDDS) model; Klahr & Dunbar, 1988). If key concepts about judging the quality of data – or more specifically estimating measurement uncertainties – are important for teaching, we also need assessment tools that probe students’ competencies accordingly. This paper describes the development of such a tool. Since the development of the tool is not yet complete, we focus on example subscales. These subscales are related to a comprehensive framework and illustrate the characteristics of the test.

THEORETICAL BACKGROUND

Experimental work with measurements is seen as an important practice in science education and, hence, appears in national science curricula (in the USA: NGSS Lead States, 2013, Next Generation Science Standards [NGSS], Appendix F, Practice 4; in England: Department for Education and Employment and Qualifications and Curriculum Authority, 1999, Science The National Curriculum for England, p. 37-38; in Germany: KMK – Sekretariat der Ständigen Konferenz der Kultusminister der Länder in der Bundesrepublik Deutschland [KMK], 2004, Bildungsstandards im Fach Physik für den Mittleren Schulabschluss, p. 11). Whenever there is measurement, there can be variability in the measurement, and thus, uncertainty about how to assess the resulting data. To judge the quality of collected data, it is often essential to capture
and discuss measurement uncertainties, and it is difficult to know how to address this issue without training. However, measurement uncertainties are an oft-neglected topic in science education (Hellwig, 2012). One concern is that teachers do not have guidance on the most important issues in measurement evaluation and the best ways to teach such evaluation (compare i.e. Priemer & Hellwig 2016). Hence, research is needed that develops and analyzes learning progressions and teaching instructions to bring this topic to teachers’ attention and to facilitate effective teaching of these concepts.

To learn about students’ understanding of measurement uncertainties, it’s important to have a way to assess their knowledge. Although there is some research on the development of teaching instructions (as outlined for example in Deardorff, 2001, and Munier, Merle, & Brehelin, 2011) and investigations about students’ views in this field (as in Buffler, Allie, Lubben, & Campbell, 2001, and Masnick & Morris, 2008), validated instruments are needed that assess students’ understanding about measurement uncertainties. Additional assessments of understanding about nature of measurements have been developed by Day and Bonn (2011), Lubben and Millar (1996), Garratt, Horn, and Tomlinson (2000), and Volkwyn (2005). However, most of these existing instruments address upper secondary or university education and focus on certain subtopics of measurement uncertainties, e.g. the reliability of data (Lubben & Millar, 1996). Hence, a tool that investigates secondary school students’ comprehensive understanding of concepts of measurement uncertainties is still missing. It is the goal of this paper to outline the development of such a tool. We do so by describing the general stages of tool development, and then detailing two of the instrument’s concepts and how they were assessed.

The development of this tool is based on a framework from Hellwig (2012) and Priemer and Hellwig (2016), who presented a comprehensive content structure model for the field of measurement uncertainty for secondary and for university education. The content is structured in four main dimensions and ten concepts for both educational levels (Table 1). Hellwig (2012) also developed subconcepts and subsubconcepts (overall more than 50) for each concept, which are not described here to keep the paper readable.

**RESEARCH QUESTIONS**

To develop a tool to assess secondary school students’ understanding of measurement uncertainties, we posed the following questions:

1. How can the concepts of the framework model be operationalized and measured?
2. What is the quality of the developed scales?

In this paper, we answer these questions for the concepts “Reliability of a Measurement and the Result” and “Comparison of a Result with other Values”.

**METHOD**

The development of the tool followed four steps: 1. the formulation of competencies for all concepts of the framework model (Table 1); 2. the operationalization of these competencies in test items; 3. the assessment of the validity of the items; and 4. an empirical test of the scales that represent the concepts.

**Step 1: Formulating competencies for the concepts**

For each of the ten concepts of the framework model (Table 1), competencies were formulated based on the content suggested in Hellwig (2012) with additional consideration of the *Guide to the expression of uncertainty in measurement* (GUM; Joint Committee for Guides in Metrology, 2008). The competencies were developed by analyzing the content of the concepts and describing performances expected by students who are familiar with the corresponding content. This was done by an expert in the field of science education, and the competencies and their assignment to concepts were validated by another expert. In this step, we also made sure that each concept consists of unique content and that there are no overlaps in the content of different concepts. Table 2 lists the competencies for the two concepts “Reliability of a Measurement and the Result” and “Comparison of a Result with other Values”.

**Step 2: Operationalizing the competencies in test items**

The competencies were used to develop test items by choosing specific situations, experiments, and tasks that are relevant for secondary school instruction. For each concept, we added an introduction page to the test booklet which gives an overview of the content to assure that students understand the scientific terms used. For example, one introduction page explained how the overall uncertainty of a measurement is estimated when a number of different uncertainties are given that all influence the measurement (the uncertainty budget). Further,
most of the concepts are illustrated with additional examples. This information was given to make sure that the test assesses students’ competencies using the concepts instead of simply remembering facts.

</tr>
</tbody>
</table>

All of the items were designed in multiple choice format (with only one correct answer) or multiple answer format (where more than one answer could be selected, and there was at least one wrong answer and at least one correct answer). Figure 1 gives an example of a test item that addresses the competence “The students are able to judge the reliability of a measurement based on the uncertainty budget and the correct number of decimals” of the concept “Reliability of a Measurement and the Result”. We created 17 items each for the two concepts “Reliability of a Measurement and the Result” and “Comparison of a Result with other Values”. We will focus on them in this paper. The full instrument includes 150 items assessing all 10 concepts.

**Step 3: Assessing the validity of the test items**

In order to validate the items of the complete model with the ten concepts we created an item-subset including item designed to assess each of the ten concepts. We presented this subset of 52 items to three experts in the field of metrology together with a list of all competencies for all concepts, and asked them to assign the items to the concepts. The items that were given to the experts were chosen at random with the exception that there was at least one item in the subset for every concept. The restriction to a subset of items was necessary due to time limitations. For the two concepts mentioned above, six items were included. We also added an eleventh category to the expert rating for items that did not fit into any of the provided categories. Finally, the experts had room to give comments.
Scales

In an experiment, Brian wants to measure the mass of an object as precisely as possible. He uses a calibrated scale (left) and an uncalibrated kitchen scale (right). That means that the kitchen scale was not tested with respect to its accuracy by comparing it with a standard scale. “Zero position” indicates how accurately the scales read 0 g when nothing was put on it. For both scales he identified possible sources of uncertainty and listed these in an uncertainty budget. The overall uncertainty was determined by rounding.

In an experiment, Brian wants to measure the mass of an object as precisely as possible. He uses a calibrated scale (left) and an uncalibrated kitchen scale (right). That means that the kitchen scale was not tested with respect to its accuracy by comparing it with a standard scale. “Zero position” indicates how accurately the scales read 0 g when nothing was put on it. For both scales he identified possible sources of uncertainty and listed these in an uncertainty budget. The overall uncertainty was determined by rounding.

<table>

</tr>
<tr>
<td>Zero position</td>
<td>0.1 g</td>
</tr>
</tbody>
</table>

Which of the two scales is more reliable and why?

- The calibrated scale is more reliable because the precision of the display digits is much better.
- Both scales are equally reliable because their uncertainty of the zero position is the same.
- The kitchen scale is more reliable because it has the smaller overall uncertainty.
- It is not possible to compare the reliabilities of the two scales because the uncertainty of the calibration of the kitchen scale is unknown.

Which of the two scales is more reliable and why?

- The calibrated scale is more reliable because the precision of the display digits is much better.
- Both scales are equally reliable because their uncertainty of the zero position is the same.
- The kitchen scale is more reliable because it has the smaller overall uncertainty.
- It is not possible to compare the reliabilities of the two scales because the uncertainty of the calibration of the kitchen scale is unknown.

Step 4: Empirical test of the scales that represent the concepts

We presented the 34 items of the two concepts “Reliability of a Measurement and the Results” (17 items) and “Comparison of a Result with other Values” (17 items) to 143 pupils from the 8th grade to the 12th grade in six different classes of three German schools in an urban area. All students were asked to answer all items. The order of the items was the same within the two concepts, but half the participants saw questions about one concept first, and half saw the other concept first. The participants had as much time as they needed to answer. No student took longer than 90 minutes.
RESULTS

Results of Step 3: Assessing the validity of the test items

In the first empirical step of item development, the three experts gave the following rating to the 52 items: 31 items were sorted to the same concept by all three experts, 14 items were sorted to the same concept by two of the three experts, and 7 items were sorted to three different concepts by the three experts. The inter-rater agreement was $\kappa = 0.67$ (Fleiss’ kappa). When restricting the inter-rater agreement to the two concepts in focus (with the six items) we obtained $\kappa = 0.50$ (three items were assigned to the same category by all three experts, two items were assigned to the same category by two experts, and one item was assigned to three different categories by the experts). All items were kept. However, items that fell into two or more categories were modified based on the experts’ comments and based on a discussion between the authors.

Results of Step 4: Empirical test of the scales that represent the concepts

Next, we analyzed the pupils’ responses to the 34 scale items. A Rasch analysis and additional tests were calculated with Winsteps and R (also R Studio). We chose Item Response Theory (IRT) instead of Classical Test Theory (CTT) because IRT has stricter conditions regarding the characteristics of the items and because it allows us to display the estimated ability of the students and the difficulty of the items on the same scale (for an introduction to IRT see for example Hambleton, Swaminathan, & Rogers, 1991). Figure 2 shows the Wright maps for the concepts “Reliability of a Measurement and the Results” and “Comparison of a Result with other Values”. The left side of each diagram displays the number of participants that reached a certain ability in a frequency diagram. This ability was scaled by algorithm of the program R (in this case here from -3 to 4). This scale is also used to assign each of the items a certain difficulty. The right side of each diagram shows these difficulties in ascending order. Thus, we can display the estimated ability of the students and the difficulty of the items in one single diagram.

The difficulties of the items lie between -0.93 and 2.70 (Reliability of a Measurement and the Results) and between -1.08 and 1.26 (Comparison of a Result with other Values). The estimated abilities lie between -2.41 and 1.99 and -2.74 and 4.45 for these concepts, respectively. The Expected a Posteriori (EAP) reliability of the Rasch-analysis for the concept “Reliability of a Measurement and the Results” is $r = 0.54$ and for the concept “Comparison of a Result with other Values” $r = 0.80$. For the WLE reliability we computed 0.75 (Comparison of a Result with other Values) and 0.49 (Reliability of a Measurement and the Results).

We also looked at the Unweighted Mean Square (MNSQ) Outfit values, which indicate how accurately or predictably the data fits the Rasch model. We decided to use the MNSQ-Outfit over the MNSQ-Infit since the MNSQ Outfits are more sensitive to items with difficulty far from the estimated ability of the participant. The MNSQ-Outfits are in the range between 0.92 and 1.18 (see Figure 3) for the concept “Reliability of a Measurement and the Results” and between 0.76 and 1.37 for the concept “Comparison of a Result with other Values” (Figure 3). Thus, the MNSQ Outfit values of all but one item are inside the interval of 0.7 - 1.3
Strand 11

recommended by Linacre and Wright (1994) and are therefore useable for a measurement (see also Linacre & Wright, 1994).

Figure 2. Wright-Maps for the concepts “Reliability of a Measurement and the Results” (left) and “Comparison of a Result with other Values” (right); all 17 items of both concepts were answered by \( n = 143 \) students.

Figure 3. Estimated Difficulties and MNSQ Outfits for the items of the concepts “Reliability of a Measurement and the Results” (top) and “Comparison of a Result with other Values” (bottom).
DISCUSSION

Assessing the validity of the test items

From the metrology experts’ ratings, we evaluated how well each item appeared to measure the concept it was intended to measure. According to Landis and Koch (1977), the inter-rater agreement of the experts can be interpreted as “substantial” (for all 52 items) and “moderate” (for the six items of the two concepts in focus). This result has to be seen in light of the restriction that the experts had eleven categories to choose from, that only a subset of the developed items of the complete test was rated, and that only six items of the two concepts in focus were included. However, the expert rating indicated that although there was agreement on many items, some of the items needed further improvement. One expert suggested to be clearer in the use of technical terms. For example, the item shown in Figure 1 must differ between gauging and calibrating. Further, some of the experts remarked that some of the answer options of specific items fell into different categories. This problem was addressed by choosing more fitting answer options for those items. To verify that all the changes of the items are improvements, and lead to clear mappings between items and concepts, a second round of expert rating is needed.

Concerning the method of the expert rating, we have to keep in mind, that assigning the items to the concepts by experts is only one way of estimating the validity. This validation procedure is also limited in the way that it can’t ensure that the content of the concept is covered completely by the items.

Empirical test of the scales that represent the concepts

The items generally fit the Rasch model. That means that the strict conditions that the IRT specifies for the items is fulfilled. The MNSQ Outfit values of all but one item are inside the interval of 0.7 - 1.3 recommended by Linacre and Wright (1994). The MNSQ outfit value is marginally beyond the threshold (with 1.37 as shown in Figure 3) for one item (Vg 1) only. That means from a statistical point of view that the item may be unproductive for the scale but it is not degrading the measurement system. Since the deviation is very small and since this item received high agreement by all three experts, we kept it in the test. The Wright maps for the two concepts show that the distribution of the difficulty of the items fit the competencies of the students quite well. However, items with lower difficulty can improve the scale “Reliability of a Measurement and the Result”. Those items could replace some of the many items with a medium difficulty, so the test could cover a greater spectrum of difficulty without increasing the number of items.

For the difference in the reliability of both concepts there might be several reasons. Most obvious it might be possible that the items of the concept “Comparison of a Result with other Values” need further improvement. But if we keep in mind that the concepts are derived from a model which includes subconcepts for each concept, it might also be possible that the concepts split up in two (or even more) subdimensions. For example it might be possible that for the participants, the presentation of a measurement result with uncertainty is another competency, different from giving and interpreting an uncertainty budget (see competencies Table 2). Further research is needed to come to a final judgement here. Currently we are
working on further analysis of the data, for example a detailed Rasch analysis including an analysis of potential subdimensions.

To assure that including new items reduces the gap in the Wright map, it is necessary to test the set of items again. This should be useful anyway since experts recommended changes to some of the items. If those changes also affect the reliability of the items, they must also be controlled when testing further improved items in a future study.

CONCLUSIONS

The results show that our test instrument to assess secondary school students’ understanding of measurement uncertainties works well for the concepts discussed. The scales and items have desired levels of difficulty and cover students’ competencies (with a few exceptions). Even though there is room for improvement (e.g. in the validity and the range of the difficulty of the items), the results of this study show that the concepts of the model can be measured well using multiple choice items. These findings show that the process of developing items for each concept, having the items evaluated by metrology experts, and then tested for coherence by actual students, is a productive method of developing and validating a scale for assessing understanding measurement uncertainty. We are currently working on improvements of the items and on the development of scales for all ten concepts.

ACKNOWLEDGEMENT

We would like to thank Sarah Heydemann and Laura Kemnitzer for their support in the study.

THE DESIGN AND IMPLEMENTATION OF AN ASSESSMENT METHOD COMBINING FORMATIVE AND SUMMATIVE USE OF ASSESSMENT

Sanne Schnell Nielsen¹, Jens Dolin¹, Jesper Bruun¹ and Sofie Birch Jensen²
¹University of Copenhagen, Copenhagen, Denmark
²King’s College, London, England

The two key purposes of assessment, formative and summative, often contradict each other when attempted used simultaneously. Summative assessment of learning will generally prevent formative assessment for learning to be realised, so the learning potential of the assessment will often be minimal (Butler, 1988). It is therefore interesting to find ways to combine the dual use of assessment, which do not diminish the learning potential. Moreover, in order to be useful and manageable, the assessment method must be easy to integrate into and should align with ordinary teaching. This study explores how such an assessment method, called the Structured Assessment Dialogue (SAD), could be designed and the rationale behind it. Then the study investigates the challenges and benefits perceived by teachers related to the uptake of SAD in their daily practice. The SADs were undertaken in science, technology and mathematics in primary and secondary schools in Denmark and Finland. The data used in this study include teacher-generated preparation and reflections forms, interviews with teachers, and an open-ended questionnaire. Our findings suggest that SAD holds prospects for fulfilling the purposes for both formative and summative assessment, with the highest prospects related to formative assessment purposes and characteristics. However, it needs time, change of classroom culture, and adjustments and careful implementation and routine building. In addition, teachers must be proficient in addressing the different aspects and levels of competences throughout the SAD.

Keywords: assessment methods, assessment of competence, inquiry-based teaching

INTRODUCTION

The two key purposes of assessment, formative and summative, often contradict each other when attempted used simultaneously. Summative assessment of learning will generally prevent formative assessment for learning to be realised, so the learning potential of the assessment will often be minimal (Butler, 1988). It is therefore interesting to find ways to combine the dual use of assessment, which do not diminish the learning potential. Moreover, in order to be useful and manageable, the assessment method must be easy to integrate into and should align with ordinary teaching.

Such an assessment method, called the Structured Assessment Dialogue (SAD), has been developed as part of a European research project Assess Inquiry in Science, Technology and Mathematics Education (ASSIST-ME). SADs are ritualized, short, 3-part assessment activities integrated as part of ordinary classroom teaching. SADs aim at uncovering student competencies while also providing students with feedback and time for self-reflection.

The next section describes different purposes of formative and summative assessment and elaborates on the characteristics they have in common as well as their differences.
Purposes and characteristics of formative and summative assessment

The differences between formative and summative use of assessment are pinpointed in wordings: Assessment for learning and assessment of learning. The same assessment method can be used for both formative and summative purposes but the use defines whether the assessment is formative or summative. Formative use of an assessment method is meant to improve students’ learning (or teachers’ teaching). Summative use of the same assessment method will judge students’ level of competence (or teachers’ teaching). We see summative and formative assessment as inherently linked, but with formative assessment focusing on student involvement, student achievement of both normative and personal criteria, and finding the next learning step (Black and Wiliam, 1998; Harlen, 2012, 2013; Dolin, Black, Harlen and Tiberghien, 2018a). Both uses of assessment rely on evidence of student performance but while the interpretation of this evidence is criterion-referenced (i.e. related to the learning goals) for summative purposes, it is also student-referenced for formative purposes. This is because students need to know what to learn next and how to do it. This is student-specific and needs student involvement to be realised. The other critical aspect of formative assessment is ‘finding the next learning step’ in a series of learning steps; a progression.

Just like summative and formative assessment can be seen as part of the same cycle, they can also be seen as two ends of the same continuum, rather than a dichotomy. This illustrated in Figure 1.

| Formative<-------------------------------------------------------------------------------------------->Summative |
|-------------------------------------------------|-------------------------------------------------|-------------------------------------------------|-------------------------------------------------|
| Informal formative | Formal formative | Informal summative | Formal summative |
| **Major focus** | What are the next steps in learning? | What has been achieved to date? |
| **Purpose** | To inform next steps in learning | To inform next steps in learning and teaching | To monitor progress against plans | To record achievements of individuals |
| **How is evidence collected** | As normal part of class work | Introduced into normal class work | Introduced as a special part of normal class work | Separate task or test |
| **Basis of judgement** | Student- and criterion-referenced | Student and criterion-referenced | Student and criterion-referenced | Criterion-referenced |

Figure 1. Formative and summative assessment as a continuum. The SAD is placed as the rectangle overlapping both.

The placement of the SAD as being able to have elements of both formative and summative assessment will be substantiated in the following.

Rationale for designing a classroom and dialogue-based assessment method

Our design of a dialogue-based assessment draws upon the Norwegian researcher Olga Dysthe (1996), seeing dialogue as a central way to learning. Dysthe is inspired by the Russian linguist Bakhtin (1981), and the key point is to open a room for student reflection in a non-authoritative environment.
Teacher-led classroom dialogue is one of the most common instruction practices worldwide (William & Leahy, 2015). Moreover, a large proportion of the information that teachers obtain through informal formative assessment is obtained through classroom dialogue (Ruiz-Primo, 2011). Hence, introducing a dialogue-based assessment method in the classroom will to a large extent align with an already existing instruction and assessment approach.

When we designed the SAD, the aim was two pronged: on the one hand we wanted to develop a method resembling an already existing dialogue-based formative assessment practice. On the other hand, we also wanted to develop a method that teachers could use for both formative and summative assessment.

Most formative assessments within the typical classroom are quite informal in nature, generally unplanned and used differently by different teachers (Shinn, 2013). However, in order for an assessment method to be able to contribute to summative purposes it must provide a relatively standardized approach to how it is administered.

To address the above factors, the format of the SAD was intended to be structured, planned and formal. This is reflected in the SAD design by establishing a concise phase and time structure, well defined assessment criteria, and an unequivocal division of roles among the participants in the classroom. In the next section, we will briefly describe the structure of the SAD. A more detailed description of SAD and its operationalization can be found in Dolin, Bruun, Nielsen, Jensen and Nieminen (2018).

In order to be effective, formative assessment has to be integrated into classroom practice (William, 2011). The SAD is intended to be an integrated component of the ordinary teaching, yet the setting is different from the ordinary teaching. As part of the setting, each student gets appointed to undertake a specific role (i.e. focus student, feedback student or self-reflecting student) and, subsequently, all students are physically rearranged according to these roles (Figure 2).

The SAD consists of three distinct phases, each with a clear and well-defined role for the teacher and for each of the students. The three phases have specific functions related to formative and summative assessment:

**Phase 1.** An assessment dialogue between the teacher and a preselected focus student based on specific assessment criteria related to a specific aspect of a competence (5-7 minutes).

**Phase 2.** Peer feedback from a group of students to the focus student (5 minutes).

**Phase 3.** Self-assessment where all students in the classroom assess their own level and reflect on their learning needs (2-3 minutes). For summative purposes, the teacher notes down the level of the focus student.

From an assessment perspective, the SAD can provide evidence for what and how students are thinking. This information can be used for both formative and summative purposes. The latter because the SAD makes the level of students’ understanding explicit for the teacher - and the
students are asked to assess themselves. From a formative perspective, the SAD holds prospects for activating students contributing to their own and peer students’ learning and to voice their understanding so that the teacher can recognize and act on it to promote learning. Hence, one SAD session will lead to the formative and summative assessment of the focus student or focus group and possibly to formative assessment of many students.

**Formative and summative assessment potentials associated with the SAD**

The prospects for learning through formative assessment of a classroom dialogue may vary and can in the worst case be very minimal (Ruiz-Primo, 2011). The limited prospects for learning may be caused by multiple factors. The SAD intends to address four factors that each are expected to severely limit the prospects for learning. The first factor is related to insufficient planning, clarifying and sharing of learning intentions and criteria with students (Black & Wiliam, 2009; Hattie & Timperley, 2007; Ruiz-Primo, 2011). The second factor is associated with a limited engagement of students’ in their own and peers’ learning, including self-assessment and peer assessment (Black, Harrison, Lee, Marshall & Wiliam, 2004). The third factor is related to absence of, or unclear, feedback (Shute, 2008). The fourth factor is correlated to lack of alignment between goals, teaching and assessment approaches (Bennett, 2011; Krajcik, McNeill & Reiser, 2008).

In the following, we will elaborate on how SAD is designed to address the first three factors. Since learning goals describe the intended consequences of teaching and learning, they could form the basis for focusing and structuring the assessment. Based on this assumption, the SAD is guided by specific learning goals identified and described by the teacher ahead of the teaching and assessment session. A teacher may not make explicit – neither for him/herself nor for the students - the criteria for assessing whether, or at which level, a learning goal is being achieved. This will make it difficult for a student to recognize his/her own level or to provide feedback and engage actively in own and others’ learning.

In the SAD, teachers are requested to subdivide the learning goals into a range of specific assessment criteria reflecting different aspects and levels of the competence being assessed. This is to avoid an unfocused assessment practice with a tendency to assess more general, trivial, or managerial aspects. Likewise, the purpose of this is to facilitate formative assessment. The rationale is that making different aspects and levels explicit will support more well founded decisions about next steps for individual students who may be at different stages in their learning and therefore requires different kinds of feedback. The subdivision of learning goals holds prospects for facilitating formative assessment by making the different aspects and levels in students learning process explicit. For summative purposes, the specific assessment criteria are expected not only to support the assessment of students’ achievements, but also to provide transparency in grading.

In addition, teachers were asked to share and clarify to students the learning goals and range of criteria. The criteria are also used in the peer-feedback as well as in the self-assessment phase. It provides students with a tool to reflect on their current level of fulfilment of criteria aligned with the learning goals and on their next steps in learning. It is intended as a way of strengthening classroom learning cultures by having students engage actively with their own
and others’ learning. Finally, providing the students with transparent assessment criteria would formalize the peer feedback, thus reduce the personal aspect among the students (e.g. friends, status).

In the next section, we will elaborate on how the fourth factor, related to lack of alignment, was addressed in the SAD design. According to Krajcik et al. (2008) consistency between goals and observable assessment criteria adapted to specific teaching sequences facilitates learning. In the same vein, Bennett (2011) argues for consistency between goals, teaching, and assessment approaches. Since teacher-led classroom dialogue is a very common instruction practice, a dialogue based assessment might feasibly facilitate consistency between instruction and assessment. In addition, a SAD session will typically be integrated in the ordinary teaching. Hence, the SAD will be situated within learning activities with which students have just engaged. Furthermore, students may be prompted to use artefacts (e.g. models, drawings, lab results) from the teaching during a SAD session. As aforementioned, the SAD is guided by learning goals described by the teacher ahead of the teaching and assessment session. This advanced clarification of learning goals might also facilitate consistency between instruction and assessment.

RESEARCH QUESTION

The purpose of the SAD is for students and teachers to gain insight into the students’ current level of attainment and the next steps in students’ learning in a useful and manageable way in the day-to-day teaching. The novelty of the SAD and teachers’ central role in enacting the SAD guide our research question:

RQ: What are the main challenges and prospects perceived by teachers for using the SAD in the daily practice in science, technology and mathematics in lower and upper secondary schools?

RESEARCH METHODS

The SAD sessions were prepared by teams of teachers and researchers in Denmark and Finland, and the research was done in close collaboration with teachers as action research (Zeichner & Nofke, 2001). The SAD was implemented 20 times in Denmark and 6 times in Finland. Students were from lower and upper secondary school (level 7-12), and all teaching units had a focus on the cross-disciplinary competences modelling or argumentation.

The entire corpus of data consists of filled out teacher preparation templates, video recordings of the student-teacher dialogue, audio recordings of feedback sessions, filled out student self-reflection forms, an open-ended teacher questionnaire, and interview with teachers.

To answer the RQ, we used data from Denmark only. The data set consists of filled-in teacher preparation and reflections forms (n=11), two semi-structured interviews of teachers, one focus group interview with teachers (Kvale, 2007), and an open-ended questionnaire for teachers (n=4). The focus group interview and the semi-structured interviews were facilitated by two of the authors. Both the interviews and the responses to the open-ended questionnaire were analysed using thematic analysis (Braun & Clarke, 2006). We analysed the interview by
transcribing, reading, re-reading and in some cases re-listening to the interviews using the RQ1 as an analytical lens. Specifically, we focused on the challenges and benefits perceived by teachers with respect to each of the four principles behind the SAD. We used the same analytical approach for the questionnaire and the teacher preparation form.

RESULTS

Benefits related to planning, clarifying and sharing of learning intentions and criteria with students

The teachers saw several advantages in the formulation and utilisation of a clear statement of learning goals and explicit assessment criteria with respect to formative assessment, such as enhancing students’ involvement in the assessment and providing transparency in the assessment. Teachers highlighted the benefits of sharing the assessment criteria with the students. A teacher wrote: “The learning becomes explicit for the students”. Adding to this another teacher said: “My students like it a lot and we will continue [to use the method]. Because they actually think that it worked - that the criteria were made clear and that they knew what to aim for”. In addition, teachers found the criteria very useful for students to provide peer-feedback and self-reflection. Moreover, teachers’ utterance also indicates how sharing of learning goals with students in the SAD becomes coherent with, and benefits, upcoming teaching by activating students in their own learning, exemplified by this quotation, “I experienced that after a dialogue the students got better at setting up goals for themselves.” In general, teachers acknowledge the SAD for facilitating students to take part in the assessment process. A teacher relates this to the following features of SAD: “short and time-bound.”, and “characterized by clear rules and roles.” According to the teacher those features enhance students’ willingness to participate.

However, teachers not only appreciate SADs’ features for facilitating students’ engagement in their own learning but also features related to alignment between learning goal, teaching and assessment approaches.

Benefits related to alignment between learning goals, teaching and assessment approaches

In order to be useful for formative assessment and manageable in the day to day teaching, the assessment method must resemble and be easy to integrate into the ordinary teaching. As mentioned above, the usefulness with respect to formative assessment depends on the alignment between teaching and assessment approaches. In general, the teachers appreciated that SAD was dialogue-based and not written. This was mainly because the SAD in this way resembled the existing dialogue-based classroom practice, and at the same time provided teachers with a better prospect in understanding the basic ideas behind student’s response. In this perspective a teacher highlighted the value of the SAD: “[…..] and it is possible to get a nuanced picture of the students’ understanding – something that a written text would not be able to capture to the same extent.”

With respect to manageability, teachers highlighted the SADs’ adjustable features. As reflected in teachers’ preparations and reflections forms and interviews, many teachers adapted the SAD
to local needs and contexts. E.g. the learning goals and their associated assessment criteria were adapted to specific teaching subjects and specific students’ needs. In this way, teachers’ use of the SAD assisted the process in aligning and adjusting the assessment with the ordinary teaching.

Teachers also adjusted the SAD to local class cultures. In classes with an ordinary teaching characterized by group work the single focus student was replaced by a group of two to four students. In classes with no need or tradition for grading, the SAD was only used for formative purposes. In this way, the adjustable feature of the SAD was used to strengthen the coherence between teaching and assessment. Furthermore, a teacher found that the restricted timeframe made the SAD a manageable assessment method to integrate in the relatively short timeframe of the regular teaching units.

Teachers use and acknowledgement of SAD to strengthen the alignment between the ordinary teaching and assessment was also extended to the subsequent teaching i.e. the assessment was used formatively to influence the following teaching. This is e.g. reflected in the teachers’ descriptions of how the SAD facilitates students to take along their observations and reflections into the next teaching unit. The extended use of the SAD was also made by teachers. A teacher e.g. made a reference to how she followed up on a students’ misconception, while another teacher made a reference to how the assessment criteria were expanded on in the subsequent teaching unit. This alignment between teaching and assessment was supported by appropriate teaching activities. For example, one teacher used SADs explicitly as a reference point to other activities: “After the SAD-sessions, our students were to write a report based on the unit, and they could use the SAD there. They were motivated to use that as a shortcut to understanding how to present material.”

The SADs’ prospects for strengthening the alignment between learning goals, teaching and assessment also relates to teachers’ perceptions of SADs’ prospects to address the assessment to different students.

**Benefits related to aligning and adjusting to different students’ learning needs, processes and achievements**

Teachers experienced that the different aspect and levels reflected in the assessment criteria were useful in facilitating the learning process for a range of students with different learning abilities. This point is illustrated in this quote: “During SAD, I mainly use the different assessment criteria for guiding my questions to address the differences between individual students’ understanding and ability.” This suggests that the teacher perceives the SAD as having potential for adapting the assessment criteria to different students. Note that this is even though the overall learning goal and its associated criteria are formulated in advance and targeted to assess students’ achievements related to a specific teaching unit. In this way, teachers’ use of questions based on the assessment criteria was used to strengthen the alignment between learning goals, teaching and assessment, and at the same time adjust the assessment to match different students.

Other adaptations used and appreciated by teachers were related to shortening or prolonging the total timeframe or single phases to fit the formative assessment to different students’ needs.
Strand 11

or give time for elaborating on new upcoming topics. This point is illustrated in this quote: “And there was something they [the students] had a hard time to understand the last time, so if we had not gotten to that, the whole thing would have collapsed. So we took two more minutes.”

In the next section we will elaborate on how the teachers relate the promise of the SAD to the formative and summative purposes of assessment, respectively.

**Benefits related to formative and summative purposes**

Several of the benefits of SAD as perceived by teachers could be related to both summative and formative purposes. For instance, all the following aspects are related to usefulness when collecting evidence and judging students’ achievements for assessment for summative as well as formative purposes, respectively: (1) clearly stated assessment criteria to enhance transparency and to guide questions and assessment; (2) alignment between learning goals, teaching and assessment; and (3) short and delimited in time and content, and (4) possible to get a nuanced picture of students’ understanding and rationale through dialogue.

In general, however, the teachers acknowledged the SAD as a formative assessment method as illustrated in the following teacher quotes addressing the feature of the SAD: “It captures the essence of formative assessment”; “The main strength is the focus on formative assessment”; and “It’s very clear to the students that it is a part of a process.” This point is also reflected in the fact that in many utterances teachers do not only describe the SAD as an assessment method but as a “teaching- and assessment tool”.

Nevertheless, the teachers also saw several advantages in the formulation and utilisation of a clear statement of learning goals and explicit assessment criteria with respect to summative assessment, such as providing transparency in the assessment. A teacher used the learning goals for clarification, and for documentation for parents’ meetings and to provide transparency in grading during the semi-annual student conversation.

As stated above, teachers described a large range of promise related the integrating the SAD in the ordinary teaching. However, teachers also encountered some challenges when enacting the SAD in their teaching and assessment practice.

**Challenges related to planning and clarifying of learning expectations**

Formative assessment is part of a learning process consisting of a series of learning steps, forming a progression. As part of the preparation for the SAD, teachers were asked to formulate learning goals with associated assessment criteria and questions to assess the different levels and aspects of students learning progress. To be explicit about the learning progression turned out to be one of the most challenging aspects for the teachers. In general teachers found it time consuming and difficult to prepare the learning goals, assessment criteria and questions: “I think it has been time consuming to formulate different levels of assessment criteria”, “I think there has been a lot of preparation; to sit down and really think through with assessment criteria and questions”, and “It is not easy to make it clear for students what the criteria are”. All teachers emphasised that they value the formulation and use of the assessment criteria reflecting different levels and aspect of students learning progression. Still, many expressed
concerns with respect to being able to incorporate this very time consuming preparation in the
day to day teaching and assessment practice.

Even with the operationalization of the learning progression into assessment criteria, teachers
found it challenging to judge the level of the focus student: “It is not easy to work with learning
progressions and planning for giving summative assessment at the end. How can I in five
minutes of dialogue and five minutes of feedback be sure that someone asks questions, which
will allow me to place the student on one of the progression steps? “

Another challenge raised by teachers relates to striking an appropriate balance between
knowing what the focus student is capable of and which questions to include in the dialogue
and, at the same time, clarifying a realistic level of learning expectations to the rest of the class.
One teacher described, “It [the task and questions] must resemble the appropriate complexity
required in a teaching situation and for the final exam. It should not be too easy […] You have
to find the right student to deal with that [the complexity]. But it’s not an easy task to strike the
balance.” Another concern voiced by the teachers related to this issue was to avoid display of
weak students’ level of achievements in front of their peers.

This confirms that an important part of planning is for the teacher to tailor the questions to the
focus-student while still making realistic assessment criteria clear to other students. Adding to
this, the teacher must ensure his/her questioning of the focus-student provides other students
with sufficient information enabling them to provide sound peer-feedback.

**Challenges related to students’ involvement in their own and others learning**

In general, teachers perceived the peer-feedback session as the most challenging part of the
SAD due to students’ inadequate “assessment literacy”, such as low assessment value with
respect to both feedback quantity and quality. E.g. a teacher wrote, “In the peer-feedback
session I missed content depth and more comments”. Teachers mainly addressed challenges
related to assessment literacy with respect to students’ limited content knowledge and praised
their peers instead of providing guidance for the next step in the learning. To address this
challenge, the teachers often perceived a need to add to or facilitate the peer-feedback session.
A teacher was planning to repeat the SAD but nuance it in the following way: “Allocating
different roles to the students in the feedback group, so that each student gets his/her own
assignment”. Another teacher was planning to provide the students with a rubric with the
learning goals divided into three different levels of learning progressions.

Finally, teachers encountered challenges related to activating all students. Teachers described
that students’ (but not all and with variation in their effort) took an active involvement in the
process. However, teachers also reported SAD sessions where it was hard to activate all
students throughout the session: “The listening students may have a hard time keeping up” and
“It is a challenge to keep the drive-over-time in the SAD so that the feedback group is serious
about their own learning (self-assessment).”
Challenges related to time frame and alignment between teaching and assessment approaches

The SADs were integrated as a part of the ordinary teaching to make alignment between teaching and assessment. The strict 5-minute time frame in the dialogue posed a challenge to most teachers to assess students’ achievements with respect to the previous teaching. The teachers describe how the time frame limits the amount and complexity of the content to be assessed. As one teacher made explicit: “It can be difficult to make as limited an assessment that it is possible to keep the time frame”. A different teacher states: “After five minutes we were just started. I was not able to address modelling appropriately”. Based on experiences from an implemented SAD, the same teacher expressed how he adjusted the next SAD to the restricted timeframe: “The more complex questions were toned down.” Another teacher was also planning to repeat the SAD but adjusted the timeframe instead of the complexity: “I probably would not obey the five minutes, but use the time that is needed on the dialogue.”

Some teachers chose a group of students to be in focus rather than just one focus student. This was done in order to make alignment to and resemble their current classroom practice (i.e. group work), moderate the feeling of high-stakes assessment and avoiding exposing a single student. However, this made the five-minute timeframe even more challenging.

Combining summative and formative assessment

Most teachers used the SAD for only formative purposes, meaning that the possibility of combining the two uses of assessment was not so well examined.

Regarding students’ self-summative assessment, teachers in general, but with exceptions, believed that the students assess themselves on too high a level of achievement. A teacher wrote “No demands for giving feedback to students self-assessment as I doubt the function, validity and seriousness.“

During the peer-feedback, which had mainly a formative purpose, there was a tendency only to comment on positive aspects: “When female friends were feedback students, they only provide each other positive feedback”. A teacher believed that the “over grading” in self-assessment and the insufficient feedback were part of a “performance culture”. This point is illustrated in the following quotes: “Students’ didn’t believe me when I told them that it (the SAD) was a kind of a play and that it would not influence the grading at all.” and “They think I will look at the (self) grade and base my grading on it.” Another challenge highlighted by teachers is related to the SAD’s physical set up: ”There is a tendency that students may experience the SAD as an interrogation. When that is the case, the students will not see the process as being useful with a view to the future.”

Due to the strictness of the formative processes based on a clear and explicit learning progression in the competences assessed, the SAD has a potential for summative use without distorting the formative aspects. This is because that any summative assessment happens at the very end of the ritual and is embedded in a formative process. We thus avoid the before mentioned domination of the summative purpose; you tend to see when the two purposes are mixed (Butler, 1987).
But it was clear that the performance culture in Danish schools made the summative use a delicate thing and the tendency to perceive the SAD as a kind of exam might hinder the formative prospects in the SAD.

**Future perspectives on research on structured assessment dialogues**

For the purposes of this paper, we have focused exclusively on teachers’ perceptions of the SAD. Since teachers’ and students’ perceptions of feedback can be different (Ellegaard et al, 2017), a future study of student perceptions of the SAD might provide insights into why, for example, the feedback part of the SAD is difficult to orchestrate. Our current corpus of data will not allow us to investigate student perceptions directly.

Another future perspective is to investigate the actual dialogues and their role in relation to teaching and learning in the science classroom. In other publications, we have developed a methodology for mapping and analyzing the SAD (Dolin et al, 2018b). The mapping we have developed integrates network analysis with a dialogical coding scheme, criteria for the dialogue, and gestures. Each dialogue is then converted into a map, which shows who is active, which criteria are addressed, and which dialogical strategies are used in the dialogue. We have used this methodology to extract a typology of dialogues. In future studies, such a typology could be used to characterize the role of different kinds of the SAD in the science classroom.

**CONCLUSIONS**

In most of the enactments of the SAD, teachers only used the formative potentials of the SAD. The formative prospects are mainly related to the SADs’ features of: (1) clarifying and sharing assessment criteria with students; (2) enabling high student engagement in their own and peers’ learning; and (3) being adjustable to students with different needs.

In addition, teachers acknowledged the SADs potential for both formative and summative purposes related to SADs’ features of: (1) facilitating coherence between teaching and assessment approaches; (2) being adjustable in time and content; and (3) being relatively easy to enact and integrate into the existing teaching practice.

The SAD has potential for combining formative and summative purposes of assessment. However, it needs careful and repeated enacting if the summative aspects should not hinder the formative prospects for instance through change of performance classroom culture, and through enhancing and supporting students’ competences in providing feedback and self-grading. Finally, teachers need time and experience in identifying and describing appropriate assessment criteria that reflect different levels and aspects of students’ learning process.

AN INSTRUMENT FOR MEASURING PUPILS’ FAMILIARITY WITH SCIENCE EDUCATION SETTINGS

Rebecca Cors¹, Andreas Müller² and Nicolas Robin¹

¹ University of Teacher Education, Institute for Teaching Natural Science, St. Gallen, Switzerland
² Université de Genève, Fac. of Science/Physics Sect., and Institute of Teacher Education, Geneva, Switzerland

How novel, or unfamiliar, a visit to an out-of-school learning place (OSLeP), such as a science center, feels has been linked to changes in young people’s interest in science and technology (S&T). However, few studies have attempted to measure how participants perceive novelty during OSLeP visits. This article describes the development, testing, and validation of a survey instrument to measure at-visit perceptions of novelty at OSLePs. Drawing from existing studies about how people perceive novelty in learning settings, researchers developed a questionnaire to assess at-visit perceptions of novelty. A total of 215 pupils completed the survey during a mobile laboratory visit (www.mobillab.ch). Through factor analysis and reliability testing, the authors identified four meaningful clusters of survey items. These survey scales, which we called novelty experience factors (NEFs), define four dimensions of pupils’ at-visit perceived novelty: curiosity (state), exploratory behavior, oriented feeling, and cognitive load. Results also offer new insights into how pupils perceived novelty at OSLePs. These NEFs were useful in a larger study that investigated relations between pupil factors, at-visit novelty, and educational outcomes for an informal science learning program. Measuring at-visit novelty is a key to better understanding the effectiveness of OSLeP experiences for promoting educational outcomes.

Keywords: science interest, novelty, out-of-school learning

INTRODUCTION

Over the last forty years, out-of-school learning places (OSLePs), such as science centers and mobile laboratories, have been developed to promote interest in science and technology (S&T) topics and careers. These programs are critical for educating our Digital Age workforce and for promoting a scientifically literate citizenry (Sjøberg & Schreiner, 2010).

Novelty is a key factor for investigation of informal science education programs

How novel, or unfamiliar, an OSLeP visit feels to people has been shown to affect the degree to which their dispositional, or lasting, interest in the topic of the OSLeP develops. For example, faced with operating unfamiliar, high-technology equipment, some people feel intrigued, while others feel intimidated by the endeavor.

Measures of at-visit novelty are lacking

Even though studies of novelty at OSLePs suggest that a better understanding of at-visit novelty is important, few have measured it. The authors reviewed eight studies that examine how feelings of unfamiliarity, or perceived novelty, related to learner knowledge gain and S&T interest development at OSLePs (Anderson & Lucas, 1997; Cors et al., 2015; Cotton & Cotton, 2009; Falk & Balling, 1982; Falk et al., 1978; Jarvis & Pell, 2005; Kubota & Olstad, 1991;
Orion & Hofstein, 1991). Only three of these studies examined at-visit, perceived novelty at OSLePs, measured as exploratory behavior (Falk & Balling, 1982; Falk et al., 1978; Kubota & Olstad, 1991). Two of the studies showed that learners who were supposed to have more familiarity with the setting, either because they lived near a setting similar to the OSLeP (Falk et al., 1978) or because they saw a pre-visit orienting video (Kubota & Olstad, 1991), exhibited more exploratory behavior. Falk and Balling (1982) also found significant links between learning setting and exploratory behavior, which varied based on learner age. They found that third graders carrying out an assignment at a nature center, a more novel setting, worked less ‘on-task’ and displayed more social discomfort than their peers who did the assignment in a familiar wooded area next to their school. In contrast, fifth graders doing the same assignment in a wooded area near their school, a less novel setting, worked less ‘on-task’ and showed more signs of boredom than their peers who were working at the nature center.

That several studies about OSLePs showed links between exploratory behavior and learning setting highlights the importance of understanding at-visit novelty when investigating the effectiveness of OSLePs. For this reason, the authors wanted to measure at-visit novelty as part of their study of a science education program in Eastern Switzerland called mobiLLab (mobiLLab.ch). The mobiLLab program was developed by faculty at the University of Teacher Education in St. Gallen, Switzerland. Each semester, staff deliver 12 experimental stations to schools so that pupils can have a half-day experience with equipment used at S&T industries in the area. Indeed, a pilot study had already elicited teacher comments indicating that the pupils’ comfort and familiarity with mobiLLab experimental equipment improved their ability to profit from a mobiLLab visit (Cors et al., 2015).

**Clues for measuring at-visit novelty**

The studies included in the literature review describe several indicators of at-visit novelty that have not been explored for studies of novelty at OSLePs, but that have been explored through related research. For example, several researchers describe pre-visit ‘orienting’ activities that should have reduced novelty, yet none measure the extent to which learners feel oriented at the OSLeP visit (Anderson & Lucas, 1997; Jarvis & Pell, 2005; Kubota & Olstad, 1991; Orion & Hofstein, 1991). However, in a related study, a parameter similar to oriented feeling, called ‘preparation and orientation,’ was linked to pre-visit classroom preparation activities before an OSLeP visit (Orion et al., 1997). Another unexplored indicator of perceived novelty named by previous studies of OSLePs is at-visit curiosity (Anderson & Lucas, 1997). Such situational curiosity has, in turn, been related to the divergent and specific components of epistemic curiosity (Litman & Spielberger, 2003). A third unexplored indicator of at-visit novelty is described by some studies as how overwhelmed by unfamiliarity learners are at by experiences at OSLePs (Falk et al., 1978; Kubota & Olstad, 1991). This feeling of being overwhelmed by new information or objects could be measured using cognitive load survey scales that have been developed for flight simulator training settings (Hart & Staveland, 1988).

This existing research provided a foundation of survey items that could be adapted to measure at-visit novelty as perceived by visitors at OSLePs. This paper describes how the authors developed, tested and validated a survey instrument to measure pupils’ perceived novelty during a mobiLLab visit.
METHODS

Drawing from this research, a 20-item questionnaire about pupils’ at-visit novelty was developed, pilot tested, and then distributed to more than 200 pupils who visited mobiLLab, a science education laboratory in St. Gallen, Switzerland, in 2015. A factor analysis and reliability testing were used to identify measures for four dimensions of at-visit perceived novelty. We refer to these dimensions of perceived at visit novelty as novelty experience factors (NEFs).

Instrument Development and Testing

The first step in developing an instrument to measure pupils’ at-visit novelty experience was to look at survey items developed for similar purposes. Twenty survey items were adapted from other studies about how oriented, curious, free to explore, and overloaded people feel in a learning setting.

Piloting of the survey took place during a mobiLLab school visit in December 2014, where 40 pupils completed the survey during a break after they worked through their first two experimental stations and before they worked through their two remaining stations. For most items, pupils were asked to mark their level of agreement with each item on a 4-point Likert scale ranging from ‘not at all true’ to ‘completely true.’ An example item for curiosity is ‘I would like to learn more about the mobiLLab science themes and topics.’ The workload items had a 4-point semantic differential scale. For example, the item ‘What did you think of the time allotted to carry out the experiments?’ had endpoints of ‘too long’ and ‘too short’ to describe visit length.

After reviewing the variation in scalar responses and written responses, we revised several survey items. Also, because teacher feedback indicated that having the students complete the surveys during the break in the mobiLLab visit worked well, that schedule was maintained.

Data collection

A total of 215 pupils in 21 different class groups at 7 schools completed the at-visit survey during mobiLLab visits during the spring of 2015. Pupils were aged 13–15 and attended a secondary school in Eastern Switzerland that would prepare them for a trade or vocational program.

Validation: factor analysis approach

Because the survey items were adapted from several different previous studies and used in a new combination, we needed to explore how the items would describe different dimensions of pupils’ novelty experience at the mobiLLab visit in particular. It was important to distinguish those items that elicited responses indicating perceptions of, for example, curiosity state, from, for example, those items that characterized exploratory behavior. By revealing how responses to certain survey items have common variance, exploratory factor analysis helps researchers to identify clusters of items, or scales, which reliably represent a characteristic about a population. For these reasons, we chose principal axis factoring (Field, 2013) to explore the items about how pupils perceived novelty at the mobiLLab visit.
Through exploratory factor analysis, we looked at how responses to certain groups of survey items explained the variance in pupil responses to the entire survey in a similar way, indicated by a factor loading of > .03. A factor loading indicates the relative contribution of an item to a factor. It can be thought of as the Pearson correlation coefficient between a factor and a survey item. For example, the item, ‘I would like to learn more about the mobiLLab science themes and topics,’ had the relatively high loading of .67 for the factor called curiosity state. This high loading shows that the survey item strongly contributes to the variation among the items of the curiosity state factor. By reviewing these survey items and examining their relatability as a group, we sought to identify groups of items that reliably represented pupils’ at-visit novelty experience.

**RESULTS**

Results show that exploratory factor analysis and reliability testing were useful ways to examine a group of survey items about perceived novelty that had not yet been used together. It enabled us to determine that there were several explanatory factors under which the items can be grouped as viable survey scales (measurement instruments), namely curiosity state, exploratory behavior and cognitive load.

First, an initial principal analysis factoring, with orthogonal (Varimax) rotation, was run with the 20 survey items, which had been adapted from other studies. The analysis produced an eigenvalue for each factor. Eigenvalues represent the amount of variation among all survey items in the questionnaire that can be explained by that factor. Four factors had eigenvalues greater than 1.1 and these same four factors were identified by oblique (Oblimin and Promax) rotations. A fifth factor also had an eigenvalue greater than 1, but was eliminated because it included only one item with factor loadings greater than 0.3. The four factors in combination explained 47% of the variance in pupil responses. The scree plot was somewhat ambiguous and the inflection supported selecting either three or four factors. Given the moderate sample size and confirmation by Oblimin and Promax rotations, we retained three factors. The items that clustered on the same factor suggested that factor 1 represented pupils’ curiosity state, factor 2 represented pupils’ cognitive load, and factor 3 represented pupils’ exploratory behavior with mobiLLab equipment. A fourth factor, representing the extent to which pupils felt oriented, showed only two items with factor loadings greater than 0.3, which together gave a Cronbach’s alpha of α=.53, too low to warrant their use as a reliable scale. However, one of the items loaded at lambda=.69, so this item was used alone to represent at-visit oriented feeling.

Next, we conducted a forced three-factor analysis to identify which survey items contributed to scales for the three remaining NEFs: curiosity state, cognitive load, and exploratory behavior. Cronbach’s alphas for these three groups helped determine that two items were not contributing to reliability of the three strong factors. The item cls2 had a loading of < .300, so it was eliminated. Cronbach’s alpha for the exploratory behavior scale turned out to be greater than .700 when exex1 was eliminated and texs4 was used in reverse form.

A final principal axis was run as a Varimax rotation with the remaining 18 items (excluding cls2 and exex1). The results are shown in Error! Reference source not found., which lists
factor loading and communalities for each item and lists Cronbach’s alphas and eigenvalues for each factor. Through this final test (N=205), three factors were identified through loadings and only these factors had eigenvalues greater than 1. By reviewing the item clustering that this last factor analysis revealed, and using common sense and reliability testing, we identified survey scales for three dimensions of at-visit novelty at OSLePs. The dimensions are curiosity state, which explains 29% of the variance in pupils’ responses to all of the survey items, exploratory behavior, which explains 12% of the variance, and cognitive load, which explains 8% of the variance.

Error! Reference source not found. provides a summary of the variables developed as a result of this study. For each NEF, the table lists the number of survey items, the percent variance each factor explains, and the reliability for each scale.

**DISCUSSION**

This study produced and tested four measures of perceived novelty at OSLePs, all of which are grounded in novelty theory. The results also provide the first psychometric validation for three measures of perceived novelty at OLSePs. That is, investigators can use these survey scales to measure pupils’ perceived novelty in terms of reported curiosity state, exploratory behavior and cognitive load. While a variable for a fourth measure of perceived novelty, oriented feeling, was identified, it was a single survey item, rather than a scale.

By looking more closely at the factor loadings from factor analysis results, one gains further insight into ways that pupils perceived novelty during their visit. First, pupils associate the feeling of being oriented with the feeling of being able to explore the equipment. Evidence of this is that items sett1 and sett2 and sett3, which were developed to describe feeling oriented, loaded for the exploratory behavior factor. Also, pupils associated cognitive load with conducting experiments, as seen by the fact that items exex2 and exex3, which measure pupils’ ease with experimenting, loaded on the cognitive load factor. Finally, the fact that item texs5 belongs not to the exploratory behavior scale, as expected, but to the curiosity scale suggests that pupils associate fun more strongly with curiosity than with exploratory behavior.

Measuring at-visit novelty can help researchers and educators to better understand the degree to which learners perceive their OSLeP experience as new or unfamiliar. For example, a measure of oriented feeling can indicate whether, and by how much, novelty was reduced by classroom preparation. Such data can help us untangle the effects of classroom preparation from the many other variables that affect learner experiences at OSLePs. Measuring at-visit novelty is key to developing strategies for leveraging both ‘negative’ novelty (cognitive load), and ‘positive’ novelty (curiosity state, exploratory behavior, oriented feeling), in order to promote the effectiveness of OSLePs.

FRAMING DOCTORAL SUPERVISION
AS FORMATIVE ASSESSMENT

Sofie Kobayashi
Department of Science Education, University of Copenhagen, Copenhagen, Denmark

This paper addresses the issue of developing autonomy in PhD education by drawing from and integrating two separate research domains within PhD education research: One domain is research that explores how supervisors can support the development of autonomy. The other domain is research into assessment criteria for the PhD. The two domains are integrated in a model of learning through formative assessment, which is translated into the realm of PhD education. The aim is to help supervisors enhancing the learning and competence development of PhD students and supporting their autonomy. The model builds on the use of explicit assessment criteria and involves PhD students assessing their own work. The model should always be adapted to the concrete domain and practices of each PhD study. Further research is suggested to uncover and develop explicit assessment criteria that are discipline specific in science and sufficiently detailed to be operational for supervisors and PhD students.

Keywords: PhD supervision, autonomy, formative assessment

SETTING THE SCENE

“they enter a domain where it is very difficult to measure success criteria. The things we think are important, independence and those things, it’s kind of difficult to measure” (Asger, PhD supervisor)

“I think I did a very good job, but finally, a lot of comments stem from that part. That means that is not a good job. That’s kind of problem that confuses me a lot. It’s very... maybe I don’t have that good competence to evaluate [my] own work.” (Wang, PhD student)

These two quotations from interviews with PhD students and supervisors set the scene for the model I bring into PhD education in this article. The supervisor points to the difficulty in explicating assessment criteria for PhD education, as the aim of PhD education is to produce independent or autonomous researchers. What is assessed in the examination process is first and foremost the thesis, which should document the PhD student’s ability to produce new knowledge formulated as original or a (significant) contribution to science (Tinkler & Jackson, 2004). On the other hand the PhD student points to one way of recognising autonomy; to be able to assess one’s own work. While we know that assessment and self-assessment requires criteria, both supervisors and PhD students would benefit from an overall framework to understand and overview the learning process in PhD supervision with emphasis on the use of criteria. Research into assessment indicates that self-regulation and hence autonomy can be supported through involvement of students in the assessment process (Boud & Soler, 2015; Dolin et al., 2017), but the link to doctoral supervision has not been made so far. The central position students get in assessing their own work help them understand their own learning process, and work towards the goals and standards of the discipline. At a higher level of learning they build competences in assessing their own work beyond the timescale of the course.
or studies. To assist supervisors and PhD students in this, I bring in and adjust a model for formative assessment in teaching at undergraduate level developed by Dolin et al. (2017).

**Intensions**

The aim is to suggest a model of the learning process in the context of PhD education and supervision that can help supervisors in enhancing the learning and competence development of PhD students and supporting their autonomy. The model involves PhD students in assessing their own work through clear and explicit criteria. The model is a further development of the model of formative assessment developed by Dolin et al. (2017).

To adjust the model to the realm of PhD education I draw on two separate research domains within PhD education research. One domain is research that explores how supervisors can support the development of autonomy. The other domain is research into assessment criteria for the PhD. I integrate these two research domains into a model for formative assessment. The model has its limitations in that there surely are learning processes that cannot be captured in this model and the model should always be adapted to the concrete domain and practices of each PhD study.

**RESEARCH INTO AUTONOMY AND ASSESSMENT CRITERIA**

**Research into supporting autonomy in PhD education**

New doctoral supervisors often point to building PhD student autonomy as the most difficult and pressing issue in their development as supervisors. The challenges that supervisors state in my workshops are for instance: “Finding the right balance between facilitating and controlling the process”, “To strike the right balance between reactivity and pro-activeness - when to push/pull or nurse - and when to ´wait´ and give time for the student to show up own initiative and own work”, or “Finding the right level of supervision (guidance versus independence)”. Delamont, Parry and Atkinson (1998) vividly describe how supervisors experience the difficulties in creating this delicate balance, while Gardner (2008) describes the dilemma from the students’ point of view.

In his much cited work Gurr (2001) refers to the two styles of supervision as ‘hands-on’ and ‘hands-off’. The assumption is that PhD students need more direction and hands-on guidance when they are dependent, and more ‘hands-off’ supervision as they become competent autonomous. I will return to his term ‘competence autonomous’ later. Gurr does not discuss exactly what supervisors can do to support autonomy, but his toolkit is suggested as a way to open discussions about this between supervisor and PhD student, and as such it is a tool to initiate meta-communication about supervision.

While Gurr depicts a rough development from dependency to autonomy over time, Kam (1997) differentiates between three dimensions of supervisor dependency: ‘work organisation and problem solving’, ‘research preparation’ and ‘communication’, and describes the specific needs that students in each category voice. Such differentiation is useful in helping supervisors to meet the needs of their students.

However, there is an aspect of supervision that it is important to consider when meeting students’ needs - the importance of shared intensions and meta-communication in empowering
the learner. If a supervisor primarily attends to the needs of a student without meta-communicating about the intentions of the help they provide, then there is a danger that the student will remain in need of help (Molly & Kobayashi, 2014; Strong et al., 2008). Meta-communication about intentions is a way of putting students in charge of their own learning process (Baltzersen, 2013) and especially when students are supported in making their own decisions the transparency will empower students and support autonomy. The model described by Strong et al. (2008) builds on Karl Tomm’s postures in collaborative counselling as shown in Figure 1. Empowerment is facilitated by shared intentions (transparency) and an open decision space.

![Figure 1. Karl Tomm’s Collaborative Approaches to Counselling, adapted from Strong et al. (2008).](image)

This is supported by the research conducted by Overall, Deane and Peterson (2011). They use research self-efficacy as an indicator of autonomy, defined as ‘how much the student believes s/he can successfully complete key tasks, such as data collection, data analyses and writing articles’ (p. 792). They then investigate how effective different types of supervisor support are in building student research self-efficacy beliefs, and they find that autonomy support combined with task-related academic support is most efficient. They do not investigate the effects of meta-communication or sharing intentions, but parts of that may be deducted from their items (p. 793-94). The autonomy support seems to consist of mainly meta-communication, e.g. ‘My supervisor encourages me to ask questions’. The task-related academic support has few items that directly suggest meta-communication, but the first item does: ‘My supervisor provides clear expectations and goals I need to achieve’. The rest of the items seem to be more expert advice, but combined with the open decision space it suggests that the style of supervision (or approaches to counselling) that Strong et al. (2008) term Empowerment. It could be interesting to investigate the importance of ‘providing clear expectations and goals’ since goals and assessment criteria play an important role in assessment.

Lovitts (2005, 2008) point to a number of components that she identifies as critical for doctoral students to make the transition from being dependent on close supervision to the stage where they are expected to be autonomous (independent) researchers. The independent researcher is seen as capable of making an original contribution to knowledge, which she argues requires creative performance. She identifies self-direction, perseverance, tolerance of ambiguity, a
willingness to take risks and intrinsic motivation as factors that are critical to creative performance, and hence completion. However, she does not suggest what supervisors can do to enhance these components, except for changing their behaviours to ‘better enhance and support the development of the subcomponents identified as most critical to creative performance’ (p. 151).

While Lovitts (2005) link autonomy and independence to creativity, other scholars emphasise the link to critical thinking and the ability to evaluate one’s own work. This is the perception that the PhD student voices in the opening of this article. Holbrook et al. (2004) find that ‘Examiners expected a balanced and critical appraisal of both the literature and the candidate’s own findings…’ (p. 112), but references to critical thinking as an intended learning outcome of the PhD process are rare and it is rather an implicit assumption in assessment, as seen in Tinkler and Jackson (2004) and also observed by Brodin (2016). It seems to be left to the examiners to be critical. One can only speculate on the lacking reference in the explicit learning outcomes on critical thinking and the ability to assess own work. What is assessed (in the first place) is the thesis, and this is a summative assessment judging whether the thesis reflects originality or a contribution to science, whether amendments are needed or whether the thesis should be rejected. PhD students are well aware of the high stake here and this wash back on how they present their research. The effect of summative assessment is that students cover up their weak points (Biggs & Tang, 2007, p. 164), and hence avoid going into too deep discussions of what they did wrong or could have done better or differently. Considering the high stake for PhD students it seems quite understandable if they hesitate to evaluate their own work critically in the thesis, but rather prepare to answer the critical questions from the assessors at the defence or viva.

Anne Lee has developed a framework on approaches to supervision, based on interviews with supervisors (Anne Lee, 2008). In her analysis and description of the five approaches (functional, enculturation, critical thinking, emancipation and developing a quality relationship (p. 270-71)), critical thinking stands out as the approach pertaining the most to supporting autonomy, and as students become more independent they can critique their own work. Lee sees the critical thinking approach as the core of supervision. Brodin (2016) links creative and critical thinking as interdependent and argues that both are necessary components of ‘doctorateness’.

Another take on autonomy is to view self-regulated learning as a step towards autonomy. Boud (2000) and Boud and Soler (2015) suggest that assessment should build student competences beyond the timeframe of a course or study programme in order to prepare graduates for working life and lifelong learning. Boud coins this as sustainable assessment, and self-assessment plays a vital role in building the competence to make informed judgement of one’s own learning. Self-assessment can enhance students’ self-regulation and reduce dependence on the teacher (Brown & Harris, 2014; Sadler, 2010). For self-assessment to be valid and reliable there is a need to inform the judgement by standards and criteria, and this makes the link to assessment criteria.
Research into assessment criteria at PhD level

Coming back to the quotations in my opening of the article, autonomous PhD students are expected to be able to judge their own work, but independence (or autonomy) is a vague goal for setting a direction in PhD education, as the supervisor stated.

In Gurr’s model, the hands-on vs. hands-off approach depends on the PhD student’s development from dependent to competently autonomous. Gurr defines ‘competent autonomous’ as the discipline neutral aim of researcher education: “The PhD process must, therefore, produce graduates with competent autonomy who, independently of their supervisor, are cognisant of the norms, expectations and standards within their discipline and are able to assess their own plans and actions to ensure compliance with these” (p. 85). The supervisors are expected to know the norms, expectations and standards within their discipline, but as shown by e.g. Gerholm (1990), the norms, expectations and standards within a discipline are often tacit, especially for experienced supervisors who have internalised the expectations of the discipline and have become experts (Patel, Arocha & Kaufman, 1999). To quote Nicol and Macfarlane-Dick (2006, p. 206): “Most criteria for academic tasks are complex, multidimensional […] and difficult to articulate; they are often ‘tacit’ and unarticulated in the mind of the teacher”. This can make it difficult for supervisors to be transparent and share intensions and directions. The research into assessment shows that feedback to students must be linked to assessment criteria (Black & Wiliam, 2009; Hattie & Timperley, 2007), and supervisors would benefit from clearer and more explicit assessment criteria to steer and underpin their feedback (Krumsvik, Øfstegaard & Jones, 2016). Pam Denicolo (2003) investigated the assessment of PhD theses in UK through a small survey carried out within the social sciences. She found that ‘the degree of consensus about the criteria is low’ and recommends that ‘the students and supervisors should be provided with clear criteria to guide the process’ (p. 90). Mullins and Kiley (2002) found that many examiners confidently used their own internalized criteria when assessing a thesis, often without consulting institutional guidelines.

Research that aims to explicate assessment criteria is an under-researched field, but especially two major contributions are worth mentioning. In her book, ‘Making the Implicit Explicit’ Lovitts (2007) provides general discipline neutral criteria as well as more specific criteria within a number of disciplines, based on interviews with supervisors in the United States. The other major contribution is a number of articles by Alyson Holbrook and her group in University of Newcastle, Australia. They have researched assessment of PhD theses through analysis of examiners’ reports in the large scale project Study of Research Training and Impact (SORTI www.newcastle.edu.au/research-and-innovation/centre/sorti/). Basing the research on examiners’ reports rather than interviews gives better insights into what examiners actually do rather than what they remember, perceive or intend to do.

An examiner’s report is first and foremost a summative assessment; it is a judgement of the candidate’s abilities to live up to the standards of the discipline assessed through the thesis. However, if the summative assessment concludes that amendments are required for the award of the PhD degree, the PhD student needs to know what to improve in order to get the thesis accepted, and formative comments in the report aim to direct the candidate towards the items
that need improvement. The assessment then has a mixture of summative and formative purposes. Holbrook et al. (2014) made an extensive analysis of formative feedback from examiners to PhD students on weaknesses and flaws in theses that were assessed ‘less favourable recommendation’ in Science and in Education disciplines. They found that more formative comments predicted a weaker thesis, and in Science especially comments on data analysis and on methods predicted a weaker thesis.

In another study Holbrook, Bourke and Fairbairn (2015) specifically analysed examiners’ references to theory in science and education disciplines. The six categories of summative comments (positive and negative) resulting from their analysis can provide PhD students with criteria they need to attend to, for instance the coverage of the literature review and considerations of strengths and weaknesses of theories. Similarly, her group studied references to the literature review (Holbrook et al., 2007), but in this study across the full range of disciplines data was not disaggregated according to disciplines. The categories of comments are therefore discipline neutral, and it could be interesting to investigate possible disciplinary differences in reference to categories like coverage, inaccuracy and application, and subcategories of for example coherent use, critical appraisal and connection with own research.

A MODEL OF DOCTORAL SUPERVISION AS FORMATIVE ASSESSMENT

The idea of formative assessment as defined by Harlen (2013) and Dolin et al. (2017) is to involve students in assessing their own work. The distinction between formative assessment and formative feedback in this model is that formative feedback is only a part of formative assessment; it is the feedback that the supervisor (or others) provides to the student with the aim of enhancing student learning. Formative assessment involves the whole circular process of students’ activities, evidence of their achievements, judgement and next steps in the learning process, with students involved in interpretation and judgement, and in deciding what and how the next steps should be taken. However, there is a need to translate the model developed by Harlen (2013) and Dolin et al. (2017) to the context of doctoral supervision to increase relevance for PhD students and supervisors.

Translation into the realm of PhD education means that the goals and the learning processes are more fluid, since the research process by nature cannot be foreseen and planned in detail. It is through the research project that competences are acquired and knowledge produced. The overall goals encompass the implementation of a research project with production of new (original) knowledge, and the communication of this in the doctoral thesis. In undergraduate studies students learn (or acquire) already established knowledge, by making sense of it and constructing their own understanding. As Bowden and Marton (1998) argue, research is also learning in the sense that the scholarly community learns new things about the World, and here the PhD student and the supervisor are sometimes on equal ground in that they both learn. In PhD education the learning process cannot be planned the same way, with clear disciplinary assessment criteria and progression steps, but the learning process is steered by the research questions and plans need to be changed as research progresses.
In formative assessment the relationship between the PhD student and the supervisor is essential. While formative feedback is typically provided by the supervisor as the knowing authority (Dysthe, 2002) or critical friend (Deuchar, 2008), or even the examiners who provide comments to the thesis (Holbrook et al., 2014), formative assessment demands that the supervisor is an ally; the PhD student and supervisor are collaborating in a partnership although one is more experienced than the other (Dysthe, 2002). The PhD student – supervisor relationship is also important for formative feedback to work optimally as pointed out by van Rensburg and Danaher (2009), but in formative assessment it is fundamental.

The PhD student is in the centre to emphasise the student centeredness of supervision (c.f. Gurr, 2001) and to indicate that the student is in charge of their own learning process. In PhD supervision this is a complex construction that can be difficult to maintain, since both sides have expectations to the role of the PhD student. Especially students coming to a Northern European university from educational systems where they are expected to ‘listen and obey’ would indirectly position the supervisor as an authority. Students coming from educational systems characterised by a performance culture with numerous tests may tend to look for judgement rather than feedback to enhance learning (Dolin et al., 2017; Midgley, Kaplan & Middleton, 2001). The construction of roles and responsibilities in a supervisory relationship is a fluid, two-way process (Davies & Harré, 1990; Kobayashi, Grout & Rump, 2015), and this calls for an alignment of expectations (Kiley, 2009).

The model is depicted in Figure 2. In practice the process would not be as formal as depicted, but as a model it can help keeping an overview of the process at a meta-level. The PhD student performs some activity, (1) in Figure 2, be it writing or practical research as part of PhD studies, to fulfil medium term goals as well as the overall goal of PhD education. Especially mid-term goals can be very different dependent on the discipline, and in health and science disciplines the goals are often perceived as completing a research project and publishing the results. Often the research questions rather than competence goals of the PhD education will guide the learning process.

Figure 2. Supervision as formative assessment based on Dolin et al. (2017)
The student activity leads to a product (2). A product is something that can be observed and explicated. If the activity is an experiment in the lab, then the product could be the results, or it could in fact also be the activity itself, observed by the supervisor. Asking questions to probe the student’s understanding is yet another way to collect data, however, here it is of uttermost importance to be transparent about the intensions; if students feel evaluated and controlled this may wash back on them and produce students who tend to perform and show their best rather than being open about their doubts and weaknesses, and this will inhibit or lessen the learning process (Tofteskov, 1996). The product has to be observable to enable discussion about fulfilment of the criteria and allow for judgement. In a sense it should provide evidence for judgement.

To reach step (3) the product is judged against criteria pertaining to the relevant goals and the ambitions and capabilities of the PhD student, i.e. both criterion-referenced and student-referenced. This double reference points to a dilemma that many supervisors find themselves in: that they should be both an ally, mentor or coach and guide the PhD student, and also are bound to set the bar high enough, to safeguard standards as gatekeepers of the discipline (Alison, Lee & Green, 2009). The criterion-referenced judgement should use criteria that are explicit, shared and clear, but in PhD education criteria are often internalised and tacit. In formative assessment the verbalisation or even development of the criteria may be part of the process, and point (4) in Figure 2 shows a way to develop or uncover criteria: PhD students in science and health disciplines especially, submit manuscripts to journals and get comments from reviewers. Criteria can be deducted from these reviews, and thereby the criteria are also external to the supervisor and the research group. The same applies to former PhD students’ theses that have been reviewed by examiners, as the work by Holbrook and her group indicates. Hence, this is a way to utilise summative assessment for a formative purpose. In situations where the product is research then the criteria are derived from the research questions. While both supervisor and PhD student are in a learning process when producing new knowledge, the supervisor would have greater expertise to assess validity of the research and explicate relevant criteria. The explicit criteria are essential; they are part of the important meta-communication and they convey a direction for PhD students to work more independently.

The use of criteria external to the supervisor and the local research group where the PhD student works ensures that the PhD student is not merely reproducing existing knowledge and methods as in a master-apprenticeship. It ensures the necessary reflectivity and critique of the social practice in the local research environment, and addresses the criticism of the master-apprentice model by for instance Russell (1998).

Notwithstanding the importance of clear and explicit criteria, the process of grasping the nature of quality is complex. A supervisor will often notice particular strengths or weaknesses in a text without referring to specific criteria; as Sadler (2010, p. 546) puts it “drawn from an undefined pool of potential criteria”. One way forward can be for the supervisor to argue why something is particularly well formulated or what and why something might be lacking. Another way to induce PhD students into the scientific thinking and the nature of quality is to invite another researcher or the co-supervisor to take part in the scientific discussions. This creates learning opportunities for the PhD student as researchers draw from their more or less
tacit knowledge in discussions with others (Kobayashi et al., 2017). To some extent (some) criteria remain tacit as they are internalised by the PhD student through the participation in scientific discussion.

The judgement of the product is used to decide on the next step in the learning process (5), be it research as learning or development of the PhD student’s skills and competences. The formative feedback describes what is needed for moving on in the learning process. The feedback that PhD students get may come from the supervisor, from peers, other colleagues in the scientific community or even from the PhD student herself (Dolin et al., 2017), and indeed the latter is central for self-regulated learning, meta-cognition and autonomy. This is why it is a good idea to ask the student for his/her own assessment as suggested by Handal and Lauvås (2005).

The small two-headed arrows in the model indicate the double role of the PhD student as both provider of products, assessment and feedback and as receiver of the same. The process may not follow the cycle fully in practice. It will often be the case that goals are revisited in the formulation of criteria, and the model should not be seen as stages in a learning process.

When the piece of writing is done, the PhD student might compare that with her first draft and realise how much she enhanced her understanding and her grasp of the topic/method/theory, applying the principles of ipsative assessment (Hughes, 2011). This form of assessment can be highly motivating and give PhD students a sense of standing on more solid ground and build research self-efficacy.

**FURTHER RESEARCH**

This model for formative assessment in PhD supervision aims to support PhD students and supervisors in the supervisory process. It stresses the importance of criteria, but the model as such does not list assessment criteria. Overall discipline neutral assessment criteria are not sufficient to provide formative feedback and there is a need for more research into operational discipline specific criteria, to supplement the current body of research into criteria at PhD level. There is also a need for research into criteria used in other local contexts to juxtapose and investigate differences arising from different educational systems and goals with PhD education.

Further research will aim is to investigate which criteria examiners use when assessing PhD theses in the different specific disciplines within science in the University of Copenhagen, Denmark. Assessment criteria that examiners are required to use are very general, and may not reflect the specific criteria used in practice in specific disciplines, or may be weighed differently in different disciplines. An analysis of examiners reports can reveal the criteria and the weighing of criteria that examiners tacitly employ. It is intended to use the same research methods as earlier research conducted in University of Newcastle, Australia to allow juxtaposing results. Such research would also enable further research into progression in researcher education and potential disciplinary differences.
ACKNOWLEDGEMENT

I wish to thank Professor Jens Dolin for his inspiration and feedback on my teaching and research, leading to the development of the model targeted at PhD education and supervision.

PISA assesses to what degree 15-year-old students have acquired knowledge and skills that are essential for life in society. French results from PISA science 2015 show that the influence of students’ socio-economic-cultural status (ESCS) on their performance is one of the highest among OECD countries. The aim of our study is to identify some of the main characteristics of PISA items, which make them difficult to understand for the students according to their ESCS. Our approach combines a quantitative and qualitative analysis. We focus on the performance gap between French students with high and low ESCS. The ESCS index was divided into quartiles (equal groups of 25%). The ESCS 1 group refers to the 25% most disadvantaged pupils while the ESCS 4 group corresponds to the 25% most advantaged students. We made a repartition of items according to their difficulty and interquartile gap (ESCS4-ESCS1). The majority of high interquartile gap items corresponds to the medium difficulty items. In order to find the characteristics that may influence students’ scores, we conduct an a priori analysis of the items which we validate by a statistical study on the scores. Several items’ characteristics identified in our analysis appear to statistically favor high ESCS students compared to low ESCS students.

Keywords: PISA science 2015, socio-economic level, context.

OBJECTIVES

The aim of the study is to identify some of the main characteristics of science tasks such as those presented in PISA, which discriminate among the students’ performances based on their economic, social and cultural status (ESCS). PISA assesses to what degree 15-year-old students have acquired knowledge and skills that are essential for life in society (OECD, 2016). In 2015, the major domain (i.e. the field with the most questions) was scientific literacy. PISA also assesses the students’ ESCS index. French results from PISA science 2015 show that the influence of students’ ESCS on their performance is one of the highest among OECD countries. In order to find the characteristics that may influence students’ scores, we conduct an a priori analysis of the items that we then validate by a statistical study on the scores. This study aims to understand the explanatory power of these characteristics. In particular, we focus on the performance gap between high and low ESCS students. This leads us to hypothesize about the difficulties encountered by low ESCS students in solving PISA Science tasks.

THEORETICAL FRAMEWORK

The first part of the framework is focused on the PISA science framework and the second on
how students, based on their ESCS, understand the different components of the tasks.

**PISA 2015 Science framework**

The Program for International Student Assessment (PISA) is an international study of 15-year-olds students that every 3 years assesses the knowledge and skills essential for full participation in society (OECD, 2016). In 2015, the major domain evaluated (i.e. the field with the most questions) was scientific literacy. French students’ level of scientific literacy has not improved since 2006 and remains within the OECD countries average.

PISA 2015 Science was based on the following components (OECD, 2016):

- Two scientific contexts of the situations on which the questions are based. Context 1 is related to health and disease; natural resources; environmental quality; hazards; frontiers of science and technology; context 2 is related to the self, family and peer groups (personal), to the community (local/national), and to life across the world (global);

- The scientific competencies (Explaining phenomena scientifically; Evaluating and designing scientific enquiry; Interpreting data and evidence scientifically);

- The domains of scientific knowledge. The PISA Science 2015 framework distinguished between “knowledge of science content” (scientific concepts in the domains of Physical systems; Living systems; Earth and Space systems), “epistemic knowledge” referring to an understanding of the role of specific constructs and defining features essential to the process of knowledge-building in science (Dushl 2007) and “procedural knowledge” (knowledge of the practices and concepts on which empirical studies are based)

The items have different formats: simple multiple choice, complex multiple choice or open responses. In parallel to the PISA science test, students completed a questionnaire measuring their Economic, Social and Cultural Status (ESCS) based on three indices: parents’ highest occupational status, parents’ highest education level in years of education, and home possessions (see Keskpaik & Rocher, 2011).

**Students understanding of the tasks’ components**

Concerning the studies of student understanding, we focused on those related to student understanding of scientific texts. Marin et al. (2007) state that scientific texts are often more difficult for students than narrative ones for several reasons. The lexicon is specialized and they provide insufficient context to clarify the meaning of these words. In the case of PISA units, this comprehension is often crucial for the student to be able to answer the question. These researchers (Marin et al, 2007) also explain that the inferences are essential for the comprehension of a scientific text. Some students would not be able to do this inferential work and some help would be beneficial.

This type of difficulty can make these texts discriminatory for economic-social-cultural status. The results of our previous studies confirm and explore the difficulties faced by low achievers. They show that, when they elaborate and arrive at their answer, low achievers mostly do not
construct correct and stable representations of what the goals of a PISA item are (Le Hebel, 2014; 2016; 2017). Consequently, low-achievers often transform the question in order to be able to answer it. In contrast to high achievers, they are not able to identify the steps they must make between the initial information and the expected final aim of the task. They are not aware of what they are expected to supply - new knowledge for instance – in order to solve the task. Frequently, PISA science items include somewhat lengthy texts and possibly illustrations that play a crucial role in answering strategies. Therefore, we refer to Delarue-Breton & Bautier (2015) who examined reading literacy and for example showed that low achievers focus on specific elements that echo their experiences or opinions whereas high achievers construct general and generic meaning.

Researchers have already tried to explain what could make PISA science tasks difficult, and also scientific statements in general. Solano-Flores et al. (2015) showed that the characteristics of PISA illustrations could have an influence on student performance. Le Hebel et al. (accepted) showed that the difficulty of PISA Science 2015 items do not necessarily have a high cognitive complexity according to the DOK scale (Webb, 2007). Therefore, other factors are a source of difficulty, especially for students from disadvantaged backgrounds, such as the unfamiliarity of certain components of the context. Indeed, Ahmed et al. (2007) explain that the context of a question can add extra demands. Contextualization of items can also trap students in the sense that they tend to use everyday knowledge (Anahi Da Silva, 2004) rather than scientific knowledge when context places the question in everyday and familiar situations.

**METHODOLOGY**

To answer our first research question, we need statistical analyses of PISA 2015 data. At the French level, the DEPP (Directorate of Evaluation, Foresight and Performance - French Ministry of Education) can proceed to various statistical analyses. They provided all the information on PISA primary results needed for the present secondary analyses. In PISA, the Economic, Social and Cultural Status (ESCS) provides a measure of the socio-economic status of 15-year-olds, with different component indices (Keskpaik & Rocher, 2011). ESCS was divided into quartiles (ESCS 1/2/3/4). The ESCS 1 group refers to the 25% most disadvantaged pupils while the ESCS 4 group corresponds to the 25% most advantaged students. The DEPP provided us with item success rates according to these ESCS groups. We calculated the difference between the scores obtained by the first and last quartile for each PISA item. The results of this operation showed that the highest interquartile performance gap was 42 points and the lowest was 3 points. We classified the different gaps obtained into four categories as follows with the medium gap group divided into two equal parts:

- low gap (between 3 and 18 points),
- medium gap with low trend (between 19 and 24 points),
- medium gap with high trend (between 25 and 29 points),
- high gap (between 26 and 42 points).

Each PISA item is associated with a proficiency level. These levels are defined *a posteriori* by PISA, that is, only after scoring students’ responses. We have estimated the level of proficiency
as a function of the success rate of the items. So, the low difficulty corresponds to a student’s highest success rate between 75 and 100%, the medium low trend difficulty refers to a student’s success rate comprised between 50 and 75%, the medium high trend difficulty equals a student’s success rate located between 25 and 50%, and finally, the high difficulty corresponds to a student’s lowest success rate between 0 and 25%. From the four gap categories (obtained on the basis of the calculation: ESCS4-ESCS1) and the four grades of difficulty defined above, we calculated the distribution of items across these eight categories (Table 1).

Our methodology consists of two main steps: an *a priori* items analysis and a statistical study on students’ scores.

**A priori analysis**

First, we took into account the characteristics of six items from PISA 2015 Science framework:

1. Context 1 (Health and disease; Natural resources; Environmental quality; Hazards; Frontiers of Science and technology)
2. Competencies (Explain phenomena scientifically; Evaluate and design scientific enquiry; Interpreting data and evidence scientifically)
3. Knowledge (Knowledge of content of science, Procedural knowledge, Epistemic knowledge)
4. System assessed (for the items assessing knowledge of science content: Physical systems, Living systems, Earth and Space systems)
5. Item format (Simple multiple choice, Complex multiple choice or Open responses)
6. Concerning context 2 (Personal, Local/National, Global) following the *a priori* analysis, we chose to refine this classification as we found PISA coding too general. We defined five components: personal/societal, personal/global, societal/global, societal, global.

Moreover, we add six characteristics defined as follows:

7. The DOK (Depth of Knowledge) corresponding to Webb’s DOK levels for science (Webb, 2007). It is a scale of cognitive demands (from 1 to 4) which reflects the cognitive complexity of the question (Le Hebel & al, 2017).
8. Dependence or independence of the question on information available to the students in the item text and/or illustration.
9. “Projection” requirements (or not) meaning that the context of the question prompts the students to project themselves, and conceive the point of view of a community possessing varying degrees of similarity to their own life. Indeed, we observed that some PISA items like the one presented in an upcoming section, require the student to play a role that she is not used to playing at school, for example taking the scientist's place (referring to the researchers’ community)
10. If the projection is direct (made explicit in the item text) or indirect (implicit).
11. If the answer is present in the text and/or illustration or not.
12. Text length (word count).

We have analyzed these specific characteristics because we hypothesize that they influence the difference of performance between high and low ESCS students.

In total, we code these twelve characteristics for all 183 items of PISA 2015 Science.

**Statistical analysis**

First, we observe that the performance gap between ESCS1 and ESCS4 is highly variable (from 0.03 to 0.42) depending on items and that this gap is not linked to item scores (Table 1).

Among the **twelve characteristics** that will potentially explain the different categories of performance gap (on the basis of success rates of ESCS4 group - success rates ESCS1 group), one of them is a quantitative variable (word count), whereas the others are qualitative (ordinal for the DOK or non-ordinal for the item format).

Multiple linear regression models are used to identify an item’s characteristics, which influence:

- the students’ score (percentage of correct answers for each item in France) of ESCS1 group.
- the students’ score (percentage of correct answers for each item in France) of ESCS4 group.
- the difference between high and low ESCS students’ scores.

We consider the test allows us to reject the hypothesis of a lack of a characteristic’s influence on the scores and on the scores’ difference when the p-value is below 0.1.

**FINDINGS**

First, we present the frequency of each defined category of PISA Science 2015 items by difficulty and by interquartile (ESCS1- ESCS4) (Table 1).

In Table 1, it appears that low and high difficulty items are less discriminative than those of medium difficulty. The medium low difficulty items are almost equitably distributed (between 20% and 29%) and the medium high difficulty tend to be more discriminative (43% for high gap in red circle).

We also calculated differences between each quartile (ESCS2-ESCS1; ESCS3-ESCS2; ESCS4-ESCS3) and it showed different distributions: for instance, in some cases we find a very big difference between ESCS1 and ESCS2 and small difference between ESCS2, ESCS3 and ESCS4, meaning that these items discriminate against the lowest ESCS students (cf. section example of item analysis). On the contrary, some items show a big difference between ESCS3 and ESCS4 and small difference between ESCS1, ESCS2 and ESCS3, meaning that the highest ESCS students perform much better than the other students. The aim of statistical analysis was to connect these qualitative item characteristics presented previously with the quantitative categories described in Table 1 in order to determine the explanatory power of a set of characteristics on the score variations according to the students' ESCS group.
Table 1. Distribution of the PISA Science 2015 items by difficulty and of the gap between ESCS1 and ESCS4.

The data obtained from the national sample of French students participating in PISA 2015 Science are analyzed following our methodology. This treatment results in finding statistical evidence that several characteristics influence performance gaps between the ESCS 4 group and ESCS 1 group (Table 2).

The first column of Table 2 shows the twelve characteristics with their different modalities. For each characteristic, the first modality (first line of each characteristic) is the reference modality for the statistical model. The second column gives the coefficient and the significance for each characteristic modality. When the coefficient is positive, it indicates that the influence of the modality corresponds to an increase in the performance gap between ESCS4 and ESCS1. A negative coefficient indicates that the influence of the reference modality corresponds to an increase in the performance gap (ESCS4- ESCS1).

Significant results are seen for the characteristics below:

- Dependence on information available to the students in the item text and/or illustration
- Item format
- Types of knowledge
- System (only Earth and Space system)
- Context 1 (only Natural resources)
- Projection (only researchers’ community)
- Answer present in item

We were obtained additional evidence from the multiple linear regression models performed on the data from the ESCS1 students’ scores and ESCS4 students’ scores.

EXAMPLE OF ITEM ANALYSIS

In this section, we will present an example of an item released from PISA 2015 Science “Sustainable fish farming” (Figure 1).

According to PISA characteristics, this item is categorized as following:

- **Competency**: interpreting data and evidence scientifically
- **Knowledge**: knowledge of content of science
- **Context 1**: Environmental quality
- **System assessed**: living systems
- **Item format**: simple multiple choice
And, in the six characteristics added following the *a priori* analysis, this item is defined thus:

- **Context 2:** societal/global
- **The DOK** (Depth of Knowledge): 2
- **Dependence of the question on information available** to the students in the item text and/or illustration.
- **Projection:** knowledge communities and this projection is direct (made explicit in the item text)
- **The answer is present** in the text (framed in orange in the example of item)
- Moreover, the **illustration** of this item is a diagram.

![Figure 1. Question 2 of item PISA 2015 Science released “Sustainable fish farming”.

This item is located at medium low trend difficulty level (with a success rate of 72%) and with a medium high trend gap (27 points). It belongs therefore to the cluster of 23 items in the red box of Table 1. When we analyzed the results, the ESCS 1 group chose response 1 four times as often as the ESCS 4 group (Figure 2). We propose several potential explanations of the different results.

There is a possible matching for the response 1 (but which influences a wrong answer). Indeed, the word “nutrients” is repeated twice: in the question and response 1 which contains the answer “more nutrients” (circle in yellow in the example of item). Le Hebel et al. (2016) had already observed, on the items of PISA 2006 Science, that low achievers from low ESCS schools use an answering strategy of transforming the question’s aim and matching the words from the text of the leading text or the question with the words of the four propositions included in the item.
So, in this “sustainable fish farming” item example, if students did not understand the real aim of the question then they might understand that the sustainable fish farming lacks nutrients because the question explains that the water returning to the ocean contains a large quantity of nutrients. So, we suppose that the students may believe that the right response is that the sustainable fish farming will need more nutrients.

Moreover, response 2 is chosen by the ESCS 1 approximately three times as often as the ESCS 4 group and to a lesser extent, the ESCS 1 group also gives response 3 twice as often as the ESCS 4 group (Figure 2). We suppose also that this answer is given because students have difficulty in focusing their attention on the real aim of the item. This can also be explained by a difficulty to find which elements in the flow of information are relevant to answer the question.

Figure 2. Distribution of responses according to ESCS groups 1 and 4 for the item “Sustainable fish farming”

This item requires a “researchers’ community” projection (Table 2) because the question refers to “researchers” and this projection is direct because it is explicitly given in this item. So this context with a direct projection implies the ability to put themselves in the place of scientists. The big gaps in the response choices between ESCS 1 and ESCS 4 could be related to this necessity for the student to make this projection as a scientist and take a scientist’s decisions. We had supposed that this projection might potentially be socio-culturally discriminative and our statistical results shows a statistically significant trend Table 2).

The correct answer to the item is response 4 (framed in green). The answer is present in the item because the item gives the exact definition of marsh grasses (framed in orange) and indicates that it is these plants that absorb nutrients. The microalgae also need nutrients but this response choice is not given in the multiple choice, so the question indicates implicitly where to find the response in the item.

As we saw in the "findings" section, when calculating differences between each quartile, we find in some cases a very big difference between ESCS1 and ESCS2 and small difference between ESCS2, ESCS3 and ESCS4, meaning that these items discriminate against the lowest ESCS students.
The example item presented above shows a curve of success rates by ESCS group and we observe that ESCS 1 group literally stands out from the other three ESCS groups with a success rate which differs already very significantly from the ESCS 2 group. Indeed, the ESCS group’s success rate is of 57% versus respectively 70%, 76%, and 85% for the three other ESCS groups (Figure 3).

![Success rates according to ESCS group for this item](image)

**DISCUSSION**

The main findings of statistical analysis show that:

- The information available to the students in the item text and/or illustration provides the ESCS4 students with an advantage compared to the ESCS1 students. It can be interpreted by the fact that ESCS1 students have difficulty in understanding the leading text of the task and in building a representation of the global meaning and goal of the item (Le Hebel & al, 2014). This most likely limits their ability to find the necessary information given in the text in order to build an answer like the example item analysis (presented in a section above) shows it.

- Concerning the item format, open responses increase the performance gap between ESCS1 and ESCS4 students compared to complex multiple choice. ESCS4 students perform more favorably to the open responses format items than ESCS1 students. In addition, the complex multiple-choice format increases the performance gap between ESCS1 and ESCS4 compared to simple multiple choice and favors ESCS4 students.

- Science content knowledge compared to epistemic knowledge gives an advantage to ESCS4 students in comparison to ESCS1 students. However, this result has to be nuanced (indicating a statistical trend). Moreover, the procedural knowledge favors
ESCS4 students significantly compared with ESCS1 students regarding epistemic knowledge. This result deserves to be explored further with other research.

- The items relative to the “Earth and Space systems” domain widens the performance gap between ESCS1 and ESCS4, favoring ESCS4 students.

- Items offering the possibility or requiring that the student engages in a projection called “researchers’ community” compared to the items offering no possible projection. It provides an advantage to ESCS4 students who score higher than ESCS1 students (statistical trend). The ESCS1 students, when solving PISA science items, seem to have more difficulty in adopting the point of view of a member belonging to researchers’ community when it is required. For ESCS1 students, this community may represent an authority whose role it is not possible for them to play. The other types of projections required by other items do not appear discriminative.

- The fact that the answer is not present in the text and/or illustration widens the performance gap between ESCS1 and ESCS4 students and gives an advantage to the ESCS4 students. On the contrary, an item in which the answer is present is generally more successful in the ESCS 1 group as shown for the item presented in this paper which was successfully answered by 57% of the ESCS 1 group.

Concerning the DOK (Depth of Knowledge), there is no statistical significance as this characteristic affects all students (both ESCS1 and ESCS4). The absence of statistical significance for context 2 (personal/societal, personal/global, societal/global, societal, global) might also be explained by difficulties common to all students whatever their ESCS group. Ahmed & Pollitt (2007) showed that context elements can have an influence on the students’ performance but our results did not reveal any effect of this characteristic on the performance gap between ESCS groups.

In line with previous studies described above, our results reveal that many characteristics are likely to interfere with the science task comprehension, in particular with ESCS1 students when the real aim of an item is not understood.

CONCLUSION AND PERSPECTIVES

Our study highlights several items' characteristics, which could permit better understanding of the heterogeneity of the students' performance based on ESCS. In particularly, it could afford a better understanding of the difficulties encountered by disadvantaged students beyond PISA science tasks. Thus, it could help teachers to target these difficulties better in their practice and to take them into account with assessment of low-achievers and their scientific literacy development.

Considering the above results and our previous results (Le Hebel & al, 2017) it appears obvious that in addition to PISA characteristics (competence, type of knowledge, depth of knowledge, PISA context, format), more specific characteristics explain PISA item proficiency.

To refine our research ever more, we have proceeded to recode some characteristics in the a priori analysis in order to refine the statistical analysis. Indeed, as indicated in the example
item, a set of characteristics can be a source of difficulty for the students and so to widen the performance gap between students in group ESCS 1 and 4.

We propose that the low ESCS students have more difficulty in adapting to PISA item situations, due to several levels of unfamiliarity for them. This approach should allow us to target the most representative items to work on in a second step of this project, in which we will focus on low and high ESCS students responding to selected PISA items. We plan to audiovideotape them in order to understand their cognitive processes better and to identify what makes the science task difficult for low ESCS students. This work could help to understand better the difficulties encountered by disadvantaged students beyond complex tasks in science and thus help teachers to target these difficulties in their practice better.

This paper guides readers through the development, design, and use of a systems mapping-based research tool. The tool specifically helps researchers analyze student understanding of systems thinking using systems maps created for student research on community-based sustainability practices. Initial attempts to analyze student systems maps applied a Structure- Behavior-Function (SBF) approach to quantify essential components of systems represented on student maps, as well as the type of connections between these components (Honwad, et al, 2010). This phase (Phase 1) only partly captured the quality, logic and complexity of connections observed in student systems maps. Consequently, researchers adapted Interaction Analysis (Jordan & Henderson, 1995) for a qualitative approach (Phase 2). Coders found that Phases 1 and 2 were often aligned in the amount of connections and/or student narratives. The qualitative approach better reflected student gains in understanding however because it incorporated the clarity and logic of what was drawn, enabling more meaningful comparisons about the complexity of system understandings before and after inquiry-based research. Because this trend was the case across multiple practices, grades, and student groupings, we believe that the resulting system mapping research tool has the potential for analyzing changes in students’ understanding of systems.

Keywords: assessment, researcher-teacher partnership, systems thinking

INTRODUCTION

Over the last century the science education researcher role has evolved from academic theorist to classroom collaborator (Nisbet, 2005). The methods educational researchers use to investigate student learning however have not advanced at the same pace (Wellington, 2015). To establish teacher and institutional buy-in for more collaborative relationships with teachers in the classroom, there is a growing need for dual purpose tools adaptive for both research and pedagogical uses (Kelly, 2004). Using student artifacts as research data is one way researchers and teachers can partner to develop and design tools that are helpful in teaching as well as assessing learning (Merriam & Tisdell, 2015). Systems mapping is one example of a co-developed student-generated artifact to assess student learning of systems and systems thinking (Abrams et al, 2017).

This paper describes an approach designed to analyze group-created systems maps, to assess students’ learning of systems thinking and environmental sustainability. While teachers used systems maps for their own teaching and classroom assessment purposes (Abrams et al, 2017), researchers saw an opportunity to gather deeper insight into how students made sense of systems and environmental sustainability phenomena within their own communities.

Our research tool enabled us to systematically analyze student representations of learning in terms of their systems thinking and conceptual growth before and after researching a classroom-selected community practice (e.g., a railroad, shopping mall, afterschool program
We believe that the Systems Mapping Analysis Research Tool (SMART) created to understand students’ systems maps, has the potential to be adapted for analysis of systems maps across topics and possibly across subject areas where systems thinking is critical to understanding scientific concepts (e.g. engineering processes, systems of the body).

The Methodological Importance and Basics of Systems Map Analysis

The National Science Standards in the United States identify systems thinking and modeling as important concepts that cut across disciplines and grade levels (NGSS, 2013). To facilitate learning about systems thinking, the pedagogical technique of systems mapping has been employed in a range of classroom settings varying in content and academic level from middle school to graduate education (Waters Foundation; Sterman, 1994; Sweeney & Sterman, 2007; Plate & Monroe 2014). However we did not locate prior literature in which systems maps were systematically analyzed using a research tool that focused on assessing students’ understandings of different system content across middle school grades.

Systems maps provide students with a way to graphically display their understandings of systems parts and relationships to exhibit how a system operates. A system is all the parts and their dynamic relationships to one another, composing a complex whole. What is considered a system depends on its functional boundaries. Some of the essential aspects of a system include: Components or the different parts (the 'who' and 'what') that are involved in the function of a selected practice; Connections between components that exhibit how students believe components are related (e.g., inputs and outputs); Feedback loops, visible when outputs are fed back into a system as inputs. The emphasis on different types of interactions helps distinguish systems maps from mind maps which are collections of brainstormed terms related to a concept, or concept maps that are hierarchical constructions of terms related to a concept.

METHODS

For the Supporting and Promoting Indigenous and Rural Adolescents' Learning of Science (SPIRALS) project, systems mapping was used as a pedagogical tool and research artifact. Pre- and post-investigation systems maps were designed as a part of the SPIRALS curriculum (www.spirals.unh.edu) to help students organize and reflect upon what they knew (pre-exploration) or had learned (post-exploration) about the level of sustainability in a selected community practice. In SPIRALS, middle school classrooms select and investigate how a practice in their community may be sustainable. One of the main curriculum goals was to make classroom science relevant to students’ everyday lives. The systems map approach was designed in partnership with middle school teachers in New Hampshire after they stated that students needed an activity to help organize their thinking before and after an investigation. A systems thinking approach was determined to be critical for students to understand how different components in a community-based practice were interdependent on each other, and encouraged them to think about community-based practices in terms of relationships and connectedness.

Students worked in groups from two students to entire classrooms to create an initial systems map representing how they believed their community-based practice worked. This map served as a springboard into a scientific inquiry about the selected practice they investigated. In the
“pre” and “post”-exploration map below, 5th grade students focused on whether and how a scenic railway practice functioned sustainably within their community. Between maps students conducted research, in this case by going on a field trip, and communicating with a community practice expert (the railroad operator). In the “pre” map (Figure 1) a few system components are drawn (e.g., rails and “the view”), some of which are connected (e.g., “Coal & Fuel” to “Money”) although not always clearly.

The “post” map (Figure 2) displays additional elements and complexity. For example, not only are there more “Materials” listed, but in this map, the materials are integrated into the system. Not only are they inputs into the train but their origins are acknowledged, as with wood resulting from logging. Also added are student narratives about the cost of diesel and the source of fuel (mines in Pennsylvania and West Virginia). Comparing the two maps, it is also apparent that the functional boundary of the Conway Scenic Railroad system, defined by the reach of the systems connections, has expanded. In this post-exploration map therefore students show greater understanding of the parts in the railroad system, as well as their interactions and reach.

**Development of SMART**

Initial efforts to analyze student systems maps began with an attempt to adapt the Structure-Behavior-Function (SBF) approach to quantify essential elements of systems represented in students maps, as well as the type of connections between these elements (Honwad, et al, 2010). Our coding spreadsheet (Tables 1 & 2) contained essential systems elements we sought to capture. Individual coders completed a spreadsheet for each systems map, listing each system component students named or drew. Coders next identified the number of other components each was connected to, and whether or not they were connected in a way that conveyed a sequential relationship that distinguished inputs from outputs (by directional arrows), or not (by line segments). Essential systems elements were then tallied to identify potential changes between pre and post maps for each student map group. As coders observed inclusion of narratives that conveyed details about components and/or their interactions, a student narrative category was added to the spreadsheet to determine whether changes in the amount of student narratives might also reflect differences in student understandings.

Our attempt to adapt SBF for systems map analyses was not entirely successful for the following reasons:

1 – The community-based practices of SPIRALS systems maps were varied in nature; therefore, from one practice to another, aspects of a system, from components to boundaries,
were not static. SBF has consistently been applied with middle school student understandings of aquatic systems (Hmelo, Marathe & Liu, 2008; Goel, et al 2010; Assaraf & Orion 2010) but not to a broad range of systems.

2 - In SPIRALS, students used multiple ways to describe system components and to indicate relationships between components. Thus, even when students investigated the same practice, maps varied because representations of system components and connections was not rigidly constrained by the curriculum. Two student groups investigated a ski mountain but one emphasized use of the facility (tourists, ski patrol) described primarily using lists, while the other focused on operational inputs and outputs (food, snow making) linked by lines.

3 – Our SBF adaptation, did not accurately reflect the clarity, logic and complexity of connections observed in student systems maps, perhaps in part as a result of the multiple grades using the curriculum and involved in the research.

As a result of these difficulties, we realized the need to develop an analytic approach that was both adaptive to many topic areas and sufficiently comprehensive to capture varied levels of systems thinking understandings. The project’s interdisciplinary team of science education researchers, educational practitioners, education psychologists, and scientists responded to this challenge by developing a more comprehensive analytic approach based on the qualitative Interaction Analysis technique (Jordan & Henderson, 1995) involving individual and then consensual coding of human activities, such as artifacts.

Phase 2 was less about determining the number of connections and more about evaluating the nature and quality of connections to make a summative statement about the overall level of systems thinking demonstrated. For phase 2 systems map analysis, individual coders wrote an overall description of a systems map, commenting specifically on the components, overall connections, directionality of the connections, and clarity of the functional boundaries around the system of interest (Tables 1 & 2). After assessing each essential systems element, coders determined an overall systems thinking rating for each map to enable pre-post comparisons. To ensure consistency across coding, each overall systems thinking assessment level (low, low-medium, medium, medium-high, and high) was operationalized to include considerations of map clarity, logic, as well as attempted and successful demonstration of complexity in regard to each essential system element. Systems maps rated low were characterized by lack of practice clarity as when components exhibited little interaction or connectivity. Maps assessed as low-medium were limited to basic depictions of systems thinking, such as primarily implied inputs and outputs. Student maps were assessed as achieving a medium level systems thinking when they indicated a moderate level of connectivity (inputs, outputs) between system components, attempting to depict more advanced systems thinking, but which were not fully developed or clear and logical enough to be considered successful. A medium-high level of systems thinking was attained when maps contain additional complexity as conveyed by better clarity and/or logic such that at least one attempted feedback loop was successful. In contrast, maps designated as displaying high levels of systems thinking contained a majority of successful feedback loops and might also link multiple subsystems together. Following individual coding, coders compared descriptions to establish a consensus on each map’s demonstration of systems thinking. Through this process, group understandings of our key
concepts were informed by curricular and expert definitions, but also incorporated evolving definitions and criteria shaped by what was demonstrated in student artifacts themselves.

After the more qualitative second phase of coding was completed with a pre- and post-exploration map pair, we compared its coding with the more quantitative initial phase to determine where the two approaches aligned and what might explain differences in coder determinations in cases of misalignment. While we used mixed methods to provide more valid and trustworthy interpretations of student work, use of multiple coders during both phases 1 and 2 of system map analysis was also employed to bolster the strength of our findings. Individual coding during phase 1 was only conducted once 80% or greater inter-rater reliability was established for greater than 20% of the eventual number of maps evaluated.

Both the quantitative and qualitative analyses highlight changes between students’ pre and post systems maps, albeit in different ways. The phase 1 coding in Table 1 corresponds to the pre map in Figure 1. In this table you can see aspects of systems thinking that learners used to demonstrate assumptions about how the railroad they were about to research operated and coder efforts to assess those understandings. Table 1 displays a total of 21 components. Student knew for example that rails, money, and at least one train, were relevant to the railroad. While some components, such as rails were isolated, other components were connected to each other in a directional way by arrows, as displayed between “money” and the use of “coal & fuel”. We differentiated between these connections and those that did not signify an understanding of how components were interrelated as in comparing how the “coal & fuel” is connected to the train (via line segment), as opposed to the money. This distinction was based on the assumption that directionality would likely signify a higher level of systems thinking than drawing line segment connections that did not attempt to represent sequencing. At the bottom of each scoring sheet we tallied the components and connections by type, as well as collecting information about whether narratives were used.

In Table 2 we see students more evolved sense of systems thinking relative to the railroad system after their investigation in the phase 1 coding. Rails for example are now connected to other parts in the system instead of being isolated. The train and money ("$"), are more integrated into the system, by being more connected to other parts and by being connected in a directional way. We see in narratives with “fuel” that students have added its source as coal mines, provided information about where those mines are, and detailed fuel costs are per trip.

</table>

Phase 1 alone was not deemed sufficient as components students drew on systems maps were not always clearly related to the practice investigated. Connections were also not always clearly and logically related to how depicted systems functioned. To better address student attempts at greater system complexity, phase 2 captured a more holistic assessment of the same essential system elements. It also incorporated explicit evaluations of clarity, logic, and complexity, and revealed that narrative versus purely graphic representations can demonstrate leaning.

Phase 2 coding of the same pre and post maps (Figures 1 & 2) demonstrates similarities and differences of this approach compared to phase 1. Coder assessment of the pre map (Table 3) displayed a low-medium level of systems thinking. The phase 2 post map in Table 4 is assessed as demonstrating marked improvement in students’ systems thinking. Coders agreed to greater numbers of systems components and connections than in the pre map (Table 3) and also to gains in clarity and logic relative to the railroad practice. The overall systems thinking assessment of medium-high reflects partial success in displaying advanced systems thinking, in sub-systems and linkage chains as well as a moderate level of connectivity between system components that are clear and logical. As there were still a number of unclear, illogical or unintegrated components on the map, it was not assessed as demonstrating a high level of systems thinking. Although the conclusions from phases 1 and 2 may align, comparison of the tables above demonstrates the greater utility of the phase 2 assessment.

RESULTS

As part of the SPIRALS project, pre and post systems maps were collected from 10 participating research sites in rural (9) or indigenous (1) communities between Spring 2015 and Fall 2016. Because the curriculum encouraged site-appropriate adaptations, some maps were created at the classroom level while others were created by small groups of 2 to 6 middle school students in grades 4 through 8. Our analytic sample consists of 19 pairs of matched pre and post maps. To reduce undue influences resulting from the loss or introduction of a new student into a small group, only full class-level maps or those with identical students creating both pre and post-exploration systems maps were included in our analysis.
Table 5 displays how pre-to-post systems map assessments of student understanding aligned and diverged. Our analytic sample contained 15 map pairs (79%) for which systems thinking improvements were observed, three map pairs (16%) for which substantial improvements were not observed, and one map pair (5%) for which demonstration of systems thinking declined.

Agreement on Systems Elements in both Phases: 9, 11, 11, 11

% Agreement by Element: 0.47, 0.58, 0.58, 0.58

Because the overall qualitative assessment tended to align with the quantitative assessment across essential system elements (components, connections, and directional connections) in only about two-thirds of the cases (63%), the coding patterns for map pairs that were not aligned were explored. Both phases of coding for the eight map pairs that were least well aligned (5 showing qualitative improvement in phase 2; and 3 assessing no substantial change between pre and post maps) were examined to explain the rationales behind coding divergences. Doing so revealed that connections were most influential in both coding phases. Focus on the nature of connections between components is logical because the complexity of interactions between system components has previously served to differentiate between lower and higher levels of systems thinking attainment (Honwad, et al, 2010; Assaraf & Orion, 2010).
In most (10) of the 16 instances when change was determined between pre and post maps, the numbers of connections and/or directional connections identified in phase 1 were consistent with the direction of the overall assessment in phase 2. In one case (1-A-156&178-E), although the number of components and connections between pre and post maps declined, the number of directional connections increased. This finding is consistent with the idea that systems thinking beyond the most basic level is determined by the complexity of the relationships that students draw, hence improvements are more likely demonstrated through student attempts to convey how components are related and not just which components are related.

In two other instances when overall improvement was detected between pre and post maps in phase 2 but was inconsistent with declines in essential systems elements in phase 1, increases were however observed in the amount of student narratives (1-S-62-E&F-1247, et al. and 1-A-4&5-160&175-E). The following excerpts from consensual coder syntheses illustrates how narratives can provide sufficient explanations about the nature of interactions between components to compensate for drawings that failed to do so alone:

“Narrative descriptions of how system functions and clarity of understanding of this system all improved on this map, which enabled identification of 3 in 10 successful feedback loops…use of bidirectional arrows however added some confusion.” (1-S-62-E&F-1247, et al.).

“Students include narrative showing improvement in their understanding from the first map…Clarity and logic of both components and connections improved drastically…especially due to elimination of the incorrect use of bi-directional arrows.” (1-A-4&5-160&175-E).

These excerpts demonstrate how counts of attempted demonstrations of directionality can be misleading as well as how student use of narratives can help clarify the nature of relationships between components that are not always clear and logical from drawings alone. Although narratives were not always clear, they were rarely illogical and hence tended to improve upon drawings that were ambiguous.

In the two remaining maps whose changes were not aligned between the two coding phases (2-BB-55-E and 1-R-61-G), the qualitative coding identified improvement while the quantitative coding, did not. This difference is seen in phase 1 by the lack of change, in these maps on the quantitative measure of student narrative or amount of directional connections, respectively. Comparison of qualitative pre- and post- map coding is instructive in determining why it may be the more valid measure in this instance. Coders indicated in the pre-research map that, “No clear practice…is evident ” and that “the many directional connections…are unclear in how they contribute to an overall system”. Meanwhile, the follow-up map is described as, “an improvement…in terms of complexity, specificity…and purposeful directionality between different components in the system in a basic but logical linear way.” These summaries demonstrate how the quality of interactions between components, that designate higher level systems thinking, was more accurately evaluated by considering the nature of directional connections to contextualize their amount.

The last map pair which were misaligned between the two coding phases (1-R-61-G), reinforces the value of the qualitative assessment. Coders explained on the original map that, “inputs and outputs are missing” and thus there was, “little indication of knowledge about
[system component] interactions.” Although in the follow-up map coders indicated that, “Relationships are… [still] non-directional” they added that, “[r]elationships among components [and subsystems] are all inferred”. In our coding, directionality was initially expected through the use of arrows, as this is how it was presented in the curriculum. In phase 2 coding however adjustments were made to distinguish between graphic display of directionality that were considered ideal, and inferred directionality, which was viewed as less ideal, when narratives indicated inputs and outputs but student drawings did not. Inclusion of inference based on student narratives enabled coders to acknowledge attempts to exhibit greater complexity in their systems thinking even when they were not capable of fully demonstrating it as intended. In this case it enabled coders to conclude that, “Complexity is inferred within the lists, but is not demonstrated in any relational way.”

When no substantial change was detected between pre- and post-exploration maps, improvements in some essential systems elements along with declines in others appeared to play a role. Although two of these three pairs displayed this mix of outcomes in phase 1 (1-O-49-D&E&F-671, et al. and 1-S-63-G&H-1267, et al.), these discrepancies again were better addressed through phase 2 coding. Reviewing the map for which phase 1 and 2 codings were completely opposite shows how this can the case. For this map pair, 1-S-62-E&F-1241, et al. consensual coding resulted in the conclusion that, “Complexity improved” but, “clarity and logic decreased”. The mixed result was then attributed to the observation that “Students increased complexity with more attempted feedback loops, as well as an attempt at adding another perhaps interrelated health subsystem related to composting. With these attempts the students at times sacrificed clarity and logic.”

These coder comments illustrate our finding that although in some post-exploration maps students attempted to demonstrate greater complexity through use of directional arrows and loops connecting multiple components, these efforts were usually not entirely successful. When narrative was not provided to supplement such drawings, the number of successfully depicted interactions between or amongst components declined. Attempts at greater complexity through subsystems followed a similar pattern. We suspect that the grade level may help explain the need for assessments that incorporate credit for attempts at complexity while acknowledging as well whether or not such attempts succeed or fail.

**DISCUSSION AND CONCLUSION**

Because the value of cross-cutting concepts such as systems thinking have been codified in educational standards (NGSS, 2013), it is important for researchers to determine the extent to which educational efforts have produced student learning. Although prior research had assessed systems thinking learning quantitatively in 4th and 7th grades (Honwad, et al, 2010; Assaraf & Orion, 2010), our effort to assess systems thinking in this manner ran counter to the impressions of the inter-disciplinary team conducting our coding. As a result, to assess students systems learning for the SPIRALS community-based sustainability curriculum, the research team developed a qualitative coding procedure to run in parallel to our quantitative coding. Although both approaches captured a range of outcomes, coders expressed more confidence in the qualitative approach that was produced in a grounded manner, iteratively from content analysis of student work itself. This process was also preferred as it produced thick and rich
descriptions to substantiate coder evaluations of the essential aspects of systems. These descriptions served as the basis for a more nuanced coding scheme as well as providing evidence to explain the differences between the two phases of coding, and our conclusion that the qualitative approach was more appropriate to our student sample.

Although our initial assessment efforts attempted to adopt relevant prior systems thinking research, our study was different because it was aimed at enabling marginalized rural and indigenous student communities to select local community practices to facilitate student engagement. As a result, unlike prior studies, our research involved analysis of different systems, as well as varied grade levels and settings (i.e., public school, charter school, private school, and an afterschool program). We believe that the broader range of settings and content areas address by our study may explain the necessity to devise a novel method to analyze maps in a consistent way that could be applied to different grades and subject matter. The qualitative assessment did appear successful in conveying a range of outcomes across grade levels and appeared to indicate that the curriculum may have been more successful when implemented in classrooms at one grade level, rather than with mixed grades and likewise may be more successful in public school settings than in charter schools. We did not have sufficient data (1 case each) to draw conclusions about the private or afterschool program participants.

There are other possible explanations for the limitations of the curriculum in helping students achieve better systems thinking outcomes as well as limitations to our assessment tool that must be acknowledged: This tool was created for a particular community-based sustainability curriculum intended for middle school students in rural and indigenous settings. Although systems thinking content experts contributed to the tool’s development, the tool evolved as it was observed that many students were unable to attain success despite attempts to display greater complexity. It would be beneficial therefore to test the tool in its current iteration on a new, larger sample of systems maps that again cut across grade levels and content areas to determine its adaptability and address the need for a tool that can be flexibly applied.

PROFESSIONAL QUALITY ASSESSMENT OF THE CROATIAN STATE WRITTEN EXAM IN BIOLOGY

Ines Radanović¹, Žaklin Lukša², Valerija Begić³, Mirela Sertić Perić¹ and Diana Garašić

¹Faculty of Science, Zagreb, Croatia
²High School Josipa Slavenskog, Čakovec, Croatia
³Primary school Sesvetski Kraljevec, Zagreb, Croatia

The aim of the tool presented in this study is to enable teachers’ qualitative analysis of the questions within the Croatian state written exam in biology, and the eventual corrections of the questions before their application in the student assessment. We have identified the two basic categories that determine the question quality: 1) the importance of questions (regarding the profession, life, curriculum, critical thinking), and 2) the influence of questions (i.e., shape and intelligibility of the questions) on students’ answers, logical reasoning and further learning path. The tool we have developed was tested for its effectiveness on a sample exam designed for students aged 13. A correlation between logical reasoning and the “importance-of-questions” categories, and the success rate of the exam was observed. This simple tool has proven to be effective for both teachers’ self-assessment and peer evaluation.

Keywords: cognitive levels, question relevance for science literacy, influence of questions to answers

INTRODUCTION

Most classroom teachers prepare and administer a series of (non-)formal (i.e., teacher-made) exams during the school year, which often enclose questions with many construction mistakes, especially essay questions (e.g., Marso & Pigge 1988). Thus, there is a growing need for greater quality control in the design and implementation of the students’ performance assessments (Dunbar et al. 2009). A tool for the expert question quality assessment in Croatia (representing a developing country regarding its national practice in advancing science literacy and national curriculum) was for the first time designed for the needs of professional quality assessment of the state biology exams (Radanović et al. 2010). In designing the Croatian tool, the following criteria, recognized as “fruitful areas” to seek the question validity evidence, were considered: question content, internal structure and response process, as well as exam scores’ relationship to other variables measuring various students’ domains, and overall learning success and achievement (Downing, 2003). From its first use, the Croatian tool has been continuously developed through the application within research, as well as within teaching, i.e., in designing written biology exams (Radanović et al. 2011, Begić et al. 2016, Radanović et al. 2017a,b ). Thus, since the launch of the Croatian tool, some assessment elements that should encourage teachers to better prepare exam questions have been introduced, and the question quality has steadily increased. The aim of the tool presented within this paper is to enable teachers’ qualitative analysis of the questions within the Croatian state biology written exams, and the eventual correction of the questions before their application in the student assessment. An additional aim is to enable the qualitative question analysis in order to more comprehensively interpret student results within the written exam.
METHOD

Based on years of experience in the usage of the question analysis with the assistance of experienced biology teachers, we have developed a tool for assessing the quality of biology written exam questions. The question quality analysis involved a multiple teacher assessments and a collective final consensus-based assessment (MacCann et al, 2004). Elements and criteria for the expert question quality assessment (Table 1) were determined by three point Likert Scale (Cohen et al. 2007).

By shaping the question assessment categories, we relied on the grounds of the PISA project (OECD. 2015) defining science literacy as the ability to engage with science-related issues, and to use scientific ideas, natural science knowledge and evidence-based conclusions as a reflective citizen (Bellová et al. 2017). We defined the two basic categories determining the quality of questions: 1) the importance of the questions (i.e., elements of science literacy) and 2) the influence of questions on students’ response.

The importance of questions (Qim) category was specifically linked to the importance of questions for the development of science literacy and basic biological concepts (i.e., students’ reasoning and conceptual development). By assessing the elements of this category, a three point scale with value range ‘unimportant – moderately important – important’ was used (Table 1). The assessment elements within this category were the following:

A - importance of questions for the profession (IP), i.e., biology – enquiring how much is the knowledge needed for answering the question important and relevant for the development of basic biological concepts, conceptual development and achievement of biological competencies;

B - importance of questions for life (IL) – enquiring how much is the knowledge needed for answering the question important and relevant for basic biological literacy and can a student apply that knowledge in present or future life (context-rich questions);

C - importance of questions for the curriculum (IC) – enquiring how much is the knowledge needed for answering the question important and relevant for development of the competences foreseen by the curriculum, and conceptual understanding of the biological terms and concepts built-in the prescribed national curriculum;

D - importance of questions for critical thinking (ICT) – enquiring how much is for answering the question important reflective thinking focused not only on understanding certain terms and theories, but also on decision making, reasoning and evaluating certain life facts, attitudes and actions; also serves for the assessment of the students’ creativity and application of the natural science methodologies, epistemological knowledge, introspection and evidence-based inference; within questions enquiring reproductive knowledge and literature understanding, as important questions are considered those demanding analysis and/or synthesis of basic biological facts extracted during the initial information sorting.

The second category – influence of questions on students’ answers (Qin) – was closely linked to the influence of the question form, structure, wording and context on the student answering (Table 1).

(Qim+Qin)/2 IMPORTANCE OF THE QUESTION (Qim) (A+B+C+D)/4 INFLUENCE OF THE QUESTION (Qin) (E+F+G+H)/4

The assessment elements within this category were the following:

**E - question shape** (QS) – enquiring technical characteristics of the question (information necessary to solve the task): whether the question contains unnecessary and/or distracting information/figure/scheme irrelevant for answering the question; whether the question (text) length and the relevant supplements are in accordance with the question cognitive level; whether the distractor length within the question is consistent; whether the question avoids or accentuates negations; whether the graphs/figures/schemes attached to the question are clear, accurate and adjusted to student age; whether the question stimulus contains all the necessary information needed for answering the question based on learning outcomes prescribed by the relevant curriculum; whether the question scores are matched with the question requirements.

**F - question intelligibility** (QI) – enquiring the adjustment of the question to students’ age and understanding; this element could be additionally checked by questioning the following: is the question imprecise, suggestive, confusing, and/or contains conceptually homogeneous distractors and/or too many technical/expert terms irrelevant for shaping an answer; it should be borne in mind that a higher cognitive level requires highly developed literacy for understanding questions and supplementary material.

**G - students’ logical reasoning** (SLR) – enquiring whether the students’ logical reasoning (without students’ understanding of the questioned concept) could affect answering the question;

**H - students’ further learning path** (SLP) – enquiring whether the question requires additional learning/experience besides the prescribed curriculum (and/or details irrelevant for conceptual understanding) and how much could it affect the answer; whether the question is focused on facts, which are not emphasized during biology classes and/or are not crucial for conceptual understanding of basic biological concepts, but could be acquired by additional learning/experience (by preparing questions for gifted students, the additional learning paths are acceptable, but only to evaluate the level of upgrade of the basic biological concepts and...
their application in solving more complex tasks – not to burden the students by memorizing additional terms).

Besides the question quality, the teachers additionally assessed the questions’ weight, using the following scale: 1) easy; 2) moderately hard; 3) hard questions. For each question, the cognitive level was assessed according to Crooks (1988), so the questions were attributed to: 1) reproduction; 2) application of knowledge and conceptual understanding; or 3) problem solving.

By harmonizing the statements using an unambiguous numerical scale (Table 1), it was possible to make a more comprehensive question quality assessment, which was initially unfeasible because of the two adverse scales (Table 2) assessing the importance of questions, and the influence of questions on students’ answers separately by averaging the scales’ scores.

Table 2. Initial scaling for the question quality assessment.

The effectiveness of the developed tool was estimated by 4 teachers by means of 148 biology written exams, each comprising 23 questions (Cronbach’s alpha = 0.583, n = 148, SE = 0.048, 95% CI = 0.48 to 0.67) targeted for students aged 13 (Begic et al., 2016). Statistical analysis was done by StatsToDo (Chang, 2014), and correlations are interpreted according to Hopkins (2000).

RESULTS

Out of 148 exams encompassed by this study, 91 were written by girls and 57 by boys. Regarding the gender ratio (Mf = 63.18 ± 10.97; Mm = 66.46 ± 10.93), there were no significant differences in the exam performance (i.e., SSR, student success rate). Students successfully answered 3 to 20 questions of the exam (Figure 1). Most students (16%) successfully answered 12 questions, reaching 67.7% of the total points.

Spearman Rank Order Correlation was proven significant for logical reasoning (SLR) and the importance-of-questions (Qim) categories in relation to the success rate of the exam (ρ = 0.44, p < 0.05).

Student success rate (SSR) of the written exam used for testing our tool was moderately negatively correlated to cognitive level (CL), indicating that students performed better in answering questions of lower CL. Furthermore, SSR was highly correlated with question shape (QS) and influence of questions on students’ answers (Qin), suggesting that better formulated questions yield higher answering rate, having a lesser influence on students’ answers.
Our results indicate that the questions of lower CL were well-shaped and easily understood by students. For answering these questions, students did not require additional learning/experience besides the prescribed curriculum, and the questions could be successfully answered by applying basic biological concepts. This was additionally corroborated by the moderate correlation between the importance of questions for the profession (biology) (IP) and the importance of questions (Qim) for the development of science literacy as well as by the negative correlation between Qim and question shape (QS) / intelligibility (QI). The observed correlation trends suggest that biologically important questions were less intelligible to students – probably because they were more ‘wordy’ and thus more demanding. The biological problem-solving questions likely required advanced reading literacy as well as advanced understanding of complex biological concepts, and could not be answered by students’ logic alone.

Higher quality questions were of higher importance for biology, and the questions of ‘higher importance’ were simultaneously targeted to evaluate higher cognitive levels of students as well as the importance of the students’ knowledge for everyday life. The questions of higher importance used in our tool-testing-exam were complex and demanding – thus, hard to construct and likely shaped with less success (i.e., often affected by the students’ logical reasoning during the problem solving tasks). Despite certain weaknesses, the questions designated as highly important for understanding biological processes and concepts (for students aged 13) represent quality questions within the present study, as they greatly encourage students’ critical thinking.

Questions important for the curriculum (IC) demonstrated highly positive and significant correlation with the influence of questions on students’ answers (Qin) (Table 3), suggesting that questions highly important for the curriculum may greatly be influenced by question shaping and intelligibility as well as by students’ logical reasoning and learning paths.

The importance of questions for critical thinking (ICT) was positively correlated with the question quality (QQ) (Table 3), indicating that the questions of higher quality within the written exam encourage development of students’ critical thinking.
Concordance as a measure of agreement between the evaluators’/teachers’ opinions indicated a weaker concordance of the reasoning among assessors (average Fleiss kappa = 0.32) (Figure 2). There was a greater concordance among teachers regarding the assessment of the importance of questions (Kendall W = 0.53; ChiSq = 46.42; df = 22; p = 0.001) than regarding the assessment of the influence of question on students’ answer (Kendall W = 0.31; ChiSq = 27.11; df = 22; p = 0.21). Significant concordance among the evaluators was recorded for the assessment of the question quality, influence of the students’ logical reasoning on answering the question, and the importance of questions for critical thinking, curriculum and life (Figure 2). There was no significant concordance among the evaluators regarding the importance of questions for biology. It suggests that the evaluators disagree in their opinions, most likely because the key biological concepts and the respective conceptual framework are not clearly defined within the existing curriculum. Furthermore, there was no significant concordance among the evaluators regarding assessing the influence of question shape and intelligibility, and students’ further learning path on answering the questions. It was again likely the result of lacking national standards and/or teachers’ experience and/or a consequence of the low number of evaluators within this study.

Figure 2 Concordance among teachers regarding the assessment
The results of qualitative question assessment may be helpful in order to get a better understanding of the percentage of answered questions and the student performance, respectively.

Out of 23 questions (Figure 3), 90% of students correctly answered on two acceptable questions - hard reproductive question 3 and easy conceptual question 6. Reproductive but difficult question number 19 had the worst success rate (the mean score of all students was less than the average score of the possible points). Poorly solved questions were questions 7 (15%) and 20 (14%), both moderately difficult and enquiring students' application of knowledge and conceptual understanding. Highly hard, medium quality question 21 was focused on checking the students' problem-solving ability, it had the highest score number, but was successfully answered by only 7% students.

**Figure 3. Comparison of points scored and index of item difficulty**

Based on the assessments, there were no bad questions. Five questions could be designated as good (9, 11, 12, 17 i 23), and the rest as acceptable (Fig. 3). The quality of questions had likely low influence on students' answering, while only 3 questions (12, 17, 23), could be labelled as important.

According to the final question quality assessment done by averaging the scales’ scores (Table 1), there were no statistically significant differences between the individual teachers’ assessments (Kruskall-Wallis H = 0.25; df = 3; p = 0.97), and the teachers were relatively well-matched in their assessments (Kendall W = 0.44; ChiSq = 39.08; df = 22; p = 0.01). Authors of the questions were shown to be less self-critical in the self-evaluation than their peers, but this difference in the self-assessment was very low (8.6%) (Figure 4).

**DISCUSSION AND CONCLUSIONS**

Already during the initial application of our tool, it was noted that the critical assessment of the elements and criteria coincide with the results of psychometric question analysis (Radanović et al., 2010). Quality of the questions has lasting effects on teaching and learning, so the technical properties of the questions should be greatly considered by developers and practitioners (Dunbar et al. 2009). Discordance among the teachers' assessments confirms that the teachers are not prone to critically reflect on the questions they shape.
The teachers infrequently completed post-hoc statistical analyses of their tests (Marso & Pigge 1988) so a relatively simple quality analyses of their exams, based on the averaging valuation (i.e., consensus) among the selected elements and criteria for the question quality assessment, would provide plenty useful and relevant information on the overall question quality. More uniform teachers’ assessments of the importance of questions might confirm the teachers’ competence within the subject (i.e., biology), their knowledge and professional expertise. As the majority of open-ended items that are successfully tested for a higher cognitive level of knowledge, it is of utmost importance that the final say in deciding whether the item is effective in written evaluation must be given by the subject scientific basis (Begić et al., 2016), because according to Schmelzing et al. (2013) such issues have high content validity and potentially poorer inter-rater objectivity. The teachers’ disagreement in the assessment of the influence of questions on students’ answers could indicate an uneven teaching experience. Such result suggests that the teachers should necessarily continuously work on their own professional development (Gottheiner & Siegel 2012) to be able to focus well on setting the question quality standards (e.g., technical preparation of the questions, adaptation of the questions to the students, avoiding questions that demand high level of logical thinking, etc.). The teacher professional development should further help teachers to close the formative assessment cycle by addressing conceptions that are elicited with assessments (Gottheiner & Siegel 2012). Additionally, there is a need to develop the result analysis criteria for the exams, and a scientifically based approach to their assessment (Golovachyova et al. 2016). The tool we developed could be used for peer-evaluation as well as for self-assessment, but only if critically applied with the recommended delay of at least 2 weeks after the question preparation. Due to small number of teachers/evaluators (n = 4) in this study, our results indicate a certain trend, but to generalize our findings, our tool should be checked with a larger number of teachers and students’ exams. The most important roles in the question quality assessment play the teachers’ experience in the classroom as well as the overall experience in the question analysis. Therefore, it is very important to encourage teachers to collaborate in qualitative assessment of exam tasks.

ACKNOWLEDGEMENT

We thank Marijana Bastić and Ivanka Podrug for assessing the item quality.

Secondary Students’ Attitudes Towards Science Based Technology - An Exploratory Study

Robbert Smit, Nicolas Robin & Christina De Toffol
STRAND 12: INTRODUCTION
CULTURAL, SOCIAL AND GENDER ISSUES IN SCIENCE AND TECHNOLOGY EDUCATION

The scope of Strand 12 is to portray and support research that investigates Equity and Diversity issues in science education. The topics presented are manifold and covers sociocultural and multicultural frameworks, bilingual studies and have a strong focus in social, ethnic and gender equity studies as well as the strand examines science education for the special needs.

The 11 papers which were submitted to the ESERA e-proceedings, fall into 4 categories:
- Science and gendered identities
- Cross-cultural, cross national and multilingual differences
- In and outside the classroom
- Children and young peoples’ attitudes to technology and ICT

Science and gendered identities

Four papers in different ways, deal with science and gendered identities.

Gonsalves and Danielsson urge physics education research to move beyond the binary models of gender that dominate the field in the paper: IDENTITY, MASCULINITY AND MATERIALITY: MAPPING OUT NEW TERRAIN IN PHYSICS EDUCATION RESEARCH. Gendered participation is investigated through an identity lens, and in particular the embodied experiences of doing physics are exemplified by interview data collected from two case studies conducted with physics undergraduate and graduate students in Sweden and in Canada. The authors show how masculinity as a performance can allow us to examine how men and women take up masculine-coded skills and how “‘environments’ and ‘bodies’ are actively constituted” in physics practices and that the intra-action of bodies and material objects can reveal gendered power at work. This paper offers a novel approach to physics education.

In a study of students’ self-concepts of chemistry Rüschenpöhler and Markic moves away from the concept of attitudes to understand and question the gender gap in Chemistry. In the paper: CULTURAL INFLUENCE ON STUDENTS' SELF-CONCEPTS OF CHEMISTRY: QUESTIONING THE TRADITIONAL GENDER GAP. The study on the one hand supports previous research in pointing out how boys have much stronger self-concepts in chemistry than girls. However on the other hand it shows how among students with multiple cultural backgrounds, girls made use of stronger learning strategies than boys. The authors suggest how self-concepts are culturally dependent and thus that teaching must facilitate crossing cultural borders in the scientific community in order to promote scientific literacy and greater social justice.

Maurines presents the results of a questionnaire of how gender (seen simply as girls and boys ideas) has impact: SCIENTIFIC COLLEGE FRESHMEN'S VIEWS OF SCIENCE AND OTHER PRACTICES: A GENDER ISSUE? The author examines the impact of the gender on three questions; one related to the characteristics of the scientific knowledge, the two others to
the characteristics of the scientist considered as a person. These are compared to the impact of
discipline(s) chosen for the high school diploma and the university major. One question
where girls and boys have different scope is on the need of creativity for doing scientific work.
Other results only briefly mentioned, reveal more differences between the groups of girls of
the different high school diplomas and university majors than between the equivalent groups
of boys. This is an interesting finding as it suggests that gender cannot be understood as a
binary category, and we suggest that the authors elaborate their analysis from a more consistent
gender perspective.

Finally Palmer presents the study SCIENCE CHOICE AT SCHOOL: GENDER AND THE
RELATIVE IMPORTANCE OF FACTORS STUDENTS CONSIDER WHEN SELECTING
SUBJECTS. The Best -Worst-Scaling (BWS) questionnaire results presented here provide
quantitative data on the relative importance of the factors that male and female students
considered in choosing and rejecting subjects for post-compulsory study at school. The BWS
give 21 factors that male and female students considered when choosing and rejecting subjects.
The result shows that 333 Year 10 (age 14–17) students find male and female students to choose
and reject subjects in a similar manner but there are differences in the degree of importance
students place on some factors. The girls find their interest, enjoyment, past ability and type of
classwork as being more important than boys do, is one example.

Cross-cultural, cross national and multilingual differences

On various cultural, national and lingual levels the three below studies portrays the differences
that appear across contexts.

Wolfs and Delhaye presents the result of a cross-national survey to science students in the end
of upper secondary school and their secularised and non-secularised views of science across
11 different countries. The paper: SURVEY OF STUDENTS FINISHING SECONDARY
SCHOOL FROM 11 COUNTRIES REVEALS INFLUENCES ON DIFFERENT
SECULARISED OR NON-SECULARISED VIEWS OF SCIENCE shows how geographical
and cultural factors turned out as better explanatory factors than strictly religious factors.
Moreover the students’ views of scriptures as symbolic and/or mythical were clearly linked to
secularized views of sciences.

A study on school level examines the multilingual science classroom in the paper:
CONTRADICTIONS AND CONGRUENCE IN MULTILINGUAL SCIENCE
CLASSROOMS: AN ACTIVITY SYSTEM PERSPECTIVE by Salloum and BouJaoude. The
paper presents an analytical framework for interaction analysis in multilingual science
classrooms in Lebanon combining Bakhtinian thinking and an activity theory perspective. The
analysis combine the subjects (science teachers), instruments (language, content of textbooks),
object (learning science content), rules (language in education policy), community (all
stakeholders in the school), and division of labour among the stakeholders and portray the
challenges encountered by the teacher in the science room. The findings showed a contradiction
between teacher (subject) and students (community) on language used in the classroom; on the
other hand, students (community) resented the school-wide rule of “all English” (Rules). Two
activity systems and the challenges embedded within them are presented in the paper.
Silva and Heidelmann study INTERCULTURALITY IN THE CHEMISTRY TEACHING: RESEARCH ON THE INSERTION OF AFRICAN CULTURAL ASPECTS IN DIDACTIC PRACTICES IN THE STATE OF RIO DE JANEIRO applies a structured questionnaire to analyse Chemistry teachers from the state of Rio de Janeiro and the insertion of the law and the African and Afro-Brazilian culture in their teaching practices. They find that a lack of commitment to ethnic-racial issues is still present both in the trajectory of teacher education and in the classroom practices of the interviewees. Therefore, more researches and work on cultural methodologies need to be part of their education and teachers need a bigger effort to keep their teacher practice from reproducing a crystalized perspective of the history and science. By analyzing the profile of the teachers who answered the questionnaires, it was observed that, although it has been more than a decade that the Law was established, many teachers are still unaware of the document.

**In and outside the classroom**

Finally two studies deals with inclusion and engagement in science in and outside the classroom.

Heidinger, Abels, Plotz and Koliander present an explorative case study in their paper INCLUSION AND CHEMISTRY TEACHING – DELIBERATING CONFLICTING DEMANDS. The study examines how the requirements of an increasing inclusion of diverse students within the classroom are met by and challenges the individual teacher when teaching a subject like chemistry at an inclusive school at middle school. Their research question is: What are the difficulties for a science teacher to apply the demands of inclusive practice to her subject-specific teaching? The final result show, how future professional development courses must not only focus on inclusive pedagogies in themselves (how to teach), but also on the reflection of implicit beliefs in inclusive science teaching. The authors’ state: “Making these implicit orientational frameworks explicit would help teachers to become aware of conflicting demands in their belief systems about inclusive science teaching which we assume to be a pre-requisite for a sustained improvement in their teaching praxis”.

Moving outside the classroom Grenon, Carroll, Fracchiolla and Concannon have studied public engagement in Ireland by the Cell EXPLORERS programme (www.cellexplorers.com) in the paper: THE CELL EXPLORERS PROGRAMME – PILOTING A STEM PUBLIC ENGAGEMENT MODEL IN IRELAND. The programme strives to connect primary and secondary level education, third and fourth level students, lecturers, researchers and the general public. And the aim is for the model to act as a sustainable avenue through which local communities can be engaged in science. The programme reached out to more than 2000 school children nationally in Ireland. The results are positive and present the impact of the dissemination of science education and public engagement activities in Ireland by involving science students as science outreach volunteers.

**Children and young peoples’ attitudes to technology and ICT**

Two studies in different ways identifies some of the challenges of childrens’ and young peoples’ interaction with technology and ICT.
In their study: RESEARCHING GENDER & ICT IN KINDERGARTEN, Ferreira and João Silva presents the findings from the project Gender@ICT', which explored the interrelations of gender and technologies among preschool children in Portugal, based on group activities (games with images related to ICT and gender), focus groups and semi-structured interviews. The study revealed that gender stereotypes are deep-rooted amongst young people, and thus that these gender stereotypes are materialized in technology. As a consequence the authors discuss how interventions must start early on to promote a diversity of gender related to ICT.

Smith, Robin and De Toffol present the paper: SECONDARY STUDENTS’ ATTITUDES TOWARDS SCIENCE BASED TECHNOLOGY – AN EXPLORATORY STUDY. The aim of the study was to foster students’ interest in STEM professions by out-of-school visits in industries. The authors present results from student questionnaires. One of the results shows how students without the experiences of interacting with technology at home, did not have the repertoire and experiences to develop positive attitudes. The authors’ argue how visits in the industry represent a unique opportunity for students to discover an interest for STEM professions and to develop attitudes to STEM in general and technology in particular.

We hope that you will find the proceedings portrayed in the four themes in Strand 12 interesting and relevant, and we encourage you to submit your work on Cultural, Social and Gender Issues in Science and Technology Education to the strand at future ESERA conference.

Henriette Tolstrup Holmegaard and Margareta Enghag
IDENTITY, MASCULINIT Y AND MATERIALITY: MAPPING OUT NEW TERRAIN IN PHYSICS EDUCATION RESEARCH

Allison J. Gonsalves¹ and Anna T. Danielsson²
¹McGill University, Montreal, Quebec
²Uppsala University, Uppsala, Sweden

In this paper, we present an argument for the use of identity frameworks in physics education research (PER) to move research beyond the binary models of gender that dominate the field. We suggest that identity can give us a lens through which we can understand gendered experiences in physics, that may illuminate new theories of gendered participation. Some such theories include the impact that masculinity has on the construction of subjects in physics, and the influence this has on students’ participation. We also argue that materiality—the embodied experiences of doing physics—need to be attended to, and can bear impacts on identity construction in relation to physics. We draw on empirical data from two studies conducted in Sweden and in Canada to explore the experiences that university students have navigating the gendered terrain of physics, and discuss the implications these theoretical perspectives have for future research in physics education.

Keywords: physics, higher education, gender

INTRODUCTION

Physics education research (PER) is a research field that deals with the teaching and learning of physics and is typically considered a sub-field of physics rather than of education (Beichner, 2009). Traditionally, PER has been primarily concerned with students’ understanding of physics concepts, but increasingly, the field is expanding to explore a rich array of cognitive as well as social aspects of the teaching and learning of physics (Beichner 2009). A notable research strand within PER is research dealing with gender issues—an interest motivated by the continued under-representation of women within the discipline as evidenced by, for example, the recent focused collection on “Gender in Physics” in Physical Review of Physics Education Research. Within this research strand is an emerging focus on identity work in physics learning, to move away from binary models of gender that tend to focus on differences between men and women (e.g., Traxler, Cid, Blue & Barthelemy, 2016). The use of identity frameworks in gender research is already well-established in science education research (Brickhouse, 2001; Francis et al., 2016), so we begin with an argument that PER work focused on gender issues can learn from this promising orientation. Subsequently, we map out two areas we perceive as particularly important in order to understand the gendering of university level teaching and learning of physics: masculinity and materiality. We illustrate our discussion of masculinity and materiality with interview data collected from two case studies conducted with physics undergraduate and graduate students in Sweden and in Canada.
THEORETICAL FRAMING

Doing Identity and Doing Gender

Brickhouse (2001) argues that “in order to understand learning in science, we need to know much more than whether students have acquired particular scientific understandings. We need to know how students engage in science and how this is related to who they are and who they want to be” (p. 286) and advocates for a perspective on science education that considers learning as identity formation. From this perspective, identity is perceived as something we do rather than something we are (Carlone & Johnson, 2007), and can be approached through the conceptual pair of performance and recognition. Identity performances can be thought of as bids for recognition (Gee, 2005), where a successful bid for recognition renders an individual as a legitimate and recognisable member of a certain community, such as a community of physicists. Thus, we focus our exploration on how the sociocultural contexts of physics disciplinary cultures construct possibilities for who can be recognized as a “certain kind of person?” (Gee, 2005; Carlone & Johnson, 2007). In the cases presented here, we looked for examples of how competence (i.e., who is a good physicist, what does doing good physics look like?) is constituted in participants’ talk about doing physics, and how this intersects with discourses of gender.

Part of doing identity work is doing gender, where gender is seen as performative and fluid and not bound by binary categories (Butler, 1999). However, acknowledging gender/identity as performative does not imply that all performances are equally feasible: who can be recognised as a certain ‘what’ is limited by situational and structural constraints (including the body of the individual). Francis (2012) has suggested that dichotomous generalisations about ‘men’ and ‘women’ cannot be sustained, rather gender is local and relational, and how gender is performed within different contexts is dependent on how that context limits or enables certain identities. As such, we look for local and contextual constructions of masculinities and femininities in relation to physics, as constituted in participants’ talk (Paechter, 2006). We do not wish to posit that masculinities and femininities are signifiers of male-ness or female-ness, nor do we wish to reify a binary system with these terms. Rather, we understand masculinities and femininities as existing on a continuum, that may be taken up in contextually meaningful ways by individuals of any gender. As argued by Gonsalves, Danielsson & Pettersson (2016) such a perspective “helps us look more carefully at the complexities of gendered experiences in physics environments, rather than simply asking questions about what women need to succeed in physics” (p. 3).

Masculinity in physics

Not only is physics dominated by men, but the discipline is also laden with masculine connotations on a symbolic level (Francis et al., 2016). However, there is a surprising lack of work analysing the construction of masculinities within physics/physics education (e.g. Gonsalves et al., 2016); rather, work on gender and physics has typically focused on women within the discipline (for a description see Traxler et al., 2016). Pettersson (2011) argues that to understand why physics is still dominated by men it is important to analyse culture and actions that are associated with masculinity and analyse men as political subjects. This entails
exploring how masculinity is imbued in the discursive practices students engage in while learning to become physicists. In this paper, we argue that an analytical focus on masculinity and materiality allow us to unpick how the norms of physics communities are constituted, and to help us to focus on how the constitution of insideness rather than to focus on the people and practices that are positioned as outsiders. As mentioned above, we are concerned with the ways that masculinity constructs competence in physics communities. For example, technical competence—physical skill and a seemingly natural affinity for tinkering—has been shown to be valorised in engineering cultures, along with the valuing of calculative rationality (Wacjman, 1991). These traits are both associated with masculinity, but are not always or only possessed by men. Our understanding of masculinity as a performance, rather than a static characteristic belonging to men, allows us to thus examine the ways that physicists (of all genders) take up these skills or transform them in order to gain recognition as competent physicists through certain practices. However, culturally, this construction of masculinity (and its associated competences) is not always viewed as a performance, and is rather seen as a characteristic possessed by men. Halberstam (1998) argues that positioning masculinity as a characteristic rather than a performance grants power to men. This can be particularly true in physics contexts, where men are often viewed as having a natural ability or affinity toward physics.

**Materiality in physics**

Experimental work is undoubtedly a core practice within physics as well as physics education (Hofstein & Lunetta, 2003) and learning physics is not confined to being induced into the discursive practices of the discipline, it also includes the *intra-action* with physical artefacts (Barad, 2003). Therefore, ways of understanding how identity work shapes and is shaped by materiality and bodies are needed. Karen Barad’s work in material feminism provides a very promising framework for physics education researchers interested in experimental practices. Barad’s concept of intra-action provides an understanding of matter as agentic, and actors’ engagements with matter produce material-discursive practices, that go beyond Butler’s (1993) approach of performativity of gender, as they include these non-human and non-organic forms of matter in the process of becoming. Understanding how ‘matter matters’ in gender research in physics education can help us to take perspectives on identity work that reside outside of the discursive, and to focus instead on how the materialities of physics practices do important, but sometimes unnoticed work on the enactments of gendered power. For example, how students are expected to dress, how they engage with laboratory instruments and machinery, and how these intra-actions signal competence in physics are all critical to the identity work students engage in when becoming physicists. In the results and discussion sections, we argue that the concepts of *masculinity* and *materiality* are important for understanding the particularities and nuances of identity work within higher education physics.

**METHODS**

Drawing from two case studies conducted in Sweden and Canada, we explored the *identity work* students do as they position themselves as recognizable physicists. This approach allows us to frame gender, and identity, as performative, relational and local and may be constrained or enabled by material and discursive contexts (Butler, 1999; Francis, 2012).
**Data collection**

The first case study makes use of multiple sources of data collected over one year, in a research-intensive university in Eastern Canada. Eleven men and women from a physics department, at various stages of doctoral degree completion, participated in the study. The participants were sampled purposefully to provide a cross-section of disciplinary sub-fields (theoretical high energy particle physics, experimental solid-state physics and observational astrophysics), to explore the various practices within the discipline. Participants also represented various stages of degree completion to provide a picture of identity work at different points in the doctoral process (see Gonsalves, 2010 for more details about the research context and participants). The data sources included field observations and ethnographic field notes, journaling, photo-elicitation interviews (Harper, 2002), and semi-structured interviews (Kvale, 1996). The participants in the study were invited to compile photo-journals, taking and describing photos of aspects of physics culture that were important to them. These photos were used as jumping off points in photo-elicitation interviews, which sought to identity critical incidents related to participants’ identification with physics. Follow-up semi-structured interviews were conducted to craft narratives of experience that yielded identity trajectories for each of the participants (Mischler, 1999).

The second case study was conducted in Sweden, involving 13 undergraduate students and 9 graduate students (MSc or early PhD) in a physics department of a research-intensive university. Semi-structured interviews (Kvale, 1996) lasting between 30 and 70 minutes were carried out with each of the participants, and then transcribed verbatim. The selection of participants was purposeful to include a diversity of students, including both men and women, participants of different ages, and of varying educational backgrounds. The author’s (Danielsson) own background in physics served to provide context to the interviews, permitting an insiders position to the field, and allowing her to build trust with participants through the sharing of common experiences. Further information about the methodology for this case study can be found in Danielsson (2009).

**Data analysis**

The data presented here from both case studies are primarily from interviews. Although we view identity theoretically as work that is done through engagement with other actors or materials, we understand that identity can be comprehended by others through stories of recognition (Carlone & Johnson, 2007). Moments of recognition and critical incidents, as narrated by participants can be salient to their identity work at the time. We understand that these identifications may change over time, but we privilege these narrative accounts to understand how individuals negotiate physics contexts, and how these negotiations have been understood and responded to be meaningful others (Johnson et al., 2011). In both case studies, a thematic analysis of the data was conducted and themes were collected that construct narratives of experience.

To explore the theoretical utility of the lenses of masculinity and materiality, we re-examined our data performing a second set of analyses. A typology was developed using the framework of masculinity and materiality through which we sifted data previously identified as ‘forms of
competence’ (discussed in Gonsalves, Danielsson and Pettersson, 2016; Gonsalves, 2014; and Danielsson, 2012). For example, if working with an instrument was identified as a form of technical competence, we then reanalysed that narrative episode and looked for interactions of masculinity with materiality. We subsequently pulled out exemplars from our previously coded data sets that we felt best illustrated the interactions of masculinity and materiality in students’ learning and doing physics identities.

**FINDINGS**

The findings presented here have been discussed in different iterations elsewhere (see Gonsalves, 2014 and Danielsson, 2012), and are reconsidered in light of our focus on the intersections of masculinity and materiality. By exploring how bodies, objects and practices in physics can influence forms of identification that are entangled with masculinity and material, this revisiting of our data raises new questions about gendered physics practices. We intend to show here that a) masculinity as a performance (rather than a static trait) can allow us to examine how men and women take up masculine-coded skills in order to gain recognition as a competent physicist; and b) “environments’ and ‘bodies’ are actively constituted” in physics practices (Barad, 2007, p. 170), and that the intra-action of bodies and material objects can reveal gendered power at work.

**Masculinity and Physics**

In our research, competence—as it is framed in the doing of physics—was seen to be imbued with symbolic masculinity. This emerged in examples of technical competence (where competence was assessed as physical skill or a natural affinity for hands-on laboratory work) previously associated with the dominant cultural forms of masculinity, wherein stereotypical femininity is conspicuously absent (Wajcman, 1991). Judy Wacjman has referred to technical competence as one of the “fundamental measures of masculine status.” and our data demonstrates that it is highly valued by experimental physicists. For example, Cecilia is one of the students from the Swedish data, who demonstrates a straightforward relationship with technical competence. At the time of the interview she was doing a master in experimental physics. Throughout the interview she identified strongly with being a physicist – and also described that she had been quite a typical engineering student in her undergraduate days, drinking beer and singing indecent songs and very much being “one of the lads” (Kvande, 1999; Danielsson, 2012). When talking about her practice in the student laboratory she said:

“Ok, I really sucked at preparation, it was always the last minute to read stuff through, just before ... ‘Some preparatory assignments, yeah, it was, damn.’ So it was always the last minute. Erm, the laboratory report I sucked at in the beginning, was good at when I finished [the education] or I didn’t suck, but ... quite bad. [...] I was skilled at ... well, when I’m doing laboratory work I’m good at daring to press all the buttons, kind of, if you have an oscilloscope ‘I haven’t used an oscilloscope in two years, turn a bit here, turn a bit here, damn, look, picture!’” Cecilia (Master student, Sweden)

Thus, she presents herself as the unafraid tinkerer, who got through the practical elements of her education without much preparation. Drawing on the discourse of technical competence
as a valued masculinity in physics, Cecilia positions herself as the kind of student who displays effortless achievement downplaying the well-preparedness that often is associated with female students. Instead, in this quote, she focuses on her affinity for hands-on work and authors herself in relation to the discourse of ‘natural ability’ (Mendick et al., 2017) - suggesting that she is not in need of manuals or preparation - she possesses a competence that is valued in physics and often associated with construction of a technical masculinity.

This discourse of technical competence can also function to position students as outsiders to physics, as seen in the case of Ruby, from the Canadian data. Ruby started out her physics career as a student who was easily recognizable as a “physics person”. She was competent in textbook learning, and was often the student who others would turn to for help in her undergrad. But in her doctoral studies, she began to see herself less and less as a physics person. In her photo-journal, one of the pictures she provides is of her toilet. When asked about it in an interview, Ruby said that she fixed her toilet, and as a result “felt like a physicist”. She argues that physicists should be able to fix things, and she also suggests that they should just be able to know how things work. Although she felt ‘like a physicist’ when she fixed her toilet, she still could not explain how it worked, which made her feel like an outsider to physics:

“I can’t just go and say, “Oh I know how this works, I know how this works.” I can’t. I don’t know how things work, I...you know if someone were to explain it to me properly I would understand it probably. But I don’t know how they work just by seeing them or examining them. I can’t figure things out for myself. I think a physicist should be able to do that. And I think if you can’t figure that, then there is something missing or in my case there is something missing.” Ruby (PhD student, Canada)

By arguing that physicists should be able to “figure things out” Ruby constructs a discourse of natural ability in relation to technical competence (Mendick et al., 2017). In her doctoral trajectory, her research and learning has progressed to relying less and less on textbook material, and more and more on ‘figuring things out’. As she moves through the doctoral program she appears to identify less and less as a physics person the more she has to rely on technical competence.

MATERIALITY AND PHYSICS

As seen in the above examples, technical competence often emerges as directly associated with physical skill in the lab or an instrument. So far we have treated technical competence as a discursive construction, but Karen Barad (2003) reminds us that technical competence implies an intra-action with physical artefacts. In intra-actions, the physicist is a part of the apparatus in ways that are ‘material-discursive’ and involve the production and reproduction of both knowledge and material bodies. Our studies demonstrate that skill on instruments in physics was at times determined by the actual material shape of bodies and their interaction with machines—which often seemed to be developed with gendered bodies in mind (Berg & Lie, 1995). This is perhaps most strongly demonstrated in the case of Lily, a solid state physicist who was working on a Scanning Tunneling Microscope (STM) in Canada. She worked on a machine that was Japanese built, and she could manipulate it reasonably well here, but found
that the size of the instrument and the strength that was needed to manipulate the ultra-high
vacuum necessitated her to take on a specialized role:

“So we’ve determined that for this instrument, there are always three people who work on
the instrument because it requires just that much care. There needs to be that many people
around to make sure that somebody can always do something. So, we always need one
person with small hands. The flanges are maximum this big [motions with hands] and you
might have to stick your hand right in. If you have big hands, you can’t physically do it.
And the screws are like 1 millimeter screws and stuff like that so, and we need someone
who is big and strong because it’s all stainless steel, and if we ever have to take a piece off
the vacuum, it’s really heavy, I can’t do it, I physically can’t.” Lily (PhD student, Canada)

The instrument that Lily works on demands the manipulation by stronger, large statured
individuals and therefore constrains the possibilities for her performance of a recognizable
technical competence in usual ways. This was augmented when she did a semester in a lab in
Germany and worked on an STM that was considerably larger than the one she was used
to. The instrument thus provoked a gendered division of labour in the lab context, one in
which the physicists’ bodies (and associated gendered assumptions about size and strength)
created affordances and constraints for intra-actions with artefacts such as the STM. The
change in size meant that Lily needed to adopt a new role or find a new way of performing
competence on this instrument. Thus, while the machine constructs a material constraint, it also
provides an opportunity for Lily, who develops recognizable expertise in the manipulation of
small, finicky objects. Thus, the effect of this gendered division of labour is subverted in a way
that permits Lily to construct a recognisable identity as a technically competent physicist.

As discussed in previous sections, students often positioned themselves in affiliation (or
opposition) with technical competence by describing their affinity for tinkering, or by
positioning oneself as naturally skilled in instrumentation, or against the need for a “manual”
or theoretical understanding of the instrument. This is illustrated in the story of Tor, a Swedish
PhD student in experimental physics. Tor strongly identifies with physics across contexts (in
and out of school). In his spare time he makes videos where he demonstrates popular science
experiments and considers physics to be the most interesting thing one can study or work with.
But, it’s a particular kind of physics Tor considers so fascinating—a deeply experimental one
that allows him to intra-act with the phenomena he is studying as unmediated as possible by
theories. For example, he contrasts experiments that result in ‘ugly graphs’ from the scanning
tunneling microscope that is able to ‘take pictures of individual atoms’ and considers the latter
as superior to the former. The intra-action with instruments he describes is one that draws on
an intimate knowledge of and relation to these instruments, he explains:

“Yesterday I was doing measurements on an instrument… Had no knowledge of the
theoretical background of the measurement, but still I could sit down at, I mean a really
complicated experimental set-up, do the measurements, without hesitation. And get good
results, and that’s just because I mean, I knew basically every small part of the set-up, you
have lens there, you have amplifiers there, you have some current sensor, you have a light
sensor bla, bla, bla… and if you look at this you can see what you’re measuring and do
it.” Tor (PhD student, Sweden)
Competence can also be recognised by acceptable intra-actions with instruments, and the strongly hands-on intra-action Tor describes here is one that allows him to be recognised as a physicist. When describing the education needed for an experimental physicist, Tor also starts by stressing the necessity to be able to handle experimental set-ups, from simple stop-watches to extremely complex instruments at CERN, thereby construing the material aspects of the physicist practice as fundamental for the experimental physicist, at all levels. Tor draws on his natural ‘affinity’ for the instrument to position himself as a recognisable physicist. This provides an example of how the affinity for working with the instrument is assumed to be natural, as masculinity is often assumed to be naturally affiliated with male bodies (Halberstam, 1998), so we see that the recognizable form of technical competence is not necessarily a purely cognitive one.

**DISCUSSION**

Placing the data from these two studies under the lenses of masculinity and materiality has helped us to determine how norms are constituted within physics communities. Rather than focussing on how (some) women are constructed as outsiders, we have tried to illustrate examples of how masculinity and materiality can construct insideness. Considerations of how masculinity and materiality intersect might provide fruitful avenues for researchers to examine physics cultures, and how they construct norms for participation. For example, Ulf Mellström (2004) argues that masculine bonds in engineering are communicated and mediated through interactions with machines. These practices produce highly gendered spaces where men form homosocial bonds and communities based on their passion for, and interaction with machines. Helena Pettersson (2011) has studied the experimental practices of plasma physicists and has similarly found that physicists created bonds with machines in ways that intersect strongly with masculinity. In Pettersson’s study, equipment was discussed as ‘exotic and sexy’ and it was demonstrated that passionate bonds to machines were important in order to establish one’s insider position within the laboratory setting. This notion of ‘boys and their toys’, where experimental set-ups are understood as expensive, high-powered ‘toys’ creates a connection between masculinity and the materiality of experimental practices. This connection continues from childhood technological play to the experimental practices in physics laboratories. We see a similar story emerging in the example of Tor, who positions himself as having a natural affinity or a ‘feeling for’ for experimental physics and related instruments both inside and outside of the laboratory context. We also see that the feelings of ‘being a physicist’ extend outside of the lab in the case of Ruby, who positions herself around technical competence both at home and in the lab context.

In all of the examples provided, we see that identity work in physics involves the negotiation of embodied relationships with experimental set-ups. At times, the physicists’ body creates affordances and constraints for intra-actions with physical artefacts. Lily, for example, makes herself intelligible or recognizable as a physicist by drawing on particular bodily affordances. In this case, Lily’s work might be seen as an example of improvisation, or creating a new intra-action that affords her agency, or the ability to be recognizable in new ways. Acceptable intra-actions with instruments include trial-and-error approaches like those described by Cecilia, as well as those drawing on an intimate knowledge of experimental set
up as described by Tor. Thus, recognizable forms of technical competence are not purely cognitive ones—technical competence may also be seen as innate—which presents problems when this masculinity is understood not as performed by as natural. This expectation may construct constraints for recognition. Thus, any novel intra-actions with instruments, like those described by Lily, might be understood as improvisational (and perhaps even transformational) acts of agency.

Physics as a discipline is often constructed as independent of societal factors (Traweek, 1988) and getting sight of the cultural production of physics and the related identity negotiations may therefore be difficult. We have argued for the fruitfulness of seeking inspiration from science education research where gender issues are conceptualised from the perspective of identity work. However, to date, such studies have predominately focused on girls/women and approached identity as a purely discursive construct. To counterbalance this, we have argued that physics education research needs a discipline-specific crafting of the perspectives developed within science education research and have provided illustrations of how analyses of masculinity and materiality can provide two entryways to understanding the specificities of gendered identity constitution within physics.

CULTURAL INFLUENCE ON STUDENT SELF-CONCEPTS IN CHEMISTRY: QUESTIONING THE TRADITIONAL GENDER GAP

Lilith Rüschepöhler and Silvija Markic
Ludwigsburg University of Education, Ludwigsburg, Germany

Cultural diversity has increased in classrooms in the past decades, but little is known about the impact of learners’ cultural identities on science learning. The aim of the present study is to explore the influence of culture on students’ self-concepts of chemistry. This study differs from traditional self-concept research in its methodology and in the underlying theoretical framework. Unlike the predominantly quantitative orientation found in self-concept research, our approach emphasizes the qualitative exploration of the field in order to reveal cultural differences. Furthermore, we employed the assumptions of self-concept published by John Hattie in his rope model. This differs from traditional models because of its focus on psychological mechanisms rather than attitudes. Semi-structured interviews with chemistry students in German secondary education were conducted (N=43). Two culturally distinct gender gaps could be found. First, the well-known difference between German boys and girls was seen again: namely that German boys have much stronger self-concepts in chemistry than girls do. Among students with multiple cultural backgrounds, however, an inverse relationship was found. Girls made use of stronger learning strategies in chemistry than boys. This leads us to the hypothesis that the possession of a strong self-concept doesn’t mean the same thing in different cultural groups. We propose a working model of three qualitatively different types of self-concept, which needs to be tested in further research. The goal must be to shape our teaching so that it facilitates crossing cultural borders in the scientific community in order to promote scientific literacy and greater social justice.

Keywords: chemistry self-concept, culture, gender

INTRODUCTION

Many German schools currently have students from more foreign countries than most of the teachers have ever seen. Largely caused by mass migration, modern European cultural diversity continues to rise. In future, we can expect migration flows both to and within European countries to remain an important and volatile socio-political issue. The process of integration and community building follows. People should receive the same chances in life (OECD, 2017), a condition which presents nations with a huge and complex task. Teachers are among the first people to feel these societal changes in school, since they work in this diverse environment every day. But even with the recognition of this situation, the impacts of diversity on learning are not well known. Our task as educational researchers is thus to support teachers in this situation full of uncertainties and to produce knowledge that can guide their actions.

One of the most important indicators of successful schooling practices, which provide equal chances for all, are the students’ learning outcomes. In other words, their achievement. Since achievement is closely related to academic self-concepts (Guay, Ratelle, Roy, & Litalien, 2010; Jansen, Schroeders, & Lüdtke, 2014; Marsh & Craven, 2006; Wylie, 1979), a great deal of educational research has aimed at understanding these concepts. In this line of research,
chemistry self-concepts have also been covered (Bauer, 2005; Lewis, Shaw, Heitz, & Webster, 2009; Nielsen & Yezierski, 2016). Yet in the last decades, self-concept research has relied almost entirely on the Shavelson concept (Shavelson, Hubner, & Stanton, 1976) or one of its derivatives as a theoretical basis. Research has been performed almost exclusively with the use of Likert questionnaires. But some researchers have criticized this approach as inappropriate in multicultural settings. Researchers still lack research methods for self-concept research in culturally diverse societies (Byrne, 2002; Byrne et al., 2009).

Our aim in the current study was to gain initial insights into chemistry students’ self-concepts when considering students with different cultural backgrounds in Germany. For this purpose, Hattie’s rope model (Hattie, 2008) was selected. This is an alternate approach to self-concept research, which tends to focus on psychological processes. According to Shavelson, a person’s self-evaluations form one’s self-concept (Shavelson et al., 1976). In contrast, Hattie’s model focuses on the strategies a person chooses to reach these evaluations. The use of these strategies varies from situation to situation and defines the different self-concepts. Among all available strategies, learning and performance goal orientations are two important indicators of self-concept according to Hattie (Hattie, 2008). In school, where students are supposed to learn and to perform every day, these goal orientations are of great importance. We therefore paid special attention to them in this study. We collected qualitative data in interviews with 43 secondary school students. The underlying goal was to find out just how much of a chance students of both sexes from different cultures have when it comes to developing a positive self-concept towards chemistry. We found two different gender gaps and have proposed a working model for understanding self-concepts, which will be described later on in this paper.

THEORETICAL BACKGROUND

Two models of self-concept

Self-concepts in science education research are usually based on the Shavelson model of self-concept (Shavelson et al., 1976), the internal and external frame of reference model (Marsh, 1986) or related constructs. The term self-concept is defined as “a person’s perception of himself” (Shavelson et al., 1976, p. 411). Highly standardized instruments for assessing a person’s science self-concepts have been validated (Marsh, 1992) and used in big school studies such as PISA and TIMSS (Martin & Mullis, 2012; OECD, 2006). The advantage of these instruments is that they are short and easy to administrate, usually consisting of Likert questionnaires or similar tools. This makes the quantification of data relatively easy and allows large populations to be assessed with reasonable time expenditures. Until today, this has paved the way for various statistical analyses of the PISA and TIMMS datasets (e.g. Lau, 2014; Lavonen & Laaksonen, 2009; Lay, 2016; Lay & Chandrasegaran, 2016; Liou, 2014; Marsh et al., 2013; Nagengast & Marsh, 2011; Yu, 2012).

Numerous studies in science self-concept research have shown that a gap exists between boys and girls. Boys tend to have stronger science self-concepts than girls do. This is particularly the case in physics, chemistry and technology-related topics (e.g. Leibham, Alexander, & Johnson, 2013; Mujtaba & Reiss, 2016; Simpkins, Price, & Garcia, 2015; Simpson, Che, & Bridges, 2016). Also, the “big fish, small pond” effect has been shown to have important effects
in the domain of science (Liou, 2014; Nagengast & Marsh, 2011). This means that the peer group influences the overall strength of a person’s self-concept. For example, a student in a group of high-achievers, who is good at science compared to the national average, but only average within his direct peer group, is quite likely to have a lower self-concept than one would reasonably expect based on his actual level of ability.

Despite these important advances, traditional self-concept research faces two difficulties in science education, where research is more focused on application. First, its power to inform teacher’s everyday practices is quite limited. The reason for this is that we cannot trace the students’ narratives backwards to unearth how they shape the learners' actions and thinking patterns employed in science classes. However, this knowledge is very important, if our goal is to be able to advice teachers how to interact with students who have different self-concepts. This kind of practical knowledge is necessary. Second, the purely quantitative approach faces methodological difficulties when applied to data collected in culturally diverse settings. The bias that can result from this have already been described elsewhere (Byrne et al., 2009; van de Vijver & Poortinga, 2005). It has therefore been argued that qualitative analyses are needed in self-concept research (Byrne, 2002).

Hattie’s more recently-developed rope model of self-concept (2008) allows for viewing self-concept differently. Hattie emphasises the role of action in his theory of the self. People don’t just possess certain self-concepts, they choose to do so. This conceptualization of people as choosers is an idea that Hattie derives from James’ theory of the self (James, 1890). The reasons for choices, such as the choice to have a strong or a weak science self-concept, are self-centred according to Hattie. The overall goal is to have a strong self and in order to achieve this, every person chooses strategies that protect, promote, and preserve the self. Hattie employs an analogy inspired by Wittgenstein (Wittgenstein, 1958), describing the self as a rope. According to Hattie’s analogy, the self is composed of a multitude of parts, including strands, yarns, and fibers (Figure 1). The more these are intertwined, the stronger the self. In Hattie’s model, the parts of the rope are the strategies that protect, preserve, and promote the self.

![Figure 1. The rope model of the self (Hattie, 2008, p. 55).](image)

The strategies which a person employs differ from one situation to another. In math, a student might tend towards deep-learning strategies (e.g. choosing tasks that challenge him) because he is good at math and he identifies himself as a math person. At the same time, in history, the same student activates performance strategies (e.g. choosing problems he can solve successfully), because making the same learning effort in every subject would overwhelm him and endanger his mental health. History doesn’t affect him as much as math does. The patterns
of strategies are situationally specific and highly individual in nature. They form what we can call a self-concept using Hattie’s lens. Self-concept in this model is not a subjective theory about one’s abilities, but rather a certain pattern of self-strategies. Research aiming at an investigation of rope model-based self-concepts would thus focus on inner actions, choices, and selection processes. It would also be of interest for researchers to know how these processes intertwine, i.e., how they interact in order to strengthen a person’s self. With the aid of the rope model, a qualitative dimension can be added to self-concept research. This choice oriented definition of self-concept guided the present study.

**Focusing on learning and performance goal orientations**

Performance goal orientations (PGO) and learning goal orientations (LGO) play an important role in academic contexts and are also part of the self-strategies Hattie describes (Hattie, 2008). Despite their similar names, these two concepts are independent from one another (Roedel, Schraw, & Plake, 1994) and go back to Dweck’s theory of motivation (Dweck, 1986, 1989). Every student possesses both orientations, but students differ in the degree to which they activate them and in their context-specific patterns of use (Button, Mathieu, & Zajac, 1996; Dweck, 1986, 1989). These goal orientations provide two different interpretation frames which can be understood as lenses. With a learning goal orientation, a student views an academic situation as an opportunity to learn. The same situation can be interpreted by another student very differently. If the second learner is performance goal oriented, the emphasis will be on the need to demonstrate existing abilities (Dweck & Leggett, 1988). The two students process the same contextual information very differently (Dweck, 1986).

Students with learning goal orientations tend to interpret their own abilities as malleable. They believe that they can learn and thus develop their abilities. This is called an incremental theory of intelligence (Dweck, 1989). In this interpretation framework, mistakes don’t necessarily mean failure, but rather provide the chance to learn and to improve one’s abilities (Button et al., 1996). This kind of person’s feeling of pride or satisfaction depends on a holistic evaluation of the learning process. Not just learning outcomes are important, but also effort is taken into account as well. These students are more likely to choose difficult tasks and show greater persistence. They tend to seek help if needed (Dweck, 1989; Dweck & Leggett, 1988).

In contrast, students with a performance goal orientation perceive their abilities as predefined, which means that they have an entity theory of intelligence. This entails a tendency to interpret mistakes as personal failure (Hole & Crozier, 2007). It also includes an avoidance of seeking help, a lower level of task persistence, a low willingness to take risks, and frequent, obtrusive thoughts that interrupt and disturb the working process (Button et al., 1996; Dweck & Leggett, 1988). They have the impression of having low control over the situation and their learning progress (Anderson, Hattie, & Hamilton, 2005).

**RESEARCH GOAL AND QUESTIONS**

The aim of our study was to explore German secondary school students’ self-concepts of chemistry. Since today’s schools in Germany are shaped by cultural diversity, especially in urban regions, the traditional approach quickly reaches its limits. If students’ self-concepts are
to be investigated, we need to switch to qualitative methods, a research approach which is currently very uncommon. To close this gap, our study focused on the qualitative dimension of self-concept according to Hattie’s rope model. The following research questions were asked:

1. Do chemistry self-concepts vary between students with different cultural backgrounds? If so, how do the students differ from one another?

2. Do the students’ chemistry self-concepts vary between the gender groups? If so, how do they vary?

METHODS

In order to answer the research questions and to gain first insights into this field, a pilot study based on semi-structured interviews was conducted. In most cases, pairs of students were interviewed in order to help them relax during the interview situation. The students were therefore asked to choose partners. In several cases, however, individual interviews were conducted. With an average length of about 10 minutes, the interviews were rather short, since they had been developed as a screening tool. The interviews were based on Hattie’s model of self-concept (Hattie, 2008). We asked interviewees questions which prompted them to describe their perceptions and their behaviour in well-known situations in chemistry class. The goal was to gain initial insights into their typical thinking patterns and, more precisely, to investigate their goal orientations, focus of attention (salience), and the subjective rationales underlying their behaviour. The interviews were recorded and analysed using Qualitative Content Analysis by Mayring (2014). The content was paraphrased and classified with special focus on goal orientations.

We interviewed a total of 43 students from six different schools in Bremen and Hamburg. Both cities are federal states in the north of Germany, in which a large proportion of the population has a migration background. The schools were chosen purposefully, so that a variety of cultural backgrounds could be included. The participants were between 11 and 19 years old, with the largest group consisting of 17-year-olds (N=15, 34.9%). A total of 60.5% of the participants were female. Most of the participants (54.3%, N=24) had a migration background. The largest group of non-German cultural backgrounds was comprised of Turkish and Kurdish students with a total of 20.9% (N=9) pupils. The sample sizes of the other groups were too small to allow for valid analyses.

RESULTS

In our analysis, we compared the data of German students to Turkish and Kurdish boys and girls¹. The interviews allowed us to distinguish between four categories:

1. learning goal orientation: the desire to engage in learning processes and change,
2. performance goal orientations: the desire to show one’s existing abilities,
3. social goals: the search for social acceptance and inclusion, and

¹ Although we are aware of the fact that Turkish and Kurdish people don’t belong to the same group, there was considerable overlap in our sample: many students stated to have both Turkish and Kurdish backgrounds. For this reason, we chose to put them into one category for the purpose of this study.
4. students’ evaluations of their own abilities: statements about how good they think they are in chemistry.

Categories 1 to 3 are goal orientated and therefore part of the self-concept according to Hattie. The statements in category 4 are what is understood as the self-concept according to Shavelson. To our surprise, we found striking similarities between the German boys and the Turkish/Kurdish girls. German girls and Turkish/Kurdish boys also seemed to share important characteristics. The four groups will be characterized in the following paragraphs below.

**German boys and girls**

Overall, German boys tended to show both strong learning and performance goal orientations. Compared to the other students, it quickly became obvious that chemistry content was most salient to them when thinking about chemistry classes. They seemed to reflect very little on the social situation in which learning takes place, but focused instead on the things they learned in chemistry class. None of the boys expressed social insecurity. In addition, quite a large number of German boys seemed to view their own abilities in chemistry as being strong. One of the older boys even planned to study chemistry at university level, because he was excited about chemistry and felt that he could succeed in it (interview 21a). In contrast, one of the boys expressed having obtrusive thoughts in chemistry class. He said that he gets “stressed” when facing difficult tasks. In this type of situation, he begins to question himself (“What if I skip that one and keep on doing the other stuff? Can I really go back and solve the ones I’ve skipped?”). This results in feeling that he has “trouble understanding just anything” (interview 22a). This is a very typical description of obtrusive thoughts, which interfere with the work process and lead to learning difficulties due to a reduced capacity to concentrate on the problem at hand.

German girls showed goal orientations that tended to contradict those of German boys. Their performance orientations seemed to have many negative implications. One girl showed signs of an entity theory of intelligence when she stated: “I just feel stupid sometimes” (interview 5a). This points to an entity theory because the term “stupid” depicts a state of being, not a process. She didn’t talk about her learning process but instead chose to describe her abilities via this term. Also, the above quote shows a negative ability self-concept in chemistry which was typical for many German girls in this sample. Regarding task choices, many girls said they tended to avoid learning goal orientations, because one can possibly experience failure. One girl said how she feels “relieved” (interview 3a) when she gets a task that’s easy for her. She seemed to be under pressure in chemistry class, which produced negative feelings. In another interview, one of the girls said that she liked simple tasks because they motivate her to approach more difficult ones. Although this can be a useful learning strategy, it shows that she needs to motivate herself to face challenges. A person with a high learning goal orientation, in contrast, would prefer to go directly to the core of the learning opportunity. German girls differed in another respect from German boys: they spoke a lot about the social context of chemistry class. One girl expressed a high degree of social insecurity, saying that “you just feel as if you had no business here and that you’re actually in the wrong place” (interview 5a). She was not the only one questioning her social position in class. Many girls showed ambiguous feelings. One

---

2 This and the following quotations from the interviews are translated from German by the authors.
girl said that “there’s no need to be so afraid to ask something that was maybe known, that you should know already” (interview 3b). On the one hand, it is a good sign. She feels less afraid, but the fact that she mentions this kind of feeling also reveals that she must have experienced (and may still be continuously experiencing) social anxiety in chemistry class. In addition, this girl noticed that there are things she should know and compares this norm to her actual abilities. This can be interpreted as a sign of inner tension.

**Turkish and Kurdish boys and girls**

Turkish and Kurdish boys showed similar patterns to those of German girls in some regards. The signs of social insecurity were as striking in this group as they were among the German girls. One boy in particular showed this. He stated that he feels “rather nervous” when speaking to the class and that he needs to “calm myself down” (interview 22b). Also, in group work the social structure seemed to be alarmingly weak. The boy said that in the end “they let me down” (interview 22b), which shows his difficulties in his peer group. On the other hand, the same boy explained that he enjoys working in groups very much, since students “take a bit more of their time” (interview 22b) to explain than a teacher could manage to do (individual support). Also, he prefers easy tasks over difficult ones because they give him the opportunity to “help others, too” (interview 22b). This again shows his social goal orientations. The student reflected upon his own abilities in chemistry in a rather negative way, especially so for tasks related to math. He believed that he has difficulties following along, because he understands the lessons “only, like, so-so” (interview 22b) and sometimes experiences difficult feelings like anger, frustration, and sadness about his performance. This negative evaluation was also found in another interview, where a student said that “we [both interview partners who were of Turkish origin] are not the smartest students in chemistry” (interview 6b).

The Turkish and Kurdish girls showed a unique pattern. On the one hand, they seemed to be partly preoccupied with their abilities in chemistry saying for example “I am not a top student in chemistry” (interview 23). In one case the participant expressed difficulties in staying concentrated on tasks (interview 1a). This student also had the impression that she was lagging behind (interview 1a). Nevertheless, learning goals in this group were clearly present. One student described her desire to learn chemistry like this: “I don’t understand it yet. At some point, I’m gonna get it. It can’t be that difficult” (interview 24a). This shows her interest in the subject as well as her belief in the malleability of her abilities in chemistry – a typical sign of an incremental theory of intelligence. Another student liked the part of chemistry learning best where “you get a mental representation” (interview 1b), which in her case points to a pronounced need for cognition. She likes to engage in real learning processes on the theoretical level when doing experiments in class. Compared to the German boys who showed similarly strong learning goal orientations, these girls showed a strong social orientation, too. Two girls (interview 1a/b) mentioned their friends and family as being relevant in chemistry learning. They liked sharing their experiences with these people. One girl expressed her social focus in this way: “the classes are fun but I think it’s more about the teacher than about the lessons as such” (interview 1a). At several points during the interview she expressed how much her good relationship with the teacher meant to her and how this influenced her experience in chemistry in a positive way.
DISCUSSION AND CONCLUSIONS

Keeping in mind that this study was only the starting point of a research project with larger scope, a first conceptualisation of the data in the form of a working model needs to be considered (Figure 2). The model does, however, need to be retested and deepened.

This working model will guide our further research. It contains two hypotheses:

**H1: Two culturally different gender gaps exist.** In this qualitative approach, we found a different access point to the gender gap between German boys and girls in science that had repeatedly been described in the literature. This became apparent via the students’ statements about their abilities in chemistry, which tended to be positive for the boys and rather negative for the German girls. Among the Turkish and Kurdish students, this gender gap seemed to be in an inverse relationship. The girls talked more positively about their abilities, while the boys remained relatively sceptical. This had not been described previously and needs to be scrutinised further.

**H2: Self-concepts differ in quality.** In this sample, we found three types of self-concept that differed not only in strength, but also in the respective patterns of goal orientations. Both the German boys and the Turkish/Kurdish girls showed a high learning orientation. However, the German boys seemed not to consider the socially embedded nature of learning (type 1), while the Turkish and Kurdish girls showed a strong social focus (type 2). These are two distinct patterns of learning goal oriented self-concepts. The German girls and the Turkish/Kurdish boys showed patterns that could be grouped together as belonging to one type of self-concept (type 3). These students tended to have feelings of social insecurity and doubts about their abilities in chemistry.

Starting from this, our findings need to be further explored in a follow-up study with in-depth interviews and a larger sample size in order to test our hypotheses. For the present, we can only identify tendencies within our samples, which could also be tested in a mixed-methods design study with an accompanying survey, based on the findings described in this paper. Another important goal would be to investigate more deeply the thinking patterns and the inner logic underlying the students’ thoughts and feelings. This could produce valuable knowledge which can aid in informing teachers’ practices.
Finally, this study shows how qualitative designs can enrich a field such as self-concept research, which has a long-standing, established quantitative tradition. Self-concept research in science education might benefit from choosing paths different than psychological research-based efforts, because the goals of the disciplines differ widely from one another. Science education must focus on informing and improving teaching practices and research approaches. Especially when working in intercultural settings, which is now common practice for the majority of teachers in Europe, qualitative approaches can help to reveal differences that would otherwise remain undiscovered. The study described in this paper should be seen as a starting point to help us rethink our teaching concepts. We are currently unaware of any German teaching materials which explicitly discuss feelings of non-acceptance. This means that a large portion of students are quite possibly lost during the teaching process, simply because we can't and don't address their inner reality.

REFERENCES

Scientific literacy encompasses the internalization of attitudes such as critical thinking and an informed understanding of the nature of science (NoS). In particular, students are expected to be aware of the characteristics of science (s), and of the personal qualities required for a scientist. We elaborated a closed questionnaire in order to explore the vision of scientific practices of more than six hundred college freshmen of the scientific and technological Paris-Sud University. After having presented the results obtained for the whole population in 2015, we examine here the impact of the gender on three questions and compare it to the impact of the scientific areas of specialisation chosen for the high school diploma and the first year of university. One question concerns the characteristics of the scientific knowledge, the two others concern the scientist him/herself, more precisely his/her qualities and the possibility for him/her to believe. Only one significant difference is noticed on these three questions between boys and girls: more boys than girls emphasize the importance of the creativity. Several significant differences exist between the populations of the different high school diplomas and university majors.

Keywords: nature of science, gender, scientific area

INTRODUCTION

The contemporary world faces many challenges that require the development of scientific activity and that each citizen become scientific-literate in order to act responsibly. Scientific literacy encompasses the internalization of attitudes such as critical thinking and also an informed understanding of the Nature of Science (NoS). In particular, students are expected to be aware of the characteristics of science comparatively to other practices related to knowledge, such as arts and religions, of their differences and similarities, of the personal qualities necessary for each practice. These components of the scientific literacy are at stake when the issues are to motivate students towards scientific careers, especially girls, or to face the challenges of multicultural societies and globalized world.

Yet, researches about the Nature of Science (NoS) show that the representations of science of pupils, students, and teachers are more consistent with a past vision (empirico-inductive, naïve realistic) than with an informed contemporary vision of science (Deng et al, 2011; Lederman, 2007). Moreover, studies on the relationships between science and religions, in particular those conducted following a worldview approach, point out that students associate science to scientism, that is to say to a worldview excluding the possibility of a religious worldview, or that they intertwined or linked the worldviews they associate to science and religion (Hansson & Redfors, 2007). This is in line with the fact that students can encounter conflicts of truth difficult to live with and reject the scientific explanation, or the fact that the scientific and religious explanatory registers are not always distinguished. Besides, studies on the representations on creativity, arts and sciences point out that science is often associated to rationality and rigor/logic only and arts to emotion and creativity only (Galveanu, 2014).
Studies on gender issues indicate that the way science is presented as rationalist and value-free is one of the reasons for the disengagement of girls from scientific studies and careers (Baker, 2003).

Given this situation and in line with on-going reforms for high school and college education in many western countries, including France, we started a research program on NoS, both from a scientific and a citizenship education perspective. After analysing the French science high school syllabuses (Maurines et al, 2013, 2014), we designed up a questionnaire to investigate the NoS vision of college freshmen of the scientific and technological Paris-Sud university. The rare studies focused on NoS in France adopt an epistemological point of view only and concern teachers. In 2015, we presented the global results to the questionnaire (Maurines et al, 2015) and examined the impact of the high school diploma on three questions related to the demarcation issue (Maurines et al, 2016). We examine here the impact of the gender on three questions, one related to the characteristics of the scientific knowledge, the two others to the characteristics of the scientist considered as a person, and compare it to the impact of the discipline(s) of specialisation chosen for the high school diploma and the university major. After presenting our NoS theoretical approach and describing briefly our methodology, we give the main results.

A CHARACTERIZATION OF SCIENCE AS SOCIAL PRACTICES AND ACTING PERSONS

Our research program is inscribed in a curricular perspective. In order to open to a wide range of possible choices both for secondary education and higher education, we chose to elaborate a multidimensional NoS framework based on all the academic disciplines studying science. Joining a research current growing for forty years in the science studies field, and more recently in the NoS field, we adopted a practice approach in order to characterize this complex and multifaceted object that science constitutes. Soler (2009) describes this practice turn as introducing shifts from normative to descriptive perspectives on science, from scientific products to scientific processes, from decontextualized, intellectual, explicit, individual, and “purely cognitive” to contextualized, material, tacit, collective, and psycho-social characterizations of science.

We adopted the approach of Martinand (1986) and regard science as social practices, which can serve as a reference for teaching. We decided to characterize scientific practices by nine dimensions: D1) general characteristics (aims, values and presuppositions) D2) objects of study D3) resources (intellectual and material) D4) products D5) scientific elaboration approaches (activities, methods, and rules) D6) scientist person (personal qualities and attitudes) D7) scientific community (members, collective work) D8) society (interaction between science and society) D9) history. For more details, see Maurines et al, 2013, 2014.

We are close to Erduran and Dagher (2014) by choosing to characterize science as practices. However our approach differs from theirs. Indeed, we consider that knowledge and practices are entangled and not separated as on the categorization they advanced. Moreover, in coherence with multiple educational aims, in particular citizen education, we introduced two dimensions to inscribe scientific practices in a larger societal context and in a history. Besides, we also
introduce a psychological dimension associated to the qualities and attitudes expected in a scientist. We consider that inquiry requires articulating creative and checking thinking (Cariou, 2015). We agree with Gauld (2005) that scientific activity needs different habits of mind which are in tension and are appropriate at different stages in the research process (for example disinterestedness/interestedness or emotional neutrality/emotional commitment), that these habits of mind could be considered as necessary for undertaking any scholarly activity and that they are not necessarily in conflict with religious habits of mind. The choice to base our multidimensional NoS framework also on psychology of science allows us to emphasize individuals and their subjectivity, which is important considering the gender issues.

**METHODOLOGY**

**The questionnaire: questions, elaboration, and analysis**

Data were collected and processed by the software “sphinx”. The questionnaire, partly inspired by the literature consisted of 16 closed questions. In order to identify the students’ views to the various dimensions of our NoS framework, we asked them either to choose items, either to rate on a four point scale their agreement with each question or with each item of each question. For most of the questions, it was possible to freely answer (for more details on the questionnaire and its elaboration, see Maurines et al., 2015, 2016). Here, we examine in more details three questions. Tables 1 and 2 present the questions and items proposed to students in relation to our NoS framework. Consistent with our approach to science as practice ensured by persons acting like scientists in a community, one question relates to the characteristics of the scientific knowledge (Table 1), the two others to the individual (Table 2).

Data were processed in several stages. We started in using the software “sphinx”. First, we analysed the global results for the whole population (Maurines et al, 2015). Then, we looked at the impact on the results of different variables such as the high school diploma and the major chosen by students for their first university year (Maurines et al, 2016). We are currently analysing the verbatim.

The sample of students

The questionnaire has been completed on computer by 662 freshmen of the Paris-Sud University in September 2013. The sample examined here (N=528) is limited to the students registered in the scientific part of the university who passed an economic or a literary high school diploma (ES-L) or a scientific one (S). The elective course followed by students having passed a scientific diploma could be mathematics (S Math), or physics and chemistry (S PC), or life and earth sciences (S SVT). The first year of the scientific university degree (L1) offers three majors: L1 MPI (mathematics, physics and computer sciences), L1 PCST (physics, chemistry and earth sciences), L1 BCST (biology, chemistry and earth sciences). There is also a preparatory year for the L1 for students who do not passed a scientific high school diploma (PCSO).

Table 3 specifies the composition of the sample and reveals highly significant differences between boys and girls consistent with the literature (TS: chi² test 1%). More girls than boys passed an economic-literary diploma (ES-L) or a scientific diploma with biology as elective
course (S-SVT). More girls than boys choose the biology major (BCST) and are in PCSO, and more boys than girls choose math or physics.

Table 3. Repartition of the 528 students, and of the girls and boys, by university major and high school diploma

Figure 1 shows another result consistent with the literature. When asked about their future job, more boys than girls mention the profession of engineer or researcher, and more girls than boys mention the profession of teacher or teacher-researcher. Most of the students of the category “others” are girls and mention the profession of doctor or veterinarian.

Figure 1. Future job desired by students

RESULTS

For each question, we will give the results for the whole sample (N=528) and then we examine the impact of the gender, the university major and the high school diploma. We will comment the significant (S: chi² test 5%) and highly significant (TS: chi² test 1%) differences between the different populations only and ignore the insignificant differences (PS: chi² test 15%). We will use italics for -S and –TS.

The characteristics of the scientific knowledge

Results for the whole sample

Students characterize scientific knowledge firstly by the fact that it evolves (Figure 2: 83.3%). It is more perceived as universal (52.0%), objective (43.4%) and obtained by a particular approach (44.1%), and less as describing reality as it is (18.0%) or true (14.2%), or dependent on the researcher or on the scientific community (19.0% and 11.3%).
Figure 2. Frequencies of citation of each item proposed for characterising the scientific knowledge

**Impact of the variables: gender, major, and high school diploma**

Most of the differences between the percentages observed and those calculated in taking into account the distribution of the students by gender, major and high school diploma (Table 4) are insignificant (PS) except one: the item “it depends on the researcher” is significantly less quoted by the S PC students (-S).

The personal qualities necessary for a scientist

Results for the whole sample

The qualities the most quoted by students (upper part of the Figure 3) are emotional qualities: curiosity and love of science. Second come the intellectual quality of rigor and the involvement quality of perseverance, the methodological and relational qualities being less important. Students consider six qualities as important (lower part of the Figure 3): the four qualities mentioned above and also two intellectual qualities they mentioned less frequently but with a higher order of importance: to be inventive, to be able to question oneself.

Figure 3. Results to the question on the qualities necessary for a scientist
Impact of the variables: gender, university major, and high school diploma

There is only one significant difference (TS) between girls and boys about the qualities of a scientist: more boys than girls emphasize the necessity for a scientist to be creative (Table 5). There are more significant differences (S and TS) between the students of the different high school diplomas and majors. Students who passed the economic-literary high school diploma (ES-L) or follow the preparatory year (PCSO) chose more often the items “to be curious, to be logical” and “to be a good observer” than the others. Those who passed the biology-geology high school diploma (SVT) or follow the biology-geology major (BCST) chose more often the items “to follow a method”, “to be rigorous”, “to be perseverant” and less often the items “to be logical”, “to be inventive”, “to have a practical mind”. Those who passed the physics-chemistry high school diploma (S PC) or follow the physics-chemistry major (PCST) chose more often the item “to have a critical mind” and less often the item “to follow a method”. The results of the students who passed the mathematic high school diploma (S Math) or follow the mathematic major (MPI) correspond to the theoretical values.

The possibility to be a scientist and a believer

Results for the whole sample

73.5% of the students consider it is possible to be a scientist and a believer (Figure 4).

![Pie chart showing the distribution of responses to the question “it is possible to be a scientist and a believer”]

Figure 4. Results to the question “it is possible to be a scientist and a believer”
Impact of the variables: gender, university major, high school diploma

Table 6 reveals no significant differences between girls and boys about the degree of agreement with the statement “it is possible to be a scientist and a believer”. There are only insignificant differences (PS) between students of the different high school diplomas and majors. Students who passed a SVT high school diploma and are registered in BCST major disagree more with the statement than students registered in the MPI or PC majors.

DISCUSSION AND CONCLUSION

According to the college freshmen of the scientific Paris-Sud University, scientific knowledge is primarily evolutionary. Second, it presents more rationalist aspects (to be universal, objective, obtained by a particular approach) than relativist aspects (to depend on the researcher, on the community) but does not seem so far to correspond to the description of the reality or to the truth. Scientists have above all three qualities: two are emotional (curiosity and love of science) and one intellectual (rigor). To a lesser degree, they have one involvement quality (perseverance) and two other intellectual qualities (imagination and creativity, to be able to question oneself).

Both as regards the question about the characteristics of the scientific knowledge that the question on the qualities of the scientist, aspects in relation to the elaboration of the knowledge or in relation to the scientific community (dimensions D5 and D7 of our NoS framework) are relatively less mentioned by students.

From these results, the same dominant representation of science that the one presented in other studies can be put forward. The activity of the researcher appears to be associated to a kind of self-determination related to his love of science and curiosity, the collective and institutional dimensions of the scientific enterprise being present but in the background (Désautels & Larochelle, 1989). However, our results seem to reflect a less rational view of science (the development of scientific knowledge is not based solely on reason, logic and method, but also on creativity and imagination), and less realistic (a minority of students consider that scientific knowledge describes reality as it is). The idea of a strict demarcation between science and other domains of practices seems less marked because only half of the students give to the scientific knowledge certain specificities (universality, objectivity, obtained according to a particular approach). Moreover, only a quarter of students consider that it is not possible to be a scientist and a believer.
The comparison of these results about the college freshmen of the scientific Paris-Sud university with the results obtained about the images of science(s) conveyed by the PC and SVT high school programs (Maurines et al, 2013, 2014) reveals similarities and differences. The qualities of rigor, and to a lesser extent of reasoning (logic), as well as curiosity, are valued by both students and programs. The idea of an evolution of the scientific knowledge is emphasized by both whereas the characteristics related to the collective dimension of scientific work are less apparent in both cases. While the programs emphasize the “elaboration” dimension, notably through the mention of observation activities and scientific and experimental approaches, the characteristics related to the way in which scientific knowledge is elaborated are not the most highlighted by students.

Besides, there is almost no impact of the gender variable on the results presented here. There is only one highly significant difference between boys and girls at the question on the qualities of the scientist: more boys than girls consider the inventiveness and intuition as important qualities for a scientist. As the gender studies show that at the symbolic level, science is often associated to masculine values (rationality, rigor and logic), this result raises the question of whether girls are trying to conform more to the stereotype of science than boys.

On the other hand, the impact of the variables “high school diploma” and “major” is more important. Disciplinary area specificities seem to be revealed at the question on the qualities of the scientist. Students who focus on critical mind come from the physical-chemistry area (S PC diploma, PCST major) and those who stress method, rigor and perseverance from the biology-geology area (S SVT diploma, BCST). Students from the literary area (ES-L diplomas, PCSO major) favor aspects (curiosity, logic, observation) reminding the image of science described by Désautels and Larochelle (1989). These results raise several questions. How to interpret the differences between the different subgroups? Are they in relation to the images of science conveyed by the different high school programs (PC, SVT, science)? Do they mean that the students from the literary area of the Paris-Sud university have a more naïve view of science than the students of the scientific areas? How to interpret this point in contradiction with that put forward by Liu and Tsai (2008)? Are the literary students of this scientific university representative of the literary population since they are engaged in a conversion toward scientific studies?

Other results not presented here due to lack of place reveal more differences between the groups of girls of the different high school diplomas and university majors than between the equivalent groups of boys. The only significant difference inside the group of boys is about rigor, which is a quality more favored by the boys from the literary area. As the qualities favored by the different subgroups of girls seem in relation with the qualities emphasized by the groups from the different disciplinary areas, the question arises how to interpret this point.

We are currently analyzing the verbatim of the question on the possibility to be a scientist and a believer in using our NoS theoretical framework and will examine whether there are differences between the different groups of students.

The results presented here should be considered as preliminary. As the study we started in 2013 was exploratory and aimed at exploring different dimensions of our NoS framework, the question arises to design another questionnaire taking into account more psychological and
cultural aspects of science in order to explore further on the gender issue. Another issue is how to consider these results in the perspective of curricular reflection for scientific teaching at secondary and university levels.

SCIENCE CHOICE AT SCHOOL: GENDER AND THE RELATIVE IMPORTANCE OF FACTORS STUDENTS CONSIDER WHEN SELECTING SUBJECTS

Tracey-Ann Palmer
Faculty of Arts and Social Sciences, University of Technology Sydney, Sydney, Australia

Science study at school has been linked to the provision of a scientifically capable workforce and a scientifically literate society. Concern has been expressed by educators, academics and policymakers that too few students are choosing post-compulsory science at school. Gender-based preferences for some science subjects has been cited as an important factor affecting choice of science at school. A Best-Worst Scaling survey was used to measure the relative importance of 21 factors that male and female students consider when choosing and rejecting subjects. Results from 333 Year 10 (age 14–17) students suggest that male and female students choose and reject subjects in a similar manner but there are differences in the degree of importance students place on some factors. Girls considered their interest, enjoyment, past ability and type of classwork as being relatively more important than boys did when choosing subjects. Girls considered their past ability and difficulty of a subject as more important than boys did when rejecting subjects. This research indicates that overall girls and boys rank the factors for choosing and rejecting subjects in a similar manner but there are differences in the importance they place on individual factors.

Keywords: gender, subject choice

INTRODUCTION

Scientifically trained individuals are needed by our society to expand our knowledge, create new and improved technologies, and investigate solutions to pressing world problems (Goodrum, Druhan, & Abbs, 2012). The study of science in the final years of school is critical in the process of training these individuals as the subject selection decisions that teenagers make influence their potential career paths (Thomson, 2005). However, when given the opportunity to choose subjects for their final years of schooling many students choose not to continue with science. For example, in Australia almost half of Year 10 (typically age 15–16) students do not choose a science subject for their final two years of schooling (Lyons & Quinn, 2010).

Extensive research has been conducted into the factors influencing students’ choice of science when it becomes elective at school (e.g. Ainley, Kos, & Nicholas, 2008; Henriksen, Dillon, & Ryder, 2015; Lyons & Quinn, 2010, Regan & DeWitt, 2015). The factors commonly cited are: students’ engagement in previous school science, their perceptions of science and its usefulness, socio-economic factors, the decreased relative popularity of science as a school subject and, gender preferences for some science subjects.

Understanding how students choose their subjects for their final years of school is an important step in discovering how science is valued relative to the other subjects that students can choose. This paper presents gender based findings from a broader study that aims to create new strategies to improve the uptake of science through improved understanding of how students
value science and make their subject selection decisions. It addresses the research question, “What is the relative importance of the factors that male and female students consider in choosing their subjects for their final years of school?” through analysis of gender segregated data from a Best-Worst Scaling (BWS) survey conducted with 333 Year 10 (age 14–17) students who had recently chosen their subjects for their final years of school. Further background to the results or method presented in this paper can be found in Palmer et al. (2017).

The remainder of this paper is organised into four sections. The first is a brief review of the research of gender-based choice of science at school. The second section describes the list of factors students consider when choosing their subjects used in this study and the Best-Worst Scaling (BWS) task used to quantify the relative importance of these factors. The results for the survey are then presented followed by a discussion of these results.

BACKGROUND

Gender-based preferences for some science subjects has been suggested as an important factor affecting choice of science at school (Ceci & Williams, 2007; Dobson, 2006; Kessels & Taconis, 2012). Within Australia, male and female students have differing subject choice preferences with respect to science (Ainley, Kos, & Nicholas, 2008; Kennedy, Lyons, & Quinn, 2014; Thompson, 2005). Male students appear to have a slight preference for chemistry and female students show preference for biology. With respect to physics, the gender bias towards males is significant. Further, boys consistently show more positive attitudes to school science than girls (Regan & DeWitt, 2015). Rebalancing the gender mix in some science subjects has been posed as a strategy to improve the numbers of students taking science (Quinn & Lyons, 2011).

The quest to explain why there is gender heterogeneity in students’ choice of science has made this topic the subject of many scholarly papers and books particularly with respect to the underrepresentation of girls in science. According to Regan and DeWitt (2015), important factors contributing to fewer girls choosing science are that girls consistently show less positive attitudes to science than boys and display lower self-efficacy in it. In addition they state that girls may identify science as being a “masculine” pursuit. Blickenstaff’s (2005) review of 30 years of research into the underrepresentation of women in STEM suggests that the problem is multifaceted and unsolved and he argues that genetic differences between the sexes are not the reason. He suggests that female participation may be increased by improvements in the teaching of science.

Other research has suggested that gender bias for science subjects is due to basic differences in preferences held by boys and girls rather than a specific result of teaching practices (Thomson, 2005). Females appear to prefer to work in areas that will self-evidently help people (e.g. biology and health) rather than in the enabling sciences (physics and chemistry) that are perceived as leading to non-traditional roles for women (Dobson, 2006). Wang and Degol’s (2013) review of literature on gender differences in STEM choices found that intellectual aptitudes and motivational beliefs are strong predictors of science choice at school. They noted that as girls achieve on average higher grades in mathematics and science at school and have higher verbal skills that intellectual aptitude may not be a factor in girls not choosing science.
They suggest that girls’ higher verbal skill may mean that girls may choose career paths that need these skills.

A meta-analysis study on gender and science research conducted by the European Commission on gender segregation in research careers stated that a change in culture of science and research was required to encourage more women to study science (Caprile, 2012). The reasons for gender preferences for certain science subjects remains unclear and continues to be a main area of interest in science education.

**METHODOLOGY**

To determine the relative importance of the factors that students consider in choosing or rejecting a subject at school, a BWS survey was completed by students who were considering their subjects for their final years of schooling.

The BWS method (Best Worst Scaling) is a well-validated technique that allows factors identified as impacting a decision-making process to be ranked according to their importance (Louviere, Finn, & Marley, 2015). The online BWS survey used in this study presented students with sets of factors believed to influence their subject selection decisions.

To generate the list of factors believed to impact subject choice, prior research was conducted in four schools in metropolitan Sydney, Australia. This included: 10 focus groups each with five upper-secondary students; interviews with 15 adult subject-selection stakeholders within schools; observations of seven subject-selection events; and a review of the literature relating to subject choice (Palmer, 2015; Palmer, Burke, & Aubusson, 2017). A list of 21 factors that students considered in their subject selection process was created and verified at a conference of science education researchers.

Consistent with the work of Shafir (1993) on choosing and rejecting choices, students in focus groups were found to use different reasoning when explaining how they chose subjects versus rejected subjects for future study. Therefore, the 21 factors for choice were presented to students in two formats relating to the differing viewpoints of choosing a subject (BWS-Choose) and rejecting a subject (BWS-Reject). Table 1 shows the list of factors and the two versions of attribute statements presented to students in the survey.

The BWS survey presented either the BWS-Choose or the BWS-Reject factors as attribute statements to students in sets. Students saw sets of factors multiple times in different combinations according to a statistical model. The BWS task asked students to choose only the best and worst option from the sets of factors presented. By comparing the choices respondents made within each set, a ranking of the average relative importance of all 21 factors was created. It is important to note that BWS scores are relative so that factors with lower scores are not necessarily unimportant for students when choosing subjects.

To determine which factors to show in which set in the BWS task, a Balanced Incomplete Block Design (BIBD) was used (Street & Burgess, 2007). The BIBD allowed the 21 attribute statements to be arranged into the minimum number of sets so that each statement appeared the same number of times and was assessed against every other statement an equal number of times. This statistical design resulted in 21 sets that each contained five attribute statements.
Students saw each of the 21 statements five times in the survey and each factor co-appeared once with every other factor.

¹Subjects for the final two years of school study in NSW Australia are offered in ‘units’ and most subjects are worth two units. Students must choose at least 12 units in Year 11.

²ATAR is the Australian Tertiary Admission Rank, the primary measure for undergraduate entry into university in Australia.

BWS analysis (or ‘MaxDiff’ analysis) was used to calculate a score of relative importance for each of the factors that impact the subject choice decision process (Marley & Louviere, 2005). When a student chose a factor as most important (best) the factor received a score of 1. Where a factor was chosen as least important (worst) it received a score of -1. The survey displayed...
each factor five times so the scores range from a minimum of -5 (where a factor was always chosen as worst) to a maximum of 5 (where a factor was always chosen as best). Scores are calculated for each individual and then averaged to produce a BWS-Score.

Students were randomly shown either the BWS-Choose or the BWS-Reject factors but not both. For the BWS-Choose survey, the instructions to students read: “Please think about how you chose your subjects for Year 11. For each of the sets of features below, please choose the feature that you find most important and least important in choosing a subject to study.” The BWS-Reject version replaced the word choosing with rejecting. Figure 1 shows an example of a set of statements presented to students from the BWS-Choose survey. Students were asked to click the button next to the statement that was most important to them and the one that was least important to them in each set.

Figure 1. Example of BWS-Choose statement set.

The survey was made available to all Year 10 (ages 14 –17) students at five schools in metropolitan Sydney, Australia. Of the 333 students who completed be BWS survey in full, 157 (47%) completed the BWS-Choose version of the survey and of these 59% were boys and 41% were girls. The BWS-Reject version of the survey was completed by 176 (53%) students of whom 51% were boys and 49% were girls.

**RESULTS**

**BWS-Choose**

The BWS-Choose survey allowed the factors that male and female students considered in choosing their subjects for study for their final years of school to be scored using BWS analysis and compared. Figure 2 shows the mean BWS-Choose score (± 1 SE) and any significant differences between the scores of males and females. These factors are listed from highest to lowest average BWS-Choose male score. Further background to the results and method can be found in Palmer et al. (2017).
Figure 2. BWS-Choose comparison of mean male and female BWS scores.

The correlation between the mean female and male BWS-Choose scores for the 21 factors is .98. These results indicate that the pattern of scoring for BWS factors is very similar between male and female students suggesting that girls and boys ranked these factors in a similar manner. There are statistically significant differences between male and female BWS-Choose scores for six of the 21 factors included in the study. Table 2 shows that females scored four factors significantly higher than boys and two factors significantly lower than boys. The factors that girls scored higher were the first ranking factor for both males and females of Interest expectation, Enjoyment experience (ranked 3rd for girls and 5th for boys), Ability (ranked 6th for both genders) and Classwork (ranked 7th for both genders). The factors that girls scored lower than boys were Parent advice (ranked 17th for girls and 14th for boys) and Peer advice (ranked last at 21st for girls and 19th for boys).

* p < .05, ** p < .01, *** p < .001

These results indicate that male and female students choose subjects in a similar manner but there are differences in the degree of importance students placed on some factors. Girls regarded peer advice and parent advice even less important than boys in subject choice and considered being interested and enjoying a subject, their past ability and the type of classwork for a subject as more important than boys in their decision-making process.

BWS-Reject

The BWS-Reject survey allowed the factors that male and female students considered in choosing their subjects for study for their final years of school to be scored using BWS analysis and compared. Figure 2 shows the mean BWS-Reject score (± 1 SE) and any significant differences between the scores of males and females. These factors are listed from highest to lowest average BWS-Reject male score.

The correlation between the mean female and male BWS-Reject scores for the 21 factors is .86. These results indicate that the pattern of scoring for BWS factors is very similar between male and female students suggesting that girls and boys ranked these factors in a similar manner.

Although the pattern is similar, Table 3 shows that girls scored four factors statistically significant higher than boys and three factors lower than boys. The factors that girls scored higher were the first ranking factor for both males and females of Enjoyment experience, Ability (ranked 2nd for girls and 7th for boys), Difficulty (ranked 7th for girls and 9th for boys), Timetable fit (18th for girls and 20th for boys). The factors that girls scored lower than boys were Teacher dislike (ranked 15th for girls and 16th for boys), Parent advice (ranked 19 for girls and 13 for boys) and Peer advice (ranked last for both genders).

These results indicate male and female students reject subjects in a similar manner but there are differences in the degree of importance students placed on some factors. Similar to the result for choosing subjects, girls regarded peer advice and parent advice, and disliking a teacher even less important than boys in rejecting a subject. Girls considered their past ability and difficulty of a subject as more important than boys did in their decision-making process.

DISCUSSION

This research seeks to inform strategies to increase the number of students choosing science in their final years of schooling. It addresses the research question, “What is the relative importance of the factors that male and female students consider in choosing their subjects for their final years of school?” The BWS results presented here provide quantitative data on the relative importance of the factors that male and female students considered in choosing and rejecting subjects for post-compulsory study at school. This study is the first time that BWS has been used to compare the relative importance of the factors that male and female students consider when choosing their post-compulsory school subjects.

Both girls and boys ranked their expectations of finding a subject interesting and enjoyable as the most important influences when deciding to choose or reject a subject. However, this research indicates that girls may be more inclined than boys to consider how much they enjoy and can succeed in a subject when choosing and rejecting subjects which may have negative implications for science choice if it is perceived as boring and difficult as some research suggests (Osborne, Simon, & Collins, 2003; Shirazi, 2013). These findings suggest enjoyment and interest are key factors on choice of science at school, particularly for girls.

For both genders the ability of students to obtain “good marks” and the need for a subject for their future career are key factors in subject choice. This suggests that supporting students to feel that they can achieve good results in science subjects and broadening students’ views of the value of science may also affect their decisions. Again, this is particularly poignant for girls who tend to underestimate their abilities in science (Regan & DeWitt, 2015). It appears that it is critical that at subject selection time that schools implement strategies that promote positive student perceptions of how they can succeed in science and that the subject can be interesting, enjoyable and useful in a range of careers.

Advice from parents and teachers was a middle ranking item for both genders and girls ranked the importance of parental advice significantly lower than boys. Boys and girls ranked peer advice as relatively unimportant with girls ranking this factor significantly lower than their male counterparts. This is an interesting result given the influence of peers on other aspects of an adolescent’s life is considerable (Ryan, 2000). The relatively low importance that students place on the advice they receive suggests that interventions aimed at changing students’ perceptions of science may be best achieved through a program that encourages students to challenge their own ideas about science rather than being advised.

Given that girls consider enjoyment more highly than boys in choosing subjects and a lack of ability more highly than boys in rejecting a subject then strategies to encourage girls to choose science may have more impact if they feature these aspects. However, the rankings of scores are very similar for both genders with each seeking a subject that is interesting and enjoyable that they can achieve good marks in and will help them in their future career. The challenge remains to help students of both sexes to see that science can be all these things.

ACKNOWLEDGEMENT

Thank you to the teaching professionals, administrators, and students at the participating schools. This work was supported by an Australian Postgraduate Award funded by the Australian Government.

SURVEY OF STUDENTS FINISHING SECONDARY SCHOOL FROM 11 COUNTRIES REVEALS INFLUENCES ON DIFFERENT SECULARISED OR NON-SECULARISED VIEWS OF SCIENCE

José-Luis Wolfs and Coralie Delhaye
Université Libre de Bruxelles, Brussels, Belgium

In this study, we examine the nature of secularised, or non-secularised, views of science of students finishing secondary education. A survey of 4,128 students in eleven countries shows mainly secularised views in Belgium, France, Italy and Spain, and mainly non-secularised views in Congo, Côte d’Ivoire, Morocco, Senegal and Turkey. In Argentina and Greece, the survey shows both types of views. We examine some explanatory factors, such as the religious affiliation of the student (if any) and the status given to sacred Scriptures by students with religious beliefs. Based on these results, we suggest some implications for research and didactics.

Keywords: secularisation, views of science, comparative education

INTRODUCTION

Numerous studies (Aroua, Coquidé & Abbes, 2012; Hrairi & Coquidé, 2002; Martin-Hansen, 2008; Mathieu, 2011; Perbal, Susanne & Slachmuyldier, 2006), led in different countries (in Europe, Africa, America, etc.), have shown that some students completely or partially reject evolution theories in the name of their religious beliefs. This also occurs among a (sometimes significant) proportion of teachers from several countries, as shown in a study (Clément, 2014) that documented creationist beliefs among teachers in over 30 countries. Beyond specific aspects related to the theory of evolution, these findings raise more largely the question of the adoption or non-adoption of a "secularised" view of science, by students or teachers.

This question has been studied to a lesser extent when it comes to science in general, rather than a specific subject. Although the concept of secularisation has been broadly studied, few of these studies (Hokayem & BouJaoude, 2008; Mansour, 2008) appear to have addressed the question of views of science in relation to forms of secularisation or non-secularisation within societies.

This article focuses on secularised/non-secularised views of science among year-12 students across countries that have quite different characteristics in terms of secularisation of society. This international ongoing research has provided us, so far, with data from 5 European countries (Belgium, France, Greece, Italy and Spain), three Sub-Saharan Africa countries (Congo, Côte d’Ivoire and Senegal), a Latin America country (Argentina) and two other countries (Morocco and Turkey). After clarifying and critically discussing the concept of secularisation, we address the following questions: What are the characteristics of a secularised view of science? To what extent do these students adopt a secularised view of science in each of the 11 countries considered? What factors (personal, educational, or societal) might explain the adoption or non-adoption of a secularised view of science?
THEORETICAL FRAMEWORK

The concept of secularisation

Based on historical factors of the particular context of Europe since the Renaissance, as well as on its usual articulation with the concept of "modernity", most researchers have attempted to define the concept of secularisation with reference to the following elements (Willaime, 2006):

- a movement to rationalise representations of the world (Baubérot, 2013; Beckford, 2003; Berger, 2011; Jonlet, 2014; Wallis & Bruce, 1992), notably in scientific, but also at a political or economic level (the emergence of "modern" states);
- a functional differentiation of institutions and activities (Beckford, 2003; Wallis & Bruce, 1992; Willaime, 2006), particularly implying that religious institutions and activities develop in their own domain, rather than controlling all the institutions and activities within a society;
- a plurality of systems of meaning or explanation (Beckford, 2003; Berger, 2011; Lambert, 2000), specifically pertaining to that which is religious;
- a movement of individual empowerment, where people who are confronted with several systems of meaning make personal choices (Jonlet, 2014; Willaime, 2006), leading to a form of religious individualisation/privatisation (Baubérot, 2013; Beckford, 2003; Lambert, 2000).

These processes are often associated to the idea of a "decline", a loss of influence (Berger, 2011; Wilson, 2016) and/or a "metamorphosis" of the religious following societal transformations linked to "modernity". It is important to note that these processes do not occur in a single direction. A society can secularise or de-secularise in relation to one or more of the dimensions considered (Berger & Pouthier, 2001). Furthermore, as several authors (e.g. Dobbelaere (Dobbelaere, 2002) point out, it is relevant to identify multiple levels of analysis of secularisation: "macro", "meso" (specific to different groups or institutions), and "micro" (relating to individuals).

The approach that is most relevant to our research is the "functional differentiation", with reference to epistemology and at a macro level, of the scientific and the religious domains. Based this differentiation, we specify the characteristics of a secularised and non-secularised views of science and investigate the factors that can explain why students from countries with different traditions adopt such worldviews.

Characteristics of a secularised view of science

To develop indicators that characterise a secularised or non-secularised view of science, we used a theoretical framework (Wolfs, 2013) based on various analyses of the relationship between science (in the ancient, medieval, and "modern" senses of the word) and the following

---

1 Science is generally described as "modern" based on its development starting the 17th century, notably through experimental method and mathematisation (Stengers, 1995, Feltz, 2008, Le Ru, 2010).
belief systems: Christianity, Islam and agnosticism-atheism (Lambert, 1999; Minois, 1990, 1998; Rasi, 2003; Urvoy, 2013). This model provides six contrasting positions:

(1) The complete or partial rejection of scientific content in the name of "fideist" views (precedence of faith over reason) – for example, based on a literal interpretation of the Scriptures.

(2) "Classical" concordism seeks to establish a form of alliance between science and Scriptures (or theology) under the authority of the latter.

(3) "Inverted" concordism aims to establish a rapprochement between science and religious – or more broadly, metaphysical – beliefs. Instead of starting from the Scriptures or a revealed tradition, as is the case with "classical" concordism, it is based on an approach that presents itself as "scientific" (e.g. intelligent design).

(4) The principle of the autonomy of the scientific approach with regard to religious beliefs. In the scientific approach, nature is explained by nature (and not by the Scriptures). Science seeks to construct representations of the world by observing methodological rules that have been defined or reformulated over time: the principle of parsimony in the explanatory process (Occam, 14th century), the search for “efficient”, and not “final”, causes (Descartes and Galileo, 17th century), and the principle of "refutability" (Popper, 20th century).

(5) The search for a form of complementarity between science and religious beliefs in forms other than concordism. (This fifth approach incorporates a particular case of the preceding one.)

(6) Rationalist criticism of religious views, in the name of science, leading to complete or partial rejection of religion.

Using this model, a secularised view of science can be defined based on two main indicators: adherence to the principle of the scientific record’s autonomy from religious beliefs, and consequently, the rejection of the first three positions (5 and 6 may provide additional information, but are not necessarily conditions.).

Factors that may influence the adoption of a secularised or non-secularised view of science

In this paper we will discuss the potential influence of two factors: (1) personal religious convictions of the student and (2) characteristics of the educational system, particularly science education regarding secularisation.

If the student identifies with a religious affiliation, that religion’s relationship with secularisation (or that of a particular denomination within that religion) can be a major source of influence. Though the relationship with secularisation has not been the same, historically and sociologically, in the history of different religions and also of different countries (Chaline & Grimoult, 2011; Charfi, 2013), there should be a clear distinction between institutional and collective aspects, on one hand, and individual aspects, on the other hand. In fact, there can be highly significant differences between believers within the same religion, when it comes to their relationship to secularisation. An important aspect to take into consideration is that of a
student’s views on sacred Scriptures, regardless of their religion. Do they interpret them literally, or in a more distanced way that is inspired by exegesis? In the first case, the student believes that the Scriptures materially explain the origin of humankind and may reject scientific approaches that appear to contradict such an explanation. In the second case, the student will consider Scripture and science to be two distinct domains, and will probably be more inclined to accept a secularised view of science.

Though we don’t present results related to these factors, it’s important to mention that several characteristics of secularisation can also be taken into consideration: the place of religion within society, the degree of plurality of religious beliefs, the degree of independence between political and religious powers, etc. The possible influence of these factors on the student’s view should be noted. A broadly secularised societal context could directly or indirectly favour the adoption of a secularised view of science. However, in the case of identity-based tensions, the opposite could also occur for religious students, based on a process of ontological over-valuation (Heine, Van der Linden, Van Den Abeele, & Licata, 2008) and/or (self) assignment of identity (Mathieu, 2011).

RESEARCH OBJECTIVES

Our aim is to examine how the aforementioned factors might relate to the adoption of a secularised or non-secularised view of science by students. The two main objectives of this research are the following:

Objective 1: To establish an inventory of the extent to which students adopt different secularised or non-secularised views of science in different countries.

Objective 2: To explore the influence of some variables that may influence students’ adoption or non-adoption of a secularised view of science: 1) their stated religious affiliation (if any) and 2) for students with religious beliefs, their views on sacred Scriptures.

METHODOLOGY

A questionnaire, containing some 30 closed-ended questions, was designed using the six ideal types defined in the reference model, with the intention of enabling relatively quick collection of data from a large sample of students. Its construction validity was tested using a principal component analysis followed by a confirmatory analysis (Wolfs et al., 2014).

This questionnaire was administered to a total sample of 5457 students from the capital cities and distant or rural areas in eleven countries. We attempted to include three different educational pathways: technical-vocational, general non-scientific orientation, and general scientific orientation. However, as data for the technical-vocational pathway is unavailable in some countries, the following results apply solely to the students on a general pathway, of which there were 4,128.

Students were asked to indicate their religious affiliation (Catholic, Protestant, Muslim, or other), as well as their level of belief (using a 5-level scale), or otherwise their non-religious affiliation (atheist, agnostic, theist). The last three categories were accompanied by a short definition: atheist (“I do not believe that a God exists and I do not adhere to any religion”),
agnostic ("I do not know whether or not a God exists, I cannot answer these questions based on reasoning, and I do not adhere to any religion"), and theist ("I believe there is a higher power, but I do not adhere to any particular religion").

They then indicated their support for each question on a six-level scale, ranging from -10 to +10. The average for each aspect is also expressed on a scale of -10 to +10. Two indicators were defined to characterise a secularised or non-secularised view of science: the rejection of fideist and concordist views, (in the classical and inverted forms) and adherence to the idea of science existing independently of religious beliefs. Combining these two indicators allowed us to outline nine patterns, which are organised into four main categories: non-secularised (in a strict form), non-secularised (in a hybrid form), ambivalent, and secularised.
