The profile “Non-secularised 1”, that appears in Table 1, is described as “non-secularised in the strict form”, in as far as it is characterised by values for fideism and/or concordism that are higher than those for the autonomy of science. The profile “Non-secularised 2” is described as “non-secularised in a hybrid form”, in as far as it is characterised by medium or high values for fideism and/or concordism, but also for the autonomy of science. The profile “Neither non-secularised nor secularised” may be associated to students that are ambivalent and undecided between the two positions (non-secularised/secularised), that are indifferent, or that reject both options for reasons that have yet to be clarified.

### RESULTS AND DISCUSSION

To reach our research objectives, we provide an overview of students’ views by country, as well as by some factors that might be related to their views, in Table 2.

The number of students in this Table is of 3,744 instead of 4,128 because it doesn’t include students who’s declared convictions were underrepresented in their country and thus statistically incomparable.

</table>

Current situation: To what extent do students finishing secondary education adopt a secularised view of science?

Columns 1 to 7 from Table 2 show the proportion of students with each type of views in each category, grouped by country and stated conviction:

- Four types of views of science: “NS1”: non-secularised (strict form); “NS2”: non-secularised (hybrid form); “Not S nor NS”: Neither Secularised, nor non-secularised; “Secul.”: secularized;

Of the 22 student groups that emerge from this categorisation, 11 have predominantly non-secularised views of science (less than 16% of students hold a secularised view of science). This first cluster of 11 is quite heterogeneous: it includes students with different religions from five countries (Congo, Côte d’Ivoire, Morocco, Senegal, and Turkey), as well as Protestants from Argentina and Muslim from Belgium.
Nine groups however, have a predominantly secularised view of science (including more than 60% of students in each case). This second cluster is composed of Catholic and Agnostic-Atheist students from four European countries (Belgium, France, Italy, and Spain) and of Agnostic-Atheist students from Argentina.

Finally, two groups show no clear tendency. In fact, Argentina Catholics and Greek Orthodox have 34 and 37.9% of students with secularised views of science.

Based on these results, it’s clear that geographical and cultural rather than strictly religious factors seem predominantly linked to secularised or non-secularised views of science. Indeed, students from Morocco, Turkey, and the three sub-Saharan African countries hold a predominately non-secularised view of science regardless of their religion, be it Islam (in Morocco, Turkey, Côte d’Ivoire, and Senegal), Catholicism (in Côte d’Ivoire, Congo and Senegal) or Protestantism (in Côte d’Ivoire and Congo).

In addition to that, in four European countries (Belgium, France, Italy and Spain), both Catholic and agnostic-atheist students adhere to a secularised view of science.

Populations with multiple cultural influences, provide data that confirm such a cultural influence on the views of science. For example, our data indicates that Muslim students in Belgium who have predominately non-secularised views of science are mostly from North African Maghreb countries, sub-Saharan Africa, or Turkey. We can thus consider that the influence of their originating culture might be an influence. Moreover, in the case of identity tensions such as a perceived devaluation of beliefs or cultural traits that sometimes accompanies immigration, students may bring components of their identity that they see as essential to the forefront through a process of ontological over-valuation (Heine et al., 2008) and/or (self)assigning of identity (Mathieu, 2011). These components may include, for example, religious beliefs and the non-secularised views that may be associated with them. As a result, there may be an accumulation of factors leading to a view of science that is little secularised. In Belgium, similar observations have been made where Protestant students originating from Central Africa remain close to the evangelical movement (Wolfs & Delhaye, 2016). Another example is the case of Greece, where there is no clear tendency in the students’ views of science. As pointed out by socio-historical analyses, Greece is situated in the midst of occidental and oriental culture (Triandafyllidou & Veikou, 2002), as well as Balkan and Mediterranean (Dépret, 2009). In fact, more specific analyses show that there is a very clear difference in views between Greek orthodox students who declare they don’t “believe much” or “at all”, and Greek orthodox students who “believe very much” (Delhaye & Kalesi, 2017).

**Does religious affiliation of the student (if any) relate to the adoption of secularised or non-secularised views of science?**

Among the Catholic students, there is a significant level of variation: in four European countries most hold secularised views, while in the three sub-Saharan African countries most adhere to non-secularised views. These results should be viewed with a high level of caution due to small sample sizes in some cases. In Argentina, results are mitigated.
Although Islam contains multiple currents, the Muslim students within our sample adhere quite predominately to a non-secularised view of science.

Protestant students from Congo and Côte d’Ivoire tend to broadly adopt a non-secularised view of science. Keeping in mind, however, that many denominations exist within Protestantism, we must take care to look for differences between the churches that are represented. We can differentiate students who simply checked the category “Protestant” from those who added the name of an evangelical church, Pentecostal, or neo-Pentecostal, or those who selected the “other religion” box and the indicated the name of a church within the evangelical movement. In Congo, out of the students identifying simply as Protestant, 1/37 held a secularised view of science, while 4/39 of those identifying more specifically with an evangelical church maintained a secularised view of science. In Côte d’Ivoire, the breakdown was 4/98 for the former category, and 3/59 for the latter. Thus, there appears to be no difference according to this criterion. In Argentina, most of the protestant student of our sample declare to belong in evangelical movements.

The question remains unanswered in Europe at the moment in the case of Protestantism, as unfortunately we do not have samples from European countries of that tradition which would have allowed for similar comparisons.

We also don’t have more countries composed by a large orthodox population to compare with Greece. This is an important limitation of this research, which we hope will soon extend to more countries.

Finally, agnostic or atheist students share a secularised view of science, as expected, with a few exceptions.

**Do religious beliefs about the Scriptures relate to the adoption of secularised or non-secularised views of science?**

The status that the students with religious beliefs (catholic, muslim or protestant) give to sacred Scriptures is a second factor that might be related to the adoption of views of science.

Columns 8 to 10, of Table 2, show the status that the students with religious beliefs (catholic, muslim or protestant) give to sacred Scriptures, and more specifically the status they assign to Adam: “Real”: real person; “SM”: symbolic and/or mythical.

It is clear that regardless of religion (Catholic, Islamic or Protestant), students in Morocco, Turkey, and the three sub-Saharan African countries are mainly characterised as holding a non-secularised view of science, reading sacred Scripture in a “realistic”, rather than “symbolic” and/or “mythical” way, maintaining a strong belief in the realistic existence of Adam (between 74% and 95%). By contrast, Catholic students in four European countries mostly adhere to a secularised view of science, attribute a symbolic and/or mythical status to sacred Scriptures, less than one in five thinks that Adam really existed. Again, Argentinian and Greek students show mitigated results. It’s interesting to point out that a proportion of 43.9% of Argentinian students do not position themselves when it comes to this question.

The distinction between the two bigger clusters of countries (Table 2) suggests, once more, a strong societal and cultural influence, but our data cannot provide explanations about the
mechanisms at work. However, a largely secularised macro-societal context in Belgium seems to have little influence on Muslim students. Most of these students have a non-secularised view of science and a literal interpretation of the sacred Scriptures and the figure of Adam.

According to the results presented in Table 2, the 11 groups cluster where students adopt predominantly non-secularized views of science is also characterized by the fact that students believe that Adam is a person who truly existed. This is more clearly illustrated in Table 3.

Table 3. Percentage of students adopting secularised views of science by status attributed to Adam (among students who answered)

<table>
<thead>
<tr>
<th>Status attributed to Adam</th>
<th>(n)</th>
<th>Secularized conceptions of science</th>
</tr>
</thead>
<tbody>
<tr>
<td>To me, Adam to whom the Bible and the Quran refer is:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>A person who really existed</td>
<td>(1920)</td>
<td>11.4%</td>
</tr>
<tr>
<td>I don’t know</td>
<td>(793)</td>
<td>51.18%</td>
</tr>
<tr>
<td>The mythical character of a symbolical narrative</td>
<td>(1287)</td>
<td>74.9%</td>
</tr>
</tbody>
</table>

Among the students who believed that Adam really existed, only 11.4% held secularised views of science – compared to 74.9% of those holding the opposite view. The difference is statistically significant (Chi² (2 d.l.) = 1351.1 p=.000) and the effect size (Cramer’s V = 0.581 p=.000) can be considered “large” in terms of Cohen’s descriptors (1988).

**CONCLUSIONS**

In this research we examined the nature of secularised, or non-secularised, views of science of students finishing secondary education. Starting from a critical discussion of the concept of secularisation and a theoretical framework (Wolfs, 2013) presenting different possible positions between science and religious beliefs, four student profiles were defined with respect to their view of science: non-secularised (in the strict form); non-secularised (hybrid form); neither non-secularised nor secularised; and, secularised. A survey of 4,128 students in eleven countries showed mainly secularised views in Belgium, France, Italy and Spain, and mainly non-secularised views in Congo, Côte d’Ivoire, Morocco, Senegal, and Turkey. In Argentina and Greece, the survey showed both types of views. We examined some explanatory factors, such as the religious affiliation of the student (if any) and the status given to sacred Scriptures by students with religious beliefs.

Even though the type of religious affiliation of students seems to be linked to secularised or non-secularised views of science, the latter seem predominantly linked to geographical and cultural rather than strictly religious factors. In fact, we pointed out in our that perceiving the nature of scriptures as symbolic and/or mythical is clearly linked to secularized views of sciences. These different aspects are likely to be mutually reinforcing.

These finding are interesting for science educators. It would be more interesting to focus on understanding social representations related to how students perceive the sacred scriptures and the secularized or non-secularized views of science, rather than focussing on how specific religious beliefs can affect students’ representations.
In fact, our results suggest that understanding of the nature of science requires understanding that the nature of religious worldviews is different. Thus, analysing students’ religious worldviews when it comes to how they articulate, or not, with scientific worldviews can be achieved by investigating, regardless of religious (or non-religious) affiliation:

- The secularized on non-secularized views of each student when it comes to science, based on whether they position scientific and religious worldviews in an autonomous, complementary, concordist (classical or reversed), rationalist or fideist way.
- Whether students perceive religious worldviews in a “realistic”, rather than a “symbolic” or “mythical” way.

Such understanding, based on models we presented in this article, can enable educators to develop activities that allow students to express their views while investigating what types of reasoning styles support them, if any, and also what reasoning styles are specifically scientific by using epistemology. For example, perspectives studying “styles of scientific reasoning” (Osborne, 2017), based on A. C. Crombie’s description of “styles of scientific thinking” (Crombie, 1994), can be particularly interesting teaching tools, because they acknowledge the specificity of the objects of reasoning when it comes to understanding procedural entities and epistemic constructs. As argued by Osborne, such a model recognizes “the need of domain specific knowledge and the complexity and situated nature of scientific practice”.

Further research could be developed in various directions. On one hand, the situational analysis could be continued in countries or educational systems with contrasting views of secularisation, and periodically replicated, in order to examine how students’ views in a given place evolve over time. On the other hand, further studying several explanatory factors would broaden this research. For example, at the epistemological level, views of science and views of religious beliefs conveyed in religion, sciences, history, philosophy, etc. courses in different target countries could be explored. At the psychosocial level, the importance and challenges of these questions in terms of identity and sentiment could be studied. And at the sociological level, the influence of other secularised societal characteristics warrants research, as well as the geopolitical context, especially against the backdrop of globalisation. Qualitative research, based on observations, interviews, or focus groups, could very well complement this first quantitative approach.

CONTRADICTIONS AND CONGRUENCE IN MULTILINGUAL SCIENCE CLASSROOMS: AN ACTIVITY SYSTEM PERSPECTIVE

Sara Salloum¹ and Saouma BouJaoude ²

¹University of Balamand, Koura, Lebanon
²American University of Beirut

This proposal outlines a multilevel framework for analysing multilingual science classroom interactions from a Bakhtinian and an activity theory perspective. We analysed classroom discourse at different levels: (A) speech genres and teachers’ and students’ multilingual language practices, (B) teachers’ and students’ meaning making of language practices and authoritarian discourse of governmental language-in-education policies, and (C) multilingual science classrooms as activity systems to identify areas of contradiction and congruence. For Levels A and B, we modified or redefined ‘language-related’ aspects of Mortimer and Scott’s (2003) framework, mainly Content, Patterns of Discourse, and Teacher Interventions. Activity theory guided level C analysis where an activity has a collective object carried out by a ‘community,’ in contrast to goal-oriented actions taken by a person or group. Through such analysis, we seek to understand teacher and student practices and actions as complex and socially situated phenomena with different mediating artefact, symbolic tools (language), and rules. Activity Systems as an interpretive model help us compare systems across schools and identify areas of contradictions and congruence for more purposeful, targeted, and contextual professional development.

Keywords: classroom interactions, analytical frameworks

INTRODUCTION AND BACKGROUND

From a sociocultural perspective, classroom interactions shape the social and academic life of classrooms (Aguiar, Mortimer, & Scott, 2010). Within multilingual classroom settings, as is the case of several MENA (Middle East and North Africa) countries, ways different languages (e.g., native and international) are used and scaffolded can be especially important for supporting meaningful science learning. Thus, there is a need to examine and enhance teaching and language practices that are conducive to quality science learning, especially for students from lower socioeconomic levels. Such students oftentimes encounter ‘linguistically structured inequalities’ (McCarty, Collins, & Hopson, 2011) or linguistic discrimination whereby poor proficiency in the international language or language of learning and teaching (LoLT) leads to poor achievement in science. Proficiency in LoLT is vital for fluency in discourses of science and science achievement. Unfortunately, access to educational opportunities that build adequate proficiency in language and science discourse is usually linked to higher socioeconomic levels. The official Intermediate Certificate examination that Lebanese students sit for in Grade 9 poses a particular concern with respect to ‘linguistically structured inequalities.’ These tests are administered in the international language (English or French) and students’ achievement on them decrees whether students progress to an academic or vocational track, thus controlling access to certain majors and careers.

School systems and teachers play a paramount role in enhancing students’ science learning in
multilingual classrooms and in minimizing ‘linguistically structured inequalities’ that lead to lower science achievement. Effective professional development is needed to build science teachers’ capacity (formal knowledge and skills and their affective practical-moral knowledge) to address the diverse needs of multilingual students of varying language proficiency and needs (TALIS 2013; Bahous, Basha, & Nabhani, 2011). Simultaneously, schools as activity systems also need to be analysed for purposeful PDs that address needs of the school holistically.

**Purpose**

The purpose of this study was to develop and use a multi-level analytical framework to investigate different dimensions of interactions within multilingual science classrooms. The Framework utilizes both a Bakhtinian perspective (Bakhtin, 1981; Mortimer & Scott, 2003) and Cultural Historical Activity Theory (Engeström, 1987, 2001). The framework analyses classroom discourse at different levels: (A) speech genres and teachers’ and students’ multilingual practices, (B) teachers’ and students’ meaning making of language practices and authoritarian discourse of governmental LoLT policies, and (C) multilingual science classrooms as activity systems to identify areas of contradiction and congruence among schools. For Levels A and B, Mortimer and Scott’s (2003) framework for analysing classroom interactions was adapted, where Content, Patterns of Discourse, and Teacher Interventions were modified or redefined to account for language variation and issues. Levels A and B analyses yielded patterns in language and pedagogical practices and the associated science conceptual understandings that emerge.

However, there was also a need for a framework to situate language and pedagogical practices in light of the macro and micro aspects of classrooms, schools and the larger society. Cultural Historical Activity Theory (CHAT) is a cross disciplinary framework that allows the study of how individuals transform social realities and themselves through an on-going process that is culturally and historically situated and one that is materially and socially mediated (Engeström, 1993; Roth & Lee, 2010). CHAT guided level C analysis, where science teacher’s classes with the various actions and practices (Levels A and B) in multilingual science classrooms constitute an activity system with a collective object carried out by the classroom ‘community.’

Through such analysis, we sought to understand teacher and student practices and actions as complex and socially situated phenomena with different mediating artefacts, symbolic tools (language), and rules. Activity System as an interpretive model helps us compare systems across schools and identify areas of contradictions and congruence for insights into purposeful and targeted teacher professional development to support teachers in addressing complex issues encountered in multilingual classrooms, hence assisting low SES students who are disadvantaged because of the overemphasis on using a foreign language of instruction and testing.

In this paper, our focus is level C analysis, specifically addressing the following questions:

1. How are teachers’ and students’ language and pedagogical practices situated in the classroom activity systems in the different multilingual classrooms?
2. What are areas of contradictions and congruence that emerge within the activity systems of the different multilingual classrooms and what do these involve?
3. How do systems across schools compare?
4. How can the developed framework inform meaningful and targeted professional development?

**Theoretical framework**

A global/macro level aspect within multilingual settings is government mandated language-in-education policies that decree the language of instruction and testing or LoLT. We consider such policies as authoritarian discourse (Bakhtin, 1981) that “demands that we acknowledge it, that we make it our own; it binds us, quite independent of any power it might have to persuade us internally; we encounter it with its authority already fused to it” (p. 342). At the local/micro level and in contrast with authoritarian discourse, Bakhtin (1981) proposed internally persuasive discourse as a personal, interactive, creative and ever changing dialogue within oneself and with others. Bakhtin’s dialogic perspective views utterances as always part of an unending chain of communication: utterances respond to preceding ones and anticipate others (Bakhtin 1986). As such, local classroom utterances interact in light of authoritarian discourse, internal persuasive discourse, and different sociocultural, socio-economic, and socio-ideological aspects and create a classroom’s “socially typifying language” (Bakhtin 1981). In Salloum and BouJaoude (2017), we proposed that different science classrooms develop and exhibit different “socially typifying languages” that emerge from interactions among various forms of “internally persuasive discourses” (e.g., among teachers and students) and the different “authoritarian discourse(s)” (e.g., high-stakes tests, mandated curricula, language in education policies, aspirations and resources within schools of different SES). Levels A and B of the developed framework examine this language.

Furthermore, Ritva Engeström (1995) suggested using an expanded unit of action to study interactions, proposing that social language corresponds to the level of (collective) activity, and so can be analysed as activity systems. Therefore, level C analysis, based on CHAT, analyses the socially typifying languages of different multilingual classrooms as complex and socially situated activities (Y. Engeström, 1987, 2001). According to Y. Engeström (2001), third generation activity theory provides conceptual tools to understand “dialogue, multiple perspectives, and networks of interacting activity systems” (p. 135) and so can shed light on interactions. It transcends dualisms among global/macro and local/micro aspects of classroom interactions; mainly, speech genres, teachers’ and students’ language practices (instruments) and their meaning-making of language practices and policies (rules). Moreover, through third generation activity theory, different activity systems (in different schools and from the perspective of students and science teachers) can be compared.

Activity theory was developed by Leont'ev (1981) and other Russian psychologists, including Vygotsky, as an alternative to behaviourism. Vygotsky argued that humans react to and act upon environmental mediating objects such as tools and instruments leading to an outcome rather than through the stimulus-response chains emphasized by behaviorists (Nussbaumer, 2012). Leont'ev defined activity as “the unit of life that is mediated by mental reflection. The real function of this unit is to orient the subjects in the world of objects. In other words, activity is not a reaction or aggregate of reactions, but a system with its own structure, its own internal transformations, and its own development”. (p. 46). A central assertion is that our knowledge
of the world is mediated by our interaction with it, and thus, human behaviour and thinking occur within meaningful contexts as people conduct purposeful goal-directed activities. This theory strongly advocates socially organized human activity as the major unit of analysis. Vygostsky’s model is represented in Figure 1 and is now referred to as the “first generation” cultural historical activity theory (first generation CHAT).

![Image of Figure 1](image_url)

**Figure 1. Representation of the first Generation CHAT (Engeström, 201, P. 134)**

While the focus of the first generation CHAT is on the individual, Engeström (1987) developed the construct of activity system to describe and account for the collective (as compared to individual) human activity in the broad historical-cultural-social contexts. This is referred to as the second generation CHAT. Engeström (1999) identified the following elements of the activity system:

1. The **object** is the problem space targeted by the activity of the organization and this goal-object is transformed into outcomes
2. The **subject** refers to an individual (individual activity) or a group (collective activity) in an organization
3. The **mediating artefacts** are cultural products that act as intermediary or auxiliary in effecting the appropriation of the cultural aspects embodied in these products. The mediating artefacts consist of physical and symbolic, external and internal mediating instruments, including both tools and signs
4. The **community** represents those individuals and or subgroups that share the same general object of the activity and define themselves as distinct from other communities
5. The **rules** are the explicit and implicit regulations, norms, and conventions that regulate and control the actions and the interactions within the activity.
6. The **division of labour** refers to both the division of tasks between members of the community and to the division of power and authority within the activity.

Schools and/or classrooms may be considered an activity system whose basic activity has the object of student learning that results in desirable learning outcomes. The elements of a classroom as an activity system are shown in Figure 2.

Engeström (1999) introduced the notion of **expansive cycle** in work teams as a qualitative transformation of the activity system as a whole. The expansive cycle starts from a dialectical tension or contradiction between the different nodes in the activity system. Change starts at the level of the individual members of the community, through the processes of internalization and exteriorization. The successful orchestration of the collective emerging individual activities will be an expansive cycle that eventually transforms the system into one that is free of the contradiction that started it. The transformed system has now different relations and interactions among its components. The second generations CHAT was criticized for its
insensitivity to cultural diversity. Therefore, Engeström (2001) further elaborated activity systems to include networks of interacting systems to address the contradictions that promote collective learning (Figure 3).

**Figure 2. The school as an activity system.**

**Figure 3. Representation of the third generation CHAT (Bakhurst, 2009, p. 201; Nussbaumer, 2012, p. 40)**

Schools are complex systems with complex needs. These needs cannot be identified by collecting data through traditional methods such as needs-assessment methods but rather through analysing the school system, identifying contradictions inherent in the system, and designing professional development (PD) activities that have the potential to resolve the contradictions, at least partially. Moreover, these PD activities need to take into account the fact that changing teachers’ classroom practices does not happen simply by providing them with the knowledge and skills needed for changing their behaviours. Meaningful and lasting change requires changing teachers’ beliefs, attitudes, and moral commitments as teachers, because teaching as a “practice” cannot be reduced to the application of formal knowledge, but should be conceptualized as an activity that is informed by teachers’ practical-moral knowledge (Salloum & Abd-El-Khalick, 2010). Professional development ought to find a balance between the need for providing teachers with the necessary knowledge and skills while insuring that their practical moral knowledge are valued and built upon.
Teacher professional development

The importance of teacher professional development (TPD) and professional learning is widely acknowledged and accepted as a means for enhancing student achievement and improving schools (Kenndy, 2016; Wei, Darling-Hammond, Andree, Richardson, & Orphanis, 2009). Even though acknowledgement of the importance of TPD and teacher professional learning are consistent, what they are, how they work and their quality and effectiveness are varied (Kennedy, 2016). Thus a large theme in research on TPD is discerning characteristics of effective PD programs and what makes them work (e.g., Caena, 2011; Kennedy, 2016; Wei, et al., 2009). We attempted to review what researchers have identified as characteristics of effective PD (e.g., Caena, 2011, Kennedy, 2016; Penuel et al., 2007; Wei et al., 2009), and compiled a list of characteristics based on the literature that concern “Mode of delivery,” or the way the PD program or experiences are enacted. Our review of the literature yielded five main modes of delivery that contribute to the effectiveness of a PD experience. Table 1 outlines the characteristics of effective PD that involve the PD’s “Mode of delivery” (e.g., Caena, 2011; Penuel et al., 2007; Wei et al., 2009).

Table 1. Characteristics of Effective TPD Based on Mode of Delivery

<table>

<tr>
<th>Mode of Delivery</th>
<th>Explanation of Characteristic</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Considerable Duration</td>
<td>PD experiences extend over a considerable duration</td>
</tr>
</tbody>
</table>
| 2. Active learning and teaching/ training | Active learning seems to have two different meanings in the literature:  
  - Activities during the PD experience or workshop are ‘active’ and engage teachers in concrete and experiential learning  
  - In the PD program as whole, teachers play an ‘active’ role in their e.g., through inquiries or PLCs. |
| 3. Provide follow-up and coaching | PD experiences are not just a “one shot” workshop, but also include time for follow-up, coaching, practice, and/or mentoring. |
| 4. Collaborative | Teachers receive encouragement to share and support their learning process |
| 5. Collective | Teachers from the same school\(^1\) are encouraged to attend the same PD’s |

Recently, Kennedy (2016) analysed TPD programs according to the ways used to facilitate teachers’ enactment and transfer of their ideas into classroom practices. She characterized four modes of facilitating enactment: Knowledge, prescription, strategy, and insight. According to Kennedy, methods of facilitating enactment fall along a continuum (especially the latter three), whereby teachers’ judgment is increasingly acknowledged as a means for affecting change in teaching practices. In this paper we interpret Kennedy’s continuum of facilitation methods as one that attempts to attend to different forms of teacher knowledge: formal propositional, craft and skills, and practical moral (Salloum & Abd-El-Khalick, 2013). Moreover, effective **Modes of Delivery** outlined in Table 1 above overlap with Kennedy’s methods of facilitating enactment and concretize them. We propose using activity systems analysis to inform our judgment of the most appropriate methods of facilitating enactment for PD experiences along with the PD characteristics that would be more likely to affect change in practice. Below we

\(^1\) Based on TALIS 2013
present sample analyses using the framework described above and demonstrate how it can be used to inform judgments about types and forms of PD experiences most appropriate the school contexts at hand.

METHODS

Data were collected from five middle school classrooms of different SES levels. Data sources for levels A and B were (a) classroom observations and a minimum of eight periods of videotaped science lessons, (b) semi-structured interviews with teachers, and (c) students’ focus groups. Other data sources included instructional materials used in the classrooms. Level A analysis discerned from the recorded teacher and students’ utterances Content (types of knowledge promoted), Discourse Patterns (IRF and IRF chains) [along with shifts in language use between home (Colloquial Arabic) and international language (English)], Communicative Approach, and Teacher Interventions. Level B analysis examined students’ and teachers’ interviews for ways they gave meanings to the language-in-education policy and classroom practices. Trustworthiness for Levels A and B analyses involved: (a) the two authors conducted Level A and B analysis together on 2 transcripts; (b) analysed independently two transcripts, shared results, and reached consensus; and then (c) analysed more transcripts individually, shared emergent themes, exchanged transcripts to check for confirming and disconfirming evidence of themes.

Results from Levels A and B (presented elsewhere) were used to create activity systems for each multilingual classroom in the different schools, where different aspects of the results were arranged to create the activity system: for example ‘Content’ promoted was considered to constitute the ‘outcome’ of the system; ‘Discourse Patterns’ and ‘Communicative Approaches’ shed light on ‘mediating artefacts.’ Teachers and students’ perspectives informed ‘division of labour,’ ‘community,’ and ‘rules. The two authors conducted Level C analysis together and created representative activity systems and identified areas of contradiction and congruence through a dialectic and reiterative process.’

RESULTS

For this paper, we present two activity systems from two private schools serving students from middle to lower middle socioeconomic level students with diverse language proficiency levels (one rural and one urban, Figures 1 and 2) along with their areas of contradiction and congruence to show how teachers’ and students’ language and pedagogical practices were situated in the different multilingual classrooms (RQ 1 & RQ 2). We later, discuss implications of convergent and divergent contradictions and coherences across the school systems (RQ3). Finally, we discuss how the areas of contradictions and coherences can inform meaningful and targeted professional development to increase the potential of transfer into the classroom practices on one hand and transformation of the school culture on the other (RQ 4).

The following trends emerged for both schools from levels A and B analyses: 1) Teachers almost exclusively used English to explain science concepts; 2) students used spoken Arabic to explain themselves and ask for clarifications, English was used to give shorter factual responses; 3) In most situation teachers’ continued using English even when students exhibited difficulties; 4) There were limited attempts to bridge English/Arabic/Science discourse; 5)
Factual and procedural algorithmic utterances dominated the discourse, and 6) Teachers’ perspective revealed that students’ language proficiency was a concern due to impact on performance on national exams (in English). Students saw the utility of English for future studies and none expressed that the policy itself is problematic but rather its implementation. Students preferred to communicate in the home language in the classrooms.

**Activity systems of different multilingual classrooms**

While there was a strict policy of using only English in teaching science in both private schools, Level C analyses of both schools revealed different areas of coherence and contradiction. These areas of are presented in red arrows in the figures and tables below.

### CHAT-based recommendations for targeted professional development

In both private schools, a main contradiction involving ‘Instrument-Object’ emerged, where it was noted that teachers’ use of instruments lead to rather surface rather than deep content learning. Of course this may actually cohere with the types of evaluations currently used in schools, which mostly assess surface level learning, yet this poses a contradiction to the goals of teaching science in general and the goals of the Lebanese science curricula. Therefore, on a basic level, targeted PD activities need to build teachers’ capacity in active methods that promote more meaningful learning. Mode of facilitating enactment for such PD activities need to be ‘strategy-based’ as per Kennedy (2016), because teachers need to become aware of and
ratify the rationale of such active methods to be able to meaningfully utilize them. Active methods involving multimodal teaching and learning (Zhang, 2016) and more interactive uses of the IWB would need to be planned for and with the science teachers. Accordingly, ‘Modes of Delivery’ of the PD activities that complement a ‘strategy-based’ mode of facilitating enactment would be PD activities that are *active* with opportunities for *coaching and follow-up*. Teachers need to be able to see how such methods look like in the science classroom, where science lessons would need to be modelled and discussed actively with the science teachers. Teachers also need to strategize how they will be trying out similar lessons on their classrooms and forms of follow-up and feedback they will have access to as they develop new uses of the ‘instruments’ available to them.

After such basic level of PD, the other common and related ‘contradictions’ that would need to be tackled both on a classroom level and school level involve the following contradictions: On one hand, there was the contradiction between teacher (subject) and students (community) on language used in the classroom; on the other hand, students (community) resented the school-wide rule of “all English” (Rules). Now although there are similarities in contradictions between the two private schools, certain differences may affect further professional development. In the urban private school, teachers and administration were more ‘formally’ cognizant and mindful of students’ linguistic needs due to the influx of students from other Arab countries. Such mindfulness of the complex and pervasive role of the ‘language of instruction,’ can more easily highlight the need for both school-wide dialogues and PD programs to address the issue. These dialogues and PD programs can adopt both an ‘insight-based’ and a ‘strategy-based’ mode of facilitating enactment. At the school level insight-based PD would involve deliberations on the enacted language rules/policies of the school and ways they are influencing science classrooms practices and learning (limiting role of home language as a scaffold for deeper learning). These would be complemented *simultaneously* with ‘strategy-based’ modes of facilitating enactment PD’s that involve the whole school community in adopting and designing school-wide strategies to support students’ language needs and promote more constructive ‘division of labour.’ In the rural private school, on the other hand, there needs to be first and foremost a focus on school-wide ‘insight-based’ mode of facilitating enactment to unravel issues and bring forth issues around students’ language needs in sciences as formal concern and an area for community growth and development. After such dialogues, strategy-based’ modes of facilitating enactment PD’s can follow to inform the newly identified areas of need and growth.

**DISCUSSION AND IMPLICATIONS**

Contradictions in both private schools highlighted the teachers’ ‘felt difficulties’ with regard to students’ language proficiency level, yet contradictions within both systems also highlight their difficulties in responding to students’ language needs and the limited use of strategies to support such students. Possibly this is a consequence of the hegemony of a ‘content’ focus, national exams (that mainly test factual knowledge), and language-in-education policy. Above we discussed based on the findings ways underscore and plan for maintainable focused and meaningful professional development of science teachers to facilitate appropriate adoption and

---

2 ‘Formally’ as opposed to ‘intuitively,’ which was the case for most school contexts.
development of more active methods in science along with content and language integrated approaches and strategies (instruments) for a more equitable teaching.

Analysing schools as activity systems produces findings that provide educators with contextualized information about the needs of students and teachers’ that are acquired from discovering the contradictions inherent in and specific to the school. The fact that this analysis takes into consideration the subjects (science teachers), instruments (language, content of textbooks, object (learning science content), rules (language in education policy), community (all stakeholders in the school), and division of labour among the stakeholders results in credible and trustworthy data about the needs of students and teachers without neglecting the needs of parents and administrators. Moreover, this analysis can identify the similarities and differences among the varied needs of different schools. This information is valuable when designing effective PD activities because it helps designers to insure that these activities are intimately connected to the classroom and the teachers’ practices, are coherent with what is going on in the school, and are focused on the interest and needs of students. Furthermore, because contradictions are identified through the analysis, teachers’ and students beliefs and attitudes are taken into consideration. Eventually, the complexity of the school as an activity system is matched with the complexity of the PD activities thus producing lasting change in the teacher practices.

INTERCULTURALITY IN THE CHEMISTRY TEACHING: RESEARCH ON THE INSERTION OF AFRICAN CULTURAL ASPECTS IN DIDACTIC PRACTICES IN THE STATE OF RIO DE JANEIRO

Joaquim Silva and Stephany Heidelmann
Federal University of Rio de Janeiro, Rio de Janeiro, Brazil

School is a place that contributes to the construction of students’ identity and it can act in the denaturalization of inequality and deconstruction the eurocentrism. Thus, Chemistry teaching should not be based on students’ passivity and memorization and it should contribute to develop their critical role in society. The Brazilian Law 10.639/03, which obliges the insertion of African culture and history in scholar curriculum, aims to create an opportunity to develop student’s criticism and reflection upon these racial historically marginalized groups. After 13 years of the regulation of this law, many Chemistry classrooms are believed not to provide students with ethical, critical and cultural aspects to support and encourage students’ decisions and inspire transforming actions. Taking the law’s objective and the teacher’s role in the educational process into consideration, this work uses a structured questionnaire applied to 59 Chemistry teachers from the state of Rio de Janeiro to analyse the insertion of the law and the African and Afro-Brazilian culture in their formation and teaching practices. Based on the results obtained that highlighted characteristics of eurocentrism and marginalization of those ethnic groups, this work reinforces the need to improve the education considering the cultural perspective, what is a priceless curricular requirement in the educational process and an essential tool in building citizenship.

Keywords: teachers’ formation and practice, African culture, education for citizenship

INTRODUCTION

During the last years, the cultural perspective in educational discussions has currently gaining more space in Brazilian society. The increasing access to the education of previously ignored and marginalized people, and the struggle of black and indigenous movements have brought with them a new demand for emancipatory proposals and recognition of groups that have been oppressed and disregarded for years (Gomes, 2012). Considering this, in 2003, the Brazilian Federal Law 10.639/03 establishes the obligation of teaching Afro-Brazilian and African culture and history in all educational institutions in Brazil (Brazil, 2003). Its main objective is to make students more distant from an Eurocentric conception of certain ethnic groups and enable them to recognize and appreciate their own culture.

The Chemistry teacher has a role that goes beyond the organization of the educational process and the work with the specific contents of science, they need to contribute to build critical and transforming citizens, who aware of their cultural construction (Maldaner, 2006).

However, the education nowadays differs from these objectives, when the biggest part of the history presented in the institutions is still the one of the winners, the celebratory history of the economically and politically more successful classes (Moura, 2005). Most of current Brazilians schools are still based on the technical rationality model, with an applicationist vision and
prescriptive discourse, which often leave cultural knowledge aside (Diniz-Pereira, 2008). It obscures the contributions of other ethnicities in the construction of students’ identity.

In this perspective, it is observed a shortage of didactic materials that should break with cultural stigmatized and prejudiced conceptions in the educational scenario (Lima & Santos; Santos, 2009; Silva, 2005). Moreira, Filho, Fusconi & Jacobucci (2011) also points out that, regarding Chemistry teaching, few studies have been carried out in order to effectively address the objectives of the Federal Law in classrooms.

Bastos (2015) emphasizes the need to work in the educational space with ethnic-racial diversity, considering and problematizing historical positions, constructions and contributions as a way of promoting acceptance, appreciation and social justice in interracial relations both in context past and present.

Therefore, the Federal Law 10.639/03 present as differential the decentralization of European culture and the Africa valorization as one of the bases for the Brazilian cultural construction. It also draws attention to the importance of reflection upon the supposed "racial democracy" (Muller & Coelho, 2013).

In this way, the Chemistry teaching cannot be limited to the discussion of the social context or to its study in a neutral, positivist and decontextualized perspective. It is necessary to provide students with a dialectical approach, aiming to develop students’ argumentative capacity, considering the cultural and social issues that permeate the construction of science. It is a question of overcoming the unilateral approach, which simply includes the cultural and social components in teaching strategies and methodologies (Santos & Schnetzler, 2010).

Searching about teachers’ behaviour in classroom and the scholar scenario is totally related to the need to understand that it is not restricted to disciplinary knowledge. Taking into consideration that studying the education also means including the teachers’ practices and knowledge built throughout their experience and training period, the present work seeks to analyse how this federal law is inserted in the teaching practice and training experiences of Chemistry teachers from Rio de Janeiro.

**METHOD**

A structured questionnaire has been prepared and applied using the Google's online forms feature. This instrument allowed the analysis of teachers' formative characteristics, considering information about their basic education and degree courses. It was also possible to identify their knowledge about the Law 10.639/03 and the insertion and effectiveness of the normative in the Chemistry curriculum.

The questionnaire was released by the authors in social medias like Facebook and Google groups of teachers in October 2016. It was answered by 59 Chemistry teachers from the state of Rio de Janeiro.

The data obtained is a small sample of the total population of Chemistry teachers in Rio de Janeiro, but it can provide the readers with a brief idea of the law effectiveness in different institutions and levels of education. The result was systematized and analysed without identifying the identity of the research participants.
RESULTS AND DISCUSSION

The participant's profile built consists on a teacher graduated in a Chemistry degree course, who gets updated by doing activities like participating in scientific events and reading articles once or twice a year.

It was also observed that the majority of the interviewees were graduated after or during the establishment of the Federal Law (65.9%), considering the period that they have been teaching (Figure 1).

Figure 1. Interviewees’ teaching time

The questionnaires answered show that 52.5% of the interviewees knows what the Law 10.639/03 is and its implications in the educational curriculum. The same percentage said to feel comfortable to work with the normative when teaching Chemistry.

Taking into consideration the teacher as a fundamental agent to build students’ critical thinking and world view, the understanding of the legal device, its historical construction, the social movements related to it and teachers’ work in the classroom becomes essential for the deconstruction of eurocentrism and prejudices that permeate the science and society marginalizing the other races and cultural contributions.

Therefore, it is necessary to think about the process of teachers’ initial and continued formation from a perspective of critical multiculturalism, in which, according to Freitas (2010, 105), "(…) race relations, racial identity and anti-racism, are points of reflection within the curriculum and as an integral part of the curricular proposal of the school."

When asking the Chemistry teachers about their formation and practice, 80% who have studied something about the African culture in the basic education and 47% who had this contact in the higher education said that the experiences were related to a specific celebration.

According to the Figure 2, the percentage of teachers who did not have contact with the Afro-Brazilian and African culture during their basic education and graduation and also the ones who were not aware of the normative established 13 years ago, shows that it is still necessary
an effort to include the cultural perspective in the curriculum. The results are not only far from considering the school as a place to deal with the prejudice, eurocentrism and cultures that had been marginalized for years, but also to consider the teacher as an important actor in this scenery.

The higher education, according to the data presented here in Figure 2, is still not considering the ethnic-racial issues as important as it should be for the Chemistry teacher training. Therefore, it is necessary to overcome the perspective of fragmented science and to reflect whether the training offered is making it possible for educators to work on ethnic-racial and cultural issues in the classroom.

When asking teachers if they work with the African culture in their lessons, the results shown in Figure 3 were obtained. In addition to that, Figure 3 shows that 33.9% of the interviewees assigned the responsibility to work with the culture to others subjects, especially the Social Sciences and History courses, what highlight the need to overcome a hierarchical science perspective. According to the Federal Law 10.639/03, the historical and cultural work should cover all areas of education, not only some specific subjects (Brazil, 2003). The results are distant from the law objectives.

Just a low percentage of teachers (5.1%) seems not to do a punctual work (1-2 times/3-4 times) with the culture in their lessons during the year (Figure 2). This result reinforces that it is necessary for teachers to understand their responsibility in students’ formation, considering their didactic practice as a possibility to overcome Eurocentrism and racial prejudice.

Considering the 47.5% of the participants who answered not to feel safe working with the theme and the others results that show that many teachers are not aware of the law and/or its importance in the educational process, it is important to reflect if the teacher formation is
providing the educators with the necessary knowledge to work with culture and ethical in the Chemistry education (Maldaner, 2006).

Figure 3. Answers to the question “Do you work with the African culture in your lessons? How many times in a year?”

In this respect, Ghelli (2004) affirms that the distance between science and history and culture, as well as between theory and practice, ends up constructing a distanced view between scientific knowledge and the day-to-day routine of people. Such compartmentalization of knowledge reflects on the reproduction of decontextualized and fragmented concepts, which compromises the understanding and the construction of critical thoughts considering the whole (Santos; Schnetzler, 2010). According to Freire (1996), it’s necessary to emphasize the importance of establishing an “intimacy” between the knowledge, allowing bigger political and social discussions.

In this way, the importance of the integration of knowledge through themes, stimulating the interdisciplinary processes and propitiating the construction of knowledge is reaffirmed (Pimenta & Anastasiou, 2012).

When associating Figure 3 with the number of participants who had seen something related to the culture during their formation in punctual celebrations, the idea of still having ethnic groups isolated from the history is reinforced. This contributes to build a stereotyped and discontinuous of African and Afro-Brazilian contributions to the Brazilian culture.

The work with the theme exclusively on commemorative or folkloric dates shows a bias in the definition of the insertion of the theme in the classroom, that is, in consonance with Araújo (2015), the study of the history and culture of ethnic-racial groups remains isolated, which is summarized as something stereotyped, discontinuous and ignoring its historical construction and current group influences.

Although the regulation of the Law 10.639/03 represents an attempt to change a scenario built in the past backed up by a set of stable values, in many ways this is perpetuated by placing the
school free of responsibilities in (re)producing inequalities between groups (Freitas, 2010). The importance of dealing with the theme in the initial and continuing teacher training due to the need to overcome a possible formative fragility and becomes more distant from a teaching job that reproduces social prejudices and stigmas.

CONCLUSION

By analyzing the profile of the teachers who answered the questionnaires, it was observed that, although there has been more than a decade that the Law 10.639/03 was established, many teachers are still unaware of the document. In addition to this, the formation of most of the interviewees was marked by the absence or punctual moments of work with Afro-Brazilian and African culture.

It is observed that a lack of commitment to ethnic-racial issues is still present both in the trajectory of teacher education and in the classroom practices of the interviewees. Therefore, more researches and work on cultural methodologies need to be part of the basic and higher education and teachers need a bigger effort to keep their teacher practice far from reproducing a crystalized perspective of the history and science.

Taking into consideration the potentialities of the education to contributes with a social transformation aspect and associating it with the data obtained in this research, it is concluded that when the learner does not overcome his formative fragilities, the omission of teaching institutions with the cultural theme discussed here, reflects in subjects and teacher’s practices that reproduce the eurocentrism and the marginalization of important social discussions.

REFERENCES

Almost worldwide inclusive school systems have been politically enacted. Also, almost worldwide the implementation of inclusion at schools is a major challenge. Most of the literature concerning inclusive pedagogy focuses on social participation and pedagogical approaches in general. Teachers, especially! at secondary level, are troubled to transfer these demands to their certain subjects. This paper presents an explorative case study focusing on the conflicts a teacher experiences when teaching a subject like chemistry at an inclusive school. Exemplarily, we present transcribed cut-outs of a videotaped teacher-student-discourse on atoms. Following the steps of the documentary method, a qualitative approach developed by the sociologist Ralf Bohnsack distinguishing between explicit and implicit knowledge, we analyse the orientational frameworks guiding the teacher’s actions during the discourse. On a surface level, her actions seem to be rather determined by traditional scientific educational approaches. Reconstructing her actions more deeply, we can show evidence for a participation oriented framework as well as for the challenges this conflicting demands of science and inclusion put on her teaching. We implicate that future professional development courses must not only concentrate on inclusive pedagogies, i.e., how to teach, but also on the reflection of implicit beliefs in inclusive science teaching.

Keywords: secondary school, classroom discourse, teaching practices

INCLUSIVE SCIENCE EDUCATION

The process of inclusion aims at “increasing participation in learning, cultures and communities, and reducing exclusion within and from education. It involves changes and modifications in content, approaches, structures and strategies, with a common vision which covers all children of the appropriate age range and a conviction that it is the responsibility of the regular system to educate all children” (UNESCO, 2005, p. 13, original emphasis). The educational goal of an inclusive pedagogy seems clear and desirable, but there is still a huge gap between the goal and classroom practice. Teachers still struggle to transfer inclusive demands to their subject teaching (Abels & Schütz, 2016). Especially, the implications for an inclusive subject-specific teaching approach are difficult to grasp for teachers. Further research on teachers’ difficulties as well as on appropriate support measures for teachers are needed (Seitz, 2006).

In this paper, we therefore explore a teacher’s difficulties with inclusive practice in the field of science education. Our research question is: What are the difficulties for a science teacher to apply the demands of inclusive practice to her subject-specific teaching? In order to answer the question, we conducted an exploratory case study at an inclusive middle school.
METHOD

For the study, a so-called inclusive middle school (grades 5-8) in a city in Austria was selected as a research field in which students with and without special educational needs are taught together. More than 20 years ago, the school began to develop and evaluate an inclusive school program. On average, five out of about 20 students in a school class have diagnosed special educational needs, primarily in the areas of mental development, learning, language and emotional and social development. Some students have special needs only in individual subjects (Abels, 2015b). The focus was on one of the two eighth grade chemistry classes. The lesson was organized in semigroups (max. 10 students) and was held by a chemistry teacher. The chemistry teacher studied Chemistry, Physics, Computer Science and Mathematics for lower secondary education at a teacher training college and has 27 years of professional experience at the time of data collection.

During the school year 2013/14, the chemistry class was accompanied by the second author as a participating observer. About 20 lessons were videotaped and informal discussions with the teacher additionally audiotaped. For this presentation we chose a double lesson analysed in depth by Documentary Method (Bohnsack, Pfaff, & Weller, 2010). Seven students of the semigroup (4 boys, 3 girls) were present. In order to fix the verbal communication and make it easier to analyze the data in group, the selected lesson was transcribed according to the rules of Kuckartz, Dresing, Rädiker & Stefer (2008).

Method of analysis: The Documentary Method

The Documentary Method is rooted in Mannheim’s sociology of knowledge and Garfinkel’s ethnomethodology, developed further by Bohnsack during the last 30 years and implemented in educational research (Bohnsack, Pfaff, & Weller, 2010), as well as in science education research projects (Bonnet, 2009; Ruhrig & Höttecke, 2015). The method distinguishes between explicit knowledge, the immanent understanding on a matter-of-fact level, and implicit knowledge “underlying and orientating habitualized social action” (Pfaff, Bohnsack, & Weller, 2010, p. 21). Applied to our research focus this means that the way science teachers design their lessons is not only depending on the content and methodical knowledge which someone is able to explicitly tell. The teaching also depends on implicit beliefs and orientations (“orientational frameworks”; Bohnsack, 2010) which influence the way of teaching in a substantial way. These orientational frameworks are not idiosyncratic for a person, yet culturally shared resources from the same socio-cultural environment. According to the documentary method, these orientational frameworks are identified by shifting the perspective from what is going on to how practice is produced (ibid.). In the analysis process according to the Documentary Method three major steps are followed:

1. In the first step, in the course of a formative interpretation the explicit meaning, the what of the interaction, is worked out. The formative interpretation helps to structure the data. For this, the interaction is categorized in upper and subtopics (Bohnsack, 2013). In this step we focussed on the science content which was discussed during the lesson and categorised it in upper topics and subtopics and we recorded the social forms which were present during different episodes of the lesson.
2. In the next step, the **reflective interpretation** of the interaction aims at making habitualized social action visible. The analysis focuses on identifying at first sight invisible patterns in the observable verbal and non-verbal language acts. On the one hand, there are patterns regarding the "academic task structure (ATS)" (ibid.), the way subject content is taught. On the other hand, patterns are sought that reflect the social participation structure (SPS) (Bonnet, 2009), the form of interaction. Thus, the aim of the data analysis was the reconstruction of interaction patterns in the inclusive chemistry teaching regarding content-related and social practices. The patterns found in the data were sharpened and abstracted in comparison with theoretical models.

3. In the last step, **orientational frameworks** of the actors are derived based on the findings of the reflective interpretation. Based on the patterns regarding the ATS and SPS we found in step 2, we derived an orientational framework of the teacher observed in this study.

**RESULTS**

**Formative interpretation**

The formative interpretation shows that the teaching goal of the chosen double lesson was a revision of the atomic structure and the introduction to atomic bonding. The two lessons can be split up into three different content-related phases (Table 1). In the first 20 minutes the teacher instructed the students to work in small groups recalling the atom structure based on their notes and subsequently they were requested to share their knowledge. Afterwards the teacher revised the Bohr Model conducting a teacher-led classroom discussion (duration: 50 min). In the third phase (15 min) she introduced a new topic (atomic bonds), again by discussing the topic with the students in a teacher-led discourse.

**Reflective interpretation**

In phase 1, there is little interaction, so the reflective interpretation focused primarily on phase 2 and 3. As these two phases show quite different patterns of habitualized action, the patterns revealed during the interpretation process are therefore presented separately:

**Reflective interpretation – lesson phase 2**

*Patterns regarding the social participation structure (SPS):*

The reconstruction of the social participation structure in phase 2 shows the following overall pattern: Convergent teacher questions dominate the discourse and lead to short answers on the part of the students, which consist in part only of sentence fragments or individual words. The topic or questions will then be continued by the teacher when the correct answer has been given by the students. Theoretically speaking, the teacher-students-discourse follows the IRE-pattern described by Mortimer and Scott (2003). The teacher asks a question (=initiative, I), the
students respond (R) and the teacher then evaluates (E) the answers in terms of their correctness according to scientific knowledge. Mortimer and Scott (2003) classify this classroom discourse as an authoritative-interactive one, because the teacher is heading at a specific scientific objective. The students only have the role of providing the correct answers to the teacher’s questions (see the following transcript excerpt).

18 T6: [...] and how is the core [of an atom] charged? (I)
19 Sf7: Positive. (R)
20 T: It is positive, ok. (E) So I have a positive charged core in the middle and then
21 I have around the... (I)
22 Sm3: Negative (R)
23 T: The... (E)
24 Sf7: Electrons. (R)
25 T: Electrons and where can they be found (I) ... where do we imagine this...
26 Sf9: In shells. (R)
27 T: In shells, exactly. (E) [...]  

This form of conversation does not seem to be unknown to the students because the speed of the turn taking is high. The teacher and the students evidently have some practice in this form of class discussion (between 2.5 and 3 speakers per 5 seconds). The content of the conversation must also – at least in broad terms – be known, because there is no time for logical reasoning, the students reproduce facts and guess. It seems therefore to be a repetition of the content knowledge.

The teacher waits for the answers and only evaluates when a suitable keyword is delivered. In the evaluation step, the teacher consistently avoids devaluations and rejections. Instead, she uses reinforcements, repetitions, or gapped sentences (see line no. 20-21 and 23). She almost never acts as a teacher who instructs the students to the scientific content directly. In the evaluation step, she does not make any content-related statements until the correct answers are given by the students (line no. 21-24). She even sticks to this strategy when the students show great difficulty in giving the right answers to her questions.

In order to bring the students to the right answers despite their difficulties, the teacher operates with logic. She selects logics from many fields of knowledge to put the students on the right track. For example, mathematical logics, discursive logics (T: If I’m asking that question.) and linguistic logics (see the following transcript excerpt) are used.

28 T: [...] in the core there are protons and neutrons. What can you identify within the word neutron?
29 Sm2: neu
30 Sm3: tron
31 T: neutr - al
32 Sm3: neutral.
33 T: What is the meaning of that word?

---

6 The following abbreviations are used in the transcript excerpts: T…teacher, Sf…female student, Sm…male student.
Another pattern regarding the social participation practices became apparent in the analysis: The communication of the participants in the discourse is prevailed by indefinite terms instead of defined statements. Above all, the students often leave chemical entities (electrons, protons, atoms, etc.) unnamed in their speech acts and replace them with pronouns. Rarely is the teacher or a student asking for an explication of what is indefinite or ambiguous in a statement.

Patterns regarding the academic task structure (ATS):

Regarding the ATS, the teacher’s questions concern atoms, protons, neutrons, electrons, the atomic nucleus and atomic shells. From a theoretical perspective, the conversation in phase 2 takes place at the sub-microscopic level of the particles (Taber, 2013; Johnstone, 2000), which is difficult to access for the students in the observed lesson. The students confuse constantly the three kinds of particles (example: T: So which particles do I have in the core? Sm2: Protons and electrons). They reproduce the vocabulary – e.g. the name of the particles – but the meaning of these entities is not captured. On the other hand, the teacher does not give the students the opportunity to link their everyday life concepts with the scientific concepts. This can be seen in the following example.

In this transcript section a student is led to the everyday life level of understanding by the teacher’s saying "noble gas" (line no. 46) (Neon is a gas?, line no. 49) and associates with neon a color (line no. 51). This is not addressed by the teacher. Another student remains with his answers on the sub-microscopic level (line no. 52), which is taken up by the teacher and corrected in terms of the technical language (line no. 53). The everyday life level and sub-microscopic level are not related to each other.

The teacher does not explicitly explain that she is at the sub-microscopic level of explanation of chemical phenomena, which is a prerequisite of students’ understanding of the nature of
chemical knowledge (Taber, 2013). Successful chemistry education has to offer students links between the different observation levels in chemistry: the sub-microscopic, symbolic and macroscopic observation level (Johnstone, 2000). The students in the observed lesson, like most novices in chemistry education do, struggled with the differentiation of these observation levels. As shown, they have problems in differentiating the entities electron, neutron, proton and constantly mix these entities and their characteristics on the atomic (=sub-microscopic) and phenomenal (=macroscopic) level.

The reconstruction of the academic task structure in phase 2 therefore confirms the impression of a mainly authoritative subject-teaching approach. The teacher is mainly concerned with the sub-microscopic level of the content taught. This can be understood against the background that being able to explain at the sub-microscopic level is the central goal of chemistry and chemistry education. In this lesson phase, the teacher only picks up those aspects in the students’ statements that agree with this goal: "The teacher hears what the student has to say only from the school science point of view" (Mortimer, & Scott, 2003, p. 33). The students are only suppliers of keywords for the teacher’s development of the right scientific view. The understanding of the foreign knowledge is not possible for students because of the lack of negotiation of the scientific view with their everyday life concepts and ideas.

Reflective interpretation – lesson phase 3

After 70 minutes of the lesson have passed, there is a change of topic. The teacher starts a thought experiment: “What happens now, if, for example, an electron is missing, this can be by chance that suddenly an electron is not there, for whatever reason.” And she asks the students to share their ideas. This kind of topic opening leads to a changed interaction, which is exemplarily illustrated with the following transcript excerpt:

54 Sm4: (Raised his hand and points to the chemistry book in his hand) But you cannot
55 freeze hydrogen so long till it happens, till it becomes helium.// Or is that
56 possible?
57 T: Aha. No, we won’t. Pay attention! We will not convert two elements, we will
58 ditch together two (She shows that with her hands).
59 Sm4: Ah, we only want that it is again...
60 Sm2: Making one positive and one negative.
61 T: Yes
62 Sm5: We want.
63 Sm2: Maybe in the heat //SM3: Yes heat.// the negative goes away and in the cold
64 the negative stays or the other way round?
65 Sm3: And then it mixes in some way.
66 T: Okay, let’s look at it.
67 Sm2: The one heating up, the other cooling down and then.
68 Sm5: Or we heat up water, and then evaporate it.
69 T: And the electrons evaporate suddenly?
70 (Sm2 laughs)
71 Sm4: Forget it.
72 Sm5: Don’t know, it is flying away?
Patterns regarding the social participation structure (SPS):

In this phase, it can be seen that the teacher tends to formulate open and challenging questions. The teacher’s share of the conversation is reduced massively. The students’ answers are getting longer: They formulate whole sentences and even series of sentences. This way students’ own ideas are introduced into the conversation which are taken up by the teacher (e.g. line no 67-69). There are more students now speaking and the speed of interaction has dropped (under 2 turn takings per 5 seconds). In this phase, the students think longer before they formulate their answers. Speaking with the model of Mortimer and Scott, it can be seen that the students assume the role of initiators in phase 3 of the lesson. Students’ ideas become much clearer in the answers (line no. 63f.). The evaluative step is changing. The teacher no longer points out the correct scientific answer, but encourages the students to think ahead (line no. 77). Thus the teacher-students-discourse leaves the authoritative I-R-E scheme and becomes dialogic and democratic (Mortimer, & Scott, 2003).

Even though the pattern of conversation in phase 3 changes significantly compared to phase 2, the following structural features are retained in a homologous manner:

- The students and the teacher continue to communicate indefinitely. Neither the teacher nor the students ask for clarification.
- The teacher does not act as an instructor.
- The conversation continues to be characterized by tolerance towards the students’ statements. The teacher does not correct the students.
- The conversation is still highly interactive. The participants in the discussion remain constantly in conversation.

Patterns regarding the academic task structure (ATS):

With regard to the ATS, in contrast to the previous phase, the perspective of the students now dominates. The scientific view – which previously dominated the discourse – takes a back seat. Everyday life ideas that are far from scientific adequacy are co-constructively developed by several students. The teacher does not interfere.

Explication of the teacher’s orientational framework

Based on these contradicting communication patterns in phase 2 and 3 we conclude that there are two conflicting orientational frameworks guiding the teacher’s activities. On the one hand the teacher shows an authoritative orientational framework regarding the nature of chemistry and its appropriate academic task structure: Knowledge on the sub-microscopic level in
chemistry is superior to knowledge on the macroscopic level and therefore chemistry has to be taught on the sub-microscopic level. Although this orientational framework appears to be predominant in phase 2, the teacher showed many strategies to facilitate participation in phase 2, too. For example, the teacher avoided critique in the process of evaluation and she avoided “indoctrination”. She persistently helped the students to find the right answer to her questions, by offering them hints which were often based on some kind of logic (mathematical or linguistic logic or common sense). So the correct knowledge was always provided by the students, as a response to her questions. Moreover, the teacher was always respectful and very permissive towards ambiguous terms and confused concepts evident in the students’ talk. In general the teacher was successful in installing a participative discourse where a high-density of teacher-students-interaction can be observed. Therefore we conclude that the teacher holds another dominant orientational framework regarding the social participation structure: Chemistry education should not be authoritative, but should provide participation and inclusion. This orientational framework obviously conflicts with the teacher’s chemistry-related orientational framework. This becomes apparent in the differences but also the similarities in the teaching practices of phase 2 and 3. These can be interpreted as two different attempts by the teacher to teach authoritative knowledge in a participatory, democratic way. In both phases the teacher’s orientational framework regarding the social participation of all students leads to a teacher-students-discourse where students are eager to participate. But in both phases this participatory orientational framework is in conflict with the authoritative orientational framework regarding the scientific knowledge: In phase 2 the scientific view is imparted in an authoritative way onto the students with no possibility for them to understand the foreign concepts because the teacher does not offer the students to link the new concepts to their existing ones. Phase 3 represents another way of resolving this conflict: For the sake of a participatory discourse the scientific view is nearly banished from the discourse. In both phases therefore inclusion fails because of its exclusive interpretation as participation on the social level. An actual participatory, dialogical way of teaching, namely the negotiation of the two perspectives – the worldview of chemistry and the worldview of the students on an equal footing – is not possible due to the lack of content knowledge of the students and due to lack of didactical knowledge of the teacher. The only way out is a superficial staging of a dialogical, democratic discourse.

DISCUSSION AND CONCLUSION

Although the teacher observed in the case study clearly shows a participatory orientation to chemistry teaching, this orientation only allows for participation on the social interaction level. Because of her authoritative orientation regarding the nature of chemistry and chemistry knowledge, she does not facilitate her students to access the world view of chemistry (e.g., by negotiating it with the students’ world view which focusses mainly on the macroscopic level). Moreover, even her participative strategies often prevent her students from understanding chemical knowledge. For example, students’ misunderstandings are not made explicit for the sake of a participatory discourse where everybody is invited to talk freely. The teacher seems to struggle to orchestrate an academic task structure which is not solely governed by the authoritative nature of scientific knowledge. Approaches like inquiry-based
learning, project-based learning and other reform-oriented pedagogies allow for participation also on the content level (Abels, 2015). Conclusively, future professional development courses must not only concentrate on inclusive content-related pedagogies, i.e., how to teach chemistry, but should also focus on the reflection of implicit beliefs in inclusive science teaching. Making these implicit orientational frameworks explicit would help teachers to become aware of conflicting demands in their belief systems about inclusive science teaching which we assume to be a pre-requisite for a sustained improvement in their teaching praxis. Though, that remains to be investigated in future studies.

THE CELL EXPLORERS PROGRAMME – PILOTING A STEM PUBLIC ENGAGEMENT MODEL IN IRELAND

Muriel Grenon¹, Sarah Carroll¹, Claudia Fracchiolla¹ and Claire Concannon¹,²
¹ School of Natural Sciences, National University of Ireland Galway, Galway, Ireland
² Present address: Otago Museum, Dunedin, New Zealand

The Cell EXPLORERS programme (www.cellexplorers.com) is an education and public engagement programme that aims to inform, inspire and involve the general public in science, technology and research by connecting primary and secondary level education, third and fourth level students, lecturers, researchers and the general public. The programme has established a unique model of sustainable public engagement for Higher Education Institutions (HEIs) in Ireland. It engages students in educational outreach activities as part of their curriculum and also works with a growing volunteering base made of students and researchers. This working model has the dual benefit of engaging children in local schools and communities whilst facilitating the training of tomorrow’s educators or researchers as science communicators. Since 2015, the development of a national network of Cell EXPLORERS (CE) volunteering teams has been initiated in order to test this model. Between 2015 and 2016, four additional CE teams have been established and trained at delivering science school visits in their community. During that time frame, the five teams delivered public engagement to more than 2000 school children nationally in Ireland. This work presents the results collected to define: 1) if the model works and 2) what aspects of the model need to be adapted for partners and why. In particular, we have assessed different aspects of the programme including its organisation, how it benefitted both the students and partners involved, and how it benefitted the pupils and teachers visited. Preliminary results suggest that the CE model is successful in part due to its mobilisation of third level science students as science outreach volunteers. Further study at a national level could lead to the adoption of the model by HEIs and its use in Science Technology Engineering or Maths (STEM) topics other than biology. This could directly impact the dissemination of science education and public engagement activities in Ireland.

Keywords: public engagement, higher education, informal learning

INTRODUCTION

In Ireland, education and public engagement (E&PE) goals have been integrated into higher education and research institutions’ mandates (Campus Engage Charter, 2014; Department of Education and skills, 2011), and is also expected by research agencies (SFI Agenda 2020, 2012). However, in many of these institutions there is a lack of training and structure to address these goals. Researchers, who are based in HEIs in Ireland, are expected to engage but cite barriers such as lack of time, opportunity, funding and training (Concannon & Grenon, 2016; Wellcome Trust, 2015). This project proposes the establishment of a science E&PE network using a structured volunteer-based model that is underused in Ireland. The network will support researchers and institutions overcome these barriers to science E&PE. The model follows the one developed by Cell EXPLORERS, an informal science education initiative started in 2012 in the School of Natural Sciences of the National University of Ireland Galway.

An important outcome of the CE programme is the training of the next generation of science
educators and researchers at E&PE. Another expected outcome is to contribute in addressing the national shortfall in science education by running nationally a school roadshow. This roadshow targets children at an age (10 to 14 years old) where they develop their aspirations for a career in science and their perceptions about what science is and what being a scientist means to them, as determined by the ASPIRES study (Archer et al., 2013). In order to change these perceptions, the CE programme addresses many of ASPIRES’s recommendations, including early interventions in primary school and embedding science careers awareness in school visits. In addition, the CE diverse team of science role models allows the programme to tackle any unconscious biases and to bust the ‘brainy’ image of scientists (Archer et al., 2013; Hillman, Bloodsworth, Tilburg, Zeeman & List, 2014; SMART FUTURE studies, 2016).

Finally, recent surveys on public attitude towards science show a lack of public trust, but also an appetite to learn more about science and to interact with scientists (Huskinson, Gilby, Evans, Stevens, Tipping, 2016). By establishing a network of science outreach teams, and by training the next generation of scientists in public engagement skills, this project would facilitate these interactions expected by the public, both now and in the future. This work describes the first stage of national development of a Cell EXPLORERS network with the creation of active teams based in five HEIs, covering eight counties in Ireland.

**METHODS**

The programme follows an action research approach in its methodology to establish the most sustainable way of delivering public engagement activities in local communities. A key activity of the programme is the delivery of the “Fantastic DNA” school visits led by teams of volunteer science students or researchers. The mode of functioning of the initial CE team located at NUI Galway and the coordination of this project has been revised and streamlined to be adapted and piloted in other Irish HEIs. It has also inspired the methodology for establishing new CE teams.

This research is aimed at studying the success of the CE model as a strategy to engage HEIs into E&PE. In this first phase of CE national expansion, success of running the CE model is defined by the set-up of four novel teams, their continuous participation in running the program and that the delivery of the target number of school visits is achieved. In addition, the involvement in the programme had to receive positive feedback from CE team members and an indication that they would remain involved in CE. Finally, the delivery of the “Fantastic DNA” school visits had to receive positive feedback teachers, children, and volunteers.

To determine success as described above, this study used yearly short team reports collected from team coordinators. Three surveys were also used with the CE volunteers. One survey, run through the Google Forms app, collected basic information such as contact details, year of study and course. The final list of active volunteers was confirmed with the team coordinator to adjust team composition. Pre- and post-volunteering surveys, anonymous and independent offered through survey monkey, were distributed online by the NUI Galway coordinator. The pre-volunteering survey gather information on the motivations and expectations of the volunteers, as well as on their previous teaching and volunteering experiences. The post-volunteering survey collected information on experience of volunteering with CE, of thoughts of any benefits gained by volunteers and on whether they would choose to volunteer with CE.
again in the future. The survey questions were developed based on results from existing volunteer surveys, piloted with the previous year’s CE NUI Galway volunteers. These had been originally designed with reference to a survey used to evaluate an undergraduate science communication module (Yeoman, James, Bowater, 2011). The same pre- and post-surveys were used for all CE teams.

Printed questionnaires were distributed to teachers and children of the visited classes to collect anonymous opinion on the “Fantastic DNA” session design and delivery by the CE team as well as any impact of the visits on children’s perception of science and scientists. The children and teacher questionnaires were updated from previous versions of questionnaires developed by CE from similar E&PE evaluation (Wellcome Trust public engagement officer, personal communication, 2014). Feedback were mailed by teachers to team coordinators who forwarded them to the CE national coordinators. Questionnaires returned were entered manually into survey monkey’s online versions of the questionnaires by a team of research volunteers and exported to SPSS. Qualitative answers to open-ended questions of volunteers, children and teacher questionnaire were coded according to categories that arose from previous evaluation data generated by the NUI Galway CE team.

Results presented in the next sections originated from data collected in 2016. In 2016, fifty-nine team members completed the pre-volunteering survey, (N=28, 5, 13, 2 & 11 for NUIG, UL, AIT, ITT & DkIT team respectively) and sixty-three team members completed the post-volunteering survey (N=28, 3, 12, 9 & 11 for NUIG, UL, AIT, ITT & DkIT team respectively). Written feedbacks were received from 1106 of the 1881 children visited and 50 of the 78 teachers visited.

NATIONAL TEAM SET UP

Four HEIs were identified as CE partners and academics/research coordinators were appointed to lead each team in each HEI. In 2015, two new CE teams were established in the University of Limerick (UL) and Athlone Institute of Technology (AIT) under the mentorship of the national coordinating team in NUI Galway. In 2016, two further CE teams were established in the Institute of Technology Tralee (ITT) and Dundalk Institute of Technology (DkIT). Following establishment and a training by the NUI Galway team on school visits, these partner teams had to deliver three further primary school visits in their geographical areas, for a total of four school visits in year 1 (2015). Eight visits were scheduled to take place in year 2 (2016) for the partners established in 2015.

Calendar for new team set up was as follow (Figure 1). Initial training of team coordinators and demonstrators took place in April/May and partners could request an extra one-day training visit in September at the time of new team members recruitment. The partner team training involved a 2-hour information session with the coordinators to introduce them to their role and associated documents and resources. This was followed by training on “Fantastic DNA” the interactive science session that the team has to disseminate in their local communities. Partners received the equipment, consumables, and printed materials to be able to deliver all school visits for the academic year. Coordinators and the recruited demonstrators trained at preparing session to get all equipment and material ready for the training school visit the following day.
Figure 1. Schedule of Cell EXPLORERS partner team set up, public engagement and national coordination activities.

This visit was arranged to a school local to the institution, and successively led by NUI Galway coordinators in the first class and the new team in the second class visited. School visits arranged by partners are most likely to take place during October/November, with all teams encouraged to run as many visits as possible during the National Science Week in November. The NUI Galway team was in charge of collecting and analysing data for this study.

RESULTS

Cell EXPLORERS partner teams set up and activities

A total of five Cell EXPLORERS team was running informal science education activities in 2016 (Figure 2). New CE teams were established in one university (UL) and three institutes of technology (AIT, ITT and DkIT) as described above. Each partner team recruited a set of active volunteers. During the academic year 2016-17, the CE active team was made of 226 team members with NUI Galway, UL, AIT, ITT and DkIT teams representing 57%, 10%, 7%, 9% and 14% of the total team respectively. Overall, the network of five teams delivered the expected number of “Fantastic DNA” visits for the roadshow during 2015 and 2016 (see below). In 2016, the team has directly engaged 9700 people, including 1881 children with the “Fantastic DNA roadshow”. The four new partners agreed to remain in the programme at the end of this first phase of CE national expansion. Results obtained in 2016 regarding the volunteer experience and the school visits roadshow are reported below.
Figure 2. National expansion of the Cell EXPLORERS programme in 2015 and 2016.

**The Cell EXPLORERS volunteering experience**

The 2016 CE group of 226 team members was made of 70% undergraduate and 19% postgraduate students as well as 11% staff. It included 79% of women and 21% of men. Individual teams have differences in size and composition (Table 1). NUI Galway involved 136 team members, the majority of whom were science undergraduates, with 78% women and more self-reported volunteering experience (73%) than teaching experience (30%). The UL team was made of 23 team members, all women (100%), belonging to the undergraduate science education degree (90%). UL volunteers were more experienced at teaching (63%) than volunteering. The AIT partner team was made of 16 staff and postgraduate researchers from a research centre with equal representation of women and men, with 71% being experienced at teaching and 50% at volunteering. ITT and DkIT were made of 90% undergraduates with 85% and 74% of women respectively.

The reported 60% of women studying life sciences undergraduate courses (Eddy, Brownell, Wenderoth, 2014; Neugebauer 2006) is unlikely to explain the high 79% of women participating to the CE programme. However, it is possible that some of the courses followed by CE undergraduate members (70% of the team) might have more than 60% women students. It is for example the case of the science education degree in UL (UL coordinators, personal communication, 2015). Alternatively, it is possible that women would be more inclined to participate in public engagement activities, similarly to what has been found in academia previously (Ecklund, James, Lincoln, 2012). More study will be required to understand the origin of the high level of woman participation in CE and what could be done to attract more male participants to the programme.

Across the five teams, members provided a positive feedback on all aspects of the programme including training and support for the activities as well as the member’s involvement and feeling part of a team (Table 2). Overall volunteers responding felt supported running the activities as they thought the training was sufficient (93%), they received enough support (93%) and the activities were well organized (95%). All respondents thought the programme is worthwhile and felt very well integrated, listened to, part of a team and that their time contribution was useful. Importantly, 90% of volunteers would volunteer again with CE in the future (not remaining in the team was due to study workload) and 98% of volunteers would recommend a friend to get involved in CE. This feedback validates both the training aspects and the group integration proposed by the CE volunteering opportunity.

Volunteering with CE is reported to be a positive experience. 92% of volunteers who responded were satisfied with the programme delivering what they expected, 13% of volunteers rated their
experience above expectation and 3% below expectation due to lack of opportunity to fully join activities. The top two favourite aspects of taking part in the programme highlighted by survey respondents were “bringing excitement to the public” mentioned by 22 respondents out of 57 and the “working with children” mentioned by 16 respondents, opportunities that are not often associated to studying science in HEIs. One hundred percent of the respondents agreed that science outreach is important for HEIs and 87% thought it should be integrated into the undergraduate curriculum.

In addition, volunteers self-reported specific gains by taking part. Students reported broadening their transferable skill set (Figure 3A and B), in particular communication (Selected by 91% of respondents) and working with children (91%). Gained skills also included working in a team (79%) and teaching skills (77%), skills that students might not have a lot of opportunity to develop in the classical undergraduate science curriculum. Seventy-five percent of respondents reported increased confidence due to their involvement in the programme. Eighty-four percent of respondents thought that their experience will help them in their careers (Figure 3B) and this would be achieved through providing them skills (61%), teaching experience (35%) or increased confidence (32%). Team members responding to the survey also reported undergoing personal development, a sense of fulfilment, increased scientific knowledge and making friends (Figure 3C).

The national “Fantastic DNA” Roadshow

The “Fantastic DNA” Roadshow is a key activity of the CE national network, delivered by 125 of the 226 volunteers of five CE teams. In 2016, it reached its target of visits and took place in 43 schools, 78 classes and 1881 children (Figure 4). This represented an expansion of “Fantastic DNA” school roadshow compared to the previous year, with 19% more schools, 30% more classes, and 15% more children visited than in 2015. In 2016, 41% of the schools visited were located in rural area. Feedback on diverse aspects of the visits was received from 1097 children of which 49% girls and 64% of visited teachers.

Fifty-one percent of the children visited answered a short five question knowledge quiz at the end of the session, which addresses five key learning outcomes of the session. Eighty percent of the children who took the quiz answered these questions correctly, indicating a satisfactory response in terms of short-term knowledge gained as a result of the session delivery. This is in
agreement with participants’ feedback on the session being appropriate to the age group and their understanding of it (see below). CE demonstrators reported engagement and interest from the children in both the session content and in science in general.

Both children and teachers agreed that the “Fantastic DNA” session is well organised and delivered by CE team members (Figure 5). The balance between presentation and activity is appropriate (Figure 5B) and the children participating understood both (Figure 5A). Both children and teachers reported to prefer the hands-on aspects of the session (Figure 6). When given the opportunity to select as many “best liked” activities in the session as they wanted, children most frequently choose “Using lab equipment” (535 times out of 3527), “Doing the experiment myself” (519) and “Fishing the DNA” (411).

Teachers ranked “The opportunity for each child to do an experiment” (Ranked first by 47% of teachers) and “The interactions between the children and local 3rd level science demonstrators” (Ranked second by 26% of teachers) as the two top most beneficial aspects of the session to the children (Figure 6B). Teachers stated that the main differences between the CE science visit and other science visit is that CE has more hands-on activities, engaged
children individually and has a greater number of instructors. These also correlated with the most favourite aspects of the session mentioned by teachers.

A. Top 3 Children best liked aspects of Fantastic DNA
- Using the lab equipment (535)
- Doing the experiment myself (519)
- Fishing the DNA (411)

B. Top 2 characteristics ranked most beneficial by teachers
- The opportunity for each child to do an experiment (47%)
- Interactions between children & local 3rd level science demonstrators (26%)

Figure 6. Best liked aspects of the CE “Fantastic DNA” session by children (A) and teachers (B). Photo of CE team member demonstrating Fantastic DNA to 5th class children (Aengus McMahon photography).

Perhaps surprisingly, 54% of the children who provided feedback in 2015 and 64% in 2016 had never met a scientist before the CE visit. Meeting CE scientists was a positive experience for a large majority of the children. Children reported learning important new facts about DNA and science in general, such as how fun it can be, how important it is, and the breadth of science and science careers. After the session, some children reported that it had stimulated their interest in studying science or becoming a scientist. Some teachers reported that since the visit, their classes had more interest in science and doing science-based activities. These aspects of the impact of the visit will be further studied and reported elsewhere.

DISCUSSION AND CONCLUSIONS

Underpinning CE sustainability is the involvement of students as volunteers to deliver outreach activities to the general public. This initial stage of the national expansion of the CE working model spans a two-year period to establish four novel active teams in addition to the NUI Galway team. Findings reported here demonstrate that the CE set up can be reproduced elsewhere. The four partner teams have agreed to continue the project for a further two years, requesting further simplification of the coordination action for the following stage of the project. All participants declared satisfaction in taking part and reported specific gains. CE volunteers, the next generation of Ireland’s science communicators and educators, have been successfully trained at delivering scientific information to the public through a school roadshow and science fair workshops. They reported both undergoing personal development and broadening transferable skill set. The dissemination of “hands on” science in schools through the “Fantastic DNA” Roadshow, a key activity of CE teams, was delivered to standard suitable to both children and teachers. It has stimulated an interest in science and allowed children to meet realistic science role models at an age at which aspirations for a career in science and perceptions about science and scientists are still developing.

Following this successful first phase of national expansion, five more partners have been identified to join the programme. A total of ten teams are to disseminate CE activities in 2017 and 2018 allowing more studies on the programme. Further studies may inform best practices for sustainability of this model for both current and future partner teams. They could lead to the adoption of the model by HEIs and its use in STEM topics other than biology. This could directly impact the dissemination of science education and public engagement activities in Ireland.
ACKNOWLEDGEMENT

Thank you to the team coordinators, all students and researchers members of the NUI Galway, UL, AIT, ITT & DkIT CE teams for their enthusiasm, hard work and commitment. Previous work used in this study was funded by Wellcome Trust People Award 12093/Z/13/z to MG. CE is supported by the NUI Galway discipline of biochemistry and the school of Natural Sciences. This work is funded by Science Foundation Ireland under the SFI Discover programme (SFI DPP14_022), NUI Galway and the Galway University Foundation. CE is part of SCIENTIX (www.scientix.eu), the community for science education in Europe.

RESEARCHING GENDER & ICT IN KINDERGARTEN

Eduarda Ferreira¹ and Maria João Silva²

¹ Interdisciplinary Centre of Social Sciences (CICS.NOVA), Faculty of Social Sciences and Humanities (FCSH/NOVA)
² Escola Superior de Educação, Instituto Politécnico de Lisboa

ICT are increasingly pervasive and embedded in everyday interactions and objects, constituting a relevant aspect of social identities. Nonetheless, ICT continues to be a highly gendered area of life in all socioeconomic and educational backgrounds, and a source of significant social inequality in enduring ways. This paper reports on an ongoing research project ‘Gender@ICT’, which explores the interrelations of gender and technologies in an educational context in Portugal, based on group activities (games with images related to ICT and gender), focus groups and semistructured interviews. This paper presents the results of the group activities and focus groups with preschool children, analysing their representations on gendered activities and behaviours. Most children evidenced stereotyped representations on ICT and gender, reproducing the ICT gender gap. Only the few children that reported diverse gender representations at home disclosed more gender inclusive perceptions of ICT, evidencing the importance of diversity in gender representations.

Keywords: gender, ICT, kindergarten

RESEARCH FOCUS

‘Gender@ICT’ research project aims to explore the embodied relationship between gender and Information and Communication Technologies (ICT) in preschool and 9th grade, based on the understanding that both gender and technologies are social constructions (Wajcman, 2007). This research draws upon Feminist Technology Studies (FTS) theorizing the relationship between gender and technology as one of mutual shaping. Objects and artefacts are not seen as separate from society, but as part of the social fabric that holds society together; technology is understood as a sociotechnical product – a fluid network combining artefacts, people, organizations, cultural meanings and knowledge (Bijker et al. 1987; Law & Hassard 1999; MacKenzie & Wajcman 1999).

Considering that technologies are increasingly pervasive and embedded in everyday interactions and objects, constituting a relevant aspect of social identities, and that research often reports on “ICT gender gap” (Kay, 2008), our problem is centred on how do technologies affect and are affected by gendered practices.

To fully participate in the economic, social and cultural life people need the competences to navigate through a complex digital landscape (OECD, 2015). Nowadays, there are still differences between girls and boys in what concerns self-reported digital competences and experience with computers, even in countries where there is gender and socioeconomic equality in access to school. These differences do not reflect material constraints, but rather the students’ interests and families’ and educators’ notions about what is suitable for them (OECD, 2015).

‘Gender@ICT’ adopts a critical discourse perspective in which gender differences in ICT use are understood as a result of gender-technology and power-knowledge relations (Faulkner &
Lie, 2007), aiming to disclose the tension between agency and structure that is worked out by individuals in particular contexts. One must consider that gender is not universal, it is the culturally local behavioural expressions of an internalized individual identity that includes understandings of masculine and feminine, tailored to the specific culture in which a child develops (Trautner et al., 2005). Gender identity is a pattern in time, it is shaped by the preceding dynamics of physical, social, and emotional experience and becomes the basis of future identity transformations (Fausto-Sterling, 2000).

Considering the stages of gender identity development, the research on ICT and gender in early education is of central importance, and there is still a need for such research (Kay, 2008). In this context the research question of this study is: “How does gender makes a difference in the construction of individuals’ relations to ICT?”. The research developed in two kindergartens is presented in this paper.

**METHODOLOGY**

The ‘Gender@ICT’ research project has three phases (Figure 1) which include focus groups, class activities (games with words and pictures related to ICT and gender) and semistructured interviews, developed in a school context. The focus groups with 9th grade students inform the structure and content of the class activities, and the semistructured interviews with ICT teachers contribute to further explore the gendered representations associated with ICT and to identify educational practices that promote gender equity. The class activities with preschool children and 9th grade students engage mixed-sex groups in games with words and pictures to explore how gendered identities and discourses are produced simultaneously with technologies. Researching with preschool children (around 4/6 years old) and 9th grade students (around 14/15 years old) give us the opportunity to analyse gender stereotypes in different stages of development. This paper reports on the results of the group activities and focus groups with preschool children.

![Figure 1. Gender@ICT research phases](image)

**Figure 1. Gender@ICT research phases**

This research took place in two kindergartens of a school cluster in Setúbal, Portugal. The school cluster Sebastião da Gama, where the research takes place, has seven schools: two
preschools and 1st cycle, three 1st cycle, one 2nd and 3rd cycle, and one 3rd cycle and secondary, with a total of 135 classes and about 3,000 students. Students’ age ranges from 4 years old to 18/20 years old. The educational system in Portugal is divided into preschool (for those under age 6), basic education (9 years, in three cycles) and secondary education (3 years).

The researcher who conducted the activities and groups is an educational psychologist in that school cluster. As such, the researcher was not an outsider, and the research data were collected within a familiar context for the participating children. Researching with preschool children requires that: focus groups should be similar to “natural groups” (i.e., pre-existing social groups, such as friends, classmates, etc.), conducted in informal peer group settings such as classroom situations, and the location of the research should be familiar to the child (Irwin & Johnson, 2005). The group activities and focus groups with preschool children, aged from 4 to 6 years old (14 girls and 18 boys), were conducted during November and December 2016 in children’s kindergarten and explored their representations on gendered activities and behaviours. Focus groups were organized with mixed-sex groups with 4/5 children while engaging in games with images to explore how gender relations are materialized in technology and how gendered identities, discourses, and technologies are produced simultaneously.

Children were asked to describe 4 images: the woman with the laptop, the man with the laptop, the woman with children, and the man with children (Figure 2). The laptop with the screwdriver was meant to direct the conversation to broken laptops, so that the conversation was not only about using computers but also about how to fix them.

Figure 2. Images used in the activities: woman with the laptop, man with the laptop, woman with children, and man with children

From a set of images (Table 1) children had to decide which toys would girls and boys more probably receive at Christmas. They had to argue and discuss until they decided. The images were all randomly spread over the table. The discussions during the group activities were audio-recorded, transcribed and analysed.

RESULTS

It was possible to observe some specificities of researching with preschool children in kindergarten. For example, occasionally a child stands up and says, “I have to poo”, and before children engage with the tasks they thoroughly touch and explore all the images.

In the images showing children and adults (Figure 2), the participants almost always identified the woman as a teacher and the man as a relative (father, brother) or physical education teacher. These ideas are clearly related to their experience, there are almost no kindergarten teachers in Portugal (only 0.2% of Portuguese kindergarten teachers are male) and it is common that the men who work in the Portuguese kindergartens relate to physical education. When asked about what the woman and the man would do if the laptop was broken, only 4 (3 boys and 1 girl) out of 32 children mentioned the possibility of the woman repairing it, although many also said that the man would go to a repair shop. In the discussion, it was clear that for all the children only men work in computer repair shops. Dialogue about repairing computers:

*If the computer is not working she cannot do anything, she will go to a repair shop.* Participant 3, Boy, 4 years old

*She cannot fix the computer because she is a woman; she is not a man.* Participant 6, Boy, 4 years old

*She can ask a man to fix the computer.* Participant 1, Girl, 5 years old

*The ones who fixes the computers are the men.* Participant 10, Boy, 5 years old

*There are only men working in computer repair shops.* Participant 9, Girl, 4 years old

The 4 children who interpreted an image as a woman repairing a computer, have direct experience with women who use it every day.

The social cultural context strongly socializes children, according to gender stereotypes; in particular toys’ marketing is highly gendered (Trautner et al., 2005). As such, in the game with toys’ images, unsurprisingly toys were mostly attributed according to gender stereotypes. Children showed difficulties in deciding about the more gender-neutral toys, and the decisions varied from group to group.

The reasons children present to decide on which toys they attribute to either a girl or a boy are closely related to their experiences at home.

One of the girls said that the ironing board could also be for a boy because her father also uses it. The other children reacted immediately saying that this was not true because their fathers did not use the ironing board. It is almost always about their own personal experience. Dialogue about pots and pan:

*Pots and pans are for the girl, boys don’t cook.* Participant 12, Boy, 4 years old

*No, it can be for both, they both can cook, my mother cooks and so does my dad.* Participant 14, Girl, 5 years old

*No, no, only for girls, my mother cooks, but my father never cooks.* Participant 2, Girl, 4 years old
The importance of social representations and changes in the gender social roles also have an impact. As an example, when they talk about weapons:

*The weapon can also be for the girls.* Participant 7, Girl, 5 years old

*Yes, it can be because women can be cops, they can go to the army.* Participant 17, Boy, 5 years old

Although they had this conversation they ended up deciding to attribute the weapon to the boy.

In line with the literature regarding ICT related toys (Trautner et al., 2005), all the boys and most of the girls attributed the laptop to boys, and the tablet and the smartphone were more equally attributed to both (Figure 3).

Figure 3. Results of the game with ICT related toys’ images

It is interesting that there is a significant difference between laptops and mobile devices. The use of mobile devices by girls, such as smartphones and tablets, is on clear rise, according to recent research (Ponte et al., 2017). One may question if the rise of girls using mobile technologies will have consequences on the interrelations between ICT and gender. At the present time the representations of ICT are still gender marked.

Most preschool children evidenced stereotyped representations on ICT and gender, reproducing the ICT gender gap. Only the few children that reported diverse gender representations at home disclosed more gender inclusive perceptions of ICT, evidencing the importance of diversity on gender representations.

**CONCLUSIONS**

The results of the first phase of research with the 9th grade students (Ferreira, 2017) revealed that gender stereotypes are deep-rooted amongst young people, in a time of their lives when they have to make academic choices that lead to professional careers. The way students identified gender practices and justified gender technological preferences illustrated how
gender stereotypes are materialized in technology. In the discourse of the participants in focus groups, gender markers correlate to technology usage. Gender stereotypes can influence and determine the future educational and professional choices of young people, contributing to maintain the stereotypes, in a cyclical process. Schools have an important role to disrupt this cyclical process, supporting the diversity of students’ interest and encouraging both girls and boys to further develop their technological competencies.

ICT is highly related to gender stereotypes, which affect boys’ and girls’ representations and practices, including their educational and career choices (Faulkner & Lie, 2007). Considering the stages of psychological development and gender identity, the cross analysis of the ‘Gender&ICT’ results of the research with preschool children with teenagers of the 9th grade, contributes to further explore how do ICT affect and are affected by gendered practices.

The research with preschool children evidenced that gender stereotypes are present from early ages, and in particular ICT related activities are perceived as highly gendered by young boys and girls. By analysing the choices and the discussions of the participant children, it is possible to say that ICT representations function as gender markers. These results indicate that intervention must start as early as possible, and kindergarten is of crucial importance to implement educational activities that promote a diversity of gender representations, namely those related to ICT activities. One cannot expect that educational initiatives to question and disrupt gender stereotypes with teenagers have significant impact, considering that it is much earlier ages that gender stereotypes are established.

Although girls are using digital mobile devices as much as boys, the laptop is still highly gendered. The laptop is related to ICT professions as it was disclosed by the activities with the images of the ‘woman with the laptop’ and ‘man with the laptop’. The representations of laptops and ICT related professions are as gendered as the industry of children's toys. Based on these results we argue that ICT, namely laptop and ICT related professions, function as gender markers. One may ask if the usage of digital mobile devices by girls will have an impact in ICT representations, namely in ICT related professions? Considering that digital mobile devices are more related to communication and interpersonal relations, stereotyped female activities, than with professions or work activities, it is likely that it won’t have a significant impact.

The next phase of ‘Gender@ICT’ research will explore the ideas and experiences of ICT teachers with both girls and boys using technology. ICT teachers have a privileged insight on young people digital practices, their views will be complementary to the results of the focus groups and class activities with children and young people. The semistructured interviews with ICT teachers will also contribute to identify educational practices that promote gender equity in ICT.

The school has a major role in promoting gender equality by providing diverse gender representations to children from all sociocultural contexts. In particular, school can make the difference to children who do not have access to a diversity of gender representations at home. It is urgent that gender equity becomes central to education. By gender equity we are not referring to equal numbers of men and women using technology, but as expressed by OECD
(2015), to greater levels of self-determination for all genders, a much greater range of opportunities for being gendered and more equal distribution of power.

SECONDARY STUDENTS’ ATTITUDES TOWARDS SCIENCE BASED TECHNOLOGY – AN EXPLORATORY STUDY

Robbert Smit, Nicolas Robin and Christina De Toffol
University of Teacher Education St.Gallen, Switzerland

As part of a bi-national cooperation project between industry and Swiss- as well as Austrian secondary schools we explore the students’ attitudes towards STEM with a special focus on science based technology. There is a shortage in STEM related professionals and interest of students for STEM careers is low. Our project aims at fostering students’ interest in STEM professions by out-of-school visits in industries. We present first results from the ongoing research study based on a student questionnaire. Our data comprises students’ attitudes towards science based technology related to value, cost, self-schemata, and socializer’s beliefs. Results indicate that attitudes are rather low in general and as expected significantly lower for girls. Best motivational predictors for career interest in science related technology are enjoyment, personal value and a high self-concept in science based technology. In addition, interviews with their four science teachers show that technology is an integrated, but not very prominent part of science instruction.

Keywords: student attitudes, science based technology, secondary school.

INTRODUCTION

There have been many calls for more young people studying STEM related subjects internationally (Kudenko & Gras-Velázquez, 2016). Multiple research studies register a growing decline of pupil’s interest in STEM subjects (Becker, 2010; Organisation for Economic Co-operation and Development (OECD), 2006b; Xie & Achen, 2009). All German speaking countries were below the OECD average in PISA 2006 with respect to the general value of science and technology. More than 50% of the students answered that science and technology is not relevant to them. This is problematic since in many European countries the shortage of engineers is growing as many active engineers will retire within the coming years. There is also the problem of a lack of STEM education teachers. Therefore, it is important to raise the interest of students for STEM professions. This is especially urgent for girls (Güdel, 2014; Riegle-Crumb, Moore, & Ramos-Wada, 2011; Robnett & Leaper, 2013). Our research is embedded within a Swiss-Austrian project that aims at developing positive students’ attitudes towards science based technology by visiting STEM related industries. Targeted social psychological interventions that focus on certain elements of student motivation have been successfully used in different educational situations (Yeager & Walton, 2011). In a first step, we are interested in the students’ attitudes towards science based technology in general. For this purpose, we developed a student questionnaire with items based on the expectancy-value model of Eccles and Wigfield (2002).
THEORY

Often technology is seen, also by teachers, as applied science (Jones, Buntting, & de Vries, 2013). However, this view is too limited (Jones, 2012). It is important that teachers and students develop an understanding of technology and science as two areas that can interact but are also distinct in nature. According to Jones (2012) technology allows people to expand their possibilities and to intervene in the world through the development of products, systems, and environments. This includes the discussion of social aspects, values and ethics in the science classroom. In Swiss secondary schools the subject of technology has not been a prominent feature of the curriculum in the past. The new Swiss curriculum 21 includes technology as part of science with respect to being able to talk about the relevance and the sustainability of technological inventions like, e.g., genetic engineering, electric engines, or communication technologies. Students should also possess the competence of using and understanding everyday tools (hair dryer, loud speaker, LED, etc.). The practical implementation of the new Swiss curriculum is still ongoing. Hence, it is reasonable to assume that Swiss science teachers do not put a lot of emphasis on teaching technology in the secondary classroom yet as this has not been an issue in the earlier curricula. Studies on science teachers’ knowledge for teaching technology in German speaking countries do not exist. A current research project by Goreth, Geißel and Rehm (2015) aims at closing this gap. Research has shown that the early years of secondary education are crucial in terms of the impact a teacher can have on students’ views of science and careers involving science (Regan & DeWitt, 2015). Therefore, it is important that Swiss secondary school teachers get professional training on how to conduct motivating technology lessons in the science classroom.

Student attitudes toward science are part of the PISA 2006 definition of scientific literacy (Bybee, McCrae, & Laurie, 2009). They underlie an individual’s interest in, attention to, and response to science and technology. Career intentions for STEM correlate with general interest in STEM subjects (Kudenko & Gras-Velázquez, 2016). A STEM background like, e.g. the parents working in the STEM field, has a positive influence on the student’s self-concept and career choice (Moakler & Kim, 2014; Regan & DeWitt, 2015; Wang & Degol, 2013). Students’ attitudes towards science correlate with student outcomes in science and in consequence predict STEM study selection (Guo, Parker, Marsh, & Morin, 2015). These findings suggest that interventions targeting the promotion of academic performance and STEM pathways, should seek to enhance both self-concept and intrinsic value. To do this, utility value interventions, such as identifying personal utility value connections between students’ lives and what they are learning in class, have been found to be effective to trigger students’ interest and promote academic performance in STEM topics (Aeschlimann, Herzog, & Makarova, 2016; Hulleman & Harackiewicz, 2009). Also out-of-school experiences seem to enhance the students’ interest for the STEM field (Henriksen, Jensen, & Sjaastad, 2015).

In investigating motivational attitudes of the students towards science based technology, the present study makes use of the expectancy-value model of Wigfield and Eccles (2002), which explains the achievement related choices by the value a student contributes to a subject and the student’s competence beliefs related to that subject (Figure 1). The competence beliefs in turn determine the student’s expectation for success.
**Research question**

What is the state of the secondary school students’ attitudes related to science based technology?

Sub questions

- Do these attitudes correlate?
- Are there gender differences?
- What predicts students’ career choice for technology related jobs?
- How do teachers teach science based technology?

**METHOD**

**Design**

Our longitudinal mixed-methods research design is embedded within a bi-national STEM implementation project. The Swiss-Austrian project started in 2016 and ends in 2018. Its main aim is to network industry and school and to motivate secondary school students for STEM related subjects. As part of the project, secondary school students in the region of St. Gallen (CH) and Vorarlberg (AT) visit a local company with a STEM background and work on STEM-tasks related to the company’s products. The teacher prepares these exchanges and reflects with the students’ afterwards. The exchanges will be repeated during the project time.

To evaluate the project, the students fill in questionnaires pre- and post of the implementation phase. In addition, we conduct teacher interviews. In the end, we intend to combine teachers’ and students’ project experiences in order to understand the effects of the project. However, since we don’t have a control group, causal effects will not be identifiable.
Participants

In this paper, a preliminary first sample of Swiss student data is analysed. The sample consists of $N = 116$ students from four secondary school classes of two schools in the Eastern part of Switzerland. The mean age is 13 years (grade 7). All of the classes participated in the project 'STEM becomes a habit in schools'. More participants as well as additional data from Austrian schools are expected in the near future. We interviewed two teachers in each school who are responsible for the science lessons. In each school, we had one female and one male teacher participant.

Instruments

The student questionnaire consists of 85 items on students’ attitudes towards mathematics, science based technology, and of some variables related to the students’ background, e.g., gender, father/mother’s job, importance of technology at home. Our items relate to the expectancy-value model of achievement by Eccles and Wigfield (2002), see Figure 1. Among the scales are three scales which cover the competence dimension of the model: Technology related self-concept and self-efficacy, as well as school related technological self-concept. Another seven scales form the value part of the model: Interest in creating or applying technology, environment-related technology, fun in technology, general and personal value of science based technology and technology related costs. Most of the items were adapted from literature: Items related to costs are adapted from Flake, Barron, Hulleman, McCoach and Welsh (2015) and Kosovich, Hulleman, Barron and Getty (2014), to interest and value from Güdel (2014) and PISA 2006 (Organisation for Economic Co-operation and Development (OECD), 2006a). Another four items asked for the students’ future job wishes as in Riegle-Crumb et al. (2011). All items are summarized in scales and checked for reliability (Cronbach Alpha).

Teachers were interviewed with a structured guideline. The coding process followed the structure of the guideline. Accordingly, codes were partly developed deductively, but also as part of the coding process inductively.

Analyses

Statistical analyses (correlations, multiple regression, t-tests) of the student data were conducted with SPSS. For the interview data, we applied computer assisted content analysis (Mayring, 2000). For this paper, we included codes related to the topics relevance, instructional design, subject content and (experimental) material.

RESULTS

In general, the secondary school students’ attitudes related to self-concept or value of technology are rather low (Table 1). In addition, it shows that female students have significantly lower values for all scales.

Related to the students’ background, it appears that around 50% of the fathers have a technology related occupation while only 9% of the mothers do. Rather unexpectedly, t-tests
reveal no significant difference for students’ career choice between groups with father or mother having a technological profession or not (mother: \( t(113) = -1.46, p = 0.15 \); father: \( t(112) = -1.34, p = 0.18 \)). Moreover, there are no such differences for any variable in the research model except for technical self-efficacy, which is higher in the group with father having a technology related occupation (\( t(112) = 2.11, p < 0.05 \)).

Students never or seldom talk about technology or are in workshops at home. Boys are more often in a workshop at home than girls, but both frequent them only rarely (\( t(110) = 2.95, p < 0.01 \)). Students where technology is more often a topic at home and students who are more often in a workshop at home show a higher technological self-concept and a technological career choice is more probable.

All scales from the expectancy-value model related to the students’ competence beliefs correlate (Table 1). The same is true for the scales related to value of technology. The competence scales and the value scales also correlate with each other except for general value of technology. Students value technology on a general level but don’t feel competent in science related technology at the same time. On a personal level, it is different: the more they feel competent the more they value technology for themselves. The cost scale has a negative relationship to all other scales, meaning the more competent a student feels and the higher the student values technology the less costs the student needs to invest to achieve success in a technology related task.

Both, competence and value scales also correlate with career choices. Interest of the students for a future job in a technology related branch is however rather low (\( M = 3.13, SD = 1.14 \)). As an exploratory research question, we investigated which of variables in our research model (Figure 1) explains the secondary students’ career interests for science based technology best.
Based on a multiple regression analysis three predictors which explain 57% of the variance in the students’ career interest were identified. These variables are technology related enjoyment, personal value and self-concept (see Table 2). The more a student enjoys technology, e.g., applying technical tools, taking apparatus apart, the higher technology is personally valued and the higher the student’s technological self-concept is, the more a student might opt for a technological job.

Note: N = 116; all predictors p < .05.

Based on the first four teacher interviews it shows that only the two teachers of one school find it important that students discuss the relevance of technical innovations in school, like, e.g., nuclear power or energy saving. Three of the four teachers mention that they think technology lessons should enable the students to gain self-confidence when a device gets broken and they need to fix it. With respect to the content of the technology lessons three teachers indicated separation processes in chemistry lessons. Two teachers of one school refer also to physics (working with electric circuits, functioning of an engine). One teacher says she has no specific lesson goals for science based technology. It was also indicated by one person that lessons with a technology content need a lot of preparation time and require a lot of experimental material. This limits the number of lessons that are spent on science based technology. One teacher also remarks that the new technology related competences in the curriculum 21 have already been part of her lessons so far.

**DISCUSSION AND CONCLUSIONS**

We expected and obtained low attitudes towards science based technology with a gender effect (Kudenko & Gras-Velázquez, 2016). As in other studies girls tend to have less favourable attitudes than boys towards STEM subjects and they show lower job aspirations in the STEM field (Wang & Degol, 2013). We also detected that science based technology is not yet a prominent topic in science lessons at secondary school in Switzerland. This is however not untypical for other regions as well (Jones, Buntting & de Vries, 2013). Hence, up to now, students who have had no contact with technology at home did not have the chance to develop positive attitudes during adolescence. Therefore, the visits in the industry as part of our project ‘STEM becomes a habit in schools’ represent a unique opportunity for students to discover undiscovered talent or interest for STEM professions. It is important to pay more attention to educating students about the career opportunities offered by science (Tytler & Osborne, 2012).
After all, students cannot aspire to that which they have never seen. The second wave of our measurements will show whether students have positively changed their attitudes. This might depend on the individual project each local school-industry cooperation has designed.

STRAND 13: INTRODUCTION

PRE-SERVICE SCIENCE TEACHER EDUCATION

Strand 13 focuses on pre-service science teacher education and invites submissions from researchers working either in preschool, primary and secondary school teacher formation. Specifically, as part of the ESERA 2017 conference, we invited researchers to submit under Strand 13 studies related to professional knowledge of teachers, pre-service teacher preparation, instructional methods in pre-service teacher education, programs and policy, field experience, relation of theory with practice, and issues related to pre-service teacher education reform.

A large number of submissions (146) were reviewed for the 12th biennial conference held in Dublin, and we would like to thank all reviewers for their time and effort. One hundred and three contributions were accepted for presentation under Strand 13: Pre-service science teacher education. Specifically, two symposia, 66 oral presentations, 26 poster presentations, and three workshops were accepted for presentation. This chapter of the e-proceedings brings together 29 submissions from seventeen different countries representing four of the continents: Europe, Africa, Asia and America, proving the international nature of the conference. The papers included in this volume illustrate the trends in pre-service science teacher (PSTs) education across the world currently, and focus on a variety of issues and science disciplines. Specifically, the volume includes studies focusing on chemistry pre-service teacher education; physics pre-service teachers; and primary and pre-primary pre-service teachers. The topics range from studies on PSTs’ content and pedagogical knowledge in specific subjects, interdisciplinary and transversal; on PSTs’ readiness to teach and assess multicultural and inclusive classrooms; on PSTs emotions when engaging in scientific practices; on orientation, interdisciplinary teaching, the use of technology in PST training and the use of video vignettes in teacher training.

We anticipate that this collective volume will become the basis of conversations discussing the changes and challenges in pre-service science teacher education across continents, and that the interest in Strand 13: Pre-service science teacher education will continue to grow.

KNOWLEDGE BASE FOR CHEMISTRY TEACHERS EVALUATED IN BRAZILIAN SELECTION EXAMS

Debora Agatha Andrade¹ and Carmen Fernandez¹,²
¹Science Education Graduate Program, University of São Paolo, São Paolo-SP, Brazil
²Institute of Chemistry, University of São Paolo, São Paolo-SP, Brazil

The literature points out controversies about the knowledge base for teaching that a teacher should dominate. As a result of this lack of definition, there is also a lack of definition about the body of knowledge that needs to be worked on in teacher training courses as well as evaluated in public teacher selection exams. The purpose of this study was to outline the knowledge base for teaching that Brazilian legislation and the public exams for selecting teachers are prioritizing. Our focus was the High School chemistry teachers. The present study brings a qualitative and quantitative survey of the knowledge evaluated in these exams, as well as the analysis of the current public legislation at the time of these chemistry teachers' selection exams. Our analysis was based on the knowledge base for teaching. The mapping of the knowledge base that a chemistry teacher must possess according to the legislation and public selection exams analyzed reveals that a Brazilian chemistry teacher must know the specific content of chemistry, have knowledge of pedagogical theories, be able to interpret texts, know the Brazilian Law of Education Guidelines and Bases of 1996, to know how to use a computer and to have knowledge of basic mathematics. This profile is very far from what the literature of teacher knowledge presents. Judging from the edicts and the public exams, as well as from public policy documents, the Brazilian future teachers basically need to know chemistry but do not need to know how to teach chemistry. From the documents analyzed, there is no specificity of knowledge that distinguishes between the teacher profession and other professions. Thus, the contribution that these analyzed documents offer is a devaluation of the teacher profession, when in fact they should act in the opposite way.

Keywords: PCK, teachers' knowledge, selection of chemistry teachers

INTRODUCTION

There is in literature a range of knowledge, skills, aptitudes and personal characteristics that are taken into account when it comes to the profile of a good teacher. Shulman (1986, 1987) contributed enormously to research on the knowledge base for teaching by developing a research program known as teacher knowledge. In an attempt to represent the knowledge base of teachers, Grossman (1990) proposed a model (Figure 1) that presents the domains of this knowledge, namely: subject matter knowledge, general pedagogical knowledge, pedagogical content knowledge (PCK) and context knowledge. In this model, the PCK occupies a central position, influencing and being influenced by the other domains of knowledge (Fernandez, 2014). The PCK is the knowledge of teachers, which combines content and pedagogy during and for teaching. A teacher with a high PCK, among other characteristics, knows the content well; knows the purposes for teaching it; knows how to conduct the learning process well; is flexible with the content, adjusting it to the level of knowledge of the students; knows how to select the more adequate ways for teaching; is aware of the context in which he teaches and the difficulties of his students and still can evaluate the learning of his students.
Figure 1. Model of the relationship between the domains of teacher knowledge proposed by Grossman (1990)

In Grossman’s model a teacher's PCK is directed by the design of the purposes for teaching specific content. According to Shulman (1986), the knowledge that the teacher develops to teach specific content in a way that favors student learning is the "amalgamation" between content knowledge and pedagogical knowledge. It is built through practice, with the use of your teaching strategies and is a kind of specific knowledge of the professional teacher. It encompasses the appropriate forms of presentations and explanations of a particular topic of the subject and also the understanding of what is difficult or easy for students to learn. With this, we can highlight the difference between a chemist and a chemistry teacher, because the PCK is a knowledge attributed to the teacher, that is, not every specialist in a given area is able to teach with the same specialty because, to teach, knowledge of specific content is only part of the story. The pedagogical knowledge of content is, in general, knowledge about how to teach content to students in a given context (Fernandez, 2014).

There is a wide range of knowledge, skills, attitudes and personal characteristics that are discussed when it comes to being a good teacher and the discussion on this issue contributes to the educational systems that can profile the teacher they want to have. (Gatti, 2013)

The public tender for teachers is the form used by the Brazilian states to make effective teachers who will teach in public schools in Brazil, unlike most private schools that prefer to select their teachers through several stages, which may include the appointment, interviews and regency of presented by the candidate to a team of evaluators of the institution.

In this sense, the selective processes of teachers can give indications of what knowledge is being prioritized to define a good teacher. In this work, we map the body of knowledge adopted by Brazilian legislation that directs the training of chemistry teachers and to map what kind of knowledge has been considered in the public tenders that select chemistry teachers for public school.

**THEORETICAL BACKGROUND**

It is a consensus in the academic literature that a teacher should master the contents he teaches. The existing doubt and discussion is in relation to the level and breadth of that domain. Shulman (1986) defended the idea that a teacher should "understand not only that something is in a certain way, but also the reason for it to be so, on the basis of what evidence this is
justified, and under what circumstances confidence in such evidence can be weakened and even denied.”

For Cooper and Alvarado (2006), the solid subject matter knowledge to be taught is fundamental, since it is necessary that the teacher has sufficient knowledge of contents to teach well. This is a consensus among teachers as well. The lack of this knowledge means that some teachers with poor training who cannot reach other ways of approaching certain content, give their classes supported in textbooks, mechanically, without autonomy to promote innovative activities or develop new strategies for teaching. In addition to subject matter knowledge, other specific knowledge required by the teacher is listed. Several researchers have studied the knowledge base for teaching using various methodologies and theoretical perspectives. Authors such as Tardif (2012), Shulman (1987), Schön (1992) and Perrenoud (2000) generated a series of classifications and typologies about teacher knowledge, some with common elements, and others with subtle differences.

According to Perrenoud (2000), "competence is the ability to mobilize resources to activate cognitive potentials to cope with a type of situation." The author establishes competency domains for the ongoing training of teachers, which includes: organizing and directing learning situations, managing the progression of learning, knowing and evolving differentiation devices, engaging students in their learning and their work, working as a team, participating in school administration, informing and involving parents, using new technologies, face ethical duties and dilemmas in the profession and manage their own continuing professional developing.

Faced with the need for innovation and change, it is already a consensus that it is no longer enough for the teacher to know the subject and teaching techniques, it is necessary also to have access to the knowledge and skills inherent in the profession and to be able to question and reflect on your job. Gatti (2013) says that there is now a great expectation regarding the intellectual education of the teacher, who must have a solid scientific and cultural background, a domain of the mother tongue as well as of the new languages related to the technology of the area in which he is a specialist. When dealing with the profile of the teacher, one should not only discuss what knowledge he has, what he knows, but also discuss his abilities and attitudes, that is, what he must know how to do.

Carvalho and Gil-Pérez (2011) report that until recently, research highlighted the characteristics of the good teacher, or the dichotomy between good and bad teacher. Nowadays, however, they inform us that the focus has now been on what knowledge teachers should have. Managers of educational systems want a teacher as close to the ideal as to spend less time and resources on in-service training. However, even if it comes from a great training course, there are certain components of the profile that will only be fulfilled with the professional experience. It is hoped that the candidate for teaching has had the opportunity to teach, plan activities, select objectives, understand contexts, and other aspects related to pedagogical work (Gatti, 2013).

For Lopes and Freitas-Reis (2015), for example, teaching sciences goes beyond the fixing of terms and concepts; is to create learning situations by enabling the student to have a scientific knowledge base in order to use them as part of their life. It is necessary to reflect on the contents to be taught, how to organize them and to approach them, taking into account the social function of these contents, which should not have a disciplinary character only.
The content knowledge needed by the teacher, according to Carvalho and Gil-Pérez (2011), encompasses the following aspects: knowledge of the history of science; knowledge of the methodological guidelines used in the construction of knowledge; knowledge of Science / Technology / Society interactions associated with the construction of knowledge; knowledge of recent scientific developments and their perspectives; know how to select appropriate content; and be prepared to acquire new knowledge.

According to Shulman (1987), the teacher has a specialized knowledge of the subject, of which he is the protagonist, which he called the Pedagogical Content Knowledge (PCK). Teachers should understand ways to represent content to learners by knowing how to turn content into teaching purposes. Although important, only the full knowledge and mastery of the specific content does not guarantee that the teacher will know how to teach successfully, an extra skill is necessary to make its students understand the content, promoting learning. The PCK represents the ways of formulating and presentation of a certain content, making it comprehensible to students. Shulman (1987) says that the PCK can include analogies, illustrations, examples, explanations and demonstrations, that is, a link between knowledge of content and pedagogical knowledge.

Grossman’s model (already presented in Figure 1) is very well known in literature, hence, can be used as an object of study and bring contributions during teacher training.

The link between content and pedagogical knowledge shapes teachers' decisions about materials, approaches, and assessment. In addition to the pedagogical knowledge of content, teachers should possess general pedagogical knowledge, including skills in the areas of classroom management and discipline. (Cooper & Alvarado, 2006). Among the various knowledge required by the teacher, such as in particular the specific knowledge, pedagogical knowledge, curricular and pedagogical content, there must be an interaction, delineating and giving rise to what we call knowledge of the teaching profession.

According to the Organisation for Economic Cooperation and Development (OECD, 2006) the selection process of teachers must take place "based on clear, transparent and widely accepted standards", highlighting what the candidate must "know" and "know how to do" in order to be effective in their profession. Also according to this organization, the selection of teachers by a central agency, often done in an impersonal way, becomes insufficient to not meet the needs of schools. There is a lack of communication and information for both the selectors and the candidates in this type of selection process. In some European countries there is a very large involvement of the school in the recruitment and selection of its teachers, that is, they have already opted for open recruitment, where each school or place combines candidates with specific vacancies. The open recruitment process, according to the organization, offers the advantage to the candidates to choose the school where they intend to teach and to make contact before the accomplishment of some contract of employment. The OECD questions, however, the effectiveness of impersonal selective processes that many countries adopt. Some of these processes fail to evaluate the teacher characteristics required in their specificities and do not allow the creation of a commitment link of the teacher to the needs of the school where they will act. More direct interaction through personal interviews and school visits by the candidates tends to improve the balance between the needs of the candidates and those of the schools.
Based on this context, the analysis of the questions of the Brazilian public tenders can reveal the types of knowledge required and thus analyze the desired profile of chemistry teacher for state public schools. In addition, from the selection policies, one can strategically define the professional profile for the teacher (Gatti, 2013).

Within this context, this work sought to what type of knowledge of Brazilian chemistry teachers have been considered in the assessments that select chemistry teachers from the public school of the state network. This research, therefore, focused on the analysis of the knowledge requirements present in the examinations of selective processes and its public tender notices, for the positions of professor of chemistry of the High School of the state public schools, that are governed by the Secretary of Education of each Brazilian state.

**METHODOLOGY**

We analyzed the official training documents of chemistry teachers in Brazil and the tests of teacher selection from 2005 to 2013. To base the analysis we used the categories of Grossman's model (Figure 1). Sixty examination tests were analyzed, in a total of 3576 of objective questions, 39 of discursive questions with their items and sub items and 16 tests in which a writing was required. There were 12 tests from the Northern region (Acre, Amazonas, Amapá, Pará, Rondônia and Tocantins states), 17 from the Northeast (states of Bahia, Ceará, Maranhão, Paraíba, Pernambuco, Piauí, Rio Grande do Norte Sergipe) 6 from the South (Paraná and Santa Catarina), 16 from Southeast (states of Espírito Santo, Minas Gerais, Rio de Janeiro and São Paulo), 9 from Central-West (Federal District, Goiás and Mato Grosso). The distribution of the tests by the Brazilian states is presented in Table 1 and in the Figure 2.

**RESULTS AND DISCUSSION**

**Analysis of the Brazilian public legislation for the training of chemistry teachers**

In the National Curriculum Guidelines for the Training of Basic Education Teachers (Brazil, 2001a), it appears that contents must be treated in three different dimensions: conceptual (theories, concepts, information); Procedural (know-how); and attitudinal (values and attitudes). The profile idealized by the document for the chemistry teacher is suggested with some skills and abilities, observed from the point of view of the components of the Grossman model as follows:

**Subject Matter Knowledge**: to have a solid knowledge of the specific content; understand concepts, laws and principles of chemistry, know the physical-chemical properties of materials and their behaviors; be prepared to engage in research and projects related to the chemical education; understand the steps and processes of a research in chemical education; follow the educational and scientific advances of the chemistry area; to recognize chemistry as a human product and to understand its relations and its historical aspects; know how to search and identify important sources of information in the area and understand the scientific-technological texts, how to interpret and use various forms of graphic representation and expressions; to know the characteristics of the chemical education research; to experience projects and curricular proposals for the teaching of chemistry; incorporate research results favorably into their practices; know how to work in a team.

Figure 2. Distribution of exams by States and Regions of Brazil

General Pedagogical Knowledge: to know psychopedagogical theories about teaching-learning process and principles of educational planning (students and learning); act in accordance with current legislation; have the ability to critically evaluate existing didactic resources in the market (curriculum and instruction).
Pedagogical Content Knowledge: prepare the students for the conscious exercise of citizenship (conception of the purposes to teach a specific content); to arouse the scientific interest in its students and to act for their intellectual development; reflect their practice in the classroom and know how to identify teaching / learning problems (knowledge of students' understanding); know how to work in the laboratory, use this space in class, use creativity in solving problems and educational challenges during chemistry teaching; be able to provide didactic and instructional resources; know how to use computers; knowing how to interpret and use various forms of graphic representations; knowing how to communicate and present research results and projects (knowledge of instructional strategies).

Context Knowledge: knows how to evaluate the role of science in society and to recognize the involvement of ethics in some decisions; know how to critique social, technological, environmental, political and ethical aspects related to chemistry in society; to be socially aware of their profession, to be able to disseminate and disseminate relevant knowledge to the community; to know the educational reality, to consider the context in which it is inserted as a professional, to know the Brazilian educational problems, to consider the social, economic and political context of the school reality; to carry out activities that collaborate with society through their professional training.

The Opinion of the Education National Council (CNE / CES 1.303 / 2001 - Brazil, 2001b) is the one that points out the National Curricular Guidelines for Chemistry Courses. This document informs that the essential curricular contents are those that involve the theory and the laboratory, and the basic curricular contents are those of Mathematics, Physics and Chemistry. The specific contents are those that differentiate each course, that is, the "professional contents", which higher education institutions are freer to format according to the professional profile they wish to form. Extra-class academic activities are those that occur through professional practice, through internships, monitoring, participation in congresses and other events, and where credit is given. The complementary contents are those offered by the institution that are more comprehensive in the theme and even common to courses in other areas. Table 2 presents the skills and abilities cited in this document and categorized according to the Grossman model.

Opinion 01303/2001 often uses terms related to specific content. The topic content knowledge appears in this text in a more specific way: in the section "to understand the steps of a research" and in the item "to know the fundamentals and nature of the researches in Chemistry", related to the idea of the substantive and syntactic structures of the Grossman model. General pedagogical knowledge appears less strongly but is still present. It is distributed in the items that compose the skills and competences as in: "knowing psycho-pedagogical theories about teaching-learning and principles of educational planning". The context knowledge category is present in "understanding and evaluating technological, environmental, political and ethical social aspects" and in several other sections. The pedagogical knowledge of the content appears timidly in some sections that we can relate to this category, such as the "searching for relevant information, knowing how to interpret and using different forms of representation".

With respect to the 60 tests of selection of professors of chemistry evaluated we had 3,758 occurrences of subjects in the 3,576 objective questions and in the twenty tests of essay questions. The final result is presented in Figure 3, where the predominance of questions that require the specific knowledge of chemistry is evident.

Figure 3. Occurrences of all categories (%) in the 60 tests of selection of chemistry teachers

The themes that predominate in the category of chemical knowledge are Aqueous solutions and concentrations (5.9% of all occurrences in this category); Stoichiometry (5.2%) and Thermochemistry (5.0%). In the Portuguese language knowledge category: text interpretation (23.1%). In the category pedagogical knowledge, the predominant theme was Guidelines and Basic Law (9.2%), evaluation (8.7%) and pedagogical theories (8.1%). In the category Others, the predominant theme is computer science and new technologies (22.9%), mathematics (14.4%) and public administration, regional geography and economy (10.2% each).

Very few tests work with essay questions. Out of 60 tests, only 20 contained essay questions. The predominance in these questions is pedagogical knowledge (41.5%), specific content knowledge (31.7%), pedagogical content knowledge (22.0%) and context knowledge (4.9%). There was not a single issue where the candidate had been exposed to a real classroom situation.

CONCLUSION

The chemistry teacher profile that has been selected in public exams for Brazilian chemistry teacher is the one who must master the specific content of chemistry, have knowledge of pedagogical theories, be able to interpret texts, know the Law of Guidelines and Bases, and know to use a computer. The official documents are broader, but they also do not approximate their guidelines to what the chemistry teacher will face in the classroom.

On the other hand, through the teacher knowledge literature presented, what a teacher needs to know is much broader and deeper than what appears as a result of this research. Judging by public examinations, as well as Brazilian public policy documents, Brazilian future chemistry teachers basically need to know chemistry but do not need to know how to teach chemistry.

PRE-SERVICE CHEMISTRY TEACHERS’ CONCEPTIONS
OF HOW TO TEACH ‘ACIDS AND BASES’

Anja Lembens¹ and Katrin Reiter²
¹²University of Vienna, Austrian Educational Competence Centre Chemistry, Vienna, Austria

The topic ‘acids and bases’ is an important part of the Austrian syllabus for chemistry in secondary schools. On the one hand, it allows the establishment of cross-connections to everyday experiences and phenomena, and on the other hand, it is a rewarding example for chemical reactions following the ‘donator-acceptor-principle’ as a basic concept. In order to teach ‘acids and bases’, teachers have to draw on (amongst other things) a proper understanding and using of the particle concept, thinking in models, dealing with different historical explanatory approaches, and planning and interpreting appropriate experiments. Furthermore, teachers have to know about the significance of learners’ conceptions for teaching and learning this topic and how to deal with them. For this reason, pre-service chemistry teacher education has to provide opportunities to learn, apply, and reflect on such knowledge and competencies so as to build up professional knowledge and skills. This paper provides an insight into a pre-service teacher education course in chemistry didactics and students’ progress on their way to developing an appropriate professional knowledge and skills concerning the topic ‘acids and bases’. Having taught this university course for several semesters, we realised that – for all our efforts – at the end of the term many students still struggle with their own misconceptions concerning ‘acids and bases’ and still confound different models. To investigate how these specific difficulties manifest themselves, we used a questionnaire and started to analyse videotapes of the students’ microteachings. Selected findings from the questionnaires compiling students’ conceptions as well as a first insight into the analysis of the microteachings will be presented and discussed. Furthermore, possible reasons for students’ persistent confusions concerning the topic ‘acids and bases’ are extracted from the literature and summarised.

Keywords: pre-service teacher education, conceptual change, microteaching

‘ACIDS AND BASES’ AS FRAMEWORK FOR AN INTRODUCTION IN CHEMISTRY DIDACTICS

The chapter ‘acids and bases’ is an important part of the Austrian syllabus for secondary schools where it is embedded within the basic concept ‘donator-acceptor-principle’. The syllabus follows the definition of acid-base-reactions as proton-transfer-reactions and also refers to it in connection with the topic ‘chemical changes’ focusing on ‘protolysis equilibrium’. Corresponding to this, all textbooks for chemistry in upper schools use the acid-base definition following Brønsted.

In order to be able to teach this and other topics successfully, chemistry teachers need a sound knowledge of chemistry as well as profound pedagogical and didactical knowledge and skills. To develop an appropriate professional knowledge and skills, student teachers have to build up a reliable bridge between chemistry-related content knowledge and knowledge of instructional strategies for teaching chemistry.
For this, they need …

- a strong and reliable content knowledge base
- knowledge and appreciation of learners’ conceptions and their specific difficulties with ‘acids and bases’
- knowledge about different representations, models and approaches to deal with ‘acids and bases’
- knowledge about student-oriented teaching and learning strategies for ‘acids and bases’ and
- skills to plan, conduct and reflect effective learning environments.

The course ‘Introduction to Chemistry Didactics’ at the University of Vienna offers an opportunity to do so. Accordingly, our teaching goal is to support student teachers to develop their ability to teach ‘acids and bases’ successfully. To introduce pre-service chemistry teachers to the challenges of teaching chemistry at school, and to start discussions about the relevance of learners’ (pre-)conceptions, the students are asked to complete a questionnaire referring to selected basic aspects of the topic ‘acids and bases’. This is aimed at stimulating students’ reflection about their own (mis-)conceptions, triggering conceptual change, and introducing the importance of knowing about learners’ pre- and alternative conceptions for fruitful teaching and learning. Building on this discussion, students are introduced to selected papers from international journals dealing with the relevance of knowing about and dealing with learners’ alternative and mis-conceptions in general as well as those concerning ‘acids and bases’. The problem of mixing up different models (Arrhenius and Brønsted) and the subsequent confusions are specially stressed (cf. Van Driel & Verloop 1999, 2002; Barke 2015). The next relevant step is to link content knowledge with suitable instructional strategies. To stimulate this, students are assigned to construct a Content Representation-table (CoRe) following Loughran et al. (2012). Based on this and to merge theory with practice, students are now asked to design and conduct a 15 minute learning opportunity (microteaching) in the context of ‘acids and bases’ in which they have to address one selected ‘big idea’ (out of the CoRe), as well as one competence appropriate for this ‘big idea’. The resulting microteachings are videotaped to give students a basis to reflect on the pros and cons of their lessons. In their final papers, students have to select two sequences of their microteachings (a good and an improvable one) and reflect on them while bringing together their theoretical knowledge and practical experience using arguments based on relevant literature. These reflections can be seen as a mirror of students’ actual pedagogical content knowledge and skills.

Based on the experience of several courses, we realised that at the end of the term many of the student teachers still struggle with their own mis-conceptions concerning ‘acids and bases’, they still mix up the macroscopic level and the sub-microscopic level and confound different models. For this reason, we decided to immerge deeper into the matter to get answers to the following questions:

- What are student teachers’ main problems while teaching ‘acids and bases’?
- What are the prevalent characteristics and manifestations of these problems?
To do so, we decided to apply the questionnaire not only at the beginning but also at the end of the courses. In addition, we started to develop an analytical framework so as to systematically analyse the microteaching videos which could then be used to identify and better understand student teachers’ main problems when teaching ‘acids and bases’. Using these insights, we aim to design and test learning opportunities to help student teachers overcome these problems.

In the following, we present a short insight into selected students’ perceptions to give an impression of the challenge student teachers as well as teacher educators face in pre-service chemistry teacher education. Firstly, we will outline the difficulties pre-service chemistry teachers seem to have with the topic ‘acids and bases’ by giving insight into selected findings from 218 questionnaires (ten closed-ended questions; most of them with the request to give reasons for the decision). Only since winter semester 2016-17, students are asked to complete the questionnaire at the end of the term as well. Secondly, we will sketch the analysis of the videotaped microteachings, which has only recently started, to identify and characterise students’ struggle with teaching ‘acids and bases’, and thirdly, we will discuss the causes that possibly lie behind these matters of facts.

**PRE-SERVICE CHEMISTRY TEACHERS’ STRUGGLE WITH THE TOPIC ‘ACIDS AND BASES’**

One of the main problems seems to be that many student teachers use the terms ‘acid’ and ‘acidic solution’, as well as ‘base’ and ‘basic solution’ synonymously. This becomes apparent in students’ answers to the questions whether ‘HCl is muriatic acid’ and if ‘NaOH is soda lye’ (Figure 1).

![Figure 1. Students’ perceptions concerning the difference between acid and acidic solution respectively base and basic solution (N = 218)](image)

For example, students’ give the following reasons for the chosen answer:

- Because muriatic acid is the trivial name of hydrogen chloride.
- Because we learned it that way.
- Because OH⁻ ions can be separated.
- Because NaOH likes to accept H⁺.
It becomes obvious that students do not distinguish between hydrogen chloride, which is a gas, and muriatic acid, which is the aqueous solution of hydrogen chloride. Furthermore, strictly speaking HCl stands for one hydrogen chloride molecule and not for the substance, the gas, consisting of a vast number of hydrogen chloride molecules. The same applies analogically to NaOH and soda lye; with the exception that sodium hydroxide consists of ions. Another point is the argument of some of the students that ‘NaOH is soda lye because OH\(^-\) ions can be separated’. Firstly, sodium hydroxide (Na\(^+\)OH\(^-\)) is a solid substance consisting of sodium ions and hydroxide ions. Secondly, the students’ reasoning goes back to the Arrhenius model and disregards the fact that it is not the release of hydroxide ions that is responsible for the basic character but the ability of the hydroxide ion to accept a hydrogen ion (proton).

In the laboratory jargon, the aqueous solution of hydrogen chloride, the muriatic acid, is repeatedly labelled as ‘HCl’ and the respective bottles are commonly marked with this label. Chemists know what they mean when they use the term ‘HCl’ while talking about muriatic acid, but learners are irritated when teachers do not distinguish clearly between acid (hydrogen chloride molecule; HCl) and acidic solution (muriatic acid; chloride ions and oxonium ions and water molecules; Cl\(^-\)(aq) + H\(_3\)O\(^+\)(aq)). In this case, learners will probably have no chance to understand acids in terms of Brønsted as particles from which hydrogen ions (protons) can be removed (Barke, 2015). The same applies for bases and basic solutions. As a result, learners at school, as well as student teachers, are not able to recognise the formation of water molecules (H\(_2\)O) out of oxonium ions (H\(_3\)O\(^+\)) and hydroxide ions (OH\(^-\)) as the driving force of the neutralisation reaction. In the laboratory jargon, scientists seldom differentiate between the macroscopic (phenomenon level) and the sub-microscopic (particle level) level (Johnstone, 2000), which also causes confusion amongst the learners because it is not clear whether the substance or the particle is referred to.

These problems are also mirrored in students’ responses to the following item: Students were asked to quote whether the statement ‘During the neutralisation acid and base react under formation of salt and water.’ is appropriate or not. Phrases like this can be found commonly as take home message in textbooks and learners’ exercise books. Only 24 out of 218 student teachers realised that this statement causes trouble in several aspects. For instance, students give the following reasons for their answers:

- \[\text{NaOH} + \text{HCl} \rightarrow \text{NaCl} + \text{H}_2\text{O}.\]
- acid splits off H\(^+\) \(\rightarrow\) turns to salt; base splits off OH\(^-\); \(\rightarrow\) OH\(^-\) + H\(^+\) \(\rightarrow\) H\(_2\)O
- Because salts have a neutral pH-value.

Student teachers seem not to be aware of the following three points: Firstly, the term ‘neutralisation’ describes one special case of neutralisation reactions, in which equimolar quantities of hydrogen ions and hydroxide ions react under the formation of water molecules and the pH-value ends up at pH 7, therefore neutral. The unambiguous term in this statement should be ‘neutralisation reaction’ instead of ‘neutralisation’. Secondly, in chemistry the term ‘salt’ is used to refer to an ionic compound in which the ions are arranged in a solid ionic crystal. The word ‘Salt’ in the mentioned take home message, on the other hand, is used for ions in an aqueous solution (e.g. Na\(^+(aq)\) und Cl\(^-(aq)\)) which is misleading. Thirdly, these ions do
not play any role in the abovementioned reaction. In the context of neutralisation reactions, the only relevant reaction is the one between oxonium ions (H$_3$O$^+$) and hydroxide ions (OH$^-$) forming water molecules (H$_2$O).

Subsequently, the focus is laid on students’ answers and reasoning to two related questions with four answers at choice in each case. Only one answer is considered to be correct (here in bold type):

1. **What is the difference between a strong and a weak acid?**
   a. Strong acids have a higher pH-value than weak acids.
   b. Strong acids contain more hydrogen atoms than weak acids.
   c. Strong acids are more concentrated than weak acids.
   d. **Strong acids ionise more than weak acids.**

2. **What has to be known so as to make a clear statement about the strength of an acid?**
   a. The concentration.
   b. The number of hydrogen atoms in the compound.
   c. **The potential degree of ionisation in water.**
   d. The pH-value.

The strength of an acid or a base is often falsely described with a pH-value that is notably low or notably high for strong acids or strong bases, respectively. Almost twenty percent of the student teachers are not aware of the fact that it is only the degree of ionisation that can be used to characterise the strength of an acid or a base.

This outcome does not seem to be alarming at first. In the following work with the student teachers, when they have to plan and conduct a learning opportunity, however, it becomes apparent that most of them have considerable uncertainties with regard to their subject matter knowledge. For example, they frequently try to show the strength of an acid using an indicator or they argue that strong acids are more concentrated than weak acids (Lembens & Becker, 2017). This problem is not only due to different meanings of the word ‘strong’ in everyday and technical language. In addition to this discrepancy in meaning in everyday and technical language, there were partially or even wholly incorrect statements in textbooks mainly for lower secondary schools (e.g. ‘strong acids have a low pH-value’) which student teachers, as well as in-service teachers pass on without further reflection.

Figure 2 shows only the participants of the last two semesters who filled out the questionnaire at the beginning and at the end of term. We can see an improvement from 54 (76%) correct answers to 58 (89%). In fact, all the participants of summer term 2017 ticked the correct answer at the end of the semester.
Figure 2. Students’ perceptions concerning the difference between a strong and a weak acid (Question 1). Semester 2016/17+17; pre and post (N = 75; pre 5 absent, post 14 absent)

Strongly interrelated with this question is question 2 (‘What has to be known so as to make a clear statement about the strength of an acid?’). The answers to question 2 emphasise the subject-specific uncertainties of the student teachers. Only half of the participants recognise the fact that ‘The potential degree of ionisation in water.’ is what has to be known to make a clear statement about the strength of an acid. Even though 176 (81%) of the same students seemed to know that the difference between a weak and a strong acid is defined as the potential degree of ionisation in water, they struggle with this closely related question. Figure 3 again only shows the participants of the last two semesters who filled out the questionnaire at the beginning and at the end of the course. We can see an improvement from 45% correct answers to 60%. However, what seems to be rather problematic for us is to know that there are still 40% of the participants with inappropriate conceptions at the end of the course.

Figure 3. Students’ perceptions concerning what has to be known so as to make a clear statement about the strength of an acid (Question 2). Semesters 2016/17+17; pre and post (N = 75; pre 5 absent, post 14 absent)
The inconsistency in the replies to these two questions show rather clearly participants’ deep uncertainty concerning the topic ‘acids and bases’.

As mentioned above, these troubles also become obvious when the teacher students plan and conduct their microteachings at the end of term.

**Microteachings reveal student teachers’ inappropriate conceptions**

Microteaching refers to a teacher education technique that consists of a well prepared and videotaped mini-lesson. This is followed by a review in order to obtain constructive feedback from peers and supervisors, and to improve the teaching and learning experience. Preparing the lesson, watching the video and reflecting about what has worked out well and which improvements could be made, provides students an authentic and intense view of their own teaching. Hattie considers microteaching as an effective method for improving student outcomes and ranks it among the top five effects on student learning and achievement (Hattie, 2012). By now, we have collected experiences with microteachings from nine semesters (with a minimum of four per semester) and have developed the impression that students often do not seem to be able to design and conduct a 15-minute learning opportunity that is free from subject-specific shortcomings. The microteachings at the end of term reveal several obstacles, such as mixing up the Arrhenius with the Brønsted model, confusing the phenomenon and the particle level, using unclear language, as well as raising subject-specific shortcomings.

A very frequent problem appears to be the fact that many students use the terms ‘acid’ and ‘acidic solution’, as well as ‘base’ and ‘basic solution’ synonymously, not being aware that they address the particle level when saying ‘acid’ and the phenomenon level when saying ‘acidic solution’. Furthermore, they are confusing themselves while referring to hydrogen ions, when talking about the properties of acids and hydroxide ions when referring to the properties of bases, not perceiving that they are mixing up two different and incompatible models.

To systematically investigate how these specific difficulties are manifesting themselves, we started to develop an analytical framework to analyse the microteaching videos with the aim to identify and understand student teachers’ main problems when teaching ‘acids and bases’. The first step was to get a general idea of which problems and misconceptions occur during the microteachings. Based on the big ideas from the collaboratively developed Content Representation-table (CoRe) (Loughran et al., 2012) and findings from literature, several categories for the analytical framework were defined as a starting point. This category-system is now enhanced and extended inductively while analysing relevant parts of the videos in detail. Afterwards, the revised category-system will be used for a detailed analysis of all video-taped microteachings.

Using the findings from the systematical analysis of the microteachings and the questionnaires, we do not only want to identify the student teachers’ main problems with the subject matter and their prevalent characteristics, but also strive to design and test more effective learning opportunities for pre-service teacher education to overcome outlasting misconceptions regarding the topic ‘acids and bases’. In order to do so, we also draw on preceding findings from the literature.
SEARCH FOR POSSIBLE CAUSES: INSIGHTS GAINED FROM EDUCATIONAL RESEARCH

Why are student teachers so uncertain while dealing with the topic ‘acids and bases’? This question suggests itself while working with the student teachers. All of them have learned about ‘acids and bases’ in school, they passed the exam of a basic lecture on chemistry called ‘General Chemistry’ and the corresponding practical course at university. Obviously these learning opportunities are not suitable to help the students to build up a scientifically appropriate conception about the topic ‘acids and bases’. At this point, the question why this happens asserts itself.

In lower secondary education, ‘acids and bases’ are mostly taught in accordance with the model by Arrhenius, which defines acids as substances that release hydrogen ions in water and bases as substances which release hydroxide ions in water. This definition remains very stable in the minds of learners which may be the reason for their difficulties in replacing this concept later on with the scientifically more appropriate model by Brønsted. Brønsted defines acids as particles from which hydrogen ions can be removed and bases as particles which can accept hydrogen ions. Using the Brønsted model, we are able to describe acid-base-reactions beyond aqueous solutions. Despite learning and knowing the new Brønsted or Lewis model in upper secondary school, learners see no significance for a conceptual change and retain the Arrhenius model they initially apprehended, and additionally, they mix up the different models without being aware of this (Lembens, 2017).

Several studies reveal that experienced teachers’ knowledge and conceptions about models of acids and bases may also be limited and confused (Van Driel & Verloop 1999, 2002). Teachers often lack knowledge of learners’ conceptions about models and their function in science, or this knowledge is not expressed in planning and conducting lessons. Justi & Gilbert (2000) show that teachers often do not refer to particular models while teaching chemistry, but rather transfer properties from one model to another, which finally leads to teaching hybrid models. This in turn inevitably causes confusion amongst the learners. Drechsler & Schmidt (2005) found that not all chemistry teachers are aware of the existence and the applicability of the different historic and recent acid and base models. To prepare their lessons, they consult textbooks which mostly neither discuss explicitly the application of models nor the distinction between the different models – thus, they also apply hybrid models.

As a consequence of such textbooks and such teaching at school, we find pre-service chemistry teachers in our university courses whose thinking is dominated by the limited Arrhenius model. They are not aware of mixing up different models, and do not distinguish between the macroscopic and the sub-microscopic level. Therefore, they are hardly able to define acids and bases beyond ‘acids have a pH-value lower than seven and bases have a pH-value higher than seven’ and furthermore, they do not distinguish between acids and acidic solutions and bases and basic solutions, respectively, while confusing the particle level with the phenomenon level. The technical chemistry courses at the beginning of their education at the university do not seem to offer sufficient learning opportunities to develop scientifically appropriate conceptions or to see the need to reflect about one’s own understanding of subject matter knowledge. The prevailing concepts seem to be extremely resistant to change, which reveals itself during the
Microteachings at the end of the course ‘Introduction to Chemistry Didactics’. Obviously, even our course does not enable all student teachers to carry out a conceptual change.

**NEXT STEPS**

The next steps on our way to develop and test effective learning opportunities in the context of ‘acids and bases’ are: to review the most common textbooks for primary and secondary chemistry teaching in Austria; to conduct interviews with experienced chemistry teachers; to further develop and validate the analytical framework for the analysis of the microteachings; to analyse the microteachings; to identify and characterise student teachers’ main obstacles; to develop, test and refine effective learning sequences and, at the end, to write an evidence-based didactical program for fruitful and effective teaching in the context of ‘acids and bases’.

**ACKNOWLEDGEMENT**

We thank all student teachers and our colleagues at the Austrian Educational Competence Centre Chemistry for irritating and fruitful discussions stimulating our reflection about our own understanding in the context of ‘acids and bases’.

Research on teacher education recognizes that there is a basic knowledge to the profession. In this paper we adopt the view that the Pedagogical Content Knowledge (PCK) is the articulating element of the Knowledge Base for Education, the core knowledge of a teacher. In the process of chemistry teacher education several actions are conducted to develop the knowledge necessary for teaching across different disciplines and activities, but still little study on the influence of the formative action of teacher educators in the chemistry teaching practice of its undergraduates. The ultimate goal is to point out the relationship between the formative action of teacher educators and the knowledge mobilized during teaching practice for chemistry student teachers. The research is qualitative in that a multiple case study was conducted with three chemistry student teachers and twelve of their trainers by having as teaching focus the content redox reactions. Therefore, the data collected with the undergraduates were based on Content Representation (CoRe), interviews, materials used in classes, field diary records and internship reports. Data from teacher's formers were based on interviews, CoRe, educational materials for teachers and written records of the classes. The analyses of the data were based on the Bourdieu's understanding to describe the relationships of power and the reproduction of practices within a field. The methodology of content analysis was used with support of the ATLAS.ti software in the analysis of the data set. It was possible to identify evidence of the influence of trainers on student's teachers from the triangulation of data. The results point out to differences in the incorporations done by undergraduates of theoretical elements and aspects of teaching practice from trainers with distinct characteristics and knowledge derived from the practice of teachers of subjects in the fields of chemistry and pedagogy.

Keywords: formative action, PCK, teacher trainers.

INTRODUCTION

The profession of teacher educator requires the development of specific knowledge, skills and abilities that are not always built in the context of undergraduate or graduate training. Teaching someone knowledge is not the same as teaching someone to teach that knowledge to others. Vaillant (2003) in mapping the situation in Latin America, points out that the Latin American trainer has little information and knowledge to support his training activities and that he continues to develop his teaching based on the education received as a student, whether in basic education or higher.

In Brazil, in order for someone to become a professor of higher education, he is asked to have a graduate education, with no request for mastery of specific skills and abilities to teach; the same is true for those who will be trainers of new teachers: they do not need to have any experience and specific knowledge for teaching.
In the context of this research, we assume that teacher trainers "are all professionals involved in the learning processes of the teaching of future teachers or those who are already developing teaching activities: teachers responsible for university courses as Teaching Methodologies and Supervised Internship, those of the pedagogical disciplines in general, those of the specific disciplines of different areas of knowledge and the professionals of the schools that welcome the future teachers "(Mizukami, 2005).

In this work we understand the knowledge necessary for teaching in the perspective of the knowledge base for teaching of Grossman (1990), namely: subject matter knowledge, general pedagogical knowledge, knowledge of the context and pedagogical content knowledge (PCK). Among the knowledge of this base, the PCK is considered the central professional knowledge of teachers (Kind, 2009; Fernandez, 2014).

We also use the idea that the trajectories of personal and professional formation influence the way of being and teaching. The linking pictures (Josso, 2006) and how we connect and learn from others tell us a lot about what we do or do not do, about our confidence in our abilities, our commitment to doing things the best way.

Every life story is a real plot. It is the social plots, the relationships with the other, that people invoke when telling their life stories and that are far from being autonomous. It is because the human being does not live alone but in a world relations. Generally, individual stories are dependent on wider social frames, sometimes embedded in them, and sometimes resulting from them. It is at this point that we come to consider a metaphor proposed by Josso (2006), of the connection figures as sailor knots. Josso justifies the use of the metaphor by saying:

"[...] The attempt to use this metaphor is to give the impression that the connection is at the same time what gives a support, that holds and that maintains a relative stability, that allows the movement in a defined perimeter, but also what prevents to leave this perimeter, which goes in, which can be hurt when trying to achieve freedom without achieving it, which undoes more or less easily to find freedom of movement. The node also refers to the complexity of the connection, joining two wires or strings to many other wires. There is, therefore, in this metaphor, also, the two and the greatest number. There is no human being who is not, re-connected, connected, or symbolically like Robinson Crusoe. Hence the importance of the theme of the connection in the understanding of our process of formation and knowledge. (Josso, 2006).

In addition, we rely on Bourdieu (1983), especially on the notions of Field, Capital and Habitus to understand how the formative action of teacher trainers influences the teaching practice of their graduates. Bourdieu assists us in understanding how the social space of university teaching is organized, how the social, cultural, symbolic and scientific capitals of the trainers influence their teaching and the power relations present between the agents of the different training areas that make up a course of chemistry teacher education.

In Bourdieu the discussions about the Field are intertwined with other notions such as those of Capital and Habitus and pass through their works at different times, addressing the most diverse areas: fashion, literature, science, religion, marriage, education, politics, among others. The Field is a social space that has a particular structure, with specific objectives, that works relatively autonomously in relation to other social spaces, refers to a "[...] universe in which agents and institutions are inserted which produce, reproduce or diffuse art, literature or science. This universe is a social world like the others, but obeying more or less specific social laws "(Bourdieu, 2004).
It is common the analogy of the field with a game, with its rules, created by its players, but that are not always clear to all who participate in the game. Some agents or institutions are able to create or change the rules and do so because of the Capital they hold and the position they hold in the field. Thus, there is a constant struggle between the agents of the field who hold the greatest amount of capital and dictate the rules of the game, the norms of the Field, and define which is, at a given moment, the set of important objects for the field. On the other side are those who threaten the position of the dominant ones by conquering enough capital to become important. The different forms of capital that allow for different structural configurations of the Field are: economic capital, cultural capital, social capital and symbolic capital.

Habitus is defined by Bourdieu as "a system of durable and transposable dispositions which, integrating all past experiences, functions at every moment as a matrix of perceptions, appreciations and actions - and makes possible the accomplishment of infinitely differentiated tasks, thanks to the analog transfer of schemes" (Bourdieu, 1983). The experiences lived by each person in function of their position in the field effect their subjectivity, composing a "matrix of perceptions and appreciations", which guides their actions in later situations. The habitus would then be the result of the incorporation of the social structures and the place of origin of the person in the field, which would "structure the actions and representations of the subjects" (Nogueira & Nogueira, 2004).

It is through habitus that the past survives at the present moment and tends to remain in the future actions of the social agents. This, according to Bourdieu (1983), is a process of interiorization of exteriority and exteriorization of interiority. Everything that characterizes a social position that the individual occupies (tastes, preferences, symbols, beliefs, gestures) is incorporated by him, not always consciously, and becomes part of the composition of the individual himself, that means becomes a habitus. And it is from this generating matrix of actions that individuals act, guided by a practical sense that was constituted in the historical moment that they lived.

Studies in the perspective of life histories show that in the first years as a teacher, we refer to images, personal and professional postures, to the performances of teachers who have remained in our memories. So, we can infer that "our formative processes do not begin in an intentionally chosen course, but in the different spaces and times where we already live the student experience" (Cunha & Isaia, 2006). That is, our history of education is marked by the course of student and teacher life that we have characterized as an ongoing process whether it is reflected or not.

**METHODOLOGY**

This research is characterized as a multiple case study (Yin, 2010) to be carried out with three undergraduate students of the Chemistry Teacher Education course from a Brazilian public university (identified anonymously as Adriano, Juliana and Rafaela ) and eleven of their training teachers (encoded as P1, P2, till P11). We used the method of life stories during the conduct of interviews. The data collection was carried out in a specific situation - the practice of teaching redox process in basic education, during 2011 and 2012. For the evaluation of the basic knowledge of the teaching we preceded a multireferential analysis (Baxter & Lederman,
Data were collected from multiple sources, including semi-structured interviews, lesson plans, teaching practice reports, teacher journals, guided reflections written by student teachers', teacher work samples and class notes written by undergraduates in various disciplines. The steps can be summarized in: i.) identification of Knowledge Base for teaching and PCK of chemistry student teachers; ii.) indications of didactic practice on student teachers classes related to their trainers; iii.) Crossing ideas and stories. Data analyzes include categories from the Model of Teacher Knowledge (Grossman, 1990) and Hexagonal model of PCK for science teaching (Park & Oliver, 2008). We also use the Atlas.ti software to help with the analyzes.

RESULTS AND DISCUSSION

In a first analysis we outline the state of development of the knowledge for the teaching of the undergraduates. In a descriptive-interpretive work, we seek to clarify what each student thinks and what each one does by teaching the theme oxireduction, pointing out how different knowledge can influence the development of the other components of the base and the PCK. We analyze the knowledge for the teaching of the trainers and show how they understand their responsibility in the training of the pre-service chemistry teachers.

In analyzing the relationships between life histories, we sought the bonds that were established between the subjects, the networks of relationships in the histories of their lives in the academic period, to understand what relationships were established and what kind of link they generated among the participants in the search. With this analysis we intend to identify elements of influence of the formative action of the trainers in the habitus and the basic knowledge of the teaching of the pre-service teachers from the bonds between the individual and collective life histories of each pre-service teacher and teacher.

At the same time, we delineate the capital and habitus of the trainers and of the undergraduates, identifying how the variation of the capital volume of each component of the university teaching field in the undergraduate course in Chemistry Education analyzed puts it in different positions in the field itself, as it generates new relations among agents and is reflected in the construction of the individual and collective habitus of the pre-service teachers, and as elements of this habitus appear in the teaching practice of the student teachers.

In the analysis of the capital and the habitus of the trainers we identify individual characteristics of each agent and aspects common to each group of teachers (of specific content and pedagogical / methods disciplines).

We present in Table 1 a summary of the constituent elements of the contents of the disciplines of the Chemical Education course and / or aspects present in the formative action of the different teacher trainers that were incorporated into the knowledge for the teaching and for the PCK of the student teachers. Formative action is composed by what is taught and how it is taught; in other words, the contents of the subjects and the teacher's conduct of the classes he teaches, the activities he develops, and the way he organizes class actions.

For the construction of Table 1 were listed the most characteristic elements of the teaching practice of each student teacher, recognized from the analysis of their knowledge for teaching
and their teaching habitus. From the description of these elements we look for in the syllabus of the disciplines taught by the trainers which of those elements were constituents of the disciplines. We analyzed the logbooks and materials provided by the teachers to identify if that aspect was commonly evidenced in the teaching practice of the teacher.

</table>
Adriano incorporates quite a lot of the idea that P6 has about conducting experimental classes: students need to do! At various times in their classes this is evidenced by situations in which the students must conduct the activities, they must organize themselves to understand the process of the experiment and act on the theoretical proposal of accomplishment of the experimental activity. Regardless of the direction of the experimental activity - investigation or verification of knowledge - Adriano requests that the students prepare the solutions, calculating the amount of reagent required for each concentration. He speaks in one of the analysis documents of his practices that:

[...] in conducting activities in this way students have the opportunity to discuss, question their hypotheses and initial ideas, and also, when they work in an investigative way, collect and analyze data to find possible solutions to the problem.

Juliana incorporates the understanding of the importance of the work with the modeling in the chemistry teaching of P7 and P10 and makes use strongly in its classes of activities with models for the oxirreduction subject, especially for the submicroscopic process of the transfer of electrons that occurs in a reaction of oxidation. Besides being present in his classes this was reported in the interview and in the CoRe. Juliana works from the knowledge of the students' alternative conceptions, for example, before beginning the development of the subject in class she seeks to know: *Can an Oxidation process be separated from a Reduction process? Why?*. To develop the idea that the two processes are complementary, she produces for her classes a didactic video that shows the reaction of a piece of metal with an acid (Zinc and Hydrochloric Acid). The video is part of a simple experiment carried out in the classroom by the student teacher to illustrate an oxidation reaction and to relate the three representational levels: macroscopic, submicroscopic and symbolic. In the video, from the visualization of the same experiment done in the room, the student teacher applies a zoom tool to illustrate what happens at the submicroscopic level with the chemical species and the particles, especially the electrons, from the ionization process to the formation of new substances. Subsequently, it inserts the symbolic representation of the reaction, the writing of the formulas and chemical equations of the reaction in the video. The use of images to represent the chemical species is very strong in Juliana's classes, which articulate them in various activities (exercises, evaluations, questionnaires).

This use of images is quite common in the practice of teacher P7. On the influence of trainers in her teaching, Juliana said in the interview:

[...] that in Higher Education certainly [there is] more [influence] because you are already in contact, you are already thinking directly in your teacher education, then you are already looking for more, try to get the teacher everything good that he brings. I certainly did not mirror in one, more in several.

Juliana assumes, in the interview, the direct influence of P2 on her teaching practice, on her way of conducting pedagogical actions, in the serious way of facing her profession and requesting the participation of the students in the class. Regarding the study of the oxirreduction theme developed in the subject of Theoretical Inorganic Chemistry by P2, Juliana assumes that *the teaching I had was good* and that the way of P2 conducting classes, based on the difficulties students had about the subject *was complemented what she explained in class* when she realized the deficiencies in the students' learning. Juliana goes on to say that *I do not think I would have learned if classes were not conducted that way.*
Referring to the Didactics teacher (P8) Juliana says she showed me what was important [...] to do in the classroom [...] everything that is done in the classroom has to think about the student. Just as she speaks of the influence of P8 on her practice, on the issue of valuing student-centered teaching, she assumes that other trainers also exert influence, whether in the process of taught content or developed teaching practice.

For Rafaela, we were struck by the incorporation she made of projects work, with special attention to the understanding of aspects of the students' reality, including activities in the field. One of the projects that two of the student teachers subjects of this research proposed for students of basic education was related to the oxirreduction theme. They articulated the CTS approach, environmental education, experimentation with alternative materials (battery building), battery and battery collection activity, textual production and discussion from a video on pollution and battery disposal. This project was proposed by Adriano and Juliana (in a group that had three other classmates) in the discipline Chemistry Teaching II, but it was in the teaching practice of Rafaela's Oxirreduction that it was improved and implemented in the classroom. She added new teaching strategies and impregnated the project with her personal characteristics of understanding chemistry teaching. Rafaela says in the interview that P1 was a remarkable teacher in his profession, because:

 [...] he related many facts, many reactions to everyday life. [...] it was a very valid apprenticeship that we carried and could be using and the very clear way of explaining it, a lot of content and, very nice thing, he liked what he was teaching and he liked to teach

We stress here the importance of all the activities developed in the classes for the training of undergraduates, even those in which it is not the teacher who teaches the class that makes them. When a teacher proposes an activity in the classroom, he does not imagine the repercussion of that activity for all students. Rafaela incorporates one of these activities in her practice, based on the observation of the theoretical proposal made by classmates. Even those activities and strategies of teaching that are not intentional in the practice of the trainer reach the graduates. Every way of acting and the importance that the trainer attributes to each teaching activity in his own discipline are perceived and sometimes incorporated into the teaching practice of the student teachers.

Analyzing the details of Table 1 it is possible to notice the absence of incorporations of any of the undergraduates of theoretical and practical elements of the formers P4 and P5. It can also be observed that the number of teachers that influence Adriano's teaching practice is balanced, four of each area, for Juliana is higher among content teachers in the area of chemistry and related (four teachers) in comparison to the number (three teachers), and for Rafaela, there are four teachers of the pedagogical area that influence their teaching practice, compared to a professor in the area of chemistry and related who exerts influence in their way of teaching oxidation.

Adriano incorporates three elements / aspects of the formative action of four teachers in the area of chemistry related, in relation to the four elements / aspects of the formative action of four trainers of the pedagogical area. We consider teacher P11 as a teacher of the pedagogical area, since it acts in the supervision of curricular internship, a discipline related to the learning of teaching practice (teaching method) and not to teaching-learning by the student teacher of...
the specific content of the chemistry. In Adriano we find a situation that is interesting, at the same time that a greater number of professors of the area of chemistry has exerted influence in its teaching practice, the number of incorporations among the teachers of the pedagogical area is greater. A possible explanation for the fact that Adriano has influences from a larger number of professors in the field of chemistry is that they have a greater power of influence in the university teaching field of the analyzed course, we refer to three of these trainers (P2, P3 and P6) who participate in the same research group (which generate distinct links) and which have a larger volume of capital than the other trainers. In this sense, when we perceive the incorporations to the teaching practice of the student teacher and to his own habitus, we reaffirm that Adriano understood the rules of the field and traces strategies to belong to him, in short, understood the sense of the game developed by the teachers of the field.

Juliana incorporates six elements/different aspects of the formative action of the chemistry trainers, with the teachers P2 and P6 influencing a significant number of actions of the student teacher practice. On the other hand, there are also six elements/aspects of the formative action of the trainers of the pedagogical area that influence the student teacher. There are two incorporations that are common to teachers in both areas. In the incorporations to Juliana's teaching practice there is a balance between the groups of teachers of both areas, but it is necessary to emphasize the predominance of three teachers: P2, P6 and P8. These are the same teachers mentioned by the student teacher in her interview as influential in her teaching, which may indicate a self-knowledge of Juliana about her own education and her practice. She is a teacher in training who assumes her identity as a teacher from the beginning of the training process (even before the beginning of the course), when she says that she observes her teachers in the way she teaches, knowing that she is also learning to be a teacher there.

Regarding the number of elements/aspects incorporated into the teaching practice of Rafaela, we have two incorporations of one professor in the area of chemistry, against seven of all teachers in the pedagogic area, two of which are common to teachers in both areas. It is noticed that the strongest influence in the knowledge for the teaching of Rafaela is of the professors of the area of didactic and teaching of chemistry (pedagogical), being that the teachers that worked with disciplines of chemistry did not have elements and aspects of its practices incorporated to the PCK of this student teacher and the physics teacher influenced her in her way of conducting classes and understanding the learning process of the students and not in the specific contents of the subjects of the area.

By comparing Figures 1 and 2, we can see that more aspects of the teaching practice of the disciplines taught by the trainers have been incorporated than the theoretical elements of the disciplines themselves, included in their specific syllabus, programs and contents. This raw data clearly indicates that in their teachers’ classes, students learn not only the contents they teach, but the way of teaching, to the point of incorporating into their teaching practice and teaching habitus characteristics of the teaching of the subjects they attended graduation student. We refer to the incorporation of aspects of the teaching practice of undergraduate trainers only, since the data we collect reinforce this more strongly, although it is explicit in the interviews of all the graduates the influence on the teacher's habitus of teachers prior to joining the course...
of Chemistry teacher education, reinforcing the idea of the construction of the teaching habitus throughout life and in different socializing instances.

**Figure 1. Theoretical aspects from the disciplines incorporated by student teachers**

**Figure 2. Practical aspects from the disciplines incorporated by student teachers**

**CONCLUSION**

The three chemistry student teachers' have very different teaching backgrounds and have had diverse influences from different trainers even though they have taken the same course. In the interviews the distinct aspects of teaching are evident, consistent with the ties established in their life histories with the formers teachers. Trainers influence the teaching practice of their undergraduates not only through the content of their disciplines, but also through their worldview, teaching, and the mode of action and teaching and assessment strategies they use.
in the classroom. However, such influences on the teaching practice of the student teachers are very diverse. While Adriano has a greater balance between influences of teachers of the chemistry area and of education and teaching, Juliana has a predominance of the influence of the chemistry trainers and in Rafaela, the influences of the formers teachers from the didactic and teaching disciplines prevail. In addition to the trainers, the graduates are also influenced by their colleagues during the initial training. Thus, it is pointed out the need for all teacher trainers, regardless of training area, to pay greater attention to their teaching and to the activities they carry out in the disciplines they teach, since, consciously or unconsciously, the training actions developed by teachers clearly influences the teaching practice of the student teachers.

In general, the incorporations derived from teachers teaching practice are based on the conduction of activities, classroom management, students' knowledge and their understanding of the subjects taught, class planning and management, and instructional strategies. Data reveal a certain balance between the General Pedagogical Knowledge and the PCK, with some characteristics that point to the Knowledge of the Context. On the other hand, of the theoretical elements that have been most incorporated there is a predominance of General Pedagogical Knowledge. There was little incorporation of elements / aspects of the Subject Matter Knowledge, specifically redox process. The knowledge most learned by the student teachers from the practice and teaching conceptions of their formers teachers are practically balanced between curricular aspects of the disciplines and aspects of the practice. Therefore, it is not enough for the teacher trainer to pay attention only to what he teaches, but we must pay attention to the way he conceives his teaching and the activities he does. According to one of the trainers: "For teachers students, your class is a practical demonstration for them. They are looking at you, evaluating you, taking you as some good or not examples."

Even if they attended a same course, the graduates got involved with different formers teachers and extra-curricular activities throughout the course which resulted in different habitus. There are not clearly aspects common to all undergraduates, that is, the incorporation of repertoires that the student teachers do of the activities and learning in the classroom are distinct, partly dependent on its network of relations with the other members of the field, the trainers and its objectives for the teaching of chemistry contents. The capital of these trainers is also reflected in the intensity of these relationships, so that the teacher in the chemical area who is more involved with projects and research ends up having a greater influence on the teaching practices of the student teachers, while in the pedagogical area it influences more that trainer who is more coherent in its practice with the theoretical elements of its discipline.

Fostering students’ motivation is an essential characteristic of every teaching process. However, teachers often lack practical methods to support it in class. There are several approaches to foster students’ motivation, such as autonomy-supportive teaching behavior (ASTB) based on Self-Determination Theory (Ryan & Deci, 2017). Although these approaches are at disposal, they do not seem to find their way into practice. Consequently, efforts are needed to transfer theoretical and empirical findings into the classroom. An intervention for pre-service teachers providing theoretical and practical approaches to foster students’ motivation might be appropriate to deal with this situation. To address this issue, we conducted a pilot study with 58 science teacher trainees (M_{age}=25.18±3.79 years; M_{semester}=7.78±1.23; 65% female). The experimental group consisted of 35 teacher trainees that took part in an intervention about ASTB. Teacher trainees in the control group (n=23) did not participate in this intervention. We assessed the teacher trainees’ beliefs about the easy implementation and effectiveness of ASTB as well as their future intentions to apply ASTB. Furthermore, the teacher trainees’ theoretical and practical knowledge were examined. The results revealed significant differences concerning the teacher trainees’ beliefs about ASTB, their future intentions to apply ASTB as well as their theoretical and practical knowledge thereof in the comparison of the experimental and control group. We found that the teacher trainees in the experimental group assumed ASTB to be more effective and easier to implement than the teacher trainees in the control group after the intervention. Moreover, the teacher trainees in the experimental group showed higher scores in the test of their theoretical and practical knowledge and stated higher intentions to apply ASTB than the teacher trainees in the control group after the intervention.

**Keywords**: motivation, teaching practices, initial teacher education (pre-service)

**INTRODUCTION**

Despite numerous approaches in the field of teacher professionalization, there is still a degree of uncertainty regarding which implementations are most effective in this area (Pressley, Graham, & Harris, 2006). Self-Determination Theory (Ryan & Deci, 2017) has proved to be a useful framework for designing school-based interventions in various studies (Reeve & Cheon, 2016). These studies show that interventions can effectively change teaching behavior in class (Reeve & Cheon, 2016; Su & Reeve, 2011). For these behavioral changes to take place, participants must recognize the relevance, the easy implementation, and the effectiveness of the communicated behavior (Reeve & Cheon, 2016; Su & Reeve, 2011). One opportunity to design a meaningful intervention is the subject-specific adaption and training of teaching behavior.

There is increasing evidence that interventions with teacher trainees are especially effective (e.g., Su & Reeve, 2011). With regard to autonomy-supportive teaching behavior (ASTB) in the sense of Self-Determination Theory (Ryan & Deci, 2017), teacher trainees are an important
target group because they tend to use controlling teaching behavior in class (Martinek, 2010). Several studies have shown that controlling teaching behavior can have a negative effect on students’ motivation (Assor, Kaplan, Kanat-Maymon, & Roth, 2005; De Meyer et al., 2016), whereas ASTB can influence their motivation positively (Basten, Meyer-Ahrens, Fries, & Wilde, 2014; Hofferber, Basten, Großmann, & Wilde, 2017; Taylor, Schepers, & Crous, 2006; Tessier, Sarrazin, & Ntoumanis, 2010). Since students’ motivation decreases throughout their school career (e.g., Jacobs, Lanza, Osgood, Eccles, & Wigfield, 2002) and teachers often lack methods to foster it (Reeve, Jang, Carrell, Jeon, & Barch, 2004; Winther, 2006), the communication of ASTB seems to be especially important.

Based on this research, we developed an intervention to communicate ASTB to pre-service teachers. To successfully implement ASTB in class, teachers need theoretical and practical knowledge about autonomy support that is in accordance with Self-Determination Theory (Ryan & Deci, 2017). Therefore, we were interested in whether our intervention would foster the participants’ acquisition of practical and theoretical knowledge with regard to ASTB. In addition, since teachers are more likely to implement ASTB when they are convinced that it is easy to implement and effective (Reeve & Cheon, 2016), we examined whether our intervention would have an impact on these beliefs and on the participants’ future intentions to apply ASTB in their lessons.

THEORETICAL BACKGROUND AND CURRENT STATE OF RESEARCH

Basic Needs Theory, a sub theory of Self-Determination Theory (Ryan & Deci, 2017), proposes that there are three innate basic psychological needs, namely the need for relatedness, competence, and autonomy. The degree to which these needs are satisfied has an impact on an individual’s well-being and his or her quality of motivation (Deci & Ryan, 2000). The need for relatedness describes an individual’s wish for meaningful interactions with significant others and striving to belong to a social community (Ryan, 1995; Ryan & Deci, 2017). The need for competence involves the ambition to perceive and extend one’s own capability and effectiveness in an action (Deci, 1975; Deci & Ryan, 2000; Ryan & Deci, 2002, 2017). The need for autonomy describes an individual’s desire to perceive him-/herself as origin of his or her action (Reeve, 2002; Reeve, Nix, & Hamm, 2003). Feeling autonomous means experiencing choice and volition in one’s action (Reeve et al., 2003).

Organismic Integration Theory, a second sub theory of Self-Determination Theory (Ryan & Deci, 2017), depicts a continuum of motivation ranging from extrinsic to intrinsic motivation. The goal of an intrinsically motivated action is the action itself (Deci & Ryan, 2000; Vallerand & Ratelle, 2002). These actions are characterized by enjoyment, curiosity, and spontaneity (Deci & Ryan, 2000; Vallerand & Ratelle, 2002). Extrinsicly motivated actions take place because the individual wants to obtain the result of an action that is separable from the action itself (Ryan & Deci, 2002; Vallerand & Ratelle, 2002). An extrinsically motivated action can be regulated in four different ways: external, introjected, identified, and integrated (Ryan & Deci, 2002, 2017; Vallerand & Ratelle, 2002). These types of regulation can be arranged on a continuum of self-determination (Ryan & Deci, 2002; Vallerand & Ratelle, 2002). An external
regulation is the most heteronomous form of regulation whereas an integrated regulation is the most autonomous regulation (Vallerand & Ratelle, 2002).

Since these subtheories describe the needs and motivation of every individual, they are important for both students and teachers. The satisfaction of the three basic needs is essential for students’ well-being and the quality of their motivation to learn as well as for well-being in the teaching profession and the motivation to teach (Martinek, 2012; Niemiec & Ryan, 2009; Reeve, 2002; Reeve & Cheon, 2016). In addition, the teacher’s motivation to teach can have a direct and indirect impact on the students’ motivation in class (Müller, Andreitz, & Hanfstingl, 2008; Pelletier, Séguin-Lévesque, & Legault, 2002). Studies have shown that students’ motivation decreases throughout their school career (e.g., Jacobs et al., 2002). One opportunity to foster students’ motivation in class is autonomy-supportive teaching behavior (ASTB) in the sense of Self-Determination Theory (Ryan & Deci, 2017). The positive effects of ASTB on students’ motivation have been found in several studies (Basten et al., 2014; Hofferber et al., 2017; Taylor et al., 2006; Tessier et al., 2010). ASTB can also have a positive impact on students’ knowledge acquisition (Boggiano, Flink, Shields, Seelbach, & Barrett, 1993; Hofferber, Eckes, & Wilde, 2014). Therefore, an intervention that communicates ASTB might be useful for the professionalization of teachers when it comes to fostering motivation. Since teachers often lack didactic-methodological skills to support their students’ motivation in class (Reeve et al., 2004; Winther, 2006), the communication of this behavior is particularly important. Furthermore, interventions dealing with the Basic Needs Theory and Organismic Integration Theory might help teachers to reflect on the satisfaction of their own basic needs and their motivation to teach.

In addition to supporting students’ motivation in class, Self-Determination Theory (Ryan & Deci, 2017) has turned out to be a suitable framework for designing school-based interventions (Chatzisarantis & Hagger, 2009; Reeve et al., 2004). Previous studies have found that these interventions can have a significant impact on not only the participants’ knowledge and behavior, but also their beliefs and intentions (Aelterman, Vansteenkiste, Van den Berghe, De Meyer, & Haerens, 2014; Reeve & Cheon, 2016). In order for changes in beliefs and behavior to occur, the participants must first recognize the relevance, the easy implementation, and the effectiveness of the communicated concepts and behavior (De Naeghel, Van Kerr, Vansteenkiste, Haerens, & Aelterman, 2016; Reeve & Cheon, 2016; Su & Reeve, 2011). Furthermore, meta-analyses show that interventions with teacher trainees are especially effective (e.g., Su & Reeve, 2011). Teacher trainees do not yet have a stable teacher personality and their teaching behavior in class is still flexible (Martinek, 2010; Tessier et al., 2010). Interventions that provide approaches to foster students’ motivation should therefore already be implemented during the teacher training phases at the university level. On the basis of this research, we developed an intervention for pre-service teachers dealing with ASTB. To check the effectiveness of our intervention, we investigated the following research questions.
RESEARCH QUESTIONS

1) Does the intervention foster the participants’ acquisition of theoretical and practical knowledge about autonomy-supportive teaching behavior?

2) Does the intervention affect the participants’ beliefs about the easy implementation and effectiveness of autonomy-supportive teaching behavior?

3) Does the intervention affect the participants’ future intentions to apply autonomy-supportive teaching behavior?

METHOD

Sample
Fifty-eight science teacher trainees in advanced semesters ($M_{age}=25.18\pm3.79$ years; $M_{semester}=7.78\pm1.23$; 65% female) participated in the current study. These trainees came from courses that had prepared them for a one-semester practical phase. Thirty-five of them were assigned to the experimental group and took part in an intervention focusing on autonomy-supportive teaching behavior (ASTB) in science lessons. The control group ($n=23$) did not participate in this intervention.

Test instruments
We developed an open-ended knowledge test that contained seven items that assessed the teacher trainees’ theoretical knowledge and eight items that assessed their practical knowledge of ASTB. We rated each item with zero, one, or two points. Zero points were awarded for an incorrect answer or when no answer was given at all. The teacher trainees received one point for an answer that was partly correct. Two points were given for a complete and correct answer. Interrater agreement for these items was found to be excellent (theoretical knowledge: Cohen’s $\kappa=.91$; practical knowledge: Cohen’s $\kappa=.93$).

The Teaching Scenarios Measure (TSM; Reeve et al., 2014) was used to examine the teacher trainees’ beliefs about the easy implementation (four items) and the effectiveness (four items) of ASTB as well as their future intentions to apply ASTB (four items). Specifically, the teacher trainees received a written scenario that depicted ASTB. The term “autonomy-supportive” was not used in or to label the scenario. After reading the scenario, the teacher trainees were asked to rate different statements with regard to this scenario on a five-point rating scale (“0=strongly disagree” to “4=strongly agree”). Both the knowledge test as well as the TSM were applied in the pre- and posttest.

In the posttest, we also investigated the teacher trainees’ perception of autonomy with nine items of the Learning Climate Questionnaire (LCQ; Black & Deci, 2000). In this test instrument, the experimental group stated their perception of autonomy during the intervention whereas the control group rated their perception of autonomy during their regular course. These items were rated on the same five-point rating scale. Internal consistencies as well as example items for all test instruments can be seen in Table 1. The Cronbach’s-alpha values for all test instruments ranged from satisfying to excellent.

**Study design**

One week before the intervention, the teacher trainees’ theoretical and practical knowledge regarding ASTB, their beliefs about this type of behavior, and their intentions to apply it in future lessons were assessed. The teacher trainees’ beliefs and intentions were measured using the Teaching Scenarios Measure (TSM; Reeve et al., 2014). After that, the teacher trainees in the experimental group participated in an intervention that was divided into two parts. In the first part, they were provided with a theory session on Self-Determination Theory (Ryan & Deci, 2017), which had a special focus on the three basic needs and the continuum of motivation (Basic Needs Theory, Organismic Integration Theory). Afterwards, two training sessions took place in which five autonomy-supportive methods were practiced and discussed. After the intervention, the teacher trainees’ knowledge, their beliefs that were related to ASTB and their future intentions to apply it were assessed again. Furthermore, the perceived degree of their own autonomy was examined using the Learning Climate Questionnaire (LCQ; Black & Deci, 2000).

The control group only attended the pre- and posttest and received no intervention. During the intervention, the teacher trainees in the control group participated in their regular course and prepared for the practical phase using different educational theories. The study design is summarized in Figure 1.
Figure 1. Study design. The Teaching Scenarios Measure (TSM; Reeve et al., 2014) assessed the teacher trainees’ beliefs about and future intentions to apply ASTB. The Learning Climate Questionnaire (LCQ; Black & Deci, 2000) measured the teacher trainees’ perceived degree of autonomy.

**Design of the sessions**

While designing our intervention, we considered the findings of recent studies and meta-analyses of interventions based on Self-Determination Theory (Ryan & Deci, 2017). Among other things, these stressed that participants should perceive their own basic needs as being satisfied during the intervention (Assor, Kaplan, Feinberg, & Tal, 2009; De Naeghel et al., 2016). For this purpose, the instructor of the intervention implemented the communicated five autonomy-supportive methods during the intervention.

Studies have shown that interventions are particularly effective if they a.) are both knowledge- and skill-based, b.) do not exceed three hours per session, and c.) utilize different types of media (De Naeghel et al., 2016; Su & Reeve, 2011). To foster knowledge as well as skill acquisition, two types of sessions were designed: One session was designed to give the teacher trainees theoretical input that teaches basic knowledge about the basic psychological needs and the different qualities of motivation according to Self-Determination Theory (Ryan & Deci, 2017); the second type consisted of two sessions designed to have the teacher trainees practice their skills in fostering their students’ autonomy in science lessons. In the training sessions, five autonomy-supportive methods were focused on: providing rationales, acknowledging negative feelings, offering choices, using neutral language, and giving informative feedback (Table 2). In terms of methodology, these sessions were based on work in small groups. In their groups, the teacher trainees analyzed videos of different teaching behavior in class, designed rationales for topics in science lessons, and performed role plays dealing with negative feelings by way of example. At the end of each session, the introduced methods were reflected on and discussed. Audio and video sequences, tablets, laptops, smartphones as well as paper-and-pencil-based tasks were used in the sessions. Each one lasted 1.5 to 2 hours.

As continuous instrumental support and follow-up activities are important for an intervention to be effective (Assor et al., 2009; Su & Reeve, 2011), the teacher trainees were provided with a.) a glossary that included important definitions and assumptions related to Self-Determination Theory (Ryan & Deci, 2017), b.) a booklet for supporting students’ motivation in class, and c.) a reader with theoretical discussions and empirical studies on the basic needs and the qualities...
of motivation anchored in Self-Determination Theory (Ryan & Deci, 2017). One follow-up activity entailed the observation of autonomy-supportive and controlling teaching behavior in class with a self-developed observation grid based on the Learning Climate Questionnaire (Black & Deci, 2000).

Statistics

First, we calculated a univariate analysis of variance to investigate the teacher trainees’ perceived degree of autonomy. To analyze the effects of the intervention on the teacher trainees’ knowledge, beliefs, and future intentions to apply ASTB, we used analyses of variance with repeated measures.

RESULTS

First, we surveyed the teacher trainees’ perceived degree of autonomy. The analysis of variance revealed a significant difference in the teacher trainees’ perceived degree of autonomy between the experimental and the control group with a large effect size ($F(1,57)=21.87, p<.001, \eta^2=.28$). The results of the Learning Climate Questionnaire (Black & Deci, 2000) showed that the teacher trainees in the experimental group stated a significantly higher perceived degree of autonomy during the intervention than the trainees in the control group in their regular course ($M_{EG}=3.68±0.27; M_{CG}=3.18±0.55$). We therefore assume that the implementation of the autonomy-supportive behavior of the instructor during the intervention was successful.

Second, when it came to the extent of the teacher trainees’ theoretical and practical knowledge regarding autonomy-supportive teaching behavior (ASTB), the analyses of variance with repeated measures revealed significant interaction effects of the factors time and treatment with large effect sizes (Table 3). The teacher trainees in the experimental group had higher scores on the theoretical and practical knowledge test than the teacher trainees in the control group after the intervention (Table 3).

Third, we found significant interaction effects with a large and a medium effect size of the factors time and treatment with respect to the teacher trainees’ beliefs about the easy implementation of ASTB as well as their intentions to apply it in future lessons (Teaching
Strand 13

Scenarios Measure; Reeve et al., 2014; Table 3). The interaction effect for the teacher trainees’ beliefs about the effectiveness of this behavior showed a tendency with a small to medium effect size (Teaching Scenarios Measure; Reeve et al., 2014; Table 3). After the intervention, the experimental group thought ASTB was easier to implement and attributed higher ratings of effectiveness to this approach than the control group (Table 3). In addition, the teacher trainees in the experimental group stated higher intentions to apply ASTB after the intervention than the teacher trainees in the control group (Table 3).

**Note.** Means and standard deviations are shown for the experimental group (EG) and the control group (CG) in the pre- and post-test separately. With regard to the ANOVA, the main effects of the factors time and treatment as well as the interaction effect of both factors for the comparison of the experimental and control group are shown.

**DISCUSSION AND CONCLUSION**

The intervention seemed to be effective regarding the teacher trainees’ theoretical and practical knowledge. Furthermore, it can be assumed that the intervention had a positive impact on the teacher trainees’ beliefs about the effectiveness and the easy implementation of autonomy-supportive teaching behavior (ASTB) as well as their intentions to apply it in future lessons. The results of all scales are in line with theory and previous empirical findings. The minor tendency we found with regard to the beliefs about the effectiveness of ASTB may be reasonably attributed to the small sample size and/or ceiling effects. One should also consider that the teacher trainees had already indicated that they thought that ASTB is quite effective in the pretest. This is probably because the teacher trainees were in more advanced semesters of their studies and may have already been exposed to classroom autonomy support and its
positive effects. Ceiling effects can further be assumed in the teacher trainees’ perception of autonomy.

Learning environments that satisfy the learners’ basic needs can have a positive effect on their motivation and knowledge acquisition (cf. Niemiec & Ryan, 2009; Reeve, 2002). Satisfying the need for autonomy is especially important for self-determined types of motivation and successful learning (e.g., Basten et al., 2014; Boggiano et al., 1993; Hofferber et al., 2017; Hofferber et al., 2014; Reeve, 2002; Taylor et al., 2006). We assume that the design of our intervention and the instructor’s implementation of ASTB fostered the teacher trainees’ perception of autonomy, the quality of their motivation, and consequently their knowledge acquisition.

Research has shown that interventions based on Self-Determination Theory (Ryan & Deci, 2017) can have an impact on participants’ beliefs (Aelterman et al., 2014; Reeve & Cheon, 2016). Our data support the results of these studies. We assume that acquiring knowledge about and practicing ASTB in an autonomy-supportive setting with a range of choice and without assessment had a positive influence on the teacher trainees’ beliefs about ASTB. It may further be assumed that the changes in the teacher trainees’ beliefs are indicators for a process of accommodating new concepts (cf. Reeve & Cheon, 2016; Tillema & Knol, 1997). Teacher trainees often harbor controlling teaching concepts and tend to exhibit controlling teaching behavior in class (cf. Martinek, 2010). The acquisition of knowledge about and the practice of ASTB might have led to a change of these existing concepts. Despite evidence of this change, we cannot confirm that the teacher trainees will actually use ASTB in their future lessons. Findings from previous studies show that the adoption and the use of new concepts are contingent upon existing beliefs about these concepts (e.g., Tillema & Knol, 1997). Tillema and Knol (1997) proved that a change in behavior can only be expected if the beliefs of an individual change. Hence, the positive impact of the intervention on the teacher trainees’ beliefs about ASTB might result in a change of their behavior.

The reported intentions to apply ASTB may also indicate whether the teacher trainees will actually use the communicated methods in their future lessons. Intention is assumed to be a significant predictor of behavior in several social psychological models (cf. Sheeran, 2002). Since the teacher trainees’ intentions to apply ASTB were positively affected by the intervention, it can be assumed that they will be more likely to apply it in their future lessons. Nevertheless, future studies should investigate whether and how the intervention affects the teacher trainees’ teaching behavior in class. Furthermore, the effects of the trainees’ teaching behavior after the intervention on their students’ perception of autonomy and their students’ motivation could be examined.

In order to further evaluate the effectiveness of our intervention, we plan to conduct follow-up surveys during the next semester. After a replication of the current pilot study, the intervention might be adapted to other subject-specific didactics and in-service teachers.

PREREQUISITES AND OBSTACLES IN TECHNOLOGY INSTRUCTION: PRE-SERVICE TEACHERS' PERSPECTIVES

Alexander F. Koch¹, Jürg Keller², Aleksandar Dunjic², Stefan Kruse¹ and Manuel Haselhofer¹

¹School for Teacher Education, University of Applied Sciences and Arts Northwestern Switzerland FHNW, Centre for Science and Technology Education
²School of Engineering, University of Applied Sciences and Arts Northwestern Switzerland FHNW, Institute of Automation

In this presentation we address the problem of technology education in the realm of restricted curricula. We asked pre-service teachers how and when they would implement technology in their lessons. Exploratory component analyses showed that anticipated obstacles and operational beliefs form reliable and overarching classes of instruction-determining factors. Besides data exploration using principal component analyses and group comparisons, correlation analysis shows significant relations between perceived obstacles and operational beliefs of student teachers. Although digitally native, it seems that student teachers rather avoid technology in their classrooms. They are insecure and demand support from colleagues at school. It seems the more knowledge the students have, the more they would avoid teaching technology, because it is too difficult. We assume that the problem here is situated in the pedagogical content competence of pre-service teachers. Discussion and future research: The results suggest that in-school collaboration could be a fruitful start to implement technology in instructional practice. As a deeper knowledge of technology correlates with more avoidance in class, one could guess that teachers do not have a systematically developed pedagogical content competence to implement technology education in classrooms. In a wider context we suggest a motivating university education for student teachers, so they can be the future collaborators at school, they demand today. We suggest (Quasi-) Experimental study designs to evaluate the efficacy of adapted teacher education and in-school collaboration in terms of technology-oriented instruction. This study only focused on obstacles and reliabilities of scales could be higher. Further research may include more content specific questions, because here the container phrase "technology" was used. Also, the sample size should be increased to achieve more stable component structure.

Keywords: technology education, beliefs, pre-service teachers

INTRODUCTION

When we talk about science and technology education today, most people would agree that technology plays a vital role in modern societies. Although academics agree that there is a clear difference between science and technology (Moore, 2011; Pavlova, 2009), this may only be true if technology is also seen distinct from engineering. The STEM acronym can be used to highlight the difference between the domains. Yet, in many cases science dominates technology and engineering, or technology and engineering are interpreted as practical application of knowledge in natural sciences (see Renn et al., 2009).

What is more, in German-speaking Europe, technology and engineering are not seen as separate entities. The term technics (Technik) is used there and it comprises the creative re-assembly of
items as well as the use of digital devices in any context (e.g. Dolata & Werle, 2007). One can thus say that the term technics includes production knowledge and application knowledge. Both knowledges comprise problem-solving and value-added purposes. Where engineering may seek problem-solving on a productive level, technology and technology-use may help in automation or controlling systems. In educational contexts engineering can be seen as a content-related topic that allows to learn about the nature, functioning, or relevance of technics; technology can add to optimize educational interactions and learning, for example by means of tablets use for and in instruction.

An example, where both ideas – understanding and application – meet is digital technology. In digital technology engineering, the objective is to improve components, e.g. make them small or more efficient. In digital technology education, a teacher may use the engineered product for educational purposes, e.g. use tablet computers to visualize a phenomenon. Within this notion of technology, technology education is supposed to teach students the processes and techniques in engineering as well as the use of technical devices. In order to avoid confusion and to imply the notion of understanding and use of technology, we will refer to tech as an abbreviation for technology and engineering.

Tech education is of primary interest in terms of STEM education and future advances in technology and engineering. Yet, by now in Switzerland, there is no designated school subject that addresses tech education specifically. In the Swiss compulsory school system, technical design is a distinct subject, but tech, as we defined it in the above section, is distributed all over the curriculum and thus usually science teachers integrate technology into their instruction as an add-on if there is time left. Teachers of other subjects may not even consider tech instruction at all. What is more, tech is likely to be dropped even by science teachers. This is especially the case if teacher do not feel themselves competent enough or see other obstacles that justify skipping a laborious and complex topic (Peschel & Koch, 2014).

In this report we want to give an overview on the Swiss curriculum 21 and show the distribution of tech education. The distribution of tech education leads to the question of where, when and how Swiss teachers implement tech education. We will focus on pre-service teachers, because they are currently educated in the framework of the new curriculum.

A SWISS BACKGROUND

The current Swiss compulsory school system does not equip pupils with a solid basis of tech knowledge. But, currently the Swiss school curriculum is undergoing a change (so-called Lehrplan 21) where tech education is supposed to be taught at a basic level. The cantons Basel-Stadt and Basel-Land already use the new curriculum since the school year 2014/15 and, therefore, already educate pre-service teachers at the local university of teacher education (PH FHNW) according to the new curriculum.

As was stated in the previous section, there is no specific tech education in the new curriculum (see Figure 1). Tech is supposed to be integrated in various subjects, e.g. physics, history, arts, graphical/ textile and technical design.
One can see in Figure 1 that any tech education in the first cycle (Kindergarten and 1st/ 2nd grade) has to be implemented in an integrated way. Most likely it seems to be a part of Nature, man, and society or Technical design. In cycle two tech may also be included in Media, information and communication technology. In the third cycle the integrated subject Nature, man, and society fans out and gets more specific. Technology and engineering become a part of the natural sciences education. Yet still, tech seems to be more a part of natural sciences instead of a stand-alone subject. As a result, teachers might treat tech as a supplementary topic.

THEORETICAL BACKGROUND

The research question is in line with the idea that teachers who are interested in a topic (e.g. tech) would also tend to teach technology, because they feel self-confident and competent in using technology. Interest seems to determine study choices and initial career paths in STEM professions (Aeschlimann, Herzog, & Makarova, 2015; Ardies, De Maeyer, Gijbels, & van Keulen, 2015). In the context of interest Ng (2012) found that undergraduate students can productively use even unfamiliar digital devices. So, the question arises whether pre-service teachers do see the opportunity to implement tech issues in their future instruction. This prospective interpretation is of high value as it shows acute threats to future tech implementation. Jones, Bunting, and de Vries (2013) name teacher education as one central predictor of successful change in the translation of a new curriculum into praxis. In our context the innovative change is tech instruction. Pelgrum (2001) summarizes major obstacles of embedding ICT in educational praxis and school report that it is difficult to find and schedule time, lack of technical assistance/ support, weak infrastructure, low teacher qualification, and that it is too difficult with low achieving pupils. Here, we want to transfer this knowledge from ICT educational research to technology education research and build up on that in a quantitative, exploratory study.

Besides the use of tech for educational purposes, there is also the dimension to teach tech in an engineering-oriented way. Yet, little is known about the choice to become an engineer or tech teacher, because one cannot sign in for that subject at universities of teacher education. Berweger, Bieri Buschor, Keck Frei, and Kappler (2014) find that women enter engineering studies if they have a high self-efficacy in successful graduation, had a solid interest in mathematics and/ or physics, and had a positive attitude toward a post-graduate turnover.

RESEARCH QUESTION

As can be read in the above sections, Switzerland is undergoing curricular changes that affect every educational entity. Especially in-service teachers are supposed to implement more tech education in their instruction. Pre-service teacher's education at the universities of education also should offer classes that allow students to prepare for future demands. Yet, the question arises what and how university classes should introduce tech classes. Especially with reference to pedagogical content knowledge and other instruction-oriented variables, such as self-efficacy, interest or the quality of educational tech equipment that is available to teachers, we ask the question whether there are reasons for student teachers to keep the implementation of tech education at a minimum.
METHODS

We asked pre-service teachers to anticipate circumstances in which they would do tech instruction and about their beliefs of their own tech use. For this we formulated questionnaire items and had them rated on a 5-point Likert-scale (0: totally disagree, 4: totally agree). We tried to assess obstacles that hinder the implementation of technology education with 23 items. For example, we asked for the material equipment at their school, for the collegial support and exchange, own competence rating, as well as for external factors as parents’ approval and students' prerequisites. On operational beliefs we formulated 15 items which comprise the use of and attitude toward tech (e.g. I am happy to just use tech devices; I could dis- and re-assemble my tech devices even blindfold; I love to play around with tech devices; Tech improves our life-standard in general).

In the sample were 69 pre-service students all mostly in their second year of undergraduate studies. 32% were future lower-secondary teachers, 68% future kindergarten and primary school teachers. They were evaluated in their second year of study.
We used SPSS 23 for statistical analyses and principal component analyses (PCA, Varimax-rotation, Eigen-value >1) to classify the items of the obstacles and operational beliefs. Orthogonality was optimized by eliminating items with cross-loadings above .32 (Tabachnick & Fidell, 2001). The Kaiser-Meyer-Olkin (KMO) measure of sampling adequacy and the Bartlett test were used to evaluate the appropriateness of the PCA. Individual components were judged regarding their unique item-component reliabilities (communalities > .40; Costello & Osborne, 2005). Components were scaled (Cronbach-alpha) and scale averages were compared with independent t-tests. Differences are reported using the effect size Cohen's d.

RESULTS

Exploratory component analysis, scale properties and correlations

Initial person-item ratios were fairly good at 5:1 (Costello & Osborne, 2005). The first PCA on the obstacles showed a seven component solution (KMO=.55), but the Bartlett test was significant and there were several large cross-loadings. Similar starting values were found in the operational beliefs (KMO=.75, Bartlett < .05, several cross-loadings).

After item-elimination a three-component solution resulted for obstacles, with loadings all beyond .50, communalities averaged at .70 and components hardly correlated. Also a final three-component solution for operational beliefs was found; KMO was .67 and communalities were at an average level of .70, the Bartlett test was still statistically significant.

The three components of obstacles were: Not enough collaborative support at school (4 items, α=.79), Lack of teaching material available at school (2 items, α=.93), and Pupil-caused obstacles (3 items, α=.62). The three operational belief components were: Self-concept in technology education (4 items, α=.82), Positive attitude toward technology (4 items, α=.69), and Rather using than understanding technology (2 items, α=.72).

Reliabilities are acceptable and standard deviations show that there is variance in answering the items and averages do not indicate any ceiling or bottom effects (see Table 1).

One can see in Table 1, that correlation coefficients between obstacles and belief components generally do not exceed a value of .44. Interesting are the correlations between collegial support and available material as well as available material with the use of technological devices. Also, a positive attitude is correlated with the demand of collegial support, just as is the relation between inter-personal assistance and the use of technology.

Group differences

Additionally, we compared primary/ kindergarten student teachers with lower-secondary ones. Independent sample t-tests and U-tests are reported in the Table 2).

Kindergarten/ primary student teachers are more optimistic that pupils can be taught tech whereas lower-secondary student teachers think pupils do not have enough pre-knowledge, they are not disciplined enough and that class-sizes are too huge (d=.83). At a level of p<.05 this effect is statistically significant.

Using a more liberal, exploratory interpretation of significance thresholds, there also occur relevant differences in the use-orientation and the self-concept. Lower levels students would
rather use than explain tech compared to lower-secondary student teachers (d=.47) and prospective lower-secondary teachers state a higher self-concept compared to kindergarten teachers (d=.38).

There are no significant differences in the attitude toward tech, the need of collegial support the quality of the equipment available at schools.

**DISCUSSION**

In summary we see that collaboration at school is a major demand of future teachers when asked to use technology in their instruction. Their digital/ technological nativity does not automatically result in self-confident technology teaching. This supports the idea that nativity has to be combined with literacy as is supported in Ng (2012). Additionally, those students who do know how to use a device would also implement this use in class, what seems to be true in kindergarten and primary schools. Student teachers in lower-secondary schools are more interested in details of technology and perhaps this detailed knowledge hinders them to initiate technology in classes, perhaps because they see the complexity and the need for thorough
preparation. This result should be used in future for more focused research on the effect of implementing and using technology in school and its pedagogical/ didactic embedding. Experimental study designs can reveal more systematic insights that can be transferred to field contexts. In the field also the effect of fostering collaboration should be studied. Yet, if one considers these results in an overarching perspective one could argue that all this is due to the individual perception of technology education. In our next project we will also address this issue and ask for individual definitions and opinions of/ on technology education. In further investigations we also intend to differentiate between experienced teachers, pre-service teachers, pure professionals (e.g. technicians) and teachers in professional vocational educational training.

Besides the results above, our study is limited in the following: We only focused on obstacles and reliabilities of scales could be higher. Also, further research may include more content specific questions, because here the container phrase tech was used. An increased sample size could also contribute to a stable component structure.

HOW PRESCHOOL PRE-SERVICE TEACHERS DETECT CHILDREN’S IDEAS ABOUT SOCIAL AND SCIENCE TOPICS?

Marta Cruz-Guzmán, María Puig-Gutiérrez and Fátima Rodríguez-Marín
Science Education and Social Science Education Department, Seville University, Spain

This study aims to establish the way in which groups of preschool pre-service teachers design and analyse an instrument to detect children’s ideas about science and social topics, after studying two coordinated subjects at University. With that purpose, a table of analysis is presented, we found that the instrument designed employs appropriate language for the age of the children, combines a reasonable number of open questions with other resources and tends to ask about meanings related to the mesocosm. However, difficulties are encountered when organizing the responses into a category system under which the levels follow clear criteria of complexity and there is coherence between the system created and the data obtained. Finally, even though pre-service teachers recognize the importance and usefulness of having knowledge of the ideas of the pupils, they do not appear to significantly take these ideas into account in the design of their proposals, which demonstrates the need to continue working with pre-service teachers on this matter.

Keywords: preschool pre-service teacher, children’s ideas, science and social topics.

INTRODUCTION

In recent decades there has been literature with studies on the ideas of preschool students related to different educational content, although it continues to be the stage upon which least research has been carried out (Kambouri, 2015; Kerr, Beggs & Murphy, 2006). The need is now recognized to have advance knowledge of those ideas before becoming involved in order to use them in the approach and help pupils to achieve meaningful learning. Therefore, in the initial teacher training for Early Childhood Education (Pringle, 2006) teaching how to design instruments which detect these ideas and analysing the data obtained must be taught. The focus of this study is to design and apply an analysis rubric on a) the quality of instruments for detecting children’s ideas designed by pre-service preschool teachers; b) the analysis of responses obtained, as well as c) the didactic implications that they draw from these.

Early childhood pupils' ideas about the content of knowledge of the social and natural environment

An educational approach that focuses on detecting and taking into account the pupils’ ideas could be contextualized as part of so-called democratic and participatory early childhood education (Allen, 2014; Avgitidou, Pnevmatikos & Likomitrou, 2013; Driver, Guesne & Tiberghien, 1985; Dayan & Ziv, 2012). Here, the pupil is given a voice, their viewpoints are taken into account, and consensus is reached with them on many everyday educational issues.

When designing an educational proposal in early childhood education, teachers need to know their pupils' prior ideas about the themes that are going to be taught later. Indeed, to achieve meaningful learning, the pupils should know, discuss, and reflect upon their own ideas.
Knowledge is built in the pupils' minds thanks to the interaction between their already existing mental models and new experiences and information. According to Sickel (2017), it is necessary to know the pupils' prior ideas and their way of seeing the world before beginning a teaching and learning process with them. In this way, it will be possible to construct shared meanings, and the teacher will be able to adjust the interventions to fit the needs of the pupils.

Cantó, Pro and Solbes (2016) state that there is a research deficit in early childhood science teaching. Despite there being fewer studies on early childhood children's prior ideas than on those of pupils at other educational levels (Kambouri, 2016), those studies still cover a great variety of topics related to the natural and social environment. There have also been reviews of studies in the literature on early childhood pupils' ideas that are related to scientific concepts (Kerr, Beggs & Murphy, 2006).

**Scientific education in early childhood education**

According to Cañal (2006), basic scientific education (BSE) is not something that is alien to young children's nature and everyday lives. Neither does it start out from scratch when it is introduced in early childhood education, but first develops spontaneously from the moment of birth in the out-of-school interaction with the environment. The main objective with BSE should be to enrich and interrelate child's spontaneous acquisitions and capacities in this field, encouraging their appropriate development through school tasks and sequences valid for that purpose.

Spanish legislation recognizes the transversal character of the scientific competence to be developed in early childhood education (BOE, 2007). The importance of taking the children's ideas into account when planning the teaching of early childhood education has already been commented on. But the reality of the classroom often shows that teachers do not always have time to identify the children's ideas, so that they assume a certain basic level of knowledge. The results reported by Kambouri (2016) from a study of early childhood teachers in the United Kingdom were very enlightening. Despite being aware of the importance of the theoretical diagnosis of their pupils' ideas, the participating teachers' actual practice was contradictory because usually they either did not identify the children's ideas or did not help them to correct those ideas. This may have been because most of the participants considered that scientific education at these ages should help in the development of skills rather than the understanding of concepts, as also has been defended by other authors (Cantó, Pro & Solbes, 2016). Half of the teachers considered it to be acceptable for a child to finish early childhood education with alternative ideas because they considered that it would not affect the child's learning and conceptual development. We believe that initial teacher training should try to change this panorama.

**Initial PECT training and science education**

Teachers tend to teach in the same way as they themselves were taught, and breaking this cycle requires good initial teacher training (Pringle, 2006). Working with real classroom experiences is essential to guide the student towards understanding and developing appropriate professional knowledge.
PECT have been studied by several authors (Akerson, Buzzelli & Donnelly, 2010; Kahriman, 2016; Saçkes & Trundle, 2014). The influence of PECT formation is really important, because it is perhaps more stable than it is often assumed to be (Smith, 1997), and the importance of quality education for individuals working with young children is widely accepted in the field of Early Childhood Education (Early & Winton, 2001).

Cruz-Guzmán, García-Carmona and Criado (2017) presented the profile of students doing the Early Childhood Education degree course at the Seville University, Spain. Most of them had a low preference for science. More than half had accessed the degree course via a study path without science subjects, but instead through social sciences, a humanities pre-university baccalaureate, or modules of professional training in education. Many had last studied science between the ages of 14 to 16, and had begun the degree course with an inadequate science background.

PECT have been asked by different authors about various educational themes, such as the promotion of children's active participation and decision-making, the role of the teacher, the way children learn, the reasons for schooling, the children's needs, pupil-teacher relationships, etc. (Avgitidou, Pnevmatikos & Likomitrou, 2013; Lin, Gorrell & Silvern, 2001). However, to the best of our knowledge, there has been no approach to PECT’s analysis of children's prior ideas about scientific themes, although we have found such studies at a different educational level or in early childhood education but with in-service teachers.

For example, Pringle (2006) studied how 56 prospective primary education teachers explored children's alternative ideas as a basis for planning their science teaching proposals. To this end, the student teachers designed a teaching and learning activity that sought to make the children's alternative ideas explicit so that they could be reformulated conjointly in a guided way. The objective was for the prospective teachers to experience in a profound way the planning and practice of a teaching activity in a constructivist classroom. It is noteworthy that the students, at the end of their study, thought that this was not realistic due to the lack of time to be able to implement large-scale activities for the identification of pupils' alternative conceptions. However, they did express excitement about the variety of ideas the children had about the specific themes that had been addressed.

Kambouri (2016) analysed the data obtained from in-service early childhood teachers in relation to their beliefs and practices in the classroom related to their pupils' prior ideas. The results showed there to be a deficit in the temporal dedication to identifying the children's ideas when the teachers planned their proposals, as well as a need to improve their ongoing training because many of them had no previous scientific training before their education degree.

**Goals of this communication**

In this context, we consider it to be of absolute importance in the initial training of early childhood education teachers for them to learn how to detect and analyse their pupils' ideas, so that they "know how to", not just "know", and then can be able to include constructivist and inquiry-based methods in their classes. This study therefore was aimed at determining (a) the instruments that the ECPT design to discover what their pupils' ideas are about the content in the area of knowledge of the natural and social environment, (b) how they analyse the results
they obtain, and (c) the didactic implications and usefulness of the results they get for their educational planning.

METHOD

Participants and Context

The participants were 38 students from the third year of preschool education, organized into 7 groups of 4-5 members. All of them were taking the courses Natural Environment Teaching for the stage 0 to 6 years and Knowledge of the Social Environment, which are carried out in coordination. On these courses pre-service teachers acquired the necessary knowledge to design an instrument to detect ideas previously held by children on a preschool curriculum topic, they applied it with a sample of 6 children of the same age, between 3 and 6 years old, analyzed the ideas of the children interviewed and wrote a report with open questions for their evaluation in the two courses. The responses of the children were not included in the reports due to a lack of space.

Analysis of the pre-service teachers’ reports

In order to analyze the quality of the work presented by the pre-service teachers a qualitative method was followed, for which an analysis rubric has been designed (Table 1), defining the categories 1.1, 3.2, 3.3, 4.1 and 4.2 as they emerged throughout this process and the rest of the categories are based on the work of Solís, Porlán, Martín del Pozo and Siqueira (2016) and Porlán, Martín del Pozo, Rivero, Harres, Azcárate and Pizzato (2011). The responses to the reports have been grouped into the different categories created, triangulating the data obtained and reviewing the coding between the three authors, organized in pairs for the analysis of the two sets of reports that were established. Subsequently, an agreement was reached on the questions where there were discrepancies (a low percentage), to such an extent that a 100% agreement was reached on the dubious responses.

RESULTS

The frequency of the three levels of formulation for each category analyzed are presented, for report (7 reports, Figure 1) and for question designed (88 questions, Figure 2). The results show that pre-service teachers predominantly choose topics which are either word-for-word curriculum topics (2/7) or fail to connect with the interests of the preschool students (3/7). 7/7 design instruments tend to combine a reasonable number of mainly open questions with other resources such as drawings, diagrams, etc. The data shows that the students do not always explicitly state the educational implications derived from the study carried out, and in designing their educational proposal, those that took the educational demand researched into account are in the minority (1/7). Nevertheless, the majority (5/6) consider the work carried out to be useful and feasible in future as a teacher.

</tbody>
</table>

The questions that the students include in their instruments employ language fairly in keeping with the age of the pupils interviewed (in 54% of cases), they usually look for meaning although we found a significant number of questions (23%) where the responses are with concrete data (names, dates, etc.) "How long does a season last?". In general, a 72% relate to the mesocosm, that which is perceptible or close to the pupil, "How do you know summer has arrived?", but they do not seek a theoretical justification of what is perceived (macrocosm or mesocosm). This may be due to the students' belief that children at the early childhood stage are unable to relate the mesocosm to the closer levels of the macrocosm and the microcosm (Level 3).
In 44% of the cases, the objectives of the questions considered tend to be clear and in line with the proposals, nonetheless, with a frequency of 33%, the objectives do not correspond to what is really being asked (level 1, e.g., "How long does the stomach take to digest food?" Objective: "To see whether they relate the resting time after having eaten a meal with the actual time it takes the stomach to digest it."). The questions are either not well formulated or are simply not relevant to the topic being studied. The objective either repeats the question affirmatively or does not specify the desired school content (39%, Level 2) (e.g. Question: "Do you know what recycling is? What is it for?" Objective: "To see if the child understands the concept of recycling as well as its usefulness.").

The results obtained with respect to the analysis performed by the pre-service teachers demonstrate the difficulty they find with the process carried out. In this way, even though we find responses in which levels of complexity are formulated following some clear criteria (level
3, 25%), the ones which do not always go up in accordance with the level of their complexity or they do not specify the knowledge for each category (Level 2) are slightly more predominant (28%). Here it is shown level 2 example. In response to the question "Is recycling good or bad? Why?", the levels determined were: I. Do not answer. II. They respond but do not give reasons for their response. III. They respond providing reasons to support their response.

In the same way, although in many cases the devised category system makes sense according to the data obtained, the systems where not all the categories created are related to or make sense according to the responses or the data analyzed is predominantly higher (33%).

The final dimension analysed concerns the educational value of the work carried out. In relation to the category 4.1, the PECT seldom declare that they will take into account the demand for learning that was investigated in their educational proposal design (Level 3, Example 1), although in 3/7 of the reports it is possible to sense an educational implication in their conclusions (Level 2, Example 2).

Example 1. Bearing in mind the previous data about the children's prior ideas, and thus about the knowledge they have about recycling, this was used as the base for the development of a project about this theme. The prior ideas obtained after interviewing the children are going to be taken into account in developing a series of activities for our project "Recycling" that are based on the different levels which they have attained (Report Group 12. Level 3).

Example 2. The completion of this study can be of help to us in the future as we have learned to analyse the children's prior ideas and from this, we shall be able to teach the chosen theme taking into account their previous knowledge (Report Group 7. Level 2).

More positively, in regard to the category 4.2, in 5 of the 7 reports, the PECT consider the work they did to be useful and applicable for their future as teachers (Level 3), and only a minority consider it to be useful but too complicated to implement, or do not openly declare its transferability (Level 2). Below we present two fragments extracted from the reports in which the students give their opinions regarding the transfer of the work they carried out:

We believe this is a good way of working with the children's prior ideas, and that it can be of use to us as teachers in the future as well as now as students (Report Group 5. Level 3).

We consider it to be appropriate and original to know what knowledge our young pupils have before going deeper into a particular theme and to take advantage of the great imagination and the many great responses they can provide us with. However, we note that the process of collecting data through the tables and matrix so as to be able to analyse the children's ideas is quite a complicated process which takes a long time to see the levels the children have reached, so therefore it would be difficult to implement in a class (Report Group 15. Level 2).

DISCUSSION AND CONCLUSIONS

This study has allowed us to verify that prospective teachers have difficulty in selecting themes that go beyond what is set out in the curriculum and are more directly linked to pupils' everyday reality. They remain anchored in traditional curricular content, and are unable to break away
and propose topics that may be more attractive to the pupils. We find that there exists a certain reluctance to break with traditional teaching, coinciding with the idea defended by Pringle (2006) that teachers tend to teach in the same way they themselves had been taught. It is therefore essential to make a break with this model in initial teacher training, and provide our students with the skills and strategies that can lead them to create their own teaching model.

Regarding the design of the instrument to detect children’s ideas, the prospective teachers show a great capacity to adapt to the children's language and to make use of different resources to facilitate their pupils’ contact with and understanding of the topics. In accordance with Solis, Porlán, Martin del Pozo and Siqueira (2016), in this way they surpass the so-called level of academic culture to that of the culture of age, using a language that is closer and more approachable for early childhood pupils. This aspect is particularly favourable because it demonstrates the PECT’s ability to be understood by their pupils and to be able to design resources that are attractive for them.

It is also noticeable that the questions the PECT put to the children relate mainly to the mesocosm. This may be linked, on the one hand, to the difficulty they often have in understanding scientific content (Cruz-Guzmán, García-Carmona & Criado, 2017; Timur, 2012) and, on the other, to the consideration that some content can not be dealt with in early childhood education as the pupils at this stage are not prepared for it (Kambouri, 2016; Cantó, Pro & Solbes, 2016). Initial teacher training is once more the key to overcoming these obstacles. Prospective teachers must improve their scientific knowledge because, unless they master the subject they have to teach, they are not actually going to be able to teach it in an innovative way. We therefore consider that it is important to give greater weight to science subjects in initial teacher training so that they can compensate this deficiency in the scientific background with which they entered university.

In our study, the prospective teachers find it very hard to analyse the pupils' ideas. There fundamentally stands out the difficulty they had in categorizing the responses, tending to create closed categories that they generally link to answers that are "right" or "wrong". This may again be related to the dominance of a traditional teaching model in which there are no alternative responses, closed and pre-defined concepts predominate, and "misconceptions" are not seen as ideas that can be made to evolve during learning. The PECT’s lack of mastery of the content (Kerr, Beggs & Murphy, 2006) makes it particularly difficult for them to determine categories and levels of complexity in the children's responses.

If prospective teachers encounter these obstacles at this stage of their training, in the future it will be difficult for them to take their pupils' ideas into account when planning their teaching because, if they are unable to organize the responses they get from the pupils and determine the different levels or stages of knowledge these represent then they will not be able to offer the pupils the means to advance to higher levels. In this regard, we consider it essential to implement a process of feedback with the prospective teachers during this type of practical work they do in their courses. Once they have prepared a system of categories and begin to analyse their data, by reflection with them we may be able to provide them instruments with which they can correct their mistakes, i.e., give them advice on the scientific content involved, on classification techniques, on restructuring the system they have created, and on using low-
Inference descriptors (Latorre, 2003). In this way, we would be helping them to overcome the obstacles they encounter, guiding them in their real and effective consideration of these ideas in planning their future educational proposal.

In addition to everything mentioned above, it should be noted that, at the theoretical level, the prospective teachers seem to be clear that the work they carried out should have a direct impact on the design of the educational proposal they make. This, however, is restricted to the declarative plane, reflecting the dominance of theoretical didactic knowledge. We therefore consider that it is necessary to work with the prospective teachers in direct contact with early childhood pupils so that our students can learn about the children's actual ideas and ways of thinking, and try to connect their aforementioned didactic knowledge with practical classroom reality. Maybe in this way the abandonment of constructivist methods that many in-service teachers present could be avoided. Kambouri (2016) notes the lack of time that practising teachers dedicate to considering their pupils' ideas, and hence the low educational implication of those ideas.

Finally, it is notable that the prospective teachers value very positively the work they carried out, considering it to be useful and applicable for their professional practice. They particularly value the learning they derived from direct contact with the children and their ideas, the recognition of their own capacity to listen, and the satisfaction they felt from taking on the role of teacher during the development of the work. In this sense, the present results coincide with those of Pringle (2006) with regard to the positive assessment of the approach to the children's conceptions, but differ in that the prospective primary teachers of her study found that activities designed to determine pupils' ideas were unrealistic due to the lack of time available.

Initial teacher training must therefore advance by offering prospective teachers the opportunity to gain depth in their own scientific knowledge and by facilitating their direct contact with the reality of the early childhood classroom.

PROFESSIONALIZATION OF FUTURE CHEMISTRY TEACHERS FOR TEACHING IN INCLUSIVE CLASSROOMS

Ann-Kathrin Schlueter and Insa Melle
TU Dortmund University, Chair of Chemical Education, Dortmund, Germany

Inclusive schooling brings new challenges for teachers, for which they need to be prepared. This paper introduces a university seminar that aims to professionalize future chemistry teachers for teaching in inclusive classrooms. The seminar’s contents and the results of its evaluation are presented and discussed. For this, the Universal Design for Learning (UDL) serves as a guiding concept. The evaluation does not only show that the future teachers assess the seminar as attractive but also indicate a significant increase regarding their attitudes, willingness, and self-efficacy concerning inclusion as well as their skills in designing lesson plans according to the UDL. Additionally, they can implement what they have learnt at school to some extent. The students rate the future teachers’ classrooms very positive.

Keywords: inclusion, teacher training, universal design for learning

INTRODUCTION

Since the ratification of the UN Convention on the Rights of Persons with Disabilities (United Nations, 2006), inclusion is a much-discussed issue. However, its successful implementation still requires a long process of various changes to the educational system. Hence, insights into the requirements of the realization of inclusive lessons are necessary. It is a new challenge for the teachers to develop a teaching practice, which supports every student in accordance with his or her individual skills, while also taking (special) educational needs of the students into account. Therefore, the teacher training provides an essential basis for implementing inclusive education at schools (Amrhein & Dziak-Mahler, 2014; Florian & Rouse, 2009). Consequently, it is the goal of this project to develop and to evaluate a seminar that prepares future chemistry teachers for teaching in inclusive classrooms.

THEORETICAL BACKGROUND

Inclusion in the teacher training

Even though inclusion is already reality in German classrooms, teachers and future teachers do not feel well prepared for the new challenges that come with it (Amrhein & Dziak-Mahler, 2014; Lambe & Bones, 2006). That is particularly due to the fact that universities show little efforts to prepare future teachers for inclusion (Körner, 2010). A study in Germany revealed that inclusion is often just part of courses in general pedagogies; it is still rare that inclusion is taught in connection with the specific subject or teaching methodology (Monitor Lehrerbildung, 2015). Therefore, future teachers gain some general knowledge about inclusion, but they do not learn how to implement it in subject-related classrooms.

To meet the requirements of inclusive teacher training, Forlin (2010, p. 8) proposes a “Whole Faculty Approach (WFA)”: The university’s different departments, divisions and discipline areas should collaborate to build up a “common understanding of what constitutes an inclusive
curriculum or what the aims should be in furthering this” (Forlin, 2010, p. 8). Recently, the German government tried to promote the implementation of inclusion in its teacher training. For this, the Federal Ministry for Education and Research (BMBF) supports projects of universities that aim to implement such whole faculty approaches (Bundesministerium für Bildung und Forschung, 2016). Comparable efforts are made internationally as well. For example, in 2009 the European Agency for Development in Special Needs Education started the triennial project Teacher Education for Inclusion (TE4I) to work out essential teacher competences for inclusive education. These competences were organized and structured as the Profile of Inclusive Teachers (European Agency for Development in Special Needs Education, 2012). However, there is still no evidence-based concept to develop those competences.

**Universal Design for Learning**

Within this study, the Universal Design for Learning (UDL) serves as a guiding concept. It is a framework for designing classrooms, which are accessible for all students by reducing construct-irrelevant barriers (CAST, 2011; Rose & Meyer, 2002). Drawing from brain research, the core of UDL consists of three principles that demand three kinds of flexibility:

I. “To support recognition learning, provide multiple means of representation – that is, offer flexible ways to present what we teach and learn.

II. To support strategic learning, provide multiple means of action and expression – that it, flexible options for how we learn and express what we know.

III. To support affective learning, provide multiple means of engagement – that is, flexible options for generation and sustaining motivation, the why of learning.” (Hall, Meyer, & Rose, 2012, p. 2)

Each principle is subdivided into three guidelines with three to five checkpoints each. These guidelines are tools to support teachers in the instructional planning phases. They help identifying potential barriers in materials and methods and offer fitting solutions to ensure that all students can learn in the best possible way (Lapinski, Gravel, & Rose, 2012).

Overall, UDL maintains the policy “Essential for Some, Good for All” (Meyer, Rose, & Gordon, 2014, p. 84): Not all students need such flexibility in the classroom to meet their individual skills but everyone benefits from it.

**THE INTERVENTION**

The developed seminar “Preparation for teaching chemistry in inclusive classrooms” is the preparation seminar for the internship semester. The internship semester contains school practice and is part of the master program of the studies. Therefore, the seminar shall prepare for this internship semester and is mandatory for all future teachers in chemistry education.

In the seminar, the students deal with different aspects of teaching in inclusive classrooms, both theoretically and practically. Table 1 shows all seminar topics.
### Table 1. Seminar’s contents and thematic blocks. Written in grey are the times of measurements.

* Sessions held by a lecturer from the special needs department

The seminar was cooperatively created by the chairs of chemistry education as well as the special needs department and the seminar sessions are organised as team teaching. The seminar sessions signed with a star are held by a lecturer from the special needs department and focus on students with learning disabilities. The reason for this focus is that in Germany, learning disability is the most common disability of special needs students and those students very often go to inclusive classes (KMK, 2016a; KMK, 2016b). A lecturer from the chair of chemistry education manages the other seminar sessions. Therefore, the students can deal with both, special educational aspects of teaching and learning as well as subject related aspects concerning inclusion. However, in all sessions both lecturers are present, so every subject can be discussed from both points of view. Moreover, four thematic blocks subdivide the seminar.

Normally, one session is structured as follows: It starts with an introduction, mainly realized with a Power-Point-presentation. After that, the students can deal with the presented topics in groups independently. At the end, they present their results.

In the seminar, the UDL serves as overarching concept and guideline. Therefore, the introduction of the UDL as a general pedagogical framework for inclusive teaching happens in session 4 and all other seminar topics refer to it. For example, the lecture in the session “Student-based experiments in inclusive classrooms” presents a hands-on learning environment which is designed to be mostly universally accessible using the UDL. This learning environment, as a specific example, shall point out opportunities and steps, which can increase the universal access in hands-on learning environments. After that, the students get time to develop a hands-on learning environment for inclusive classrooms on their own in groups.
RESEARCH QUESTIONS

Adapted to the evaluation steps by Kirkpatrick (1979), the developed seminar is evaluated on the basis of the following levels: (1) attractiveness, (2) cognitive changes, (3) implementation at school and (4) effect on the students. The research questions are based on these four levels:

Attractiveness: Q1): How do the future teachers assess the seminar?

Cognitive changes:

Q2): Which impact does the seminar have on the
   a) attitudes concerning inclusion?
   b) self-efficacy expectations concerning inclusion?
   c) willingness to teach in inclusive classrooms?

Q3) Do the future teachers improve their skills in designing lesson plans according to the UDL?

Implementation at school: Q4): Are the future teachers able to put into practice at school what they have learnt in the seminar?

Effects on the students: Q5): Which effect do the implemented lessons have on the students in the classrooms?

STUDY DESIGN AND METHOD

The study is an intervention study with a pre-post-follow-up-design (Error! Reference source not found.). Moreover, the analysis of a comparison group shall ensure that some of the measured effects can be traced back to the seminar and not to other factors, such as the test rerun.

During the first two sessions of the intervention group, the first measurement takes place. The future teachers’ attitudes, willingness, and self-efficacy concerning inclusion are tested by paper-and-pencil-tests (6-point Likert-scale from $1 = I \text{ completely agree}$ to $6 = I \text{ completely disagree}$; $\alpha_{\text{Attitudes}} = .900$, $\alpha_{\text{Willingness}} = .904$, $\alpha_{\text{Self-efficacy}} = .894$). Moreover, to measure their skills in designing lesson plans according to the UDL, the future teachers must plan lessons for inclusive chemistry classrooms. This analysis is made by using an encoding manual (4-point Likert-scale from $1 = \text{ no}$ to $4 = \text{ yes}$; ICC unjust = .857). After that, the intervention with eleven sessions follows. During the intervention, a survey (5-point Likert scale from $1 = I \text{ completely agree}$ to $6 = I \text{ completely disagree}$; $\alpha = .879$) measures the quality of four thematic blocks. The future teachers’ work behaviour during two working phases is filmed and assessed by an encoding manual ($\kappa$ between .709 and .851).

During the last two seminar sessions, the second measurement takes place. Besides the attitudes, willingness, and self-efficacy tests as well as the lesson plans, this time of measurement includes a survey to measure the seminar’s overall assessment (5-point Likert-scale from $1 = I \text{ completely agree}$ to $6 = I \text{ completely disagree}$; $\alpha = .837$), focused on the quality of the working phases and lecturers’ delivery. After the seminar, the future teachers can implement what they have learnt in the subsequent internship semester. During this internship semester, the future teachers have an accompanying seminar for three days at university.

</table>
In the first session of this seminar, the future teachers can ask questions and develop lesson plans for their inclusive classrooms with their fellows. Then, the future teachers have to implement their developed lesson plans at school. To evaluate the implementation at school, three aspects are analyzed: One of these is the future teachers’ written lesson plans. These are analyzed by the same encoding manual which is used to assess the future teachers’ skills in designing lesson plans according to the UDL during the seminar (ICC\textsubscript{unjust} = .840). The second aspect of this evaluation is their developed work sheets, analyzed by assessment criteria (4-point Likert-scale from \textit{1} = \textit{not met} to \textit{4} = \textit{met}; ICC\textsubscript{unjust} = .923). Thirdly, the videos of the implementation at school are analyzed by using an encoding manual (\(\kappa\) between .764 and .980) as well. Additionally, guided interviews with the future teachers survey their subjective assessment of their implemented inclusive lessons after the implementation. These interviews are analyzed by the means of an encoding manual (4-point Likert-scale from \textit{1} = \textit{incorrect} to \textit{4} = \textit{correct}; ICC\textsubscript{unjust} = .959). Furthermore, guided interviews with three students per class – preferably students with different performance levels – are used to measure the effects on the students regarding the lessons’ universal access experienced by the students. For this, encoding rules (4-point Likert-scale from \textit{1} = \textit{incorrect} to \textit{4} = \textit{correct}; ICC\textsubscript{unjust} = .959) are used as well.

In the last session of the accompanying seminar, there is the third time of measurement to evaluate the seminars’ long-term impact on the future teachers’ attitudes, willingness, and self-efficacy. Overall, this process has already been completely conducted two times in the past while a third seminar turn was analyzed without the implementation at school in the internship semester. Figure 1 shows the study’s time-course.

![Figure 1. Study's time-course](image)

The comparison group consists of future teachers from a different, but comparable university, which participate in their preparation seminar for their internship semester. Their seminar is a subject-related teaching methodology seminar with no focus on inclusive education. In the second and penultimate session, the survey measures attitudes, willingness and self-efficacy as well as the future teachers’ previous experiences concerning inclusion of the future teachers in the comparison group.

**RESULTS**

This chapter will present the study’s results, following the four evaluation steps. Overall, 39 future teachers participated in the developed seminar and 18 future teachers completed the internship semester. Eleven future teachers formed the comparison group. Therefore, it is a small sample size, which is why the results should be treated carefully.
Attractiveness

The future teachers’ perception of the quality of the thematic blocks and of the working phases as well as lectures served to assess the seminar’s attractiveness.

Table 2 lists the results of the seminar quality questionnaire. As the means show, the future students feel very positive about the quality of all thematic blocks.

Table 2. Seminar quality of the four thematic blocks and the aggregated data of all blocks (Total). The descriptive statistics of the seminar quality survey from \( I = \text{very incorrect} \) (negative) to \( 5 = \text{very correct} \) (positive) are shown.

</tr>
</tbody>
</table>

However, there are also some differences in the future teachers’ assessment noticeable. The second block exhibits a lower mean than the others. A univariate analysis of variance (ANOVA) with repeated measures confirms this difference \( (F = 8.56, p < .001, \eta^2 = .290, n = 22) \). Applying the post hoc test demonstrates that Block II is rated significantly worse than Block III and IV (Table 3).

Table 3. Seminar quality of the thematic blocks: Pair-wise comparison by post hoc test.

At the seminar’s end, a survey measures the quality of the working phases and the performance of the two lecturers. The means in Table 4 show that the future teachers assess the working phases and both lecturers as positive.

Overall, concerning the first research question the results indicate that the future teachers assess the seminar very positively.
Table 4 Assessment of the working phases and lecturers’ performances (Lecturer CE = Lecture from chemical education department; Lecturer SN = Lecture from special needs department). Cognitive Changes

The future teachers’ attitudes, willingness and self-efficacy expectations concerning inclusion serve as the first parameters to analyze cognitive changes. For that, a survey measures these three parameters at the beginning (pre) and at the end (post) of the seminar as well as at the end of the internship semester (follow-up). A graphical overview of the results serves Figure 2. An immediate and a long-term increase is visible.

Figure 2. Presentation of the means of the attitudes, willingness and self-efficacy before (pre) and after (post) the seminar as well as at the end of the internship semester (follow-up) of the intervention group (n = 18). p < .05: *; p < .01: **; p < .001: ***.

A paired $t$ test confirms this observation (Table 5). The seminar was able to achieve a significant positive change in the three parameters both immediately and in the long term.

In addition, a comparison group shall ensure that no other factors, for example the test rerun, cause the measured effects regarding these changes. Figure 3 serves as a graphical overview of the means of the attitudes, willingness and self-efficacy before and after the seminar of the intervention and comparison group. It shows a slight decrease of the three parameters in the comparison group. This suggests that the three parameters increase in the intervention group more than in the comparison group.

An unpaired $t$ test of the residuals confirms that other factors do not cause the measured significant changes (Table 6).
Table 5. Immediate (Pre-Post) and long-term (Pre-Follow-up) changes of the attitudes, willingness and self-efficacy from 1 = very incorrect (negative or small) to 6 = very correct (positive or high). Comparison by paired t test.

Concerning the second research question, the results indicate that the seminar has a positive impact on the future teachers’ attitudes, willingness, and self-efficacy.

As a second parameter to analyze the cognitive changes, the future teachers’ skills in designing lesson plans according to the UDL before and after the seminar are analyzed. For this, the future teachers had to develop lesson plans before and after the seminar. These lesson plans are evaluated based on the implementation of UDL-elements. The comparison of the future teachers’ skills before and after the seminar shows a significant improvement ($t = -12.20$, $p < .001$, $\delta = 2.01$, $n = 37$).

**Implementation at school**

There is a big difference between knowing principles as well as techniques and using them. Therefore, the implementation of the seminar’s contents at school in the subsequent internship semester is also measured.

The future teachers had to plan inclusive lessons using what they have learnt in the seminar. In this context, they developed lesson plans as well as work sheets and they tried to implement their lesson plans. Their efforts were videotaped. By analyzing these three aspects according to the elements of the UDL, the results show that the future teachers implemented what they have learnt to some extent. For example, the analysis of the lesson plans happens by using the same encoding manual that was already used to analyze the lesson plans before and after the seminar. With a maximal value of four, the future teachers achieve an average of $M = 2.44$ ($SD = 0.32$, $n = 17$). This shows they can still enhance the quality of the implementation. In addition, the analysis of the videos reveals great differences among the future teachers regarding the quality of their implementation at school.

Immediately after the implementation, interviews with the future teachers indicate that they rate their gained experiences at school as positive and the UDL was helpful for the development and implementation of inclusive lessons.

According to the fourth research question, the data show that the future teachers are able to put into practice what they have learnt but the quality of the implementation can be enhanced.

**Effects on the students**

Interviews with three students per class detect the effects on the students. These interviews are conducted immediately after the future teachers’ inclusive lessons. In these interviews, the students assess how accessible the future teachers’ classroom was for them. With a maximal value of four, the students assess the accessibility with an average of $M = 3.33$ ($SD = 0.37$, $n = 50$). This result indicates that the inclusive classrooms implemented by the future teachers are accessible to the students.

**DISCUSSION**

This study identifies some possibilities to prepare future chemistry teachers for teaching in inclusive classrooms. The results show that the future teachers improve their attitudes, willingness and self-efficacy concerning inclusion as well as their skills in designing lesson plans according to the UDL. In addition, the future teachers are able to implement what they
have learnt and the students assess these implemented classrooms as accessible for them. Nevertheless, the transfer of knowledge into practice seems to cause some problems for the future teachers since the implementation in school can still be improved. However, this is not surprising, as their teacher training is not completed yet. The future teachers have to take their exams at university and after that finish a traineeship, which takes one and a half year.

These results reveal possible improvements. To improve the transfer from theory into practice video vignettes showing critical situations in inclusive chemistry classrooms could be implemented into the seminar. In doing so, the future teachers could gain some realistic insights in the inclusive classrooms. They could discuss it and work out some alternative behaviours.

Since the UDL is a framework of the general pedagogy, other departments can use this seminar conception with subject-related adaptions. This has already occurred in the subjects English, Music and Physical Education at TU Dortmund University. This constitutes one step towards the WFA (Forlin, 2010).

Overall, there are more courses and seminars necessary to prepare future (chemistry) teachers for teaching in inclusive classrooms. This requires the cooperation of the whole university in designing a common understanding of inclusion and shared concepts future teachers can work with. For that, the developed seminar can provide some indications.

ACKNOWLEDGEMENT

I want to thank my research group at TU Dortmund for their support with my Ph.D. -project and the participating students and future teachers.

PROFESSIONALIZATION OF PRE-SERVICE CHEMISTRY TEACHERS FOR THE COMPETENT USE OF ASSESSMENT

Ann-Kathrin Nienaber and Insa Melle
TU Dortmund University, Chair of Chemical Education, Dortmund, Germany

Since 2005, the right of each student for individual support has been anchored in Germany (Schulgesetz für den Land Nordrhein-Westfalen, 2005). Therefore, it is important that teachers regularly analyze their teaching in order to adapt future lessons to the current learning level of the students and to give individual support. This has been particularly important since 2006. At this time, Germany signed the UN Convention of the Rights of Persons with Disabilities and is therefore committed to introduce an inclusive education system (United Nations, 2006). With the increasing heterogeneity in German classrooms, a formative diagnostic assessment of the current learning level is indispensable. Therefore, it is necessary to make diagnostic tests universally accessible or modify the task level. The aim of this project is to professionalize future chemistry teachers in dealing with these new challenges and to show them how to implement inclusive diagnosis in their classes. For this reason, a seminar was developed in which the teacher students learn how to formulate and evaluate learning objectives. The seminar is located in the master program of the studies. They get to know different task formats and how to adapt them to heterogeneous learning groups with the help of test accommodations and modifications. Additionally, the Universal Design for Assessment is used for support (Lovett & Lewandowski, 2015). Hereby, learning objectives and diagnostic tests are not only taught theoretically, but are also created independently by the teacher students. A checkup of what has been learnt takes place in the subsequent internship semester. There, the teacher students apply in the classroom what they have learnt in the seminar. In order to evaluate the effectiveness of the seminar, we used pre- and post-tests and the implementation in the internship semester is evaluated. In this paper, we report the first results of the main study.

Keywords: teacher training, assessment, inclusion

MOTIVATION

Since 2005, every student in the state of North Rhine Westphalia (Germany) has the right to individual support (Schulgesetz für das Land Nordrhein-Westfalen, 2005). In order to fulfill this obligation and to be able to ensure adequate individual support, teachers have to diagnose the learning outcomes of their students. Despite the demands for diagnosis and individual support, school performance has only been improved to a limited extent as international school performance comparisons (TIMSS, IGLU) show. Hence, an increase in the diagnostic competencies of teachers (Fischer et al., 2014) is required.

A further challenge for teachers is posed in the form of the UN Disability Equality Convention, where Germany agreed to convert its school system into an inclusive one (United Nations, 2006). Handling these two demands has become a law of teacher training in Germany, e.g. in Northrhine Westfalia (LABG, 2009). For this reason, universities are obliged to improve diagnostic competencies in the teacher-training. Therefore, we developed and evaluated a university seminar that deals with this topic.
THEORETICAL BACKGROUND

Inclusive teaching requires regular pedagogical diagnosis (Prengel, 2013). For this purpose, a formative form of assessment is useful. This method enables to recognize students’ current learning needs and, therefore, adapt the following lessons to them accordingly (OECD, 2005). As a consequence, formative assessment primarily aims at the improvement of teaching and learning in the classroom (Black & William, 2009). Accordingly, the main element of the seminar developed is to specify learning objectives and to check the individual progress of the learners towards these goals (OECD, 2005).

Furthermore, information about the use of formative diagnostic tests in inclusive classrooms is given to the teacher students. If some students in heterogeneous classes are unable to participate in the test under regular conditions, test accommodations concerning the environment or the layout are recommended. An overview of the aspects that should be observed is provided by the Universal Design for Assessment (UDA) (Lovett & Lewandowski, 2015). Lovett and Lewandowski adapted the Principles of Universal Design (Story, Mueller & Mace, 1998) for creating tests. In many studies the effects of different alterations in the test layout or test environment were investigated. For example, a study by Kettler et. al. (2012) tested the effects of reducing barriers in test layouts, they were able to show that students with and without disabilities received higher scores. Furthermore, Shinn and Ofiesh (2012) created an overview of the types of test alterations that reduce influences of disabilities. If test accommodations are not sufficient to participate in the diagnostic test due to the special education level, it is possible to use modifications by creating different content levels (Kettler et. al., 2012). This means that students who are overburdened or subchallenged by the regular performance level will receive a diagnostic test with an appropriate level of performance.

METHOD

The procedure of the main study with about 25 students is based on the results of a pilot study. In the following illustrations, it is only the main study is referred to. The seminar consists of seven seminar sessions, in which the contents for the formulation of learning objectives and how to evaluate them are taught to the teacher students. In the subsequent internship semester, they can practice what they have learnt in the seminar in the classroom.

We evaluated the seminar on four levels based on the theory of Kirkpatrick and Kirkpatrick (2006). This way, the appreciation of the seminar, the cognitive change, the practical implementation, and the effect on the learners are measured.

To evaluate the appreciation of the seminar, we used a test of attractiveness after the seminar (open questions, 5 Items; 5-point-Likert-scale, 26 Items, $\alpha = .884$).

For the evaluation of the cognitive change we surveyed the teacher students three times: Before, and after the seminar, as well as after the internship semester. At each time, we used a competence test for measuring the skills in handling learning objectives and diagnostic tests (16 Items, coding manual: ICC$_{unjust} = .845$). Additionally, a test for measuring the attitude, self-efficacy, and willingness of the teacher students was conducted before and after the seminar (5-point-Likert-scale; 21 Items, $\alpha = .889$).
After the internship semester, we used a coding manual ($\text{ICC}_{\text{unjust}} = .765$) to analyze the diagnostic test that had been created by the teacher students. We measured this for the level of practical implementation.

To gather the effects on the learners, the teacher students applied a questionnaire. The questionnaire asked the learners about their opinion on the diagnostic test and the degree of difficulty (5-point-Likert-scale, 5 Items).

**CONTENTS OF THE SEMINAR UNIT**

In the seminar unit "Diagnostic tests in chemistry classes", students learn the theoretical structure of learning objectives, diagnostic tests and individual task types. In addition, they learn special features for usage in an inclusive classroom. These theoretical constructs are put into practice by the teacher students in each individual session, e.g. by creating their own diagnostic tests in the working periods of the seminar. Thus, a seminar is always composed of a theoretical input through Power-Point-presentations and practical working periods, which are characterized by a variety of methods. All results will be presented by the teacher students to each other, explained and discussed with the other teacher students. The focus of the seminar is on three topics which are repeatedly linked with each other. These includes the formulation of learning objectives according to Mager (1977), test accommodations in test design and test environments according to Lovett and Lewandowski (2015) as well as the modification (Kettler et. al., 2012) of individual task types. The aim is to prepare teacher students as comprehensively as possible for various special educational needs. The individual seminar sessions are listed in Table 1 and are explained in more detail below.

Session 1
The seminar unit starts directly with a task, which serves to establish a personal relation to the importance of diagnosis for the students. In this way, a change of the inner attitude towards the significance of pedagogical diagnostics for their own teaching should be achieved. For this purpose, we present the teacher students fictitious statements, similar to those they know from their own school days. These fictitious statements are worded through the perspective of students that either lack any diagnosis by their teacher or are diagnosed incorrectly. After a guided conversation, there is a Power-Point-presentation on diagnostics and the close connection between diagnosis and individual support. In order to clarify and differentiate the most important concepts on the subject of learning objectives and diagnostic tests, the method of group puzzle is used. On the basis of a pre-defined mind map in DINA-3-size and matching texts, the teacher students become experts in one area and impart the newly acquired knowledge to the other teacher students, while they can record everything in keywords on the mind-map-printout.

Session 2
The second seminar session deals with the formulation of learning objectives. The concepts already learned are repeated at the beginning of a classroom conversation. This is followed by a presentation on the various functions of learning objectives and the formulation according to Mager (1977). This gives a comprehensive impression as a basis and can be well developed later in the teacher training. Furthermore, the subdivisions according to Mager (1977) are linked with the behavioral and content dimension according to Gage and Berliner (1996) and a schema is provided for formulation. The Power-Point-presentation is interrupted by short questions and work phases in which, for example, words that can be used as operators have to be assigned to the different requirements (KMK, 2013) by actively sorting the terms on the blackboard by the teacher students. After the informative input, the teacher students have to formulate learning objectives independently and assign them to the terms learnt in the first seminar session.

Session 3
The third seminar session is dedicated to the use of diagnostic tests in inclusive learning classrooms. By using the Think-Pair-Share method, we work out which particularities are to be taken into account when formulating learning objectives in lessons with inclusive students. After that follows a link between the Universal Design for Learning (CAST, 2011) and the related model of Universal Design for Assessment (UDA) (Lovett & Lewandowski, 2015). The UDA mostly represents the possibilities of test accommodation, which are explained in detail in the seminar. The aim is to create a test for all learners in order to achieve the maximum possible fairness. A summary of the principles is given in Table 2. In order to grasp the guidelines adopted by Universal Design and applied to tests (Story, Mueller & Mace, 1998), teacher students work in groups on different texts. In the end, each group formulates a guideline and a teaching example and presents it to the whole group. As a supplementary model to the test accommodation, the modification is to be considered which aims to offer a differentiated diagnostic test at different levels (Kettler et al., 2012). The model of the modification is briefly
explained, but not in full detail, as numerous examples will follow in the following three seminar sessions.

**Sessions 4 to 6**

The contents of the following three seminar sessions are structured in a similar way as each seminar session deals with a different task format. The teacher students get to know a total of 15 different task types which can be classified into three common task formats: closed, semi-open and open. The teaching method changes in each session. In addition, at the beginning of each of the three seminar sessions, the task format is briefly introduced and at the end, all advantages and disadvantages are collected in the plenary session. In seminar session four, five types of tasks are presented in a closed task format. The structure, the criteria and the possibilities of modification are explained for each task type. This is accompanied by specific example tasks. Afterwards, the teacher students create their own tasks in small groups and differentiate them on three levels. They use the self-defined learning goals of the second seminar session. Laptops and textbooks are made available to the teacher students. In order to provide feedback for all participants, the results are exchanged and feedback is given to each
other. Finally, the teacher students discuss selected examples in the plenary session. The focus of the fifth seminar session is on semi-open task formats. This time, the topic is worked out by the teacher students. In pairs of two, they receive posters on which they find a sample task and the name of the task type. They have to find criteria and develop modifications independently. In addition, the assigned example task is to be differentiated in three levels. The seminar session ends with a gallery walk to present all results. Seminar session six is very similar to the fourth seminar session, but with the subject of the closed questions. It is supplemented by a summary of all modification options.

Session 7

The last seminar session is a practice unit in which the teacher students have to reapply their acquired knowledge and link it thematically to new knowledge. Laptops, textbooks, curricula and materials from the other seminar sessions are available. The assignment requires the teacher students to choose a topic and to use the curriculum to formulate learning objectives. On the basis of these learning objectives, appropriate diagnostic tests have to be developed. Each task format should be represented once. When creating the diagnostic instrument, the teacher students have to take a given setting of a class composition into account and adapt the diagnostic test to the individual characteristics of the students. In this seminar session, the teacher students receive support from the lecturer and open questions can be answered.

RESULTS

The first results of the main study are presented below. So far, not all of the collected data have been evaluated. Therefore, the following results are preliminary.

Cognitive Change

The teacher students significantly improved their ability to handle learning objectives and diagnostic tests in inclusive classrooms ($p < .015$, $\delta = 1.331$, $n = 9$).

The self-efficacy, attitude and willingness of the teacher students concerning the use of diagnostic tests in the inclusive classrooms are significantly improved (Self-efficacy: $p < .001$, $\delta = 1.20$, $n = 25$; Attitude: $p = .002$, $\delta = 0.71$, $n = 25$; Willingness: $p = .004$, $\delta = 0.64$, $n = 25$) (Figure 1).

Appreciation of the seminar

The seminar is perceived as attractive by the teacher students ($M = 4.48$, $1 = \text{negative}$ to $5 = \text{positive}$, $n = 25$).
DISCUSSION AND CONCLUSIONS

Impact of the seminar unit

The first impression of the main study corresponds to our expectation as the seminar improves the teacher students’ competence, self-efficacy, attitude and willingness significantly. Especially the self-efficacy has been improved to a great extent. Moreover, the teacher students consider the seminar as attractive.

Practical implementation

Subsequently, we will analyze the diagnostic tests, which have been conducted by the teacher students in the internship semester.

Effects on the leaners

Furthermore, the questionnaires for the students about to their opinion on the diagnostic test and the degree of difficulty will be surveyed.

ACKNOWLEDGEMENT

Finally, I would like to thank my working group for the support and all the participating teacher students and students for their cooperation.

STUDENT PHYSICS TEACHERS’ ORIENTATIONS

Jens Klinghammer, Thorid Rabe and Olaf Krey
Martin Luther University of Halle-Wittenberg, Halle (Saale), Germany

Assuming that orientations determine how (future) teachers think and act, an insight into student physics teachers’ orientations seems to be important. Orientations are basic mental structures of implicit knowledge. Student teachers’ orientations towards teaching and learning physics are primarily influenced by physics lessons they experienced in their own school time. Practical experiences as part of pre-service teacher training can irritate these orientations. Therefore, this case-based study (N = 17) aims at the reconstruction of the student physics teachers’ “frameworks of orientations” concerning teaching and learning physics in the context of a first teaching experience, the so-called school-practical training. Narrative interviews have been conducted and the documentary method is applied for the interpretation of the interview transcripts.

Keywords: implicit knowledge, practical training, documentary method

INTRODUCTION

Science education research suggests what Korthagen (1993) summarises as: “teachers teach the way they have been taught, and not as they have been taught to teach” (p. 324). Pre-service physics teachers’ lesson planning and classroom acting seem to be strongly influenced by what they experienced as pupils during their school time (e.g. Fischler, 2000). Based on these experiences made in numerous lessons, student teachers already have a specific image of teaching and learning within their subject matter before they enter university (Gustafson & Rowell, 1995). This experience-based image of physics teaching can be described as practical experience-based implicit knowledge, also called atheoretical knowledge by Mannheim (1954) or tacit knowledge by Polanyi (1966).

Because this experience-based implicit knowledge seems to be highly relevant to lesson planning and particularly to classroom behaviour, there is the risk that student physics teachers reproduce formerly self-experienced physics teaching. For this reason, the question, “Why do teachers who go through science teacher preparation programmes aimed at reform-minded instruction still teach the way they were taught?”, represents a big issue in science teacher education (Abell, 2008, p. 1413).

Therefore, it has to be taken into account, that student teachers learning in university is related to their experience-based implicit knowledge of teaching and learning physics. Throughout the university teacher training programme the student teachers gain theoretical professional knowledge that might be in contradiction to this implicit knowledge of teaching and learning physics. The necessity of thinking experience-based implicit knowledge as a part of the teacher's knowledge becomes obvious (Helsper, 2002).

THEORETICAL BACKGROUND - IMPLICIT KNOWLEDGE

Assuming that there is a link between (pre-service) teacher’s cognition and their classroom activities, the investigation of pre-service (science) teachers’ knowledge seems to be important
(van Driel, Berry, & Meirink, 2014). Recent science education research on teacher professionalization attempts to map the relationships between the professional knowledge of (pre-service) physics teachers and their actions in physics teaching as well as the student learning achievement in physics lessons (e.g. Fischer, Borowski, & Tepner, 2012).

In German science education research, Cauet’s (2016) study in this area raises the question of whether studies so far test relevant knowledge. The results, that neither “teachers’ content knowledge (CK) nor their pedagogical content knowledge (PCK) correlated significantly with their support of students’ cognitive activation in the classroom”, indicate that the explicable knowledge gathered in professional knowledge tests has limited measurable relevance to physics teachers’ action in science classroom (Cauet, Liepertz, Borowski, & Fischer, 2015, p. 462). Furthermore, the tested physics teachers’ professional knowledge does not “explain any variance of student learning gains” (ibid.). Consistent with these results, Vogelsang’s (2014) research on (pre-service) physics teachers’ professional knowledge and their performances in science classroom suggests, that there is “a very small correlation between the level of competence (or professional knowledge) and actual teaching quality – some evidence even implies that there is no correlation at all” (Vogelsang et al., 2016, p. 36). Although it usually is assumed in the cognitive psychological approach of expertise research (Baumert & Kunter, 2013), Vogelsang (2014) even doubts the general assumption of the transformation of explicit knowledge into teaching action. Therefore, he proposes the analysis of the actual action-guiding resources in the sense of Neuweg’s (2011) knowledge II (Vogelsang, 2014).

Neuweg (2011) distinguishes three forms of teacher knowledge. Knowledge I represents explicit (professional) knowledge in an "objective sense", acquired in teacher education (ibid., p. 452, see Figure 1). Knowledge II comprises explicit and implicit knowledge in a "subjective sense" of action-guiding mental structures (ibid.). Knowledge III frames knowledge in a sense of "competence", which can be reconstructed by an outside observer through the analysis of action episodes (ibid., see Figure 1).

![Figure 1. Forms of teacher knowledge according to Neuweg (2011, p. 453, translated by the authors)](image)

The focus of previous research on professional knowledge of (pre-service) physics teachers in Germany can be classified as research on explicable (theoretical) knowledge I. Fischler (2011) criticises, that in “the current mainstream of research projects on teachers’ professional
development under a cognitive psychological perspective, the ideas of Polanyi, Schön, and of Neuweg [...] play only a marginal role” (p. 45). The proposed consideration of the action-guiding mental structures (knowledge II), in particular the investigation of the tacit (Polanyi, 1966) and implicit (Neuweg, 2004) dimension of this knowledge, represents a desideratum in science education research. The implicit knowledge of (pre-service) physics teachers about teaching and learning physics has hardly been investigated so far.

Besides the mainstream research on teacher professionalization under a cognitive psychological perspective, there are approaches that underline the importance of implicit knowledge. Other - in German science education research not widely considered - lines of research, like the structural approach to teacher professionalism, emphasise this desideratum, too. Instead of considering the competencies of professionals, the structural approach focuses on typical “structural” problems of practice (in our case teaching physics) that professionals (in our case pre-service teachers) have to deal with (Bonnet & Hericks, 2014). In the context of the structural approach to teacher professionalism, Helsper (2002) refers to the necessity to consider biographical, experience-based and implicit knowledge as a part of the teacher's knowledge. From this perspective of teacher professionalism, it is rewarding to reconstruct the action-guiding knowledge that structures the practice of teaching physics. Moreover, typical subject specific problems of teaching physics that professional science teachers have to deal with can be examined.

**Methodological conclusions - reconstructive research approach**

The nature of implicit knowledge described by Neuweg (2004) and Polanyi (1966) entails methodological consequences. The first “experience-dependence aspect” indicates that implicit knowledge is conceptualised as experience-based knowledge (Neuweg, 2008, p. 729). From a learning perspective, the experience-dependence suggests that implicit knowledge rather is acquired through socialization than through verbal instruction (Neuweg, 2004). Therefore, a constructivist-structuralist socialization perspective according to Pierre Bourdieu (1977) seems appropriate to understand the nature of implicit knowledge (Hummrich & Kramer, 2017). For this reason, Bourdieu’s (1977) theory of habitus is an important theoretical framework within this study.

The statement “we can know more than we can tell” (Polanyi, 1966, p. 4) summarizes a second characteristic feature of implicit knowledge, called “non-verbalisable aspect” (Neuweg, 2008, p. 727). According to Michael Polanyi’s (1966) knowledge theory (*tacit knowing view*), implicit knowledge is that knowledge “which manifests itself in behavior in a wider sense, that is, in the processes of perception, judgement, anticipation, thought, decision-making or action, and which is not, not completely or not adequately explicable […] by the subject” (Neuweg, 2008, p. 725). From a methodological point of view, the non-verbalisable aspect is not compatible with frequently used subsuming-logical research approaches like quantitative research methods as well as methods of qualitative content analysis. To investigate the implicit knowledge of (pre-service) physics teachers about teaching and learning physics, these often applied methodologies in science education research are not appropriate.
This study considers the identified methodological constraints by using a qualitative-reconstructive research approach. Based on a praxeological approach referring to Karl Mannheim’s (1954) sociology of knowledge, the reconstruction of “social practices in order to reveal their meanings, significances, effects, interdependencies etc.” allows analysing the atheoretical and implicit knowledge, which is embedded in the social practices itself (Herbert & Kraus, 2013, p. 8). This analytic perspective includes a shift from the question what happens to how reality is constituted (ibid.).

A research methodology based on Bourdieu’s (1977) habitus concept and Mannheim’s (1954) sociology of knowledge is the documentary method (Bohnsack, 2010). The documentary method allows the reconstruction of the “implicit knowledge that underlies everyday practice and gives an orientation to habitualized actions” (Bohnsack, Pfaff & Weller, 2010, p. 20). The reconstruction of the implicit knowledge by interpreting social practice (praxeological approach) includes the assumption that implicit knowledge is documented in the way of speaking about the social practice. To investigate the nature of this action-guiding and implicit knowledge, the documentary method with the concept of the “framework of orientation” is suitable to analyse pre-service physics teachers’ narrations about teaching and learning physics. In the following, the term "framework of orientation" refers to the structure of implicit knowledge at a specific point of the individual biography (Helsper, Kramer, Brademann & Ziems, 2007).

In German educational science, only little research using the documentary method is done (Bohnsack, Pfaff & Weller, 2010). Within the German science education community, only a few researchers have successfully applied this praxeological approach. Sander and Höttecke (2016) chose a qualitative approach based on the documentary method and explored the tacit dimensions of pupils’ judgment and decision-making on socio-scientific issues. Krüger (2017) analysed interviews with pupils by using the documentary method to reconstruct pupils’ frameworks of orientations about the diachronic nature of science. Ruhrig and Höttecke (2015) interviewed science teachers to reconstruct science teachers’ orientational frameworks when dealing with uncertain evidence in science teaching.

This study takes place in the context of a practical training. In the perspective of the structural approach to teacher professionalism, practical training is considered appropriate to irritate experienced routines as well as the embedded action-guiding knowledge and orientations (Kramer, 2013). In the course of a practical training, within critical teaching experiences crises can occur. (Implicit) knowledge can be result of a crisis solution and belongs to the sphere of routines which have either already proven themselves or whose probation is expected to be promising (Oevermann, 2006). If this (implicit) knowledge no longer proves to be successful in a new practical experience, a crisis will arise in which new orientations will be developed and proved. An initial transformation of (implicit) knowledge is therefore structurally linked to the condition of crisis or at least critical teaching experiences (Oevermann, 1991). Following this, critical teaching experiences as crises can be important to irritate implicit knowledge and orientations. In Germany, the first opportunity to gain teaching experience in the course of university pre-service teacher education usually is a practical experience called the school-practical training. As seen from a research-oriented perspective, the school-practical training
as such a potentially critical teaching experience offers an opportunity to investigate the student physics teachers’ action-guiding frameworks of orientations and their potential changes in the context of this practical training.

**Research questions**

This case-based study aims at the reconstruction of the student physics teachers’ “frameworks of orientations” in the context of the school-practical training. The following research question will be investigated:

What “frameworks of orientations” concerning teaching and learning physics can be reconstructed?

**RESEARCH DESIGN - CASE-BASED STUDY**

The design of the case-based study is orientated towards the school-practical training (see Figure 2). A special feature of this particular practical training is the close supervision by science education experts. The school-practical training consists of a preparation seminar at the beginning, followed by two individual planning consultations with the science education expert and two physics lessons taught by each student teacher with subsequent feedback from the other student teachers and the science education expert. In addition to this, the student teachers join several hours of classroom observation during the other student teachers physics lessons. At the end, there is a seminar to reflect the experiences made in this practical training (see Figure 2). Usually a period of three months passes between the preparation seminar and the seminar to reflect the experiences.

**Sample**

All participants study at the Martin Luther University of Halle-Wittenberg in order to become physics teachers at secondary schools.

While the sample of the first survey period (summer term 2015) comprises six student physics teachers, the sample of the second survey period (summer term 2016) consists of eleven student physics teachers (see Figure 2). Overall, the sample of 17 participants includes five women and twelve men.

At our University, the school-practical training can be completed twice in the course of university pre-service teacher study. Ten participants attend their first school-practical training (4th semester) and usually have had no practical experience before. Seven participants join the school-practical training for the second time (usually 8th semester) and have previously done longer school internships.

**Narrative interviews**

Two narrative interviews (each lasting about 60 min) were conducted with every participant. The first interview (see Figure 2, blue) takes place after the preparation seminar whereas the second interview (see Figure 2, red) was recorded after the second physics lesson taught by that particular student physics teacher.
In the first interview, the student’s self-made drawing of a physics teaching situation is used as an interview stimulus. The drawing has been made in the course of the preparation seminar in response to the task: “Draw yourself as a physics teacher in a self-chosen teaching situation.” A few days later, the first interview (blue) takes place (see Figure 2). In this interview, the student physics teachers talk about their physics class experiences during their school time and about the physics teaching situation in their own drawing.

In the course of the school-practical training, the second physics lesson was recorded. Scenes taken from this videotaped physics lesson had been used as interview stimuli. The second interview (red) was conducted a few days after that second lesson (see Figure 2). First of all, the interviewees talk about their teaching experiences in general. After that, in the sense of stimulated recall interviews (Calderhead, 1981), the students narrate about specific teaching situations in the videotaped lessons.

Each part of the interview starts with open questions to encourage the interviewee to talk about their own experiences (King & Horrocks, 2010). This procedure is recommended assuming that these detailed narrations about the experiences offer the possibility to reconstruct action-guiding orientations (Nohl, 2010). At the end, more structured questions are used (Flick, 2014).
Figure 3. The steps of the documentary method (based on Trautrim, Grant, Cunliffe & Wong, 2012, edited by the authors)

**Documentary method**

For the interpretation and analysis of the interview transcripts, the documentary method is applied. The documentary method allows access to the student physics teachers’ implicit knowledge, which is embedded in the practice of teaching physics itself as well as, which is most important here, in the practice of speaking about teaching physics (Bohnsack, 2010).

Figure 3 illustrates the steps of the documentary method. The essential steps are described in the following (see Fig 3). The data to be analysed are the transcribed narrative interviews. In the first step, the formulating interpretation refers to the analysis of *what* is said (Nohl, 2010). The researcher examines topic changes and rephrases *what* is said in the text. In doing so, the investigation of the theoretical knowledge is possible. In addition, this step leads to a distancing and alienation from the material. A second step is necessary to investigate the implicit knowledge beyond.

The reflecting interpretation is the second step to investigate *how* something is said (ibid.). The researcher explores *how* the topic is treated. Assuming that *how* we say something is influenced by our orientations towards the topic, the reconstruction of “how” leads to the deeper meaning of the word and the underlying framework of the topic. By doing so, the exploration of the *modus operandi* and its underlying unconscious mental structures is possible. The researcher has to examine in which framework the topic is dealt with. Therefore, the “framework of orientation is the central subject of documentary interpretation” (Bohnsack, 2010, p. 110).

By these two separate steps, the researcher changes the analytic stance and goes beyond the explicit meaning of communication to examine the implicit dimension of talk (ibid.).

The third step is the comparative analysis (Nohl, 2010) (see Figure 3). The comparative analysis investigates how the different interviewees responded to the same questions and in which diverse ways they tackled the issue. At the end, different typologies can be generated.
from the reconstructed orientations (ibid.). In this paper, the last step of the documentary method will not be illustrated.

**EXEMPLARY INTERPRETATION**

Of course, no detailed documentary interpretation can be presented in this paper. However, it is possible to give at least a brief superficial insight into the data material and suggest an idea of interpretation. Due to the translation, the original wording and especially its meaning cannot be reproduced exactly. While reading the exemplary interpretation, this should be kept in mind.

**Simon - the actor on a theater stage**

The short interview transcript (see Figure 4) is part of Simon’s first interview (see Figure 2, blue). Simon’s drawing of himself as a physics teacher in a teaching situation three days before is used as a stimulus in the interview. Simon explicates what was going on in his mind when he created his drawing.

"(...) Um, well [the idea was] that he made the students come closer first, so they see better, secondly um, that the teacher here is not only so * in an impersonal way so to speak basically standing in front there to follow through with his lesson plan, but rather that he involves his students * um, what’s happening, what does one see here anyway” [00:34:53]

![Figure 4. First short part of Simon’s interview transcript. The little stars (*) are short breaks.](image)

In the following, the steps regarding the interpretation of the teacher’s role in Simon’s narration are shown briefly. The interpretation suggests that Simon can be described as an actor on a theater stage. The first step is the formulating interpretation to analyse what is said: He made the students come closer, so they can see better. He added that he was not standing so impersonally in the front to follow his lesson plan. Instead, he involved his students and asked questions. At this level, aspects of Simon’s explicit theoretical knowledge are pointed out.

Within the next step, the reflecting interpretation is used to analyse how something is said. The analysis of the verbs related to the teacher or the students is very meaningful. Whereas Simon as the teacher “made”, “is standing”, “follow[s] through” and “involves”, the students only “see” and are “made” to “come closer” to the front desk by the teacher (see Figure 4). The analysis suggests that the teacher is more active than the students are. The students are passive and see the experiment on the teacher’s desk. A second valuable strategy is the analysis of the implicit relation between teacher and students. The students have to “come closer”, which implies that there was a distance between teacher and students before (see Figure 4). There seems to be some kind of a natural distance between teacher and students. Moreover, it is beneficial to analyse special words, which are unusually used in a specific context. The use of “in an impersonal way” is very unusual in German language and supports the idea of a natural distance between Simon and his students. A first idea of the interpretation could be that Simon controls the action and the students are passive in this situation as well as there is a kind of natural distance between teacher and learner.

Of course, this is a short transcript and a small data basis. That is why the documentary method requires a more detailed look at many other interview sequences. Due to limited space in this
paper, only one more sequence is presented. This second scene takes place only a few minutes after the excerpt mentioned above. In this second short transcript, Simon explains how his drawing developed (see Figure 5). The first step again is the formulating interpretation of what is said: Simon has drawn the table and the experiment, because this is “what's actually going on in this scene” (see Figure 5). He has drawn the blackboard and himself as a teacher. Simon has drawn the students around the experiment, from an arts perspective the “audience is drawn at the end”, followed by the speech bubbles.

The next step (again) is the reflecting interpretation to develop an idea of Simon's implicit orientations. The analysis of the order of the drawn items is very useful. Students were drawn almost at the end. They seem to be less important than the table, the experiment, the blackboard and the teacher (see Figure 5). Here again, it is a valuable strategy to analyse striking words. Simon used the word “audience” related to the students. If you think of an “audience”, a conceivable interpretation implies a group of people, which is listening or watching in a passive way. So, the students seem to be entertained by the teacher like an audience by a stage actor.

Figure 5. Second short part of Simon’s interview transcript. The little stars (*) are short breaks.

Now, there are more hints, which strengthen the first interpretation. According to the documentary method, other interview sequences have to be analysed to prove this interpretation. These two transcripts offer at least an idea of the origin of this interpretation about the teacher’s role in Simon’s narrations. A conceivable interpretation suggests that Simon can be described as an actor on a theater stage. He as teacher seems to be in the center, controls the situation and the attention. The students as learners appears to be a group of people, which is listening or watching like an audience in a passive way. There is some kind of natural distance between teacher and the entertained students. Therefore, Simon can be described by the metaphor of an actor on a theater stage with his students as the audience.

Outlook

The previous analysis perspective in the interpretation of Simon’s narrations focuses on the orientations about the teacher’s role. In the context of the comparative analysis (see Figure 3), the investigation of other participants allows to reconstruct different orientations concerning this analysis perspective. By doing so, various contrasting concepts of the teacher’s role can be described. Due to limited space in this paper, only one more example called Niklas will be mentioned. Whereas Simon’s implicit orientation about the teacher’s role can be described as an actor on a theatre stage, Niklas’ role seems to be more like a technician, who keeps the engine (the lesson) going. Niklas as teacher rather not permanent structures, designs or adapts individual teaching situations, because physics lessons seem to follow natural fixed rules and are not very complex. He only intervenes in a physics lessen, when the automatically running lesson get stuck. If Niklas has fixed a problematic situation, the lesson goes on. Like cogs in a
machine, the lesson seems to continue independently and appears to be no longer dependent on Niklas. This second example is intended to illustrate that thru the comparative analysis different implicit orientations about the teacher’s role can be contrasted.

Besides orientations about the teacher’s role, other analysis perspectives like the orientations about the student’s role as well as about the teacher’s handling of students’ questions can be focussed. In addition, it seems to be rewarding to reconstruct the orientations referring to how student physics teachers deal with unexpected situations and with uncertain experimental results. Moreover, their orientations about the role of experiments in teaching physics as well as about the relation between physics and mathematics can be analysed. Furthermore, it appears to be worthwhile to investigate the orientations regarding to how student physics teachers manage complexity of teaching situations and negotiate epistemic authority. By analysing these perspectives, the frameworks of orientations concerning teaching and learning physics can be reconstructed.

In addition to this, a second research question will be addressed in this ongoing study. The transcripts of the second narrative interviews (see Figure 2, red) are used to answer the following research question: To what extent do the “frameworks of orientations” alter during the school-practical training? The second part of the study faces the question whether in the context of the school-practical training an irritation of the action-guiding frameworks of orientations can be reconstructed. The transformation of the individual “framework of orientation” will depend on whether the relatively short practical training provides sufficient opportunities for crisis and coverage (in the sense of Kramer, 2013).

DISCUSSION

In summary, our first results indicate that it is rewarding to analyse narrative interview sequences of student physics teachers by using the documentary method. As shown rudimentarily by using the examples Simon and Niklas, it is possible to reconstruct contrasting characteristics in several analytic perspectives, which as whole form different action-guiding frameworks of orientations about teaching and learning physics. The reconstruction of the frameworks of orientations allows access to the underlying implicit knowledge that, so the assumption, primarily structures the teaching of (student) physics teachers. By doing so, insights into the unconsciously implicit knowledge beyond the explicit (professional) knowledge can now be described.

In further research it is necessary to discuss similarities and differences in the theoretical conceptions of implicit knowledge (Neuweg, 2011), tacit knowledge (Polanyi, 1966), a-theoretical knowledge (Mannheim, 1954), incorporated knowledge or habitus (Bourdieu, 1977) and frameworks of orientations (Bohnsack, 2010) in more detail.

Moreover, it also has to be discussed whether the methodological theory behind the documentary method entitles such a longitudinal perspective as used to answer the second research question in this case-based study. This study consequently faces the methodical question whether changes in the “frameworks of orientations” can be reconstructed at all. However, the documentary method seems to be suitable to reconstruct the unconsciously implicit knowledge of student physics teachers about teaching and learning physics.
The implicit knowledge base of (pre-service) science teachers about teaching and learning physics has hardly been investigated so far. For this reason, foundational research has to be done in the field of implicit knowledge of (pre-service) science teachers. Moreover, the assumption that this experience-based implicit knowledge is highly relevant to lesson planning and particularly to classroom acting, has to be investigated and proved in science education research. This may provide an insight into the problem, why teachers who go through science teacher preparation programmes aimed at reform-minded instruction still teach the way they were taught (Abell, 2008).

From a theoretical perspective of the structural approach to teacher professionalism, typical structural subject specific problems of teaching physics that (pre-service) science teachers have to deal with can be examined. Furthermore, this study also underlines Neuweg’s (2011) argumentation regarding the different forms of teacher knowledge. The consideration of his ideas about teacher knowledge lead to a desideratum in the cognitive psychological model of teachers’ professional competence (Baumert & Kunter, 2013). It has to be extended by implicit knowledge as a sociological gained construct. At the moment, we are far away from a satisfactory model of teachers’ complex professional competences, their development as well as their impact and interaction in real teaching situations. For this reason, there is still a lot to be done in this field of science education research.

MODELING INQUIRY-ORIENTED INSTRUCTION OF BEGINNING SECONDARY SCIENCE TEACHERS

Lyrica Lucas and Elizabeth Lewis
University of Nebraska-Lincoln, Nebraska, USA

New national science education standards, the Next Generation Science Standards, in the United States (US) promote inquiry-based instruction through an integrated emphasis on scientific practices and disciplinary content. Thus, it is important for beginning science teachers to reach proficient implementation of reformed teaching practices by the end of their induction phase in order to become effective science teachers. Yet, extant science education research studies on development of beginning teachers’ classroom practices is rare. In this study, we collected data from a longitudinal study of science teachers from two teacher preparation programs - a bachelor’s program with teacher candidates who had less than a major in science and a 14-month master’s degree program with candidates who had at least a major in science - in a large, Midwestern university in the US. These data were used to examine the impact of observation-level and teacher-level characteristics on the likelihood of an observed science lesson being at or below a proficient inquiry level on the Electronic Quality of Inquiry Protocol (EQUIP) instrument. Using observation-level and teacher-level data, two-level hierarchical generalized linear models were built to investigate the relationship between proficiency in inquiry-oriented instruction and the predictor variables at both levels. The parameters estimated in the best fitting model for the data indicate that observation-level variables do not significantly predict the likelihood of an observed science lesson being at or below a proficiency level on the EQUIP scale. Among the teacher-level characteristics, only the teacher preparation program was found to be statistically significant. Controlling for all other variables in the best-fitting model, the likelihood of an observed lesson being taught at the proficient inquiry level was significantly higher for teachers with a stronger science background who graduated from the master’s program. Limitations of the study and future research directions are discussed.

Keywords: secondary science teachers, inquiry-oriented instruction, multilevel generalized linear models

INTRODUCTION

An inquiry-based approach to teaching and learning for science education reform has been promoted in science teacher preparation programs in response to science education policy, research literature, and standards frameworks for teaching science in the US since the early 1990s (NGSS Lead States, 2013; NRC, 1996). Supovitz, Mayer, and Kahle (2000) defined inquiry-oriented instruction as a “student-centered pedagogy that uses purposeful extended investigations set in the context of real-life problems as both a means for increasing student capacities and as a feedback loop for increasing teachers’ insights into student thought processes” (p.332). Teachers need to be well-versed in inquiry-based instruction to promote student learning of science through experiential, active learning that emplys scientific practices, or thinking like a scientist (NRC, 2000). Yet, an examination of the literature on the preparation of science teachers reveals that little is known about new teachers’ induction period; we need more research on how secondary science is taught by beginning science teachers (Bianchini,
2012). Unfortunately, even the existing research (e.g., Luft, Firestone, Wong, Ortega, Adams, & Bang, 2011) has failed to improve our understanding of the effectiveness of teacher preparation for the purpose of reformed-based science teaching.

This study sought to add to the knowledge base on teacher preparation and growth over time by modeling how beginning science teachers’ use of inquiry-based science instruction develops throughout the first four years of in-service teaching. Using 455 coded classroom observations of 51 science teachers from two teacher education programs in a large, Midwestern university, the effects of observation-level variables and teacher-level variables on the level of reformed science instruction was examined. Since the data are hierarchically organized (i.e., class observations nested within teachers), multilevel models were used to properly account for the hierarchical (correlated) nesting of data (Hox, 2002; Raudenbush & Bryk, 2002; Snijders & Bosker, 2012).

We specifically investigated the relationship between observation-level variables (i.e., time, level of observed lesson (HS vs. MS), length of observed lesson (block vs. regular), and mode of observation (video vs. real-time)) and teacher-level characteristics (i.e., teacher’s sex and education program) on the likelihood of an observed science lesson being at or below proficient use of inquiry in an observation instrument used to measure the level of inquiry-based instruction. Using observation-level (Level 1) and teacher-level (Level 2) data, hierarchical generalized linear models were built to investigate the relationship between proficiency in inquiry-based instruction and the predictor variables at both levels. The following research questions were posed in this study: (1) What is the likelihood of a science lesson being at or below proficient inquiry instruction levels taught by a typical science teacher? (2) Does the likelihood of being at or below each proficiency level vary across science teachers? (3) What is the relationship between the time of observation and the likelihood of an observed lesson being at or below a proficiency level while controlling for observation- and teacher-level characteristics? and, (4) What is the relationship between the teacher education program and the likelihood of an observed lesson being at or below a proficiency level while controlling for observation- and teacher-level characteristics?

**METHOD**

We collected data as part of a longitudinal study of beginning science teachers’ professional practice using four cohorts of students who completed an intensive, 14-month graduate teacher certification program at a large, Midwestern university (Lewis, Musson, Pedersen, 2013). The intensive program prepares science majors and professionals to become highly qualified K-12 science teachers. This study builds upon prior exploratory work (Lewis & Musson, 2013) and the specific teacher education program details shown in Table 1 are described and presented elsewhere (Lewis, McCarty, and Musson, 2014; Lewis, Rivero, Musson, Lu, & Lucas, 2016). Science teachers who completed a bachelor’s degree in secondary science education from the same university were also recruited to serve as a comparison group.

Over four years, five researchers observed and coded lessons using the Electronic Quality of Inquiry Protocol (EQUIP) instrument (Marshall, Horton, Smart, & Llewellyn, 2008) to measure the level of inquiry-based instruction in middle and high school science classrooms. By design, every teacher participant was targeted to be observed up to six times within one academic year. The validated EQUIP instrument has 19 items; each item employs a scale of 1 to 4 to describe the level of inquiry-oriented instruction in an observed science lesson. Level 1, the lowest level in the scale, corresponds to “pre-inquiry” (a teacher-centered classroom, i.e., lecture-based) and Level 4, the highest level, to “exemplary inquiry” (an open-ended and engaging student-centered classroom). For instance, in terms of instructional strategies, a teacher may be observed to “predominantly lecture to cover content” (Level 1) or “occasionally lecture but used classroom activities that promoted strong conceptual understanding” (Level 4). In this study, the EQUIP score for an observed lesson corresponds to the median score for all the 19 items in the instrument. We assume that the four-item outcomes form an underlying latent variable that is inquiry-oriented instruction behavior.

The data has a two-level structure with a set of classroom observations conducted over time that are nested within teachers. The variation of outcomes within subjects over time is at the lowest level (Level 1) and the variation of the underlying mean outcomes between subjects is at level two (Singer, 1998). Since the data gathered via the EQUIP instrument are categorical, ordinal data, multilevel generalized linear models (GLM) were used in modeling the data. The data are multinomial, violating standard linear mixed model assumptions such as normality and homogeneity of variance (Hox, 2002). In contrast with hierarchical linear models (HLM) that
has continuous, approximately normally distributed outcomes, GLMs are appropriate for many kinds of non-normally distributed outcomes (e.g., binary, unordered categorical, ordered categorical, counts, censored, zero-inflated, and continuous but skewed data). The models were estimated and interpreted using SAS PROC GLIMMIX. The variables included in the models are shown in Table 2.

</table>

At the observation level, the variables included in the model are time of the observation in years, the level of the observed lesson (i.e., high school vs. middle school), the length of the observed lesson (i.e., block vs. regular), and mode of the observation (video vs. real-time). In this study, the time of observation refers to the post-program year of teaching when the observation was done. A lesson could be observed in the high school level (Grades 9-12) or middle school (Grades 7-8). It could be designed for a block period (90 minutes) or a regular period (50 minute). The mode of observation could be through the use of a video sent by a participating teacher or via a real-time observation, which could be done in-person or through a teleconferencing software such as Skype or FaceTime. Program and sex were included in the models as teacher-level variables. The program refers to the teacher education program completed by the teacher (i.e., bachelor’s degree vs. master’s degree in science teaching). Both teacher education programs are offered in the same college of the university and graduates from both programs were endorsed to teach science.
The outcome variables from the EQUIP scale are polytomous, ordinal-type. In SAS PROC GLIMMIX, a multinomial distribution and a cumulative logit link were used to allow for the computation of the cumulative odds for each EQUIP category (i.e., 1=Pre-inquiry, 2=Developing inquiry, 3=Proficient inquiry, 4=Exemplary inquiry), or the odds that an outcome would be at most, in that category (O’Connell, Goldstein, Rogers, & Peng, 2008). In this study, we were interested in the probability of being at or below a proficiency level defined in the EQUIP scale and in the influence of observation (Level-1) and teacher (Level-2) characteristics on this probability for each category. The conceptualization of the models in a generalized linear framework is represented by a set of equations in the next section.

**RESULTS**

Three proportional odds logistic models were estimated with the EQUIP data. In all of the models, the default convergence criterion (GCONV=1E-8) was satisfied. Table 3 shows the distribution of EQUIP scores for all observations from the response profile generated by SAS PROC GLIMMIX. The scores were distributed in the first three categories of the EQUIP scale, but not the fourth.

The ordinal empty means, random intercept only model, is represented by two logit-based model equations (1). When dealing with polytomous outcomes, multiple logits are simultaneously estimated (M-1 logits, where M=the number of outcome categories). For the case of three outcomes as shown in Table 3, two logits are simultaneously estimated by the model.

\[
\eta_{1ij} = \log \left( \frac{P(R_{ij} \leq 1)}{1-P(R_{ij} \leq 1)} \right) = \gamma_{001} + U_{0j}; \eta_{2ij} = \log \left( \frac{P(R_{ij} \leq 2)}{1-P(R_{ij} \leq 2)} \right) = \gamma_{002} + U_{0j} \tag{1}
\]

The two intercepts in the model represent the log odds of an observation in a typical teacher being at or below the first two levels of inquiry-based instruction (i.e., pre-inquiry and developing inquiry) in the EQUIP scale. These log odds can be used to calculate the probabilities of being at or below each proficiency level by using the following equation (2) wherein \( \phi_{ij} \) stands for cumulative probability.

\[
\phi_{ij} = \frac{e^{\eta_{ij}}}{1+e^{\eta_{ij}}} \tag{2}
\]

Parameter estimates for Model 1 are shown in Table 4. Using the model equations, the log odds of being at the pre-inquiry level for an observed science lesson in a typical teacher is -1.58, resulting in a probability of 0.17. Similarly, the log odds of being at or below the developing inquiry level is 1.98, resulting in a cumulative probability of 0.88. Finally, the cumulative
probability of being at or below the proficient inquiry level adds to 1. To calculate the actual probabilities of being at each level, cumulative probabilities of adjacent categories are subtracted from one another. As a result, the predicted probability of an observed lesson being at the pre-inquiry level for a typical teacher is 0.17, 0.71 at the developing inquiry level, and 0.12 at the proficient inquiry level.

*Note:*<sup>p</sup><.05; **=likelihood ratio test significant; Values based on SAS PROC GLIMMIX. Entries show parameter estimates with standard errors in parentheses; Estimation Method=Laplace.

<sup>a</sup>Best fitting model

The empty, unconditional model with no predictors provides an overall estimate of the intraclass correlation (i.e. ICC = \( \tau_{00} / (\tau_{00} + 3.29) = 0.92 / (0.92 + 3.29) = 0.22 \)). In multilevel GLMs, there is assumed to be no error at Level-1, therefore, a modification was needed to calculate the ICC. This modification assumes that the outcome originates from an unknown latent continuous variable with a Level-1 residual that follows a logistic distribution with a
mean of 0 and a variance of 3.29 (Snijders & Bosker, 2012). Therefore, 3.29 was used as the Level-1 error variance in calculating the ICC. The ICC indicates that approximately 22% of the variability of being at or below a proficiency level in the EQUIP scale is accounted for by the teachers in the study, leaving 78% of the variability to be accounted for by the observations or other unknown factors. However, it should be noted that the ICC is somewhat problematic to interpret due to non-constant residual variance. Model 1 also indicates that there is a statistically significant amount of variability in the log odds of being at or below a proficiency level between teachers \[ \tau_{00} = 0.92; z(50) = 2.75, p<.05 \].

Model 2 includes the fixed effect estimates for observation-level variables (i.e., time, level, the length of the observed lesson, and mode of observation). The fixed effect estimates illustrate the relationship between an observation-level characteristic and the log odds of being at or below a proficiency level in the EQUIP scale. The value of each fixed effect estimate remains constant across logits although there are two estimates for the intercepts. This means that the fixed effects are assumed to be the same for each cumulative odds ratio. Model 3 was similar to Model 2 with the addition of teacher-level fixed effects. Table 4 presents a summary of the results and estimates for all three models considered in the model-building process as well as model fit information.

We compared the three models in terms of fit in order to decide the best fitting model for these data. Based on the changes in the -2 Log Likelihood between nested models, Model 3 is the best fitting model for these data; it fits significantly better than Model 2 \( \chi^2(2) = 13.92, p<.001 \) and also better than Model 1 \( \chi^2(6) = 6.12, p<.05 \). The addition of teacher-level variables improved model fit.

**DISCUSSION**

To address our research questions, the parameter estimates from the best-fitting model (Model 3) were used. The first research question requires finding the likelihood of being at or below each proficiency level in inquiry-based instruction for an observed lesson taught by a typical science teacher. Using Model 3, we found that the probability of an observed lesson being at the pre-inquiry level for a typical teacher was 0.45; 0.52 at the developing inquiry level, and 0.03 at the proficient inquiry level. These predicted probabilities are interpreted based upon all variables in the model being equal to zero. As a follow-up, in our second research question, we were interested to know if the likelihood of being at or below each proficiency level varied across science teachers. Looking at the error variance estimate for the random intercept, Model 3 indicates that there is a statistically significant amount of variability in the log odds of being at or below a proficiency level between teachers \[ \tau_{00} = 0.51; z(48) = 2.08, p<.05 \]. The probability of being at or below a proficiency level varies considerably across teachers.

For our third research question, we found that there was no statistically significant relationship between the time of observation and the likelihood of an observed lesson being at or below a proficiency level while controlling for observation- and teacher-level characteristics. The final, fourth research question refers to the relationship between teachers’ education program and the likelihood of an observed lesson being at or below a proficiency level while controlling for observation- and teacher-level characteristics. To answer this question, we used the parameter
estimate for teacher education program (b=-1.51, p<.05), which indicated a negative, statistically significant relationship between teachers’ education program and the likelihood of an observed lesson being at or below a proficiency level. Specifically, as we move from a lesson taught by a science teacher with a bachelor’s degree in secondary science education to a lesson taught by a teacher with a master’s degree with an undergraduate degree in an area of science, the likelihood of an observed lesson being at the proficient level increases.

To make a more meaningful interpretation, we calculated the corresponding predicted probabilities for observed lessons taught by teachers in different preparation programs and controlled for other observation- and teacher-level characteristics. Using Model 3 parameter estimates in Table 3, the log odds of an observed lesson taught by a teacher graduate of the master’s degree program (program=1) being at or below the pre-inquiry level is 0.18, resulting in a probability of 0.15. Similarly, the log odds of being at or below the developing inquiry level is 6.43, resulting in a cumulative probability of 0.87. From these values, we found that the probability of an observed lesson being at the pre-inquiry level for a graduate of the master’s program is 0.15; 0.71 at the developing inquiry level, and 0.13 at the proficient inquiry level. These predicted probabilities are interpreted for the case of program=1 and all other variables in the model being equal to zero. This means that the predicted probability of an observed lesson (at the beginning of Year 1, taught in middle school on a regular schedule by a male teacher with a master’s degree, and observed in-person) to be at the pre-inquiry level is 0.15. For a teacher with a bachelor’s degree, the predicted probability of an observed lesson being at the lowest proficiency level is 0.45. Thus, controlling for all other observation- and teacher-level characteristics, an observed lesson taught by a graduate of the bachelor’s program has a higher probability of being at the lowest proficiency level in the EQUIP scale compared to a lesson taught by a graduate of the master’s program. In other words, the master’s level teachers enacted reformed-based science teaching more frequently.

Figure 1 compares teachers by teacher education program in terms of the change in probability of EQUIP score outcomes across years of teaching. For both groups, the likelihood of an observed science lesson to be teacher-centered or being in the lowest level of the EQUIP scale decreases as the teachers gain more experience. However, teachers from the master’s program start at a higher level; they are more likely to create and implement more inquiry-based lessons and continue to improve as they gain teaching experience. Thus, teachers with a master’s degree in science teaching appear to show accelerated growth in the in the used of inquiry-based teaching practices compared to teachers with only a bachelor’s degree in secondary education with science endorsement.

These findings imply that differences in teacher education affect the long-term development of inquiry practices in the first four years of teaching. However, there are several limitations that need to be taken into account when interpreting these results. Adding new observation data from the fifth year of the longitudinal study could increase the precision of the models. It could also allow us to better understand and describe the growth of beginning teachers since the first 5 years are commonly considered to encompass the notion of beginning teaching (Loughran, 2014). The findings regarding the particular ramifications of the teacher education programs are also context-dependent; the results may only be transferable to similar program designs.
Also, several background variables such as age, science credits hours, and work experience could be contributing to differences in the performance of inquiry-oriented science teaching. Finally, there were several factors that were not considered in building the models that may have a significant impact on the enactment of inquiry-based instruction such as size and diversity (i.e., racial diversity and socioeconomic status) of the students in the observed lessons, the amount of in-service teacher professional development activities, subject matter knowledge, and teacher beliefs and self-efficacy in teaching.

Although it appears that lessons taught by graduates of the bachelor’s program have a higher likelihood of being in the lowest level of the EQUIP scale corresponding to a more teacher-centered approach, it should be noted that the features of the two teacher education programs were not systematically investigated.

Figure 1. Change in probability across years of teaching. (a) Teacher has a bachelor’s degree in secondary education (science endorsement). (b) Teacher has a master’s degree in science teaching.

Teachers from the master’s program could have a stronger science content knowledge due to their completed science degree prior to taking a graduate-level master’s program on teaching. Also, they were older and may have worked as a science professional which may have led to the development and mastery of science process skills that are important in the teaching of science as well as their understanding of the nature of science. More studies that explore how
the master’s level program accelerates new science teachers’ growth would be productive (Lewis, Rivero, Musson, Lu, & Lucas, 2015).

In this exploratory study, the variables were entered in aggregate into the models. Thus, the modeling process did not consider specific predictors alone and as a result there may be possible interactions within the models. More complex hierarchical models that use longitudinal data on teachers, schools, and school districts are needed to capture the intricacies of teacher change.

CONCLUSIONS

This study examined the effect of observation-level variables (i.e., time, lesson (HS vs. MS), length of observed lesson (block vs. regular) and mode of observation (video vs real-time)) and teacher-level characteristics (i.e., teacher’s sex and education program) on the likelihood of an observed science lesson being at or below a proficiency level in the EQUIP scale. Using observation-level (Level 1) and teacher-level (Level 2) data, we built two-level hierarchical generalized models to investigate the relationship between proficiency in inquiry-based instruction and the predictor variables at both levels. The parameters estimated in the best fitting model for the data indicate that observation-level variables do not significantly impact the likelihood of an observed science lesson being at or below a proficiency level in the EQUIP scale. Among the teacher-level characteristics, only the teacher preparation program was found to be statistically significant. Controlling for all other variables in the full model, the likelihood of an observed lesson being at the lowest proficiency level is significantly lower for teachers who graduated from the master’s program. These findings imply that differences in teacher education preparation determine the future development of reformed science teaching. Future research that identifies aspects of instruction (e.g., discourse, assessment, instructional strategies, curriculum design) that display the least growth during the induction period would be useful in designing and improving programs for teacher professional development. Finally, it is important to build other models to explore which variables account for the unexplained variance in the enacted teaching practices of beginning secondary science teachers.

ACKNOWLEDGEMENTS

EFFECT OF THE ACTIVE PARTICIPATED MATERIAL DEVELOPMENT PROCESS ON PROSPECTIVE SCIENCE TEACHERS' ASTRONOMY SELF-EFFICACY BELIEFS

Cigdem Sahin and Ummu Gulsum Durukan
Giresun University, Giresun, Turkey

The purpose of this study was to investigate the effect of the active participated material development process on the Prospective Science Teacher (PSTs') astronomy self-efficacy beliefs. The study was carried out using mixed-methods research. PSTs’ astronomy self-efficacy beliefs were examined using qualitative and quantitative data in detail. The study group was composed of 27 junior PSTs from a State University from the West Black Sea area in Turkey. The study group were determined purposively. The data collecting tools used were the Astronomy Self-Efficacy Belief (ASEB) scale and reflective journals written by PSTs. The ASEB scale was applied twice to the PSTs, at the beginning of the active participated material development process and at the end of the process. The reflective journals were written by PSTs during the material development process. The quantitative data obtained from the ASEB scale were analysed with paired t-test in the SPSS 23.00 statistical packet program. The qualitative data obtained from journals were analysed according to content analysis. Qualitative data were coded and themes and sub-themes created from these codes. Providing validity of the qualitative data codes were created by two researchers in the consensus. Also the percentage of consistency between two researchers' coding were calculated for providing reliability of the qualitative data. Quantitative results revealed that a significant difference was observed in favour of the post-test average scores. Additionally, there was significant difference in favour of the post-test average scores of the PSTs’ personal science teaching efficacy belief; however, there was not a significant difference between pre-test and post-test average scores of the PSTs’ personal science teaching outcome expectancies. Analysis of the journals revealed three inter-related sub-themes affecting PSTs’ astronomy self-efficacy beliefs, labelled as: Technological knowledge, Pedagogical knowledge and Content knowledge. These sub-themes describe participants’ views of their quality PST training and thinking about active participated material development process. Educational outcomes were discussed in relationship with study findings.

Keywords: astronomy education, astronomy self-efficacy beliefs, prospective science teacher education.

INTRODUCTION

Teachers’ self-efficacy beliefs have a crucial role in preparing teachers for effectively overcoming the challenges posed by reform initiatives to prioritize quality science teaching in the elementary classrooms, and in the implementation of necessary reform-based pedagogical strategies (Smith & Southerland, 2007; Thomson, DiFrancesca, Carrier & Lee, 2017). It is important that teachers feel capable of successfully implementing reform strategies in their classroom. Teachers' personal efficacy beliefs affected their job satisfaction and students' academic achievement (Caprara, Barbaranelli, Steca & Malone, 2006). Teachers' self-efficacy beliefs affect the quality of the learning environments they prepare to promote the level of academic progress their students’ achieve (Bandura, 1993). Innovative strategies globally in
science programs have shown up in elementary science programs in Turkey, too. One of the emphasized topics in the innovative science instructional program is astronomy. In other words, astronomy is at the forefront in the elementary science program in Turkey (URL-1, 2018). In conjunction with this, is the belief that improving of the science teachers’ astronomy self-efficacy beliefs are very important. So it is seen as a need to make efforts to improve the astronomy self-efficacy beliefs of the prospective science teachers during the undergraduate education process. There are studies to determine PSTs’ astronomy self-efficacy beliefs in the literature (Gunes, 2010), but studies on efforts to develop PSTs’ astronomy self-efficacy beliefs are limited in the literature (Ceylan & Bozkurt, 2017). Also it was determined that prospective teachers (Trumper, 2001; Frede, 2006; Gürbüz, 2016) and even teachers have alternative concepts related to astronomy topics and concepts (Brunsell & Marcks, 2004; Kikas, 2004). Teachers are able to reflect alternative concepts to their students (Bradley & Mosimege, 1998; Yağbasan & Gülçicek, 2003). It is very important and necessary for the teachers to have adequate knowledge of the field in order to improve the conceptual meaning of the students in a clear way from the alternative concepts and to educate them equipped with the knowledge of the field during their undergraduate education. A teacher with sufficient scientific knowledge may be more successful at solving alternative concepts that students have. However, it emerges that science teachers need to be aware of some specific teaching techniques and methods in order to help their students to remedy alternative concepts (Küçükközer, 2004). At this point, it is believed that the prospective teachers should have knowledge about the special teaching methods and techniques and they should apply them for these methods and techniques. Cerrah-Özsevgeç (2007) found that active participated material development process was effective in completing the lack of knowledge and remedying alternative concepts of prospective biology teachers. Cerrah-Özsevgeç, Ayas and Özsevgeç (2010) determined that handbook preparation process was effective in prospective biology teachers' understanding of the endocrine system. However, the effect of the active participated material development process on prospective science teachers' astronomy self-efficacy beliefs is not known. The aim of this study was to investigate the effect of the active participated material development process on prospective science teachers' astronomy self-efficacy beliefs.

**METHOD**

The study was carried out according to mixed-research method. In this study both quantitative (scale) and qualitative (journals) data were collected, and the study employed was a sequential explanatory mixed-methods design (Creswell et al. 2003), which consisted of collecting quantitative data and then qualitative data to help explain or elaborate on the quantitative results. According to a sequential explanatory design, collection and analysis of quantitative data was followed by the collection and analysis of qualitative data, with priority being given to the quantitative data; the qualitative data help further explain the results from the quantitative data and analysis. Participants’ astronomy self-efficacy beliefs were examined using both qualitative and quantitative data in detail. The participants of this study were 27 third grade Prospective Science Teacher (PST)s from a state university at west Black Sea area in Turkey. The data collecting tools used were the Astronomy Self-Efficacy Belief (ASEB) scale and reflective journals written by PSTs. ASEB scale was developed by Riggs and Enochs (1990).
and translated into Turkish by Ozkan, Tekkaya and Cakiroglu (2002). The scale is a quintet Likert type scale composed of 23 items and two sub-factors which are Personal Science Teaching Efficacy Belief (PSTEB) and Science Teaching Outcome Expectancy (STOE) (cited in Gunes, 2010). Gunes (2010) calculated Cronbach alpha reliability coefficient of PSTEB sub-factor as .87 and Cronbach alpha reliability coefficient of the STOE sub-factor as .78. In this study the calculated Cronbach alpha reliability coefficient of ASEB scale was .77, Cronbach alpha reliability coefficient of PSTEB sub-factor was .82 and Cronbach alpha reliability coefficient of the STOE sub-factor was .70. These findings showed that the ASEB scale had reliability. The ASEB scale was applied to participants twice, at the beginning of the active participated material development process as pre-test and at the end of the process as post-test. Participants wrote reflective journals during the active participated material development process.

The quantitative data obtained from the ASEB scale were analysed with paired samples t-test in the SPSS 23.00 statistical packet program. The qualitative data obtained from reflective journals were analysed according to content analysis. Data were coded and themes and sub-themes created from codes. Providing validity of the qualitative data codes were created by two researchers in the consensus. Also the percentage of consistency between two researchers' coding were calculated for providing reliability of the qualitative data. The percentage of consistency between two researchers' coding were calculated as 90%. Quotes from participants’ statements in their reflective journals were presented for providing of the qualitative data validity.

The PSTs have studied instructional technologies and material development courses in the third grade at the undergraduate program. They learn information such as the importance of material development, material development principles, and kinds of instructional materials as theoretical lectures. And they prepare lesson plans, working sheets, graphic materials (concept, knowledge, mind map), concept cartoons, and develop three-dimensional materials.

In this study the PSTs prepared concept, knowledge, mind maps and concept cartoons according to gains of the “The Solar System and Beyond” unit at the elementary school 7th grade science curriculum. This unit consists of celestial bodies (3 gains), solar system (2 gains), and space researches (4 gains) issues (MNE, 2013). In the future the PSTs will teach astronomy issues elementary school 7th grade students according to these gains. The data collecting process and teaching sequence through ten weeks of this study is presented in Figure 1. Examples of concept, knowledge, mind maps and concept cartoons of the PSTs are shown in Appendix 1.

**FINDINGS**

Findings obtained from the astronomy self-efficacy belief scale are shown in Table 1.

- Lecturer assigned to the PSTs the task of preparing concept cartoons containing all the gains until next week.  
- Lecturer wanted reflective journal writing of the PSTs. |

![Image](ESERA17_Strand13_Figure1.png)

**Figure 1. The data collecting process and teaching sequence through ten weeks of this study**
When Table 1 was considered, it was noted that there was a significant difference between the pre-test and post-test points \( t_{(20)} = -2.217, p<.05 \). The average of the pre-test and the post-test show a significant difference in favour of the post-test. When the pre-test and post-test score averages were examined, it was observed that the pre-test score average of participants is \( \bar{X} = 3.52 \); whereas the post-test score average is \( \bar{X} = 3.67 \). Besides, \( \eta^2 \) effect values of the astronomy self-efficacy belief scale scores of the participants are medium effect values, which support this condition.

According to Table 2, when the pre-test and post-test average scores of PSTs’ personal science teaching efficacy belief were compared using the paired sample t test, a statistically significant difference was observed in favour of the post-test personal science teaching efficacy belief sub-factor score averages of the working group \( t_{(20)} = -4.491, p<.05 \). When the pre-test and post-test personal science teaching efficacy belief sub-factor score averages were examined, it was observed that the pre-test score average of participants is \( \bar{X} = 3.42 \); whereas the post-test score average is \( \bar{X} = 3.72 \). Besides, \( \eta^2 \) effect values of the astronomy self-efficacy belief scale scores of the participants were high effect values, which support this condition. Also when the pre-test and post-test average scores of participants’ science teaching outcome expectancy were compared using the dependent t test, a statistically significant difference wasn’t observed in between pre-test and post-test science teaching outcome expectancy sub-factor average scores of the PSTs \( t_{(25)} = -.680, p>.05 \). When the pre-test and post-test science teaching outcome expectancy sub-factor score averages were examined, it was observed that the pre-test score average of participants is \( \bar{X} = 3.63 \), and the post-test score average is \( \bar{X} = 3.69 \). Besides, \( \eta^2 \) effect values of the astronomy self-efficacy belief scale scores of the participants were small effect values, which support this condition.

**Table 2.** The statistic findings obtained from paired sample t test of the personal science teaching efficacy belief (PSTEB) and the science teaching outcome expectancy (STOE) sub-factors of the astronomy self-efficacy belief scale

Findings obtained from the reflective journals were presented in Figure 2. When Figure 2 was examined, it is seen that PSTs stated their ideas about the active participated material development process at the content knowledge (CK), pedagogical knowledge (PK), technological knowledge (TK) sub-themes in the Technological Pedagogical Content Knowledge (TPCK) themes.

Quoted from the statements in the reflective journals of two PSTs for the TK sub-theme:

“We decided to use Gliffy program as the group when preparing the concept map. But it was a bit difficult for me to use this program. Because, I’ve never used this program before. Then I learned to use the program (1)”

“...Preparing the concept map is quite difficult in the technological environment. However, hand-crafted maps provide convenience even if they take time (5)”.
Quoted from the statements in the reflective journals of three PSTs for the CK sub-theme:

“I realized that I have many misconceptions when I prepared the concept map. After I prepared the map, I removed my misconceptions (1)”.  

“...I learned that the comet I know as a star is not a star... (3)”.

Quoted from the statements in the reflective journals of three PSTs for the PK sub-theme:

“I learned to take into consideration students' thoughts while preparing concept cartoons. I learned what misconceptions students might have... (1)”

“I learned to prepare maps for gains ...(5)”.  

“It helped me to understand students’ misconceptions. We will take into consideration these misconceptions in their mind as we teach our students in the future when we are teachers. Concept cartoons are mostly based on misconceptions. But the information on other maps is heavily weighted. The pupil teaches more (11)”.

Figure 2. Data obtained from participants’ views about graphical materials preparing process

“...I had some problems while I was preparing maps due to my lack of content knowledge or because of my misconceptions But, by doing research I completed my lack of content knowledge and removed to my misconceptions ... (9)”
RESULTS/CONCLUSIONS-RECOMMENDATIONS

In this study, the active participated material development process has been effective in the improvement of PSTs’ ASEB. This case is hopeful. The PSTs’ previous efficacy beliefs are likely to predict their future efficacy beliefs (Thomson et al., 2017). There was positive and significant relation between PSTs’ astronomy conceptual knowledge with astronomy self-efficacy beliefs (Gunes, 2010). Besides, the active participated material development process has been effective in the improvement of PSTs’ content knowledge (CK), pedagogical knowledge (PK), technological knowledge (TK) and Technological Pedagogical Content Knowledge (TPCK). CK, PK and TK are complex and interconnected (Thomson et al., 2017). As well as this result is very important to predict their future STOE beliefs. There is a significant relationship between elementary pre-service teachers’ science pedagogical content knowledge and science outcome efficacy (Thomson et al., 2017).

Cerrah-Özsevgeç (2007) and Cerrah-Özsevgeç, Ayas and Özsevgeç (2010) found that the active participated material development process was effective on remedying prospective teachers’ misconceptions and lack of content knowledge. These studies also showed that this process improved the prospective teachers’ pedagogical content knowledge. Results in this study are parallel with the results of other studies in the literature. According to the results of this research it might suggest that the effect of the active participated material development process in another science issues should be search on students’ and prospective teachers’ self-efficacy beliefs.

INQUIRY AND MODELING IN PRE-SERVICE TEACHER TRAINING TO IMPROVE SCIENTIFIC, EPISTEMIC, PEDAGOGICAL KNOWLEDGE, AND EMOTIONAL SELF-REGULATION

María Martínez-Chico, María Rut Jiménez Liso, Rafael López-Gay and Miguel Romero
University of Almería, Almería, Spain

The need to promote "scientific practices" as they help students to elaborate an appropriate image of scientific activity, requires training competent teachers to teach them in Elementary school classrooms. To achieve this, we focus the initial training on promoting an evolution in the “spontaneous teachers’ thoughts”, by engaging them actively in those practices and reflecting on the learning process, in order to develop: Descriptive and explanatory Scientific Content knowledge, inquiry process understanding, Epistemic knowledge, Pedagogical knowledge and emotional and learning self-regulation. The design of part of the course “Science Education I” which includes two inquiry cycles (descriptive and explanatory-predictive both related to Sun-Earth movements), is presented and the multiple instruments designed to evaluate its effectiveness are shown. Preliminary results from student teachers’ discussions reveal the important role of accurate descriptive knowledge to construct a model. Moreover, the responses given in the self-learning regulation activities show they recognize an enhancement in their epistemic and scientific content knowledge. These results, among others, seem to indicate the efficiency of the proposal design in promoting the teachers’ professional development.

Keywords: pre-service teacher training, sun-earth, model-based inquiry

INTRODUCTION

The NRC (2012) emphasizes the need to promote "scientific practices" in response to the huge flood of proposals reduced to hands-on activities without considering the importance of minds-on activities. Osborne (2014) attributes this problem to the confusion of the goal of science with the goal of learning science consisting of building an understanding of the ideas about the world surrounding us, and the lack of a common understanding of what inquiry means.

If we aim to promote scientific practices in Elementary schools, it is necessary to train competent teachers to incorporate them in their instruction. A prospective teacher’s personal view of teaching science is a strong predictor of a prospective teacher’s actual practice of teaching science (Crawford, 2007). Therefore, an important aspect of preparing teachers to teach scientific practices be to provide them with experiences that will change their view of teaching science into one with includes the scientific, epistemic, pedagogical aspects as well. With this purpose, we address initial training as a process of changing the spontaneous teachers’ thoughts consisting of conceptions, ideas... about science, nature of science and science teaching and learning, which, to be plausible, it requires learning experiences alternative to their previous experiences that serve as a reference to teach science (Martínez-
Chico, 2013) while they are *learning by doing* (Haefner & Zembal-Saul, 2004), and reflect on the learning process experienced.

To facilitate the promotion of scientific practices in Elementary schools, the kind of knowledge children have which is descriptive - experiential, close, immediate-, and their own explanations about the world, as well as the competencies which they are to develop such as “explaining phenomena scientifically” what includes the ability to describe or interpret phenomena and predict changes should not be ignored (OCDE, 2016).

Considering all these aspects, to enhance the pre-service Elementary School teachers (PET)’ competence to teach science we focus on promoting: Descriptive and explanatory Science content knowledge, Inquiry process understanding, Epistemic knowledge, Pedagogical knowledge. Furthermore, as science-based learning processes are not merely cognitive but are highly charged with feelings and self-regulation, we cannot ignore the common negative emotions towards science and teaching science (Evagorou et al., 2014), and therefore, the training should be extended to the affective dimensions (Brígido et al. 2010).

As research has shown that inquiry-based teaching practices have a positive effect on student learning, particularly students’ engagement in the cognitive dimensions of inquiry and teacher-led inquiry activities (OCDE, 2016), we focus the initial teacher training on Inquiry-Based Science Education, an approach drawn from constructivist learning, facing the need to express and discuss students’ misconceptions and the need for students to understand the epistemic basis of science (Osborne, 2014).

In this paper we summarize a teaching sequence in which PETs experience two inquiry cycles on Sun-Earth movements, with an integrated theory-practice approach, trying to overcome the common critics from teachers that consider initial training programs too abstract and theoretical (Darling-Hammond & Bransford, 2005). Another purpose of our research is to obtain evidence of the activity sequence effectiveness and the different instruments used aiming to explore the evolution on PET’s Scientific content knowledge, inquiry process understanding and epistemic knowledge, pedagogical knowledge and self-learning and emotions perceptions when they engage in scientific practices to construct both, descriptive and explanatory knowledge.

Specifically, the research questions we address in this paper are:

- How effective is this design to construct scientific knowledge (descriptive & models)? Is the construction of descriptive knowledge useful for modelling?
- How do they perceive their learning of scientific contents and epistemic knowledge? Do their perceptions correspond to what they have learnt?
- Which emotions do they recognize having felt throughout the proposal?

**METHODOLOGY**

**Context of the Study and Participants**

The participants of the study were 175 pre-service teachers (PETs), studying to become elementary school teachers at a University in the south of Spain. All the participants were in their 2nd year enrolled in the Science Education I course, which lasted 30 weeks.
The purpose of the course is to train the PET on science education, initiating them into the scientific practices through learning experiences as learners, as thinkers and as designers, to engage their future students with scientific practices. None of the elementary pre-service teachers had a background in science.

Part of the course which has been presented (Table 1) was implemented at the beginning of the course 2016/17, over 25 in-class hours. For some activities (A9 and A10), the participants were expected to work in small groups (4–5 PSTs).

**Activity Sequence**

Part of the course presented (Table 1) includes both: An Inquiry-based cycle (to construct descriptive knowledge about how sunlight hours change throughout the year) and a Model-Based Inquiry cycle (to explain the descriptive knowledge previously constructed), including times for self-regulation by analyzing what and how they have learned and felt (underlined activities).

The science content matter chosen for this study is Celestial Motion from an Earth-Based Perspective. The election of this topic is due to different reasons: it is useful for teachers to have a clear understanding of the subject matter that they are teaching (NRC, 2007) and this specific science content is a fairly repeated part of the curriculum and text books; to construct a proper view of Science, apart from considering the current understanding of natural systems, the process whereby that body of knowledge has been established and is being continually extended, refined, and revised, must be consider (NRC, 2007), and this subject matter offers the possibility of understanding both; the contents around those ideas help us weed out peripheral ideas and instruction that focuses on the rote memorization of disconnected facts, as a result of presenting the contents in an unproblematic, abstract and decontextualized form for students (Plummer & Krajcik, 2010); the common lack of understanding of these concepts may hinder students’ progress towards more advanced understanding in the domain (Plummer & Krajcik, 2010); prior research has demonstrated that neither children nor adults hold a scientific understanding of the big ideas of astronomy and different misconceptions are perpetuated by everyday sayings, the school, the teachers discourse, etc. (Atwood & Atwood, 1996; Trumper, 2001; Plummer & Krajcik, 2010); by working from another reference system different from the traditional one, students learn to change their own perspective, starting from a close perspective, according to a reference system focused on our situation (flat horizon in a specific locality of the Earth), and advancing towards the perspective of "looking from outside the Sun-Earth System" (side view of the Earth), reflecting on the progression followed. With this we allow the difficulty of looking from the earth, habitual difficulty in most children and adults as Plummer, Zahm, and Rice (2010) show and we avoid the inconsistency of ideas promoted by the "forced" introduction of concepts that do not serve to explain the observations (such as the use of the heliocentric model to explain the variation of the Sun's hours throughout the year).
Table 1. Activities included in the inquiry cycles

<table>
<thead>
<tr>
<th>Inquiry cycle to construct descriptive knowledge: Sunlight hours</th>
<th>Comments</th>
<th>Purpose of the activity</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Activity 1. What has changed from the days before and the days after September 22?</strong></td>
<td>With this activity we try to embed the scientific contents in the ongoing experiences of the learners, creating opportunities for them to approach these contents, contextualizing in a real-world situation. Learning occurs from the classroom through the real practice experience and vice versa, so that students get involved in looking for explanations of known phenomena. As PETs will probably use verbal language to express their ideas, in the sharing it will become evident that this language is insufficient and, if no group has done so before, the teacher proposes expressing their ideas through graphic language highlighting their usefulness (in this case, to represent the change of a variable over time).</td>
<td>Promote PETs’ engagement in scientific questions</td>
</tr>
<tr>
<td><strong>Activity 2. Does the number of sunlight hours change in Almería? How do they change?</strong></td>
<td>A desirable quality in every teacher is to understand what the learners want to express, without making judgments about whether the ideas are correct or not from the beginning. Therefore, after each student has drawn their graph, they can be given a short script to analyse the ideas of their peers: Does the magnitude change? Which is the maximum/minimum value and on what day does it reach it? Which times does the magnitude increase each day? Which periods does the magnitude decrease each day? Is the rate of change constant? When is it greater? When is it smaller? It is important they realize this activity is not about judging whether their partners say is correct, but about learning to understand what they mean.</td>
<td>Ideas interpretation and identification of misconceptions</td>
</tr>
<tr>
<td><strong>Activity 3. Interpret each graph that your classmates present and describe what they think.</strong></td>
<td>One of the scientific practices that should be promoted is ‘Engaging in argument from evidence’ (NRC, 2012). PETs are asked to suggest different ways to contrast their hypothesis. It is expected that they answer the corresponding magnitude (hours of sunlight) should be measured every day in Almería, but to obtain an approximate graph it is not necessary, it is enough to measure one day per month. It is convenient to ask them to express how they would measure that magnitude on a specific day. Once their ideas are expressed and discussed, we propose, if they didn’t do it before, to use data of the sunrise and sunset in Almería from other research groups (collective dimension of scientific work), thus, we show that evidence does not always have to come from experimental data.</td>
<td>Look for evidence (considering not only experimental designs, but also reliable information searching)</td>
</tr>
<tr>
<td><strong>Activity 4. Which evidence can we look for to confirm or reject our response? Write down what you plan to do and how you are going to present the results.</strong></td>
<td>After performing the look for evidence PETs compare the results with what they thought initially. The sharing will take place at the beginning of the next class. It is important that they identify the differences and emphasize that the change of their ideas is now supported by evidence, characteristic of scientific activity. The work done allows us to know how the duration of the day in Almería changes throughout the year. After analysing the graphs carefully, the educator reviews and unifies the results considering the light refraction in the atmosphere, identifying the changes in Hours of sunlight: - The 1st semester (winter and spring) the number of sunlight hours increases and the 2nd (summer and autumn) decreases, - In winter and autumn there are less than 12 sunlight hours, while in spring and summer there are more than 12 hours, -The change occurs at a higher rate near the equinox days and changes very little near the solstice days, -There is symmetry with respect to June 21 and December 21 Some activities are proposed to apply the contents learnt.</td>
<td>Analyse data and adapt descriptions or explanations Identify differences between previous thoughts and results</td>
</tr>
<tr>
<td><strong>Activity 5. Communicate your results: Indicate where the evidence was found, present results, and list the modifications you incorporated to what you thought initially.</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Activity 6. Unifies results and perform application activities.</strong></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Activity 7. If December 21 is the shortest day of the year, why is it not the coldest day? If June 21 is the longest day of the year, why not the hottest day?

We will refer to the thermal inertia. We all know that we do not take off our coat as soon as we turn on the heating or put it on as soon as we turn it off, that is, the temperature of the environment does not immediately reflect the amount of energy that is provided (especially in environments with abundant water, as is the case of the surface of the Earth). The main reason for this conception is the association between hours of light and temperature. So, if in summer each day is hotter until, for example, August 10, we can expect that until that day there will be increasingly hours of sunlight. The origin of this idea is therefore sensory, social, and perhaps school (examples of textbooks are shown).

Analysis of the justification of their initial models. Identification of misconceptions

Activity 8. Learning and emotional self-regulation questionnaire is issued.

Learning and emotions self-reflection of is performed. Students reflect on science learning and on the felt emotions based on this experienced sequence.

Self-regulation on experienced learning and emotions

Activity 9. Would it not have been easier and quicker for the teacher to explain the right ideas from the beginning?

Reflection on students’ conceptions, constructivist view of learning and differences between the everyday epistemology used by people and scientific epistemology are performed.

Throughout the activities carried out, some ideas that do not coincide with the scientific ones have been revealed and its possible origin has been discussed. We can remember some of those ideas or misconceptions, asking why we think that way, and how to promote meaningful learning of science content.

Reflection on students’ learning and the teaching approach followed

### Inquiry cycle to construct explanatory knowledge

<table>

<th>Activity statement</th>
<th>Comments</th>
<th>Purpose of the activity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Activity 10. How does the number of sunlight hours change in ...?</td>
<td>PETs begin by making predictions about how the number of hours of sunlight changes throughout the year in different locations on the globe. They are asked about self-confidence in giving their answers, finding low levels of self-confidence. Next, we reflect on epistemic aspects. Until no, we have constructed descriptive knowledge based on evidence, but science does not only focus on collecting empirical data in a particular way, about what happens in each locality. Science uses models to explain what is already well known (for example, what happens in Almeria) and to make predictions whose veracity can be contrasted (for example, what happens in other locations). Throughout the next activities we will construct a model that allows us to explain these worked contents and make predictions.</td>
<td>Formulation of scientific questions Predictions Communication and expression of ideas</td>
</tr>
<tr>
<td>Activity 11. Use (audio-recorded) verbal language, drawings, and models to expose your understanding of how the sun and earth move in a way which explains that in Almeria: on December 21, there are &lt;12 sunlight hours; on March 21 there are 12 sunlight hours; on June 21, there are &gt;12 sunlight hours. Activity 12. What can each model explain and what cannot? (recorded session)</td>
<td>In small groups, the students record their discussion and conclusions, which can be supported with pictures, drawings, videos... To help them express their ideas, some porexpan balls are provided to use them as if they were the Earth. It is expected that they reproduce what they remember of their stage as schoolchildren, as for example that the Earth moves around the Sun, it is even possible that they assume a certain inclination on the Earth's axis, or that they draw the image that their book or their teacher showed, representing the trajectory of the Earth as a very flattened ellipse with the Sun in one of the foci of the ellipse... In any case, their models will be insufficient to explain the known changes in the number of sunlight hours... It is important to discuss the inadequacies found in each of the proposed models. We then conclude that we need to construct a model.</td>
<td>Communication and expression of ideas (initial models) Evaluation of models</td>
</tr>
<tr>
<td>Activity 13.1</td>
<td>What should the position of the Earth and the Sun be on the equinox day so that there is 12 sunlight hours in Almeria?</td>
<td></td>
</tr>
<tr>
<td>---------------</td>
<td>---------------------------------------------------------------------------------------------------------------</td>
<td></td>
</tr>
<tr>
<td>Activity 13.2</td>
<td>What should the position of the Earth and the Sun be on December 21 so that in Almeria there is less than 12 sunlight hours?</td>
<td></td>
</tr>
<tr>
<td>Activity 13.3</td>
<td>What should the position of the Earth and the Sun be on June 21 so that there is more than 12 sunlight hours in Almeria?</td>
<td></td>
</tr>
</tbody>
</table>

After discussing the insufficiencies of models mainly based on the Sun-Earth distance, we discussed some elements that we will consider when constructing our model (based on evidence): the observer will be located outside the Earth to be able to consider what it happens in all locations; we will consider the Earth as a spherical body that rotates around an imaginary vertical axis that passes through the Poles; the rays reach the earth's surface parallel. Therefore, the sunlight always divides the planet into two equal parts (semispheres), one illuminated and the other not. Then, PETs are invited to use the porexpan balls, to try to improve their models to explain what happens in Almeria in the equinoxes and solstices regarding to sunlight hours. How should the rays arrive? From above? What would happen if they arrived from above? And if they come from below? Should they arrive inclined? What would happen if they arrived inclined? Raising questions of this type we intend to orient PETs in the construction of the model. Among all the class, we construct a static model about the relative position of the Sun and the Earth in the four singular days of the year:  

<table>
<thead>
<tr>
<th>Activity 14</th>
<th>The constructed model explains the changes in the sunlight hours in Almeria. Does it allow us to make predictions of what will happen in other locations?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Activity 15</td>
<td>Compare your predictions with those you did before constructing the model (A10) and identify the main differences.</td>
</tr>
<tr>
<td>Activity 16</td>
<td>What were your answers based on at the beginning?</td>
</tr>
</tbody>
</table>

Then, we address again the questions asked in Activity 10: *How does the number of sunlight hours change in...?* So that PETs use the model to make predictions for the different locations, finding now high self-confidence in their responses. The purpose of the activity is to promote students to make predictions by using the constructed model, to check whether it is useful.  

<table>
<thead>
<tr>
<th>Activity 17</th>
<th>How can you know if the predictions are correct? Look for evidence using the USNO website and simulations.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Activity 18</td>
<td>Learning and emotional self-regulation questionnaire. Reflection on the results of the two questionnaires (A8 and A18).</td>
</tr>
</tbody>
</table>

PETs look for evidence to confirm, or introduce changes, and if necessary reject the model. If their predictions are correct, it can be considered as a proof that the constructed model is useful. Another evidence in favor of the model can be the images coming from the satellites (advanced scientific and technological knowledge).  

| Activity 18 | Learning and emotions self-reflection is performed. Students reflect on science learning and on the felt emotions based on this sequence experienced. |

**Construction of a model to explain evidence-based descriptive knowledge**

**Using a model to explain phenomena**

**Compare initial/final predictions, and reflect on their self-confidence**

**Look for evidence to check the model reliability**

**Self-regulation on experienced learning and emotions**
When the implementation of the activities begun, the PETs did not have any previous experience with inquiry, modeling, or scientific practices.

Data Collection

To check the effectiveness of our training course on the different aspects stated before, we have designed different instruments shown in Table 2 which also work as learning activities, as they contribute to promote their pedagogical content knowledge. Some collected data (underlined) have already been analyzed (Martinez-Chico, 2013; Martínez-Chico, López-Gay, & Jiménez-Liso, 2013), and other results are commented on below (in bold).

Data Analysis

All data were open-coded, considering themes that related to the evaluated aspects. Specifically, the reflections in PSTs’ discussion analysis (alongside activities A10 and A11) were analyzed looking for themes on the role of the descriptive knowledge when PSTs construct an explanatory model. From the open-coding of the responses on PSTs’ audio-recorded discussions the findings presented in the next section were found.

With the double aim of knowing the evolution in their perceived scientific content knowledge and the emotions experienced along the sequence, PSTs' responses to a Learning & emotional self-regulation questionnaire implemented in activities A8 and A19 have been analyzed.

FINDINGS

Findings from PSTs’ audio-recorded discussions

The PSTs’ discussion analysis shows the important role of the descriptive knowledge when they construct an explanatory model.

This activity sequence design allows them to move from inconsistent towards a model to explain a precise knowledge of reality.
Usually, they state inconsistent models from their ideas on the Earth's elliptical Orbit around the Sun to explain the seasons because of the distance between the Sun and the Earth, which causes them to enter a loop in which some misconceptions lead them to an erroneous model that explains erroneous descriptive knowledge.

Nevertheless, when they try to construct the model to explain a precise knowledge of reality (descriptive knowledge previously constructed -about sunlight hours-) they introduce partial modifications to their initial models such as ‘the inclination’ of the Earth's axis, and they argue on its validity (or not) according to the descriptive knowledge they already have. This process leads them to identify the insufficiency of their initial models, particularly when explaining the existence of days with more than 12 sunlight hours.

**Findings from PSTs’ responses to a Learning & Emotional Self-regulation questionnaire**

The analysis of PSTs' responses to a Learning & emotional self-regulation questionnaire implemented in activities A8 and A19, shows an evolution in their perceived scientific content knowledge (Figure 1).

![Figure 1. Effect size in PSTs' responses to the Learning & Emotional Self-regulation questionnaire](image)

Results show a high effect size on all items, which means that they acknowledge to have learnt about scientific contents and epistemology (>2) such as identifying the insufficiency of a model to explain the existence of seasons, or the evidence needed to test the constructed model.

The most remarkable results are those related to the use of the Sun-Earth model to explain and make predictions. These results about their self-learning perceptions can be complemented with PSTs’ responses (predictions about sunlight hours) before and after constructing the Sun-Earth model (A9, A16), which indicates an enhanced explicative and predictive knowledge.

Most of the emotions that PSTs recognize to have felt when learning are "positive". Furthermore, concerning the evolution in PSTs’ emotions, a clear reinforcement of "positive" emotions (interest, concentration, and confidence) is found although there is also an increase in insecurity.
**DISCUSSION AND CONCLUSIONS**

A teacher training proposal focused on scientific practices through a Model-Based Inquiry approach, that includes learning self-regulation moments, structured in two inquiry-based cycles (in order to construct descriptive knowledge and a model to explain it) is presented.

Different instruments have been designed to check the effect of the course, and some findings related to scientific content and epistemic knowledge acquired and learning recognition are presented. On one hand, it has become clear the important role of the descriptive knowledge to construct a model. On the other hand, student teachers realize they improve their knowledge mainly of constructing and using models to explain and predict, something that coincides with their learning outcome. Moreover, the emotions felt are mainly positive, except for the case of insecurity, something that can be interpreted as normal (as a necessary emotion in the learning process) and that must be recognized by students as such in order for them to be able to regulate it.

These results, amongst others (obtained through the instruments presented in Table 2), allow us to consider the training proposal as an appropriate option as it facilitates professional development to teach scientific practices. Teacher training can be focused on different aspects (argumentation, modelling, inquiry…), but due to time limitations we are forced to focus on only one. Therefore, we opt to focus on inquiry-based learning which we have observed to be much more efficient given that it allows the construction of descriptive knowledge and models, epistemic and pedagogical knowledge. Engaging in scientific practices supports the development of the most appropriate understandings of science and scientific inquiry, and that PET become more accepting of approaches to teaching science (Haefner & Zembal-Saul, 2004). Nevertheless, implications include considering teaching designs performed by prospective elementary teachers to support the development of robust professional knowledge.

METHODOLOGICAL GUIDELINES FOR POTENTIATING ENVIRONMENTAL EDUCATION IN TEACHING TRAINING

María del Carmen Acebal-Expósito, Vito Brero-Peinado, José Antonio Rueda-Serón and Carolina Martín-Gámez
University of Málaga, Málaga, Spain

This research is a result of the innovation project, PIE 15-141, "Environmental Education in University Teaching Training" at the University of Málaga, whose main objective is to mobilize the cognitive, attitudinal, affective and conative dimensions of environmental awareness in Preservice Secondary Science Teacher Training Program and of the Grade of Primary and Child Education Teacher and with the intention of developing in the students the capacity to create, design and to specify learning situations whose axis is the environmental education. Based on a qualitative methodological analysis of the proposals of individually developed didactic interventions, in the different groups that constitute the work sample, a series of difficulties are detected to identify nearby environmental problems, belonging to its immediate environment, and didactic deficiencies to propose and design activities related to those problems. These results determine the need to generate methodological recommendations contextualized or methodological implications that will be addressed with the purpose of further progress in this project. In this way, a second assessment will be carried out following the application of the new guidelines, the report of which will be part of another communication. This work is part of the 'R & D Excellence' project EDU2013-41952-P, funded by the Spanish Ministry of Economy and Finance through its 2013 research call.

Keywords: environmental education, teacher training, didactic orientations.

INTRODUCTION

Environmental Education for future teachers has a determining aspect, since among the particular characteristics of Environmental Education, its axiological component stands out. When education professionals have been involved in an environmental training dynamic they have shown difficulties to: identify sources of knowledge, recognize and assess environmentally worrisome situations as well as limitations to exemplify own actions favorable to the environment. However, as positive aspects, future teachers have shown a predisposition toward environmental education as a generator of environmental awareness, since they consider it a mobilizer of sensitivity and respect, at the same time they point to the school as the place where it is most easily generated (Acebal, 2010).

On the other hand, there is a determination in their own formation, initial and permanent, as necessary to transmit from the master model, the necessary values for the development of competences of environmentally committed citizens (Acebal, Brero and Sampietro, 2015). In analyzes carried out on curricular perspectives for the training of trainers in environmental education, emphasis is placed on the need to incorporate the environmental perspective in vocational training (Sauvé, 2003).

Recent international publications coincide in previous statements such as the case of Shiang-Yao (2015) who states "teachers have satisfactory levels of knowledge and attitudes of the environment, but have low levels of environmental action that promote dissemination in them".
Other researchers have highlighted the existence of a personal teaching epistemology constructed through experience, first as a student and then as a teacher, which mediates the attitudes and behaviors presented by the teacher in class. This personal teaching epistemology can be an obstacle to didactic change but it must also be considered the starting point for new didactic constructions (Tobin and Espinet, 1989; Carretero and Limón, 1996).

Teachers with their initial personal epistemology must appropriately take on the existing didactic knowledge and for that they must be involved in the reconstruction of this knowledge. Thus, a training model consistent with these constructivist approaches will use the metaphor of teachers (in initial or ongoing training) as new researchers working in teams replicating didactic research directed, in an initial phase, by an expert researcher (the tutor, adviser or coordinator) in those investigations (Furió, 1994a, Furió and Gil, 1999). The didactic change of the teaching staff that includes the Environmental Education, has to be conceived as continuous and "natural" in the "learning to teach science", and essential for their professional development. This implies that teachers must be prepared not only to teach science but also to work collectively and self-assess their task. And this will only be possible if education is planned as a didactic hypothesis that tries to solve school failure and is tested through appropriate designs as in any research (Furió, 1994).

This research considers the study plans of the new degrees in the field of the European Higher Education Area (EHEA), which represent an important change in traditional methods of teaching and learning. Among the most significant aspects, subject to this change, are the development of competencies and the role of evaluation in the educational process (Blanco-Fernández, 2010; Zabalza, 2003). Habitually, the teacher training activities should set out tasks and learning situations as a rehearsal to which the teachers will have to carry out as part of their teaching tasks (Carrascosa, Martínez, Furió and Guisasola, 2008).

Perrenoud (2004) talks about ten new competences, proposed based on the Geneva reference in 1996, considering that they are priorities based on their coherence with the new role demanded of teachers, the evolution of continuing education and educational reforms that are being implemented in different countries. Starting from the concept of competence that the author manages as a capacity to mobilize several cognitive resources to deal with a type of situations, it establishes several aspects or considerations, one of which it is pertinent to underline: professional competences are created, in formation, but also at the expense of the daily task of the practitioner, from one work situation to another. That way, the ten families of proposed competences are:

1. Organize and animate learning situations,
2. Manage the progression of learning,
3. Develop and evolve differentiation devices,
4. Involve students in their learning and in their work,
5. Work as a team,
6. Participate in the management of the school,
7. Inform and involve parents,
8. Use new technologies,
9. Face the duties and ethical dilemmas of the profession,
10. Organize their own continuous training.
These are some of the skills that all teachers must develop and are directly related to the subjects or subjects they have to teach. That is to say, the development of these competences will be closely related to the didactic knowledge of the contents held by the teaching staff (Shulman, 1986 and 1993) and, therefore, their teaching and learning acquires special relevance in the specific subjects of the degrees involved in this work.

Perrenoud's competences are closely related to some of the curricula included in Preservice Secondary Science Teacher Training Program and Grade in Early Childhood and Primary Education Teachers at the University of Malaga, such as:

- Plan, develop and evaluate the teaching and learning process, promoting educational processes that facilitate the acquisition of the competences of the respective teachings, taking into account the level and previous training of the students as well as the orientation of the same, both individually and in collaboration with other teachers and professionals of the center (General competence).

- Develop and apply didactic methodologies, both group and customized, adapted to the diversity of students (General competence).

- Know strategies and evaluation techniques and understand the evaluation as an instrument of regulation and encouragement to the effort (Competence collected in the subject "Learning and teaching of the subjects of the specialties").

As stated at the beginning of this section, one of the most novel and complex aspects of the European Higher Education Area (EHEA) is the role of evaluation in the teaching and learning process (Brown and Glasner, 2003). Through educational evaluation, in addition to informing students about their strengths and weaknesses to correct errors and consolidate successes, the awareness of competency acquisition can be developed through self-evaluation activities focused on reflection and regulation (Valero and Díaz de Cerio, 2005).

It is important that the teachers in formation know and use self-evaluation techniques and strategies as an instrument of reflection and regulation of their own learning. The development of these competences in the teaching staff will undoubtedly result in their competences to promote them, in turn, in their students.

This research gives continuity to a line of work already started in the Knowledge Area of Experimental Sciences, related to the teaching and evaluation of the competences of teachers in training (Arjona, España and Márquez, 2008; Rueda, Acebal and Brero, 2010; Sacristán and España, 2010). It is integrated into a framework where some other lines of research that are carried out in the department are related, such as: environmental awareness and its relationship in the training of teachers, innovative methodologies in science to promote attitudinal change, environmental identity/ multiculturalism, the formation of critical thinking from the didactic of Social Sciences.

As innovative aspects, the coordination of the mentioned subjects according to each grade or post-grade is proposed to program and develop in a coherent and integrated way training activities that ultimately result in the acquisition of environmental attitudes that promote the predisposition to contextualize intervention situations education for environmental education.
In this research we highlight aspects such as:

The consideration of Environmental Education as a generator of training and evaluation activities, from the interdisciplinary consideration that favor the multiplier effect, so necessary, in the different levels of the educational system.

The integration of a good number of subjects of several specialties of Preservice Secondary Science Teacher Training Program and Grade of Early Childhood and Primary Teachers, involving a high number of students.

The promotion of self-evaluation of students and their relationship with the development of important competences for future teachers of secondary education, high school, infant and primary education.

The promotion of coordination among the teachers of the areas involved, this being an aspect pending improvement.

The interdisciplinarity as an idea is totally coherent with the principles of Environmental Education and, for its part, the need for intra and interdisciplinary coordination is a permanent demand of the undergraduate and postgraduate students and faculty.

**WORK DESCRIPTION**

The development of this research work coincides with the first stage of the Educational Innovation Project PIE15-141 of the University of Malaga, "Environmental Education in teacher training", and which takes place during two consecutive school years.

This work was carried out during the academic courses 2015-2016 and 2016-2017 in the subjects related to the design and development of programming and training activities; the biology and geology curriculum; teaching innovation and initiation to educational research in the areas of Preservice Secondary Science Teacher Training Program at the University of Málaga and in Experimental Sciences Teaching and Teaching of Sciences in Grade in Early Childhood and Primary Education of the University of Malaga.

**Objectives**

- Identify the difficulties for the design of teaching-learning activities around Environmental Education.
- Encourage the empowerment of an environmental awareness of teachers committed to their immediate and global environment to determine educational actions consistent with environmental education.
- Design meaningful methodological guidelines that provoke the necessary change for the assessment and adoption of interdisciplinary and cooperative work strategies among the teaching staff.
- Design evaluation resources to enhance the self-assessment and regulation of student learning.
Methodology

Initially, a questionnaire was developed to assess different dimensions: cognitive, evaluative and behavioral aspects; capacity to identify environmental problems and the relationship between environmental problems and teaching contents that generate their inclusion in the design of educational activities (Figure 1).

This questionnaire was agreed and validated within the teaching team of the project. Subsequently, the students' responses were analyzed and evaluated, from which didactic orientations were developed.

5. Design an educational activity for one of the environmental problems identified, to carry out with the students of a course of their choice.

Figure 1. Questionnaire own elaboration.
In this research we will focus on the analysis of the answers that refer to two questions of the questionnaire:

1. Identify at least three local environmental problems.
2. Design educational activities for each environmental problem identified to carry out with students a course of your choice.

The sample of students consists of 181 students from various groups of teachers in training corresponding to the degrees of Teachers of Early Childhood, Primary and Secondary Education.

ANALYSIS OF RESULTS AND CONCLUSIONS

From the analysis of the answers to the first question, four environmental problems are identified only, highlighting the reference to waste in relation to others. The other problems mentioned are, in order of greater or lesser frequency, transport, water, biodiversity.

Concerning the second question, practically all of the activities proposed are not detailed in a didactic way, but only in a brief manner. The development of objectives or competences, methodology or specific tasks to students is not considered.

Description of the categories of problems and types of related educational activities.

The category of Waste, 80.11%, includes all those references to solid urban waste that the students denominates in a different way. The majority refers to garbage both domestic and in public spaces.

The Transport, 8.28%, agglutinates the answers that correspond mainly to the use of the own car or public transport.

The Water, 6.08%, groups answers mostly related to irresponsible consumption of the same.

Finally, Biodiversity, 4.97%, gathers mostly references to exotic pets as invasive species and hunting. (Table 1)

Regarding related Educational Activities: the first type Reuse, recycle, separate refers mostly to proposals on paper recycling, simple objects made from plastic containers and the identification of containers according to kinds of waste.

The second type of space cleanup corresponds with project ideas to clean public places such as the school playground, squares, parks and beaches.

In the third type of activities proposed, field trips, are grouped those responses related to visits to recycling plants and environmental reserves.

The fourth group, Information Workshops, represents proposals for invitations to experts to discuss issues related to waste pollution. Campaign of diffusion, identifies suggestions of elaboration of poster or decals that would be distributed in the next community.

Finally, the Other category includes ideas of activities methodologically little or nothing related to the problem.

<td>Relative percentage of the total sample of activities not related to the problem</td>
<td>2.1</td>
<td>3.9</td>
<td>0.4</td>
<td>6.4</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The relationships established between problematic and proposed activities (Table 2) tend to repeat patterns of activities that result from their own learning experiences in previous studies. In this sense, it is clear that the problem of solid waste, with 80.11% of the references, has a relative percentage of 78.5% of proposals for related activities, the rest of proposed activities, 2.1%, have no relation to the problem.

The students that have identified Transport, 8.29%, only represent 4.5% of the total sample with their related activities, and the remaining 3.9% have not proposed related activities.

On the other hand, in the case of those who identified Water and who represent 6.1%, they have made related proposals, representing 6.1% of the total sample. With a similar frequency and relation, we observe the correlation between the problematic Biodiversity, which reaches 4.95% and related designed activities that get 4.7%.

1779
Conclusions and methodological implications

The results of this research work can be applied in the subjects of other specialties of the Preservice Secondary Science Teacher Training Program, as well as in other subjects of the grades of teacher in Early Childhood and Primary Education. Specifically, the innovative, formative and evaluative tasks that arise within this project can be transferred to the subjects assigned to the Knowledge Area of Experimental Sciences Education in the Grade of Teacher in Early Childhood Education (Health, Hygiene and Infant Feeding and Sciences Education) and Teacher in Primary Education (Science Teaching and Experimental Science Teaching).

In the light of the analysis of the responses of the teachers in training, a series of orientations and recommendations are proposed on which to emphasize their training program. It is necessary to make explicit the objectives and competencies for each activity designed in the educational proposal that include the cognitive, attitudinal, affective and conative dimensions of environmental awareness.

To leave clearly expressed and grounded the environmental content, preferably as a result of a previous investigation of problems close to the student's environment; the recommended methodology is one that allows significant learning, not repetitive and topicality; that also allows to demonstrate the ways in which the students can make a rewarding self-assessment from the possibility of being able to act positively in their environment.

Regarding for the typology of environmental education activities: adapt and update the typical ones, such as paper recycling, separation of waste, cleaning of spaces, and generate innovative activities such as action research projects in context such as opinion and dissemination campaigns, actions related to activism, proselytism and others that generate habits of sensitivity, commitment and inherent behaviors.

ACKNOWLEDGEMENT

This work is part of the ‘I+D Excelencia’ project EDU2013-41952-P, funded by the Spanish Ministry of Economy and Finance through its 2013 research call.

CHALLENGES OF SCIENCE TEACHER EDUCATION IN LOW-INCOME NATIONS – THE CASE OF ETHIOPIA

Mekbib Alemu¹, Per Kind², Mesfin Tadesse¹, Mulugeta Atnafu¹
and Kassa Michael¹

¹Addis Ababa University, Addis Ababa, Ethiopia
²Durham University, Durham, United Kingdom

Science education in the low-income nation of Ethiopia have poor attainment and enrolment. The shockingly low attainment in the lower levels of education is troubling teacher education as well. In this study attempt was made to explore the challenges of physics teacher education in Ethiopia based on data collected from 16 Teacher Education Colleges, 432 pre-service physics teachers in their final year of study, and 31 college lecturers. From the qualitative and quantitative analysis of conceptual test results, interviews, and classroom videos the following major results have been found. At the end of one-year intervention with dialogic teaching, both the comparison and treatment pre-service teachers were found to score very low in selected TIMSS items from population 2 tests; pre-service teachers slightly but significantly favoured didactic over dialogical teaching and quite sharply favoured both of these over naïve inquiry teaching: Physics teacher education lecturers predominantly use the lecture method in their classrooms but intervention found to shift their style significantly to dialogical teaching; finally, it was found that pre-service teachers learning is highly influenced by weak English language proficiency, low motivation, and expectation of low social status for the teaching profession.

Keywords: dialogic, pre-service, conceptual, orientation

BACKGROUND

Low-income nations have poor educational attainment and enrolment compared to most middle- and high-income nations. Education in low-income nations is suffering from low enrolment and high dropout rates. Two decades ago, UNDP described this as a global learning crisis and aimed for “universal primary education” as one of its Millennium Goals. From 2000 to 2015 this effort paid off and enrolment in low-income nations increased from 83 to 91%. Despite this global picture, enrolment in primary education in Sub-Saharan Africa did not even reached the global threshold. In this group of countries, to which Ethiopia is a member, the fast-developing enrolment rate due to the global effort jumped from around 52% in 1990 to 80% in 2015 (UN, 2015). However, there are discomforting reports that low income nations are still falling behind from the target of enrolment rate of 100% and struggling with high dropout rates (Global Partnership for Education, 2014).

A much more serious problem of the education system in low-income countries is low attainment. Even those who were enrolled in primary education at a relatively high number are leaving school without being able to read and write (Global Partnership for Education, 2014; Hill & Chalaux, 2011). Furthermore, participation in international learning assessments, such as PISA and TIMSS, revealed that there is as large as two standard deviations between scores of students from the low-income countries and high-income nations (Martin, Mullis,
Foy, & Hooper, 2016; OECD, 2012). Progress is also very low for children in low-income nations to fill the observed huge gap (Beatty and Prichett, 2012).

Attainment, however, maintained low and the Department for International Development (DFID) in the UK, together with the Economic and Social Science Research Council (ESRC), therefore launched a large-scale research programme, Raising Learning Outcome in Education Systems (RLO), to investigate ways of improving the overall quality of education in low-income nations. The current paper is based on a study in the RLO programme looking at STEM subjects and aims to analyse quality of physics teacher education for middle schools in Ethiopia. More specifically, the paper asks

- How does the level of conceptual knowledge among Ethiopian pre-service teachers compare to students in high-income nations?
- What are the pre-service teachers’ pedagogical orientations and conceptions of “good teaching”?
- What pedagogy dominates teaching in Colleges of Teacher Education (CTEs) and how does this pedagogy align with pre-service teachers’ orientation?
- What contextual factors influence quality of physics teacher education for middle schools in Ethiopia?

LITERATURE REVIEW

As Ethiopia did not participate in the international examination, the above data may not directly apply to our current case. Nevertheless, other studies comparing the Ethiopian case with other developing countries attest that the problem is even much worse than what has been observed above. The Young Lives Study (www.younglives.org.uk), a long-term international study of childhood poverty in Ethiopia, India, Peru and Vietnam, has been important to analyse education in Ethiopia. The study has followed 12,000 children over 15 years and gathered information from educational authorities, homes and schools. The study points out that mass education is a relatively new phenomenon in Ethiopia compared to the other three nations and that the fast-growing expansion of inclusion rate has had a negative effect on attainment (Beatty & Pritchett, 2012). For mathematics and reading literacy, Ethiopia is the lowest scoring among the four Young Lives nations and has the faster widening learning gap as the children grow up. The nation also has a big attainment gap between urban and rural areas. Joshi and Verspoor’s (2013) study of Ethiopian education, to be reported to the world bank, corroborated the finding in Young Lives study.

Two problems have been targeted in several Development Programmes launched by Ethiopia’s Ministry of Education: the low progress made by children over one year of education and the high failure rate of students in Grade 10. Many home factors influence these problems (Singh, 2014), but quality of teachers, teaching and curricula are also seen as important (Pritchett & Beatty, 2012; R. Singh & Sarkar, 2012). Ethiopia was not included in the ROSE project (Sjoberg & Schreiner, 2010), but students in other comparative African countries showed very positive attitudes towards school science. It is therefore a paradox that many researchers in Ethiopia report attitudes as one of the biggest problems for educational attainment, particularly in physics and mathematics (Weldeslassie, 2016). Attitude is also regarded as a problem for recruitment to teacher education (Woldehanna, Tassew, Mekonnen, & Jones, 2009).
In Ethiopia, there are more than 80 different languages and there is a policy to provide primary education with the different vernacular languages. Different regions use the mother tongue language in primary education to a different level. Teacher education colleges use a combination of the mother tongue and the English language. For example, the 9 CTEs in this study have a teacher education for the second cycle primary with the English language as a medium of instruction.

**METHODOLOGY**

The study had a sample of 432 pre-service teachers (Mean age 20.37 years) and 16 CTE lecturers from nine different CTEs spread geographically in three Ethiopian regions (Amhara, Addis Ababa and SNNP). Participant pre-service students were 336 (77.8%) male and 96 (22.2%) female. Furthermore, these participants were differing in entry profile to teacher education. Even though majority of them joined the CTEs after completing grade 10 still a significant minority, N=126 (29.2%) of them were from grade 12 completes. The present study focused on the senior year of a three-year teacher education programme and used a mixed methodology design, including a series of data gathering tools. A test containing released items from TIMSS measured physics conceptual understanding. This allowed item-by-item international comparison and development of a local scale for correlation to other variables in the data set. A validated pedagogical orientation questionnaire (Horizon, 2012) was translated into Amharic and used together with 16 focus group interviews of pre-service teachers to investigate conceptions of “good teaching”. Interviews also focused on motivation for working in education. Video observations of sixteen physics lessons and individual interviews with all CTE lecturers were used to investigate pedagogical practices in teacher education. Physics curricula and teaching material were studied in content analysis.

Interviews and video observations were transcribed and translated into English for thematic analysis in the software Nvivo. Video analysis focused on communicative approach (Mortimer & Scott, 2003), including amount of time teacher and students were talking and the quality of utterances made by teachers. Analysis of interviews focused on themes related to didactic (teacher-led) and dialogical (student-led) teaching, and contextual factors as well. Scales for conceptual understanding and pedagogical orientation were analysed in SPSS, using ANOVA and correlations, after Rasch scales had been developed in Winsteps.

**FINDINGS**

**Level of Physics Conceptual Knowledge Among Ethiopian Pre-Service Teachers**

For international comparison of physics conceptual knowledge among Ethiopian pre-service teachers the natural comparison would be items from TIMSS Population 3 (Final year of secondary school). However, trialling showed these items were too difficult. Items, therefore, were selected from Population 2 tests (Grade 8 students) and allocated into two groups as generalist and specialist items. A physics item was considered ‘specialist’ if the pre-service teachers just took a course related to the physics content to which it belongs. An example of this item by item comparison of students of grade 8 from the international data with the final year pre-service physics teachers scores is presented in Figure 1.
It can easily be seen from Figure 1 that Ethiopian pre-service physics teachers, in their final year teacher education, could score somewhere between the highest and lowest TIMSS score for grade 8 students internationally. What could be seen from Figure 1 is only a fluctuation around the average score. Another example of the relatively lower score of the pre-service teachers is presented in Table 1.

**Table 1. Percent of students who got correct on TIMSS sound wave items**

<table>
<thead>
<tr>

<td>15</td>
</tr>
<tr>
<td>Sound Wave 3</td>
<td>11</td>
<td>71.5</td>
<td>32</td>
<td>17</td>
</tr>
</tbody>
</table>

Once again, we can see that in all of the three sound wave items Ethiopian pre-service teachers scored less than the TIMSS average and a little bit higher than the lowest. That is, final year Ethiopian pre-service physics teachers had a level of conceptual knowledge similar to Grade 8 students in the international tests. They scored substantially lower on all open-ended items requiring writing, but higher on some MC items. Furthermore, when the test was repeated towards the end of the academic year, progression was low with an average increment of 0.2 of a standard deviation.

Slightly better performance was observed among grade 12 entry pre-service teachers compared to those from grade 10. Table 2 presents the data for three Electricity items, as an example.

**Table 2. Percent of Grade 10 (N=) and Grade 12 (N=) entry students who got correct on the three TIMSS Electricity items**

</tr>
</tbody>
</table>

Student entering teacher education from Grade 12 scored significantly higher than students entering at Grade 10, and this difference increased over the academic year. This better performance implies that those with better entry profiles will better benefit from teacher education program than those with weaker profiles, as far as conceptual learning of physics is concerned. This is a conformation of results found elsewhere, for example studies by Sadler.
and co-workers (2013) for middle school students and Baumert and his associates (2010) revealed similar results for mathematics pre-service teachers.

**Pre-Service Teachers’ Pedagogical Orientation and Conception of “good teaching”**

Questionnaire for pedagogical orientation had three constructs: didactic (teacher-led), dialogical (student-led) and naïve inquiry led teaching. Of these, pre-service teachers slightly but significantly favoured didactic over dialogical teaching and quite sharply favoured both of these over naïve inquiry teaching. All scales, however, had low reliability and ceiling effects, suggesting many pre-service teachers struggled to see the difference between the constructs and exhibited random dispositions to the three orientations. In interviews, the pre-service teachers talked heartily about student involvement as good teaching and wanted physics teaching to be less abstract and more related to everyday contexts. What has been observed could possibly be a conflict between the intention of the teacher education program and what pre-service teachers experience as students. It seems that teachers’ knowledge originates from teachers’ own school learning experiences, teacher education and professional development programs, and teaching experiences (Friedrichsen et al., 2009). Obviously, for these pre-service teachers, the last one does not apply as they do not have teaching experience that affects their knowledge about the different teaching approaches. The general rhetoric around teachers and teacher education is about “student centred” teaching and in the teacher education program the pre-service teachers are lectured about the importance of student-involving instruction. Nevertheless, since their school years, including CTE classes, they are predominantly being taught with didactic approaches. Thus, the observed difference in students’ preference to didactic teaching over dialogic and enquiry oriented teaching in the questionnaires from their talks in the interviews is an indicator of this confusion.

**Pedagogy dominating teaching in teacher education**

Qualitative analysis of classroom videos, especially from teachers’ camera, in both the comparison and the intervention groups helped to identify the different pedagogical approaches the physics teacher educators employed. Comparison between treatment and comparison classes were made in early stage of the intervention as well as at the end of the year. The table (Table 3) presents the data from the post-intervention video records for the 31 lecturers.

Observations from classrooms generally demonstrated a strict didactic regime despite the attempt to transform the classes into dialogic approaches. We observe substantial differences between treatment and comparison groups. In the comparison group, teachers on average spent 72.77% of the time on lecturing. This is reduced to 21.97% in the treatment group. In contrast, teachers on average spend 4.96% on group work in the comparison group, while teachers in the treatment group spent 42.35% of the time on group work. Although students in some lessons did problem solving, students’ ideas and answers were rarely discussed in plenary in neither the comparison nor the treatment groups.

<td>1.52</td>
</tr>
</tbody>
</table>

Dialogical teaching (teacher having a whole class (true) dialogue) which occurred in the treatment group occasionally (11.45% of class time), was almost non-existing in the comparison group. An important type of teaching for dialogic teaching, which is “meta-teaching” that involves whole class discussion and teacher summarizing the discussion are occurring less frequently in the comparison groups compared to the treatment group. A “mean” (50 minutes) lesson in the comparison group has 2-3 minutes introduction, 38 minutes lecturing, 6 minutes with students solving tasks individually or in groups, and 1-2 minutes summary by individual students and 1-2 minutes general summarizing by the teacher. The similar lesson in the treatment group has 3-4 minutes on the introduction, 8-9 minutes on lecturing, 22 minutes on group work, 8-9 minutes on dialogical teaching and occasional individual presentations by students, and 5 minutes on general summarising by the teacher. In other words, the big difference is in lecturing versus group work, but also a more balanced use of time across more types of activities in the treatment group compared to the comparison group. This is the “mean” picture.

While a pedagogic shift has been observed from comparison group to the treatment group, a distinct variation also observed among the individual lecturers. Looking at the variation in lessons we find many differences, however, more so in the treatment group than the comparison group. The comparison group (ordinary teaching) has a strong dominance of lecturing in ALL lessons, with time allowed to individual problem solving (individual seatwork in Figure 2) being the only deviation. As the comparison group lecturers had little choice they all seem to depend on lecturing throughout. The bar chart in Figure 2 presents the case of two lecturers from the treatment CTEs from the video data towards the end of the year.

However, as can be seen from Figure 2, the treatment group lecturers seem to significantly differ from each other though they abandon lecturing and replace it with group learning in general. In the example displayed in Figure 2, lecturer 1 dominated his teaching by group work, lecturer 2 moderated group work with more of dialogic teaching components. The important elements of dialogic teaching, such as whole class discussion and teachers’ summaries are given appropriate considerations in the case of lecturer 2 in contrast to the other one.
Figure 2. Percentage of lesson time used for different activities by two lecturers from the treatment group

**Contextual factors influencing teacher education**

In Ethiopia, the medium of instruction, especially starting from upper primary (Grade 7 and 8) and in teacher education, is formally the English language. Thus, the physics teacher education in the linear program is expected to be conducted in English. Nevertheless, in this study the English language emerged as a problem from interviews, conceptual tests and classroom observations. Both CTE lecturers and pre-service physics teachers were observed to have difficulties in expressing their ideas and engage in classroom discussions using the official language of instruction. Most of the lecturers were limited to stating textbook information in the English language instead of using it as a communicative means. In both small group and whole class discussions pre-service teachers mostly use the Amharic language with sporadic mentioning of physics technical terms and phrases in English. Thus, the research implied that the desire to use the English language in Physics teacher education without proficiency is a serious impediment system wide.

From pre-service teachers’ interviews (focus group interviews) what repeatedly immersed is that they neither their chose to join teacher education nor wanted to study physics. Even those who claimed to have some degree of motivation to become physics teacher qualify their motivation as a “profession for the time being”. This problem of motivation seriously affects their learning as well as desire to implement effective but demanding pedagogical approaches in their future teaching. Most of the time, pre-service teachers attribute their low motivation to the “too-low salaries for teachers” and the difficult nature of the subject matter of physics “to learn as well as to teach” it.

Furthermore, many of the pre-service teachers are also worried about the low status of teachers in society.
DISCUSSION

Findings in this study suggest that low level of physics attainment in compulsory education in Ethiopia (Little & Rolleston, 2014) carries on as a problem into teacher education. The nation is in need of strong academic candidates for engineering education and sends the weaker candidates to teacher education. The curricular content as implemented in the classroom was found to be very advanced compared to students’ level of conceptual knowledge revealed in the tests. Lecturers typically aimed their teaching at the highest achieving students. The existing physics curriculum is far too abstract for the majority of pre-service teachers and suited only for the best candidates recruited from Grade 12. The majority of them (77%) are recruited from Grade 10, and many with failed exams in physics. Due to a didactic teaching tradition, not suited for the academically weaker students, the gap between the two groups of students is growing through the teacher education years. Similar problems are known from other low-income nations (Pritchett & Beatty, 2012), and caused partly by the international push for increased enrolment. The Government in Ethiopia has chosen to let candidates into teacher education and further into teaching jobs in spite of failing exams at both levels and also strong evidences of low motivation to the teaching profession. The research suggests changes should be made to the physics curriculum and that pedagogy needs improvement. The current study illustrated that changing the pedagogy in teacher education is possible. However, low entry profile and contextual factors seem to militate against the effectiveness of the change in resulting in the desired learning outcomes. A longer-term solution should focus on the role of English as a teaching language and introduce standards for pre-service teachers going into teaching jobs.

TEACHERS’ PERCEPTIONS ON THE OBSTACLES IN THE TEACHING OF SCIENCE THROUGH THE GOWIN V

Edith Herrera¹, Mariona Espinet² and Mercè Izquierdo²
¹Universidad del Bio Bio, 8ª Region, Chile
²Universidad Autònoma de Barcelona, Catalonia, Spain

This investigation addresses reflective teaching in a learning community that brings together science teachers in initial training (STIT), mentor professors (MP) and a university professor (UP), who is the co-author of this work. The reflection centers on the practical teaching session of STITs when they propose a change in teaching practices at their school focusing on science inquiry and modeling, using the Gowin V diagram (GVD) as a support structure for scientific activity at school. The research question raised is: What are the perceptions of the STITs and MPs regarding the obstacles to the practical implementation of science teaching by inquiry and modeling using the GVDs? A content analysis is performed of the transcripts obtained from (a) semi-structured interviews by case study (STIT-MP); (b) individual interviews of the five STITs and their MPs; and (c) a focus group in which one STIT and MP participated, and another focus group in which only the STIT participated. The analytical framework is based on the model of pedagogical reasoning and action by Shulman and Schön. The results indicate the dimensions in which there is a consensus between the STIT and MP, and point to the development of two levels of reflection based on the consideration of obstacles to the use of the GVDs as an opportunity for educational change in science classrooms.

Keywords: Gowin V diagram, science teacher training, science inquiry and modelling.

INTRODUCTION

The investigation presented in this report addresses reflective teaching in a learning community that brings together the science teacher in initial training (STIT), a mentor professor (MP) and the university professor (UP). The reflection focuses on the practice of the teaching of STITs when they propose an educational change in science teaching at their school focusing on science inquiry and modeling, using the Gowin V diagram (GVD) as a support structure for scientific activity at school (Izquierdo et al, 1999 and Caamaño, 2011). We approach the professional knowledge acquired by the STIT and the MP in this experience from the connotation of reflective teaching given by Zeichner (2010), and we characterize it based on two frames of reference. On the one hand, we have adopted the reasoning model proposed by Shulman (1987) on reflection in relation to pedagogical activity, and on the other hand we have used the ideas of Schön (1992) on the importance of reflection “on actions.” The question that has guided the research we present is: What are the perceptions of the STITs and MPs about the obstacles to the practical implementation of science teaching using inquiry and modeling with the GVD?

The model of pedagogical reasoning and action

In the characterization of professional knowledge, we have followed the model of reasoning proposed by Shulman (1986) in pedagogical actions through the understanding of the important concepts to be taught, obtained through the reflections made by the professors. Figure 1 shows
the pedagogical model of this research, which we understand as a cycle in which the teacher achieves an understanding of the content he teaches in such a way that it allows him to convert it into representations that would be for the students, so as to make it "teachable". It also includes the ideas of Schön (1992) about the importance of the reflection "on the action" in the training of teachers, by making it easier for each participant (PFI-PG and PU) to feel they are an important part of the process, with a discourse and experiences that educate the others (Moss, 2010) and that make it more likely for them to improve from the others (Canning, 2011).

![Figure 1. The model of pedagogical reasoning and action of Shulman (1987) and Schön (1992)](image)

This model suggests that in the preparation and teaching, the professors are inspired by sources of knowledge that we have identified as: knowledge of the content, didactic knowledge the of content, curricular knowledge, general didactic knowledge, knowledge of the goals and objectives, knowledge of the students, and knowledge of the contexts, frameworks, and educational management. Shulman (1987) points out that these sources for understanding make the process of reasoning and pedagogical action possible. The process of transformation that each teacher carries out is related to the different sources of knowledge, the most important of which is the didactic knowledge of the content. This owes to the fact that this method for knowing and understanding the subject is what distinguishes a professor from a specialist in the field. In this sense, the author indicates that the didactic knowledge on the subject (PCK) is built with and on the basis of the knowledge of the content, the general didactic knowledge, and the knowledge of the students.

Schneider and Plasman (2011) have studied for the didactic knowledge of content for two decades, and have identified five broad fields of PCK: (1) orientation for teaching science, (2) how to think about science, (3) instructional strategies in teaching science, (4) the science curriculum, and (5) the evaluation of science students. All these areas of the PCK have components that characterize the field of knowledge.

Therefore, a description of the expected PCK of science professors is rather complex, and even more so for teachers undergoing their initial training, and as described by Borko and Putnam (1995), the teachers' knowledge has a significant impact on the decisions made by the professors. Therefore, "... to help teachers change their practice, we must help them expand and develop their systems of knowledge." (Borko and Putnam, 1995, p. 37).
The role of reflection in the construction of professional knowledge of the PFI.

A key aspect of the initial training must be the consideration that future teachers of science and teachers learn to teach not only from practice, but also from a rigorous analysis of that practice. This reflective approach clearly expresses the ideas of a questioning taking place "in" and "on" the action (Schön, 1983, 2002) and those of the professor as researcher (Stenhouse, 1987, Perrenoud 2010). According to Schön (1983, 1987), the point at which it becomes clear that reflection is necessary comes when a familiar routine produces an unexpected result, when an error resists being corrected, or when, for whatever reason, we begin to observe the results produced by the routine actions in a different way. This author emphasizes that professionals must learn to frame and rethink the problems they face, test various interpretations, and modify their results (Hatton and Smith, 1995, p. 3).

On the other hand, Zeichner (1993) points out that the reflection done on the basis of the practice is based on two essential principles. The first recognizes the professional status of educators and their central role in the teaching and learning process; the second establishes the capacity of the teachers to generate pedagogical knowledge. From this perspective, the teachers' knowledge is useful and allows them not only to develop practical knowledge but to investigate their practice and to produce theoretical knowledge, so this understanding goes beyond and is not limited merely to applying ideas created by other people.

The reflection, shared as part of a formative triad (PFI-PG and PU) allowed us to question the practice carried out in a space of broad reaching conversation, without hierarchical relations; in fact, it enabled the interaction and participation among everyone and the valuation of different viewpoints and experiences from different reference contexts (Walkintong, 2005). One essential aspect among the participants was to break away from the hierarchical view on the process of the practice (Zeichner, 2010; Russell & Martín, 2011), to feel like they are among their peers, and to pose convergent or divergent positions, to offer solutions, to ask questions, and to build new alternatives from the situations that have been established. Specifically, in the case of our study, the obstacles perceived by the participants while proposing a different class to the traditional one.

From our perspective, the training of a future teacher from this point of view suggests the integration of theory and practice, not so much in the traditional requirement that theory should illuminate practice, but rather that from a reflection "on the practice", a theory may then be built.

METHODOLOGY

This descriptive investigation corresponds to a multiple-case study (Stake, 1998). The subjects were five STITs, all of them women, studying their fourth year of a degree program in Pedagogy in Natural Sciences, at the University of Bio Bio in Chile, as well as five MPs from five different schools. The change in the initial training required the STITs to learn how to design a different class, characterized by integrating science teaching by modeling (Izquierdo 1995; Izquierdo et al, 1999; and Caamaño, 2011) with the use of the GVD as support strategy for science inquiry and modeling (Windschitl et al, 2008). The research was carried out during the six weeks of pedagogical practice of the STITs. Before it began, we met with the MP of the
establishment, and the STIT to organize the teaching unit and orient the classes. After that, the MP and UP observed the classes of the STITs, and once they finished, reflected on the obstacles facing their teaching for each case study. The instruments used for collecting the data included: (a) semi-structured interviews for case study (STIT-MP); (b) individual interviews with the five STITs and their MPs; and (c) the focus groups, one of which included the participation of the STITs and MPs, and the other focus group with only the STITs. The thoughts expressed by the STITs and MPs regarding the obstacles were analyzed by semantic networks, following the model of pedagogical reasoning and action of Shulman and Schön, which includes the following dimensions: (a) understanding of the concepts; (b) transformation of their design to the context; (c) method of teaching with the GVDs; and (d) evaluation.

**DISCUSSION AND CONCLUSIONS**

The results of the reflection on the obstacles faced by the STITs and MPs in teaching in the classroom using investigation and modeling with the GVD are presented based on the model of pedagogical reasoning and action of Shulman (1987) and Schön (1992) through semantic networks, as shown in Figure 1.

A. Understanding of concepts and objectives. All the STITs questioned their scientific competences. The STITs (1, 2, 5) recognize the gaps in their conceptual understanding by establishing their design and complexity by means of hierarchizing them (STITs 2, 3, 5). For their part, the MTs point out that the concepts need to be organized before teaching them, as shown in Table 1.

B. Transformation of their design to the context. Adapting and transforming the didactic proposal to the context. The STITs 1, 4, and 5 indicated their difficulties in creating questions ready for investigation (STITs 1, 2, 4). Both MTs and STITs indicate how complex it turned out to be for their students to work with a contextualized problem with the GDV by relating...
the concepts, constructing their research-ready design, and incorporating scientific arguments in preparing their conclusion (Table 2).

C. Forms of teaching. In the classroom, the difficulty of STITs 1, 4, and 5 in instilling discipline became clear. The work mechanism that was most effective for the STITs and MTs was their exposure to the professor following the group collaborative work, due to the necessity to improve the management of the classroom climate by the STIT. All STITs agree that this change of focus favors developing scientific research skills in their high school students; only STIT 1 and MT (2, 4.5) refer to it in developing the scientific method (Table 3).

D. Evaluation of teaching. For the STITs and MTs, this dimension involved confronting their own beliefs about their didactic model "of teaching the same way I was taught" (the traditional model) against the alternative model of investigating and modeling using the GVD. In the interaction between STITs and MTs, it became clear that there were low expectations on their students' learning abilities (STITs 1, 2), and how the fear and insecurity in the case of STITs 1, 4, and 5 influenced their practical development with this innovation (Table 4).

**DISCUSSION AND CONCLUSIONS**

The obstacles for which the greatest consensus between the STITs and MPs has been reached were, firstly, those related to understanding the concepts and objectives of the GVD. And secondly, they also coincide in their identifying of the complexity their students face in relating the concepts, constructing their researchable design and incorporating scientific arguments in its conclusion.

The STITs and MPs show discrepancies in relation to the obstacles to the acquisition of scientific skills and the scientific method. In the STIT-MP interaction, different levels of reflection were shown on the basis of the identification of obstacles. While STIT1 only acknowledges the obstacles and repeatedly notes the security given by the traditional model, “With the traditional class, you are clear on the concepts your professor gives you to guide you, and how they will be given to you at any time during the class, it’s easier to schedule it.” (Focus grup STIT [7:72] [51]).

STITs 2, 3, 4 and 5 point out that the obstacles served as an opportunity for them to learn to change their way of teaching:

"The reality of the classroom helped me grow, in the sense of being able to stand in front of a classroom to teach a different kind of class, using GVD. Now I believe that the changes in my
offering to the class depends on myself, and not on limiting myself to the traditional class with
the textbook.” (STIT 4- M T [36: 40] [70]).

In the reflexive triadic space, the PFIs had the opportunity to question their lack of creativity
in conceptualizing a problem or phenomenon in keeping with the subject matter of the class,
together with their MTs, which was reflected by STIT 3: What are the activities that would
allow my students to learn better? Or STIT 4 in: How am I going to design my class? It also
involved a critical and flexible attitude for them in assuming their own limitations and
incorporating improvements into their work (Zeichner, 1993). For their part, the MTs valued
the leadership of the STITs as indispensable in achieving learning, indicating that “it's
impossible to learn in a chaotic situation”, and in the classroom, it is the teacher who is
responsible for providing a climate conducive to learning.

The result of the shared reflection between the STIT, MP, and UP generated professional
knowledge that involved a collaborative exercise to improve the practical teaching session of
the STIT based on the identification of obstacles. We believe that the initial training from this
approach differs from the traditional focus, in which theory enlightens practice, but is enriched
when theory is constructed on the "reflection on practice" by linking the initial training of the
STITs with practical training at schools and from research.

RESEARCH ON TEACHING AND LEARNING IN BIOLOGY, CHEMISTRY AND PHYSICS IN ESERA 2013 CONFERENCE

Jarkko Lampiselkä1, Arja Kaasinen1, Päivi Kinnunen2 and Lauri Malmi2
1University of Helsinki, Helsinki, Finland
2Aalto University, Helsinki, Finland

This paper provides an overview of the topics in educational research that were published in the ESERA 2013 conference proceedings. The aim of the research was to identify what aspects of the teacher-student-content interaction were investigated frequently and what have been studied rarely. We used the categorization system developed by Kinnunen, Lampiselkä, Malmi and Meisalo (2016) and altogether 184 articles were analyzed. The analysis focused on secondary and tertiary level biology, chemistry, physics, and science education. The results showed that most of the studies focus on either the teacher’s pedagogical actions or on the student-content relationship. All other aspects were studied considerably less. For example, the teachers’ thoughts about the students’ perceptions and attitudes towards the goals and the content, and the teachers’ conceptions of the students’ actions towards achieving the goals were studied only rarely. Discussion about the scope and the coverage of the research in science education in Europe is needed.

Keywords: science education, didactic triangle, meta-study

BACKGROUND

Holistic understanding in the field of the educational research is important for anyone who is mentoring and tutoring pre- and post-graduation students. Such knowledge calls for carrying out many years of systematic research on the different fields of education. This is not an easy task, and typically the researchers specialize in a narrow area of expertise in order to gain deep insight in some special area. However, the research community as a whole could achieve versatile and holistic understanding on the field, even though individual researchers may concentrate on narrower areas. While this may seem self-evident, we wish to raise the question, whether we, as a research community, have indeed studied the instructional process from a wide enough range of viewpoints.

Several researchers have done a considerable amount of work in order to build a big picture of the research in science and technology education. For example, Tsai and Wen (2005), Lee et al. (2009), and Tsai et al. (2011) analyzed almost 2000 papers published 1998–2007 in the most popular journals of the science education research. They searched for trends in research topics from preschool to the university graduate level. They analyzed the origin of the authors, and the nature of the contribution, that is, whether the papers included empirical work, theoretical work, a review or presented a position. They found out that the number of papers in both learning-conceptions and learning-contexts categories had increased during the years. Lin et al. (2012) found that more than 70% of the papers had a focus on learning contexts, and the number of such papers had significantly increased during the somewhat same years. Chang et al. (2009), in turn, found out that conceptual change and concept mapping are one of the most researched areas in the field. Other much-researched topics were professional development, and the nature of science and socio-scientific issues. Some other aspects include, for instance,
research type and design, authors' country, and research foci (Lin, Lin & Tsai, 2014; Wu et al., 2013; Tan, Chai, Tsai & Lim, 2012). Another recent approach to identify emerging research themes and core publications, as well as to get an overall picture of the research field, is citations analysis (see, e.g. Tang & Tsai, 2016; Tand et al. 2016; Tang et al., 2014). However, all the studies mentioned above have used a data driven approach, that is, the classifying categories have emerged from existing data. Such a method shows what research is being published, but can reveal only those aspects found in the data. Kinnunen’s (2016) and others’ approach allows us to reveal such aspects of research, which the theoretical framework suggests, but which have not been researched and thus provides guidance for future research.

The categorization system has its origin in the didactic triangle as presented by Kansanen and Meri (1999) (Figure 1). Kinnunen (2009) extended it considerably when presenting her new categorization system, which has been later on applied with some adjustments in several studies by Kinnunen et al. (2010; 2013a; 2013b; 2014; 2016). The triangle presents the relations of three main aspects in the instructional process, the teacher, the student, and the content to be learned. The vertical arrow describes the teacher impact on the student - content relationship, typically regarded as the teaching. However, in this context it covers both the teacher’s pedagogical actions, his/her views of students’ learning and their actions to achieve the learning goals, as well as teacher’s reflection to his/her didactical actions. The diagonal arrow, in turn, describes the student's experience of the pedagogical activities and feedback on them. These aspects and their various relations form the basis for identifying categories for research foci.

![Figure 1. Didactical triangle.](image)

The foundational view of the didactic triangle as teacher-student-content relationship can be extended to a broader view to take into account the different educational and societal dimensions (Table 1). Similar relationships exist across teaching organizations, students studying in degree programs and the contents of several courses or a whole curriculum. The pedagogical actions of the organization influence the students’ learning processes during their degree studies, and students are frequently asked feedback on these courses. Furthermore, similar relations exist in the society in an even wider scale, between the educational organizations of the whole society, citizens and the general goals of education. Finally, teaching and learning phenomena can also be discussed in an international context (international level), as some pedagogical actions, such as PISA evaluation studies, are operated as international activities. We can present multiple scope of the didactic triangle, as follows in the Table 1.
Table 1. Extension of the didactic triangle from the course scope to the teaching organisation, society, and international scopes.

In this study, we analyze science education research papers published in ESERA 2013 conference. We see the ESERA-conference as one of the most important conferences in the field of research of science education and therefore the conference proceedings represent one of the most important data pools in this area.

Our main research question is: On which aspects of the teaching and learning process have biology, chemistry, and physics education researchers focused in ESERA 2013 conference?

**METHOD**

Our typology identifies research in eight main categories, and several subcategories within them (Table 2). Here we do not go in depth concerning the development of the categories since it has been documented in detail in our previous work (Kinnunen et al., 2016). Three categories derive from the nodes of the triangle and five other categories derive from the interaction pathways (Figure 2). Two interaction pathways were divided into subcategories to better separate different forms how the relations may manifest themselves; the student - content relationship (Category 5) and teacher’s impact on it (Category 7). All of the categories are applicable in different levels.

![Figure 2. Coding of the areas of interest (1 - 3) and the interaction pathways (4 - 8) in the didactical triangle.](image)

Most papers included content which could be categorized in several categories, for example, a description of a novel teaching intervention (7.3), pretest results (5.1) and posttest results (5.3), as well as students’ feedback on the intervention (8). We decided to report only the three most significant categories in which the paper could be included. Thus we, for example, did not
include category 8, if the student feedback was included in one paragraph or a few sentences only.

Additional dimensions include the scope of data collection in the paper, if any (course / organization / national / international) and educational level (from pre-school to university), as well as data analysis methods. The guidelines that we have applied concerning the scope dimension include the following: 1) course scope denotes data collection in a single course, which may have parallel versions, 2) organization scope denotes the same/similar course in several institutes, or several courses/whole program in one institute, 3) national scope is used in cases where the data covers significant share of national level education, like several courses in several institutes, and 4) international scope is used in cases when data is collected from at least two countries and the results include some comparison between countries. We acknowledge that the borderlines between these categories cannot be strictly defined, and in several cases the decision was made by consensus after joint discussion.

Finally, we listed also for each paper, the country of origin of the authors, as well as, whether the papers used quantitative and/or qualitative data analysis methods or was merely descriptive in nature. This information was collected to allow us identify any finer nuances among the main categories.

We chose to analyze the papers published in the ESERA 2013 conference proceeding which was the newest publication on the time the analysis started. The data pool comprise 327 papers of which 184 papers were approved for analysis and 143 papers were excluded. The research group focused on the biology, chemistry and physics education and on the upper secondary and the tertiary level education. These disciplines and the educational levels had best match with the expertise and the educational background of the research team. All other papers were excluded from the data pool.

The analysis started by each author of this paper individually reading the articles and identifying all research foci, scope and levels based on the categorization system. To improve the quality of the analysis, the group selected one tenth of the reviewed article randomly and re-reviewed the categorizations. It was agreed beforehand that majority of the reviewers (three fourths) must categorize the paper similarly and only small variance was allowed to exist. Some variance might exist in manuscripts that comprised more than one foci. The re-review showed that individually done categorization produced too much variance and the entire data pool had to be re-analyzed. The analysis method had to be improved and re-analysis was done in pairs. Two researchers read the manuscript independently and then they had a pair discussion about the categorization. Final categorization was based on the pair discussion. Most problematic cases were introduced to the whole research group. The research group discussed the paper profoundly and the final categorization was based on the co-decision. Consensus was also used in a few cases where the paper had a very descriptive nature and we could not conclude clearly what categories would be relevant (in these cases there were not any research questions mentioned, nor clear reported data to help us in decision making). In these cases the paper was deemed out of scope.
Table 2: List of categories and their definitions. The number of the categories correspond to the numbers of the nodes/arrows in the Figure 2. Note that each category operates at four levels: course, teaching organisation, society, and international levels

RESULTS AND DISCUSSION

The data pool comprise 174 papers published in the ESERA 2013 conference proceeding. All papers were classified based on the Kinnunen’s and others (2016) categorizing system. Distribution of papers in different categories are shown in the Table 3. Most popular aspects were the student-content/goals relationship (Category 5, 51 %) and teacher’s impact on that relationship (Category 7, 27 %). Some interest was paid on the content/goals of the education (Category 1), the teacher-content/goals relationship (Category 6), and the students’ feedback on the teacher’s teaching (Category 8). All the other aspects were much less studied. In this
study we will concentrate on the most frequently studied aspects whereas findings concerning
the other aspects, such as, how the distribution of the papers differ between ESERA 2013
proceedings and NorDiNa journal forum, or Europe and the other countries, or in different
disciplines, or many other aspects will be reported elsewhere.

Table 3: Distribution of foci in different categories in ESERA 2013 conference. Note that most papers included more than one foci.

Category 5

When we took a closer look to the figures in Category 5, we found out that majority of the
studies were concentrating on either students’ knowledge and attitudes (5.1/28%) or students’
 improvement in these areas (5.3/24%), but notably less studies concentrated on the students’
study methods (5.2/11%) (Table 4). Most popular combination of foci were investigating both
the students’ knowledge or attitudes and their improvement in these aspects (5.1 & 5.3/30%).
All other viewpoints were notably scarce.

Few tentative explanations could be given to the findings. From the school education point of
view, the Category 5 lists all the studies that deal with the students’ studying in its manifold
manners. Learning the contents and the change of the attitudes belong to the foundational goals
of the education in all levels. Therefore, the generality of the Category 5 is somewhat self-
evident. From the research point of view the situation is the same. Analysing the learning
preconditions and investigating the students’ studying habits and finding out what they have
learned comprise the foundational ground for the teachers’ teaching plans, the curriculum
development and more general educational changes.
However, the distribution of the studies in different subcategories in the Category 5 was uneven and we wish to make few notions and remarks based on the finding. In an ideal situation the studies would distribute evenly in different subcategories. We could say that we have studied well the entire learning process and we have a good comprehension about it: the prerequisites of the learning, the students’ studying habits and the learning outcomes. Unfortunately, our findings show that this is not the case. The distribution of the studies in different subcategories is uneven and clearly we pay much more interest on the preconditions and the outcomes than on the studying methods.

One tentative explanation for this could be the easiness. The studies about the preconditions and the outcomes of the studying process are somewhat easier to carry out than investigations of the studying methods. The preconditions and the outcomes may be investigated by questionnaires, tests, web-forms and quizzes whereas the investigations concerning the studying methods typically require some form of observations and/or interviews. They might require that the researcher spends considerable time in the classroom collecting the field data or analyses other observational data, such as audio or video recordings. The classroom observations take much time both to collect and to analyse the data than the simpler “paper-and-pencil” tests, which might show it as an unattractive, time-consuming and demanding approach.

Another tentative explanation could be the nature of the data. Unfortunately, the teachers, the school heads, the parents, and the policy makers are often more interested in the quantitative aspects than the qualitative aspects. They follow intensively what grades are needed to enrol to the school, how the students’ course grades change during the school year and how many of them continue their studies to the next educational level. Much less interest is paid on the students’ well-being and their actions in lessons and in everyday life. These so called soft values are taken into consideration merely on populist speeches and writings, but weigh much less in the school budget debates. It is fair to say that the educational policy and the educational research are in dualistic relationship; they both depend on the other, also benefits from each other. The policy makers need quantitative data to support the decision making process and the researchers produce it. The researchers need resources for their research that is perhaps more easy to get if the outcomes of the research are usable from the financier point of view. Consequently, research on preconditions of the learning (5.1) and the learning outcomes (5.3) are measure more frequently than the student’s studying (5.2)

We should also take into consideration the areas of interest of the academic audience and not to blame only the needs and interests of the policy makers. It is plausible that many of the studies focusing on the classroom actions are descriptive in their nature and for that reason they seem uninteresting from the academic audience point of view. A study reporting merely the students’ study habits without evidence on their learning progress might be too tedious or even considered insignificant.

However, there is also the third option for the small number of studies in the Category 5.2 that somehow we justify the students’ study methods by the claim that good learning results speak for themselves. If the students’ performance tests show that they are progressing in learning well and there are no bad news heard from the school, is there really a need for investigating
the teaching and learning habits at all? They must be good, shouldn’t they? We wish to note that this kind of thinking pattern is a threat to all education and we should never justify our actions just by easily observable and collectable data. On the contrary, we should know much more about the students’ study methods and increase the number of research focusing on this issue. The better we comprehend how the good learning results are gained the better we can avoid the pitfalls on this path.

Finally, we should take into consideration the possibility that most of the studies of the Category 5.2 are published somewhere else, for example, in the forum of the ethnographic or the social science studies.

**Category 7**

Altogether 27% of all research papers focused on the teacher's impact on the student-content/goals relationship (Category 7). This made it the second most frequently studied aspect in the didactical triangle. The majority of the studies were concentrating on the teacher’s pedagogical actions (7.3/92%) and all other viewpoints were notably scarce. Only very few studies were focused on how teachers see the student’s understanding or attitude to the goals or contents (7.1/1%) and none of the studies focused on teacher’s view on the student’s actions achieving the goals (7.2/0%). Also the studies focusing on teacher’s reflections on his or her own teaching were rare (7.4/3%) as well as studies focusing on more than one point of view (7.3 & 7.4/3%). See the Table 5.

</table>

We begin the analysis of the Category 7 from the school education point of view. This category comprises all the studies that deal with the teacher’s teaching in its manifold manners. The research on the teacher’s didactical actions and the continuous refining of our conception of the teaching - studying dynamics comprise one of the cornerstones of all educational actions. Research on the teacher’s teaching constitutes the foundational basis of the educational development and therefore the generality of the Category 7 was not particularly surprising. However, the distribution of the papers in the different subcategories was even more uneven than in the Category 5 and the striking majority of the studies were placed on one subcategory that deals with the teacher’s didactical actions (7.3). True, the teacher’s didactical actions are in the heart of instructional processes and partly explains its’ frequency among the study foci.
Another tentative explanation to the uneven distribution of the papers is the category 7 could be the nature of the publication forum. The primary aim of the ESERA conference is to serve as a publishing channel for the latest scientific findings in the area, but by the same token it serves as a springboard for young researchers, as well as a discussion forum for the experienced researchers. It is not particularly uncommon to submit to the conference proceedings a well prepared working paper, a descriptive paper without study design, or manuscripts about the first hand research findings of the ongoing research. In other words, the threshold level for the acceptance of a manuscript in the conference proceedings is somewhat lower than in the academic journal and therefore descriptive papers may be a bit more common. For example, we compared the categories 5 and 7 and found out that actually the descriptive papers were more common in the Category 7 than 5. Nearly one third of the papers in the Category 7 were classified as descriptive (27/88 or 31%) whereas only little above one fifth of the papers in the Category 5 (27/123 or 22 %). Another notable aspect was that in the Category 7 all these papers were placed in the one subcategory 7.3 where as in the Category 5 the papers were distributed to all three subcategories or to the combination of these subcategories. A plausible explanation for this is that the description of the pedagogical activity (often augmented with pedagogical design arguments) was used only to explain the intervention and the main focus of data collection and analysis lied in Category 5. Actually, in only a few papers the teacher’s actions were the target of data collection, for example, in the form of observations or interviews.

From the research point of view, there is the possibility that our instrument lacks at least some resolving power in this particular area. We acknowledge that, perhaps, the analysis instrument has not yet reached of its complete form and still needs refinement and improvement. For example, we did not separate pedagogical actions from assessment practices, which could have been categorized as its own subcategory of the Category 7. Therefore, we understand that the accuracy of the instrument could be better and it may produce obscure results in some occasions. Even though resolution of the instrument could be improved, it does not explain why similar finding was found in the NorDiNa journal data pool, too (see Kinnunen et al, 2016). Therefore, at this point of the research we have some challenges to define if the instrument lacks resolving power in this particular area or is it an accurate observation and a true finding that we tend to focus our research very much in this small yet important area of interest.

On the other hand, the small number of the studies in any other subcategory was duly noted. Only a few papers focused on how the teachers perceive the students’ knowledge or attitudes (7.1/1%), or on the students’ actions in different kind of learning situations (7.2/0%), or on the reflection of their own teaching (7.4/3%). It seems that we pay much more interest on the teacher’s teaching actions than on the teachers themselves. Many academics and scholars underline the importance of the reflective thinking in order to improve his or her own teaching, but our finding shows the opposite. The teacher’s thinking, their views on the students’ thinking or their own reflections are studied very infrequently. As argued before, we acknowledge the possibility of limited resolving power of our instrument in this particular area of interest. However, we have investigated the other areas of interest, too, such as the teacher - the content relationship (Category 6) and the teachers themselves (Category 3), which corroborate the finding in the Category 7. In both latter mentioned cases, the frequency of the studies are not
even close to the popularity of the Categories 5 and 7. More elaborated analysis of this area will be presented in the follow up studies.

To sum up, we wish to justify the question that have we as a research community been too much occupied with ensuring that what is taught is right and true and should not we be more concerned about the finding that we know too little about how the teachers perceive the students as learners, or the teachers themselves? It is well documented that the teacher’s awareness and beliefs concerning the purpose of the school work, the rules governing learning, and the possibilities the learning environment offers, are crucial for educational changes. We hope that these studies are reported elsewhere, in some other academic forums that concentrate more specifically on research in these aspects. The other publishing forums could be those that have a more broad pedagogical scope, such as, ECER conference (European Conference on Educational Research) or EARLI conference (European Association for Research and Instruction).

**CONCLUSIONS**

The educational research in science education across Europe and beyond seems to focus on either student’s knowledge and skills or teacher’s teaching, but many other points of view of the teaching, learning, and the studying process are poorly investigated. Especially alarming is the lack of studies focusing on students’ study methods, student’s feedback to teachers’ teaching actions and teacher’s reflections of their own teaching actions. We truly hope that these other viewpoints are not really missing but are published in other publication forums and therefore do not appear in our data pool. Nevertheless, more research in this field is necessary.

Implications of this study range from classroom instruction to educational research and beyond. Research has direct and indirect influence to society, especially to national curriculum development actions, educational practices and more broadly to the education as a whole. If the educational research focuses on few aspects only, it is plausible that the researchers, the research group leaders, the policy makers, and many other relevant stakeholders do not get all the relevant information that are needed for educational change and at least in some extent may jeopardise the educational renovations. For example, our data pool shows that categories 5 and 7 are much more studied than any other aspect in the didactic triangle. Similar findings were noted in Kinnunen’s and others study on 2016 that investigated the science education research published in NorDiNa journal and therefore the findings of our current study does not seem just a single finding, an anomaly, but some sort of trend that is important do investigate more.

From the ESERA conference point of view it was interesting to find out what kind of research has been done, how it is done, what kind of findings has been reported and compare the trends with the countries outside the Europe. The ESERA conference proceedings covers educational research from the pre-primary level to the university level, many disciplines and many nations. The conference is namely European, but participants represent many nations and continents outside Europe. In our data pool, about three fourths (73%) of the papers were classified as European and the remaining one fourth comprise all other nationalities (27%). The data pool is rather small and therefore generalizations are highly tentative. However, the distribution of
studies in different categories in the didactical triangle is very much similar between Europe and other nations. We will present more detailed findings on this issue in the follow-up studies.

From the methodological point of view, the data-analysis method designed by Kinnunen and others (2016) and applied in this study produce more reliable results if the content analysis of the papers is based on a group work rather than each researcher reading the papers individually. As a thumb rule, the more researchers read the same paper, the more reliable the results of the analysis will be. We found out that individually done categorization produces too much variance, but work-in-pairs clearly improves the quality of the analysis. Work-in-groups would produce even more reliable results, but based on our experience in the previous study (Kinnunen et al., 2016), the more people read the paper, the slower the analysis becomes. Therefore we recommend the work-in-pairs or the work in small groups (3 - 4 persons) for those who plan to apply our methodology in their own study.

COMPETENCE-BASED TEACHER EDUCATION: DEVELOPING A MODEL FOR INTERDISCIPLINARY TEACHING-LEARNING CONCEPTS

Eva Kriehuber, Christina Beck, Florian Boch, Anna-Teresa Engl, Andreas Helzel, Tina Pickert, Christian Reiter, Bettina Blasini and Claudia Nerdel
Technical University of Munich, Munich, Germany

This study analyses competence-based teacher education, which addresses the current developments in the German education system. The changing conditions call for teaching concepts that integrate content knowledge (CK), pedagogical content knowledge (PCK), pedagogical knowledge (PK) and teaching experience in the natural sciences. Based on the examination of established models and theories, our research group created a Munich Model which identifies and structures potential influence factors and their interrelations underlying the German education system. The model focuses on innovative teaching-learning concepts which suggest a cross-disciplinary integration that can be applied to biology, chemistry, physics and mathematics. Strengthening the interdisciplinary perspective, the model provides teaching methods of experimenting, modelling and verbalizing that are significant for all natural sciences. According to the design-based research approach, first applications of the model in biology, chemistry and physics pursue further theoretical development and empirical evidence. This competence- and evidence-based understanding offers valuable insight not only to teacher education but also to higher education in natural science.

Keywords: conceptual models, higher education, initial teacher education (pre service)

CURRENT DEVELOPMENTS IN THE GERMAN HIGHER EDUCATION SYSTEM

Strengthening the quality of teacher education in the field of natural sciences continues to be an important aim for German universities. Specifically fostering the students’ professional capabilities is critical to enhance their success as future teachers (Bauer & Prenzel, 2012; Grossman, 2011). The responsibility for the education system in Germany is determined by the federal structure of government, meaning educational conditions and teacher education differ between the 16 federal states. Basically, teacher training is divided into two stages, a course of higher education at university and practical pedagogical training at school and teacher training institutes (preparatory service). In the first period at university the training is composed of (i) a scientific component; (ii) an educational science component; (iii) teaching practice. This article focuses on this first period for teaching careers at (1) Gymnasium (upper secondary academic track) and (2) in vocational subjects at upper secondary level or at vocational schools. Both types can be studied at the Technical University of Munich in Bavaria. In the former case the scientific component involves at least two equal subjects (e.g. Chemistry and Mathematics) and the subject-related didactics. In the latter case, students have to choose a vocational subject area (including at least one year working experience) and a second teaching subject. The current changes in the German education system regarding the implementation of national education standards and the resulting new curriculum call for a further development of the universities’ teacher education that stresses competences to integrate, adapt and apply...
knowledge. While European countries, such as Finland established a competence-oriented teacher education Germany still shows a discipline-focused university curriculum (European Comission, 2011; Jorde & Dillon, 2012).

To support an innovative development of teacher education, the Federal Ministry for Education and Research launched the “Quality Offensive” (Qualitätsoffensive) as a competitive policy initiative and funded 59 German universities, which highlights the relevance attributed to this aim. As a part of this initiative, our research group at Technical University of Munich therefor aims to create teaching concepts that integrate content knowledge (CK), pedagogical content knowledge (PCK), pedagogical knowledge (PK) and teaching experience in the natural sciences.

THEORETICAL BACKGROUND

To identify potential influence factors on the development of a multi-disciplinary knowledge, one must be aware of the basic structures underlying the education’s processes (Shulman, 1987; Abell, 2007). Theoretical models discuss the process of teacher education, its influence on the development of teachers’ competences and the resulting effects on the successful learning of pupils (Terhart, 2012). Furthermore, learning opportunities models analyse the relations of factors provided by teachers and factors used by students (Helmke, 2015) and the COACTIVE study, which structures determinants and consequences of professional competencies of teachers (Kunter et al., 2011). The models were evaluated in terms of common elements and their interrelations in order to identify a conceptual pattern (Parchmann, 2010). By establishing a strong theoretical basis, the models offer valuable insight which was subsequently adapted to this study’s specific research interest.

THE MUNICH MODEL

Based on this theoretical analysis, our research group created a Munich Model (Figure 1) in order to evaluate relevant elements and processes of natural science teacher education at the Technical University of Munich. The model consists of five elements, namely university lecturer, teaching and learning concepts, teaching activity, learning activity and students, which are embedded in a context. While the elements university lecturers, students and learning activity closely refer to influence factors discussed in the established models, both elements teaching and learning concepts and teaching activity specifically apply to the natural science teacher education. The very centre shows the teaching and learning concept, which is specified by a cross-disciplinary integration of PCK, CK, PK and teaching experience based on thematic adjustment deriving from the disciplines, structural adjustment of the temporal order and interpersonal collaboration of relevant actors. The closely connected element teaching activity highlights the common methods of the natural sciences biology, chemistry, physics and mathematics, defined as experimenting, modelling and verbalizing. Both teaching and learning concept and teaching activity reveal the education’s further development that needs to be applied at university level to be transferred to school level eventually. To support the process between teaching and learning the model takes reciprocal interaction between the teaching and learning activity as well as feedback between university lecturers and students into account,
highlighting the importance of implicit and explicit communication underlying successful educational concepts.

FIRST APPLICATIONS OF THE MUNICH MODEL

Our research group developed exemplary concepts for the students of teacher education in the field of natural sciences at the Technical University of Munich. In biology CK, PCK and PK is linked with the help of the model organism honeybee. In chemistry successively acquired knowledge is integrated in final seminars such as “Advanced Aspects of Chemistry”. In physics the awareness of professional competences in increased with respect to school experimentations by providing additional teaching materials, such as simulations and videos.

The Munich Model will continue to serve as a basis for evaluation in terms of the design-based research approach (Collins, Joseph & Bielaczyc, 2004). The practical application of the model thus examines the theoretically identified elements and strengthens its empirical evidence. This competence- and evidence-based understanding offers valuable insight not only to teacher education also to higher education in natural science research. Connecting the different disciplines is regarded as necessary to bridge the gap from theoretical, easy structured exercise to complex professional problems with a practical application of knowledge.

Chemistry: Focus on Structural Adjustment

In the field of chemistry, the focus lies on the structural adjustment of the subject combinations biology and chemistry (B/C) and mathematics and chemistry (M/C) which are available in teacher education for Gymnasium. In order to standardize the subject combinations’
requirements and contents as well as their competence-orientation, innovative teaching and learning concepts were developed and implemented during different stages of the study program. In the following, three examples of these concepts are presented:

**Basic Laboratory Course in Inorganic Chemistry:** Prior to the structural adjustment, the subject combinations (B/C and M/C) differentiated in terms of their content and scope. Yet the students were expected to accomplish the same competences at the end of their study program. The structural adjustment therefore aims to standardize the conditions, to strengthen the aspects of PCK as well as to deepen the teaching practice. These didactical aspects involve the competence to experiment, the appropriate technical capacities, the accurate handling of chemicals and laboratory facilities as well as the safety arrangements and disposal process. Furthermore, the experiments are discussed regarding their theoretic content and practical applications (such as a qualitative substances’ analysis). Also, the accurate experiment protocol is an important aspect. An additional seminar focuses on the teaching practice and how the experiments could be realized. In advance to the course, a teaching video on the online platform Moodle offers instructions on how to set up the laboratory facilities and visualizes basic working techniques.

**Supplement Course to Chemistry of Non-metals:** A further seminar specifically addressing students in teacher education complements the corresponding lecture and provides insight to scientific content. The lecture is designed for both students in teacher education as well as chemistry students and therefore demanding in terms of scientific knowledge. The supplement seminar thus strengthens the scientific basics such as chemical equation and complex Lewis- and structural formula and their comparisons. Taking into account that chemistry students participate on such seminars in their regular study program, it is critical to develop such seminars for students in teacher education as well. Furthermore, the specific focus on students in teacher education allows the discussion about school context, applications and limits of different models as well as challenging theories.

**Advanced aspects of inorganic Chemistry:** The course is an optional module for the Master program for both subject combinations (B/C and M/C). In this course cross-disciplinary concepts deriving from the basic chemistry, the inorganic chemistry as well as the physical chemistry are being discussed in the context of the First State Examination (*Erstes Staatsexamen*). This session aims to address concepts of chemical processes, their range of applications as well as their evaluation and precise oral (and written) presentations. In their presentations, students have to link their scientific knowledge with given examples, choose appropriate media and accurate scientific language. This approach to complex scientific research questions also highlights the didactical reduction and reconstruction. The developed courses and seminars are implemented to the university’s study regulations as optional sessions and recorded to the students’ academic qualification.

---

1 After the first period of teacher education for Gymnasium students in Bavaria still have to pass a central organized First State Examination.
Physics: Focus on Content Adaption through School Physical Understanding

Many lecturers report that students hardly rely on their content knowledge from their physics courses (especially theoretical physics) for the preparation and planning of lessons (school internships or as part of seminars). At best, students reproduce what they still know from school. One possible reason for this might be the enormous gap between physics at university level and on a school level. Overcoming the first transition is rather the responsibility of the usual physics courses than of didactics courses. Subsequently the main task of didactics is to connect the theoretical physics of the university with school physics to assist the second transition. However, with only few compulsory courses in didactics and the huge spectrum of subject contents, physic didactics can hardly achieve this aim. Furthermore, many themes lack teaching material, which links physics on a university and school level. The aim of the work in the field of physics is to provide a low-threshold offer of courses and course supplements, which complement the theoretical physics course, enrich the follow-up regarding school physics and serve for the later lesson planning. In order to achieve this goal, the courses “School Physical Extension Course of Electrodynamics” and “School Physical Extension Course of Quantum Mechanics” provide suitable content on an e-learning platform using digital teaching and learning formats. Students benefit from further support in these topics, as they appear in the Gymnasium, and because university-students have serious difficulties in the according courses in theoretical physics. Starting in the 5th or 6th semester in the bachelor program, students can take part in the courses parallel to the corresponding courses in theoretical physics.

School Physical Extension Course of Electrodynamics: The structure of this course is in close relation to a course of theoretical physics of electrodynamics. The focus lies on the connection to the Gymnasium, with some remarks to the lower secondary level. Each unit centers a simple school experiment and its theoretical description. Units contain two main sections. Firstly, the concepts and representations of theoretical physics are examined from a didactic point of view. Secondly, the major part of a unit is the interconnection of theoretical physics and the contents of the physic didactics as well as textbooks. The way of an elementarization and didactic reconstruction, and its success, is examined in detail. Additionally, the main content of the university content knowledge is practiced. Part of the electrodynamics of the upper secondary level for example are aspects of special relativity. This field represents a very difficult subject, even for many physicists. However, a (prospective) teacher needs a deep and profound understanding of this material in order to be able to elementarize, teach and adequately reply to student issues in the classroom. A theoretical physics course at the university usually only touches this subject lightly.

School Physical Extension Course of Quantum Mechanics: This course is only loosely based on a corresponding course in theoretical physics. Merely the foundations of quantum mechanics, sometimes also called postulates of quantum mechanics, and the presentation of the theory with the Dirac-notation, are discussed similarly. Courses in theoretical physics continue and focus mainly on working with basic examples such as particle in a box, harmonic potential or the Coulomb potential. Illustrative questions, e.g. the measurement problem or Bell’s inequalities, are rarely further discussed. The e-learning course picks up such topics and discusses them extensively as they are often presented in school books and thus prompt
questions by pupils. At school these scientific topics are reflected by four (in Germany well known) teaching concepts for quantum mechanics: 1st: Berlin Concept (Fischler & Lichtfeldt, 1992), 2nd: Bremen Concept (Niedderer, 1992), 3rd: Munich Concept (Müller & Wiesner, 2000), 4th: The Karlsruhe Physics Course (Herrmann, 2000). Beside scientific correctness of the respective elementarization, also the models and modeling in physics and physics didactics and their visualization is focused. In physics didactics, the Bohr atomic model is critically discussed. In all teaching concepts, however, there are different alternative models for the calculation of atomic energy levels. As part of the e-learning course, the in accuracy varying models are analyzed to the extent that a new model was created which reproduces the well-known formula of the hydrogen atom.

Once these e-learning courses have been developed, they can be continued with little effort. Furthermore, they have a modular structure, thus individual elements can be used in other courses of physic didactics and could therefore contribute to a comprehensive digitalization concept. By critically examining the existing materials for linking university and school physics, existing shortcomings of both school and university textbooks can be addressed, improved and extended. The results go beyond the mere teaching of existing content, but constitutes original material for future publication in journals.

Mathematics: Focus on Thematic Adjustment in the Vocational Education Studies

Developing innovative teaching-learning concepts for students in mathematics vocational education, the main aspect to take into account, is their heterogeneity. There are various reasons for the students’ heterogeneity including the different professional qualifications, the selected specialization of their studies or the lack of specified times for the curriculum. However, students in different stages of their study program, with different prior knowledge attend the same lectures.

Analysis 1 for Vocational Education: To get an understanding of the students’ different qualifications a basic test regarding school mathematics was developed. Based on the findings a preparatory course specifically for students of mathematics in the vocational education will be established. The preparatory course addresses the different levels of knowledge, challenges and requirements of the students in more detail. Furthermore, the preparatory course highlights the importance of content knowledge for future teachers, straight from the beginning of the study program. This should strengthen the students’ motivation and interest for mathematics. In addition, the didactical as well as pedagogical aspects are accentuated, by training how to identify pupils’ difficulties, give feedback and ways to structure a lesson.

Linear Algebra 1 for Vocational Education: Bachelor modules for vocational education in mathematics consist of a lecture, an exercise and a supplement course. Specifically, the supplement course offers the chance to develop new teaching and learning concepts linking pedagogical content knowledge and mathematics. During the supplement course the students select a mathematical proof and present their approach to their fellow students. Prior to this course, a presentation discusses appropriate ways to address mathematical proofs, potential difficulties and aspects of PCK. To highlight the relation between the students’ future professional practice and the theoretical material of the university lecture, final school
examinations (integral/differential calculus) were chosen as topics. In their presentation, students incorporate aspects of teaching methodology. Furthermore, the module offers the use of digital media. By means of an iPad and the teaching-learning App “Explain Everything”, the students independently created a teaching video, which is discussed in the supplement course. The use of digital media offers the chance to get to know a new working method, which engages the students in an interactive way. Thus, not only the scientific knowledge is trained but also the use of digital teaching methods.

To allow the sustainable implementation, the regular staff will continue the new teaching-and-learning concepts. Assistance for the implementation is given by providing the guideline presentation for students and an additional how-to manual for iPads and the used Apps. After repeated concept testing, the method is to be continued on a permanent basis and included to the curriculum.

**Biology: Integrated Teaching-Learning Concept based on a Model Organism**

The biology curriculum shows, that different research fields such as botany, microbiology, molecular biology, ecology, physiology, behavioural biology or zoology are taught isolated from each other and therefore lack systemic understanding. The following teaching learning concept thus aims to link the fields based on the model organism of the honey bee. The concept consists of the *lecture Beekeeping (Apiculture)*, a *following didactic seminar* and subsequent teaching practice.

*Lecture Beekeeping:* The scientific lecture “Beekeeping” presents theoretical and practical scientific knowledge and is open for students from different study programs (teacher education and natural sciences). It focuses on the species’ variety, the connection of organisms with their environment as well as the threats caused by anthropogenous and natural influences. Horizontal connection to further areas, such as botany, is shown by the pollination performance of bees. The lecture is complemented by a microscopic labwork course for university level addressing the functional anatomy of bees, the identification and treatment of diseases among bees as well as the evaluation of biodiversity. The model organism of the honey bee provides a wide range of applications throughout the curriculum. This lecture is open for students from different study programs.

*Didactic Seminar:* The scientific lecture is complemented by a biology didactic seminar “Innovations in teaching Natural Sciences – The Model Organism Honey Bee”, addressing specifically students in teacher education for Gymnasium and vocational education. In this seminar, selected topics of the lecture are presented in a didactical way. The seminar focuses on methods of natural science epistemology, such as the process of thinking and working, as a core competence for future biology teachers. The seminar also involves molecular biological analysis at the out-of-school learning environment “Schülerforschungszentrum Berchtesgadener Land” to introduce current research methods such as DNA-extraction, PCR, restriction digests of DNA and the gel electrophoresis, which are usually not used at schools. The technical facilities, the methodical processes as well as the settings are discussed in terms of scientific, didactical and practical aspects. A further experiment for advanced pupils is the classic conditioning of honey bees regarding scents. The experiment focuses the different
phases of scientific insight as well as the possibilities and limits of the respective research methods (light microscopy vs. molecular biology). The students prepare the practical application in a didactical way and identify the scientific epistemology and research questions.

School practice: The subsequent teaching practice takes place at either a collaborating Gymnasium or at some authentic contexts outside the classroom such as laboratories or the Schülerforschungszentrum Berchtesgadener Land. Furthermore, the developed concepts may also be realized as a seminar addressing advanced pupils at the Technical University of Munich. The didactical aspect offers the link of theory and practice in the biology study program. During the development of their projects, the students are supported by a professional teacher as well as a didactic lecturer. Thus, they can benefit from the expertise of a teacher while planning the practical application with pupils at the Gymnasium. Also after the students submitted the experiments’ plan and application, the teacher reflects and discusses the work to suggest challenges and improvements. Furthermore, the teacher reviews the lessons taught by the students and discusses further option of teaching practice to strengthen the training for school practice.

The presented concept linking biology science (CK), didactical science (PCK) and school practice based on the model organism honey bee, has been established successfully and is appreciated by the students. The concept can be applied to different research fields and model organisms and thus serves as an example for competence-orientated teaching-learning processes.

**Professionalization Concept**

Strengthening the sustainable implementation of competence-oriented teaching, a professionalization program offers training and coaching. The program addresses lectures in the field of teacher education, who differ regarding their scientific knowledge, their cross-disciplined understanding as well as their individual pedagogical competence.

**Professionalization Trainings:** To date, eleven trainings created a setting to discuss the different aspects of competence-orientation (e.g. metacognitive strategies or teaching method for concepts such as cooperative learning or inquire-based learning). A further focus lies on digital learning (e.g. digital learning at schools or in higher education). The trainings are separated into subject-specific sessions (e.g. digital learning in the teacher education for chemistry and physics) and cross-discipline sessions addressing lecturers from different fields (e.g. giving and receiving feedback). The content of one training series is repeated in the subsequent training series, to enhance successful learning. The trainings are designed discursively to support the exchange between the participants. To meet the individual needs of the participants, the group consists of six to ten lecturers and takes three hours.

**Professionalization Coaching:** To strengthen an individual approach and offer specific support, a professionalization coaching offers direct support in seminars, lectures or tutorials in teacher education. Depending on the design of the session and also the number of participants (lectures, students), different tools can be applied to the coaching process: observing and evaluation tools of the session, video recordings of the lecturer or interviews with the students. The results are discussed responsively with the lecturer. The way and the scope of the coaching
is up to the lecturer. The coaching should at least cover two sessions but can be extended to the whole semester (6 months).

The elements of the Professionalization Trainings and the Professionalization Coaching complement each other: the training sessions, group discussions and questionnaires analyse the challenges and needs of the participants, which subsequently can be addressed on the coaching sessions. Coaching methods, that are most successful reciprocally discussed in the training sessions. This interplay creates a sustainability, which is strengthened by teaching videos that are created so far. The sustainable documentation of teaching videos will be developed further to contribute valuable insight to the trainings and coaching sessions. Sustainable learning success will be achieved by continuous repetition and ongoing support.

**DISCUSSION**

The innovative teaching-learning concepts strengthen the competence orientation by linking and connecting science (CK), didactics (PCK), pedagogy (PK) and school practice. The previous examples show that this aim can be achieved in different ways: structural adjustment, content-related alignment, digital complementary documents, and online courses to adapt cross-disciplinary competences. It is critical that lectures highlight the interrelations between disciplines so that the students become aware of their meaning.

The Munich Model shows that there are influence factors which are constituted by university specific conditions. These factors include the established standards of German teacher education, the teaching examination regulations and the university’s specific study regulations as well as different university locations. For the successful development and implementation of innovations, it is yet important to take those factors into account, as they shape the context.

Strengthening competence orientation to teacher training, explicit references highlight the interrelations between corresponding themes deriving from science and didactics. Identifying the link between the lectures, redundant repetitions can be revealed and avoided. As shown in the examples, competence orientation may not only be achieved content-wise but also in terms of teaching-learning activities: working methods, scientific language, use of media. Especially the natural sciences chemistry, physics and biology focus on the process of epistemology and its implementation by means of practical experiments. Especially the working method modelling offers different options of digital or analogue visualization, which can be compared and discussed in terms of their benefits and limits. The use of digital media promotes the communication competences and prepares the students for teaching at school. The app “Explain everything” for example offers processes of verbalisation and the training of appropriate scientific language. Participating on scientific lectures and intensive courses strengthens the in-depth knowledge and facilitates the approach to the respective field of science. In mathematics, this aspect is realized by supporting students individually and drawing on appropriate media to enhance verbalisation processes. A further important aspect regarding competence orientation is the close collaboration with partner schools of the university. This exchange offers the possibility to implement an innovative concept to school practice. A further success factor is the option to present different aspects of the scientific field on the basis of one model organism as shown in biology and the teaching learning concept of the honey bee.
Moreover, the professionalization concept establishes the dialogue and collaboration with different faculties in order to enhance didactical, pedagogical and practical processes as well as digital teaching and learning.

The continuous exchange with different actors allows a cross-disciplinary basis for communication. The aim is to create a common language, in order to build teaching-learning concepts that can be integrated across faculty borders. Including all actors involved actively, and taking their ideas and decisions into account prevents a refusing attitude towards innovative developments (Gräsel & Parchmann, 2004), and thus strengthens the sustainable implementation of innovative teaching-learning concepts.

IDENTIFICATION OF LEARNING OPPORTUNITIES FOR THE PROMOTION OF DIAGNOSTIC ABILITIES IN PRIMARY TEACHER EDUCATION DURING LONG-TERM INTERNSHIPS

Sandra Stegemann and Stefan Rumann
University of Duisburg-Essen, Essen, Germany

Diagnostic abilities are seen as a crucial aspect of professional knowledge. Study results point out that these abilities should be already promoted during teacher education at university. Furthermore, recent research shows that formal learning opportunities in the first phase of teacher education are important for the development of professional knowledge. Because of the relationship between theory and practice, internships play an important role in this phase of education. However, there is a lack of knowledge regarding future teachers’ learning opportunities in practical situations. The present study attempts to identify possible learning opportunities concerning the promotion of diagnostic abilities during long-term internships in primary teacher education for a special German subject ‘Sachunterricht’. ‘Sachunterricht’ combines several disciplines of social and natural sciences at primary school. In this study, experts from school and teacher training centres will be interviewed to gain insight into their expectations concerning the relevance and viability of potential learning opportunities. The results are analysed using qualitative content analysis. Additionally, a questionnaire is developed and given to a larger group of teacher mentors from school and teacher trainers of teacher training centres. The goal of the questionnaire is to figure out, to what extent teacher trainers agree with the interviewees.

Keywords: internship, primary teacher education, diagnostic abilities

INTRODUCTION

Long-term internships implemented in teacher education at university are, as a rule, subjectively rated positive. As an example, master’s degree teacher students from University of Duisburg-Essen considered the experiences they made throughout the ‘Praxissemester’ - a special long-term internship in the first phase of the teacher education in the federal state of North Rhine-Westphalia- as an important preparation for the second phase of teacher education in Germany. The direct exchange with students and teachers provides them a realistic insight into ‘how school is run’ and ‘what is important at school’. From the educational policy perspective, high expectations are associated with this long-term internship: The framework for the contents and structure (MSW, 2010) embraces a broad range of intended learning and development goals. Due to the high relevance of diagnostic abilities of teachers for the initiation of sustainable learning processes in class (Helmke & Schrader, 1989 quoted in Helmke, 2012; Brunner et al., 2012), competences for diagnostic abilities are formulated and can be found in this framework. These competences cover a wide range of diagnostic activities, as they are described for example by Ingenkamp & Lissmann (2008): from the diagnosis of the students’ current abilities and interests to the development of assessments of the students’ learning progress (MSW, 2010).
For the acquisition of diagnostic abilities during the internship, appropriate learning opportunities are required. It has not been clarified yet, which of the diagnostic abilities postulated by the curriculum are already considered in teacher education at school and which learning opportunities are given or can be implemented under the conditions of the subject ‘Sachunterricht’ (Hascher, 2012, König, Tachtsglou, Darge & Lünnemann, 2014).

AIM OF THE STUDY

The study’s purpose is to identify and operationalize learning opportunities in the subject ‘Sachunterricht’, which promote the diagnostic abilities given by the competences and standards stated by the framework for the contents and structure of the long-term internship.

THEORETICAL BACKGROUND

Learning Opportunities as a Basis for Students’ Learning Processes

Following the model of the COACTIV research program (Kunter, Kleickmann, Klusmann & Richter, 2011; p. 67) explicitly provided learning opportunities in teacher education at university are seen as a prerequisite for the development of future teachers’ professional competence (Figure 1).

![Figure 1. Model of the determinants and consequences of teachers’ professional competence from the COACTIV research program (Kunter et al., 2011, p. 67).](image)

Results with moderate effect sizes from the follow-up study COACTIV-R (Kleickmann & Anders, 2011) confirm that the development of professional competence is influenced by differences in the explicitly provided formal learning opportunities. Considering the diagnostic abilities as part of the professional competence of teachers (Brunner et al., 2011), it can be expected, that they can be promoted by learning opportunities in various learning settings at university. Results of recent research focusing on teacher judgment accuracy, show the compelling need to promote diagnostic abilities throughout teacher education at university and the further education level (Südkamp, Kaiser & Möller, 2012). Therefore the special long-term internship in the first phase of German teacher education seems to be an appropriate opportunity to foster these abilities in a practical context.

In internships the connection between theory and school practice is of major significance. Thus, learning processes of the students are stimulated and organized by addressing theories and concepts in various university courses (Arnold, Hascher, Messner, Niggli, Patry & Rahm, 2011). But how could learning opportunities at the learning place school be designed? In
practice, the academic reflective knowledge (Radtke & Webers, 1998) has to be used depending on action situations in the lessons of the subject ‘Sachunterricht’. Following Arnold et al. (2011) learning opportunities in teacher education at school can be seen as *action situations* arising from practical actions, which give the students the opportunity for focused experiences (Arnold et al., 2011, p.224). Thus, related to the present project learning opportunities in the long-term internship are defined as explicitly provided action situations for students, in which the teacher students can carry out diagnostic activities in the subject ‘Sachunterricht’ and in which they can discuss diagnostic issues based on theory.

The action situations are provided or enabled by the teacher mentors from school and the teacher trainers from teacher training centres.

Table 1 shows the implementation of these *action situations* in the teaching-learning settings according to the framework for the ‘Praxissemester’ (MSW, 2010):

### Table 1: Teaching-Learning Settings in the ‘Praxissemester’ at school.

<td>reflection of lesson planning and teaching</td>
</tr>
<tr>
<td>small specific student research projects</td>
<td></td>
</tr>
</tbody>
</table>

In these teaching-learning settings action situations need to be established, in which students’ diagnostic activities are initiated considering various approaches (cf. König et al., 2014):

- Classroom observations, in which the teacher students have the opportunity to observe teacher mentors and other teacher students performing diagnostic activities,
- Lesson planning and teaching, in which teacher students plan diagnostic activities based on theory and reflect their realization supported by the teacher mentors and teacher trainers,
- In small specific student research projects the teacher students have the opportunity to focus on diagnostic issues (for example: to evaluate student misconceptions),
- In introductory courses at the teacher training centres, teacher students’ practical experiences in the field of assessment can be discussed and analysed based on theory.

Considering the theory-practice problem the identification of potential learning opportunities are of high relevance for school practice and teacher educational research.

The identification of potential learning opportunities allows linking learning experiences at university with learning experiences in school practice deliberately. If this connection is missing, following Arnold et al. (2011, p. 227), teacher students would learn in ‘separated

---

1 Missing connection between teacher education at university and school practice (Weyland & Wittmann, 2015).
worlds’. This could lead to the situation, that the usefulness of theory for school practice is in question (Weyland, 2012, p. 61).

Potential learning opportunities are identified by using the expertise of teacher mentors from school and teacher trainers from the teacher training centres for the subject ‘Sachunterricht’, who have experiences supporting students during the ‘Praxissemester’.

**RESEARCH QUESTIONS**

The study is expected to provide answers to the following research questions:

- **RQ1:** From the view of teacher mentors from schools and teacher trainers from teaching training centers: Which action situations concerning the promotion of diagnostic abilities are seen as relevant and viable by the teacher mentors and teacher trainers?

- **RQ2:** Which parameters lead to these perceptions?

- **RQ3:** Which of the identified action situations are actually implemented in this teacher training situation?

**RESEARCH DESIGN AND METHODS**

Figure gives an overview of the design of the study.

**Interviews with teacher mentors from schools (TM) and teacher trainers from teacher training centres (TT)**

(TM = 3 / TT = 7)

**Qualitative content analysis** (Mayring, 2015)

**Communicative validation** (Steinke, 2013)

1. **Questionnaire:** to check, if further teacher mentors from schools (TM) and teacher trainers from teacher training centres (TT) agree with the statements of the interviewed teacher mentors and teacher trainers 

   \( N = 100-150 \)

2. **Questionnaire (during the ’Praxissemester’):** to check, which action situations are actually implemented in the long-term internship

   \( TM: N = 50; \) students: \( N = 50; \) TT: \( N=3 \)

**Figure 2. Research design and methods of the present study.**

For answering research questions one and two interviews with teacher mentors and teacher trainers are conducted. The interview guide follows the main principles of Helfferich (2009). Therefore, the interview is separated into different phases. This allows focusing on different dimensions, which are necessary for answering research questions one and two. Table 2 gives an overview of the different phases of the interview.

Hereafter, the interviews are analysed using qualitative content analysis to identify possible learning opportunities. The results of the interviews are presented to the experts for communicative validation (Steinke, 2013). Based on the results a questionnaire is developed, to check, if other teacher mentors and teacher trainers agree the assessments of the
interviewees. During the internship, teacher students, teacher mentors and teacher trainers will be asked which learning opportunities have been provided and used. Therefore, a second questionnaire will be developed and used. Thus, the third research question will be answered.

FIRST RESULTS - THE INTERVIEW AS A METHOD TO IDENTIFY POTENTIAL LEARNING OPPORTUNITIES

For the generation of learning opportunities/action situations and for answering research questions one and two, guided interviews with teacher mentors (TM) and teacher trainers (TT) have been conducted and audiographed (TT: N = 6; TM: N = 3 participants).

The first four interviews have been carried out between June, 2017 and July, 2017. In accordance with Kuckartz (2014, p. 78), after the transcription an initiated text work has been conducted: The transcripts have been analysed considering the research questions by marking relevant or noticeable text segments.

In the following, first remarkable statements from the interviews are presented.

Relevance of lesson planning and teaching for acquiring diagnostic abilities (Phase I-RQ1):

All participants appreciate the long-term internship as a valuable opportunity for the students to learn how to plan lessons for ‘Sachunterricht’ aligned with the learning preconditions of the students in authentic application situations. Thus, they generally support the relevance of diagnostic abilities and the viability of their promotion during the internship.
But at present, debriefing sessions are not explicitly used to promote diagnostic abilities. This can be drawn from the answers to a further interview question from Phase II. This question aims at identifying action situations, which are already used for the promotion of diagnostic abilities in the context of reflection of lesson planning and teaching in debriefing sessions (actual state analysis).

Referring to this, the interviewees said, that the debriefings are not yet explicitly used for diagnostic issues.

*Reasons for the missing implementation of action situations promoting diagnostic abilities in debriefing sessions (Phase II- RQ 1 &2):*

All teacher trainers stated the cause of this missing implementation in the personal advisory needs of the teacher training students. It seems, as if subject didactic issues are hardly relevant for the students. Even though the students have already the possibility to reflect their teacher personality during further internships of the Bachelor’s programme, it seems as if it is still one of the most important aspect in the ‘Praxissemester’.

One teacher trainer assumes a progression of relevant issues during the debriefings in the different phases of teacher education as described in Figure:

```
Step 3  diagnosis of content and methodological skills
         (e.g. laboratory skills; relevant issue in the second phase of teacher education –
         a practical phase at school)
Step 2  diagnosis of social skills and basic structures for managing lessons
Step 1  teacher personality (acting confidently in the classroom)
```

*Figure 3. Progression of relevant issues during the debriefings, as it is assumed by one of the interviewed teacher trainers.*

Moreover, the teacher trainers consider the lesson content as a necessary aspect of the debriefing sessions. Three teacher trainers report difficulties of the students to analyse the lesson content adequately. Especially referring to supposedly ‘easier’ contents, the students seem to reflect their own knowledge in the run-up to the planned lesson not sufficiently (interviews 1, 2).

From the view of the interviewees, the lack of explicitly provided action situations in the debriefing sessions can be partially explained by the low amount of debriefing sessions and missing binding agreements on main topics (e.g. focus on a subject didactic issue – interview 4).

The first analysis gives a first hint of which aspects could complicate the implementation of diagnostic action situations in practice.

**OUTLOOK - FURTHER INTERVIEW AND DETAILED ANALYSES**

In a next step, further interviews with teacher trainers (\(N = 2\)) and teacher mentors (\(N = 3\)) will be conducted. The learning opportunities identified will be presented to the interviewees for
communicative validation. After the compilation of the results, the learning opportunities not considered by the interview participants will be in the focus of a further discussion between the interviewees. On basis of the results of this discussion, a questionnaire will be developed in order to check if further teacher trainers \((N = 25)\) and teacher mentors \((N = 100-150)\) agree with the assessments of focus groups. To answer the third research question, a questionnaire will be used to ask teacher trainers \((N \approx 3)\), teacher mentors \((N \approx 50)\) and teacher students \((N \approx 50)\) during the internship which learning opportunities could have been used.

INTERDISCIPLINARY PROJECTS: INTEGRATING NEW PERSPECTIVES IN TEACHER TECHNOLOGY EDUCATION

Claudia Stübi and Alexander F. Koch
School for Teacher Education, University of Applied Sciences and Arts Northwestern Switzerland FHNW, Centre for Science and Technology Education

The University of Applied Sciences of Northwestern Switzerland (FHNW) has developed a program called EduNaT (Education Natural Science and Technology) to promote the interest for natural science and technology education by interdisciplinary projects between the different schools within the University of Applied Sciences. The collaborations between the six disciplines benefit from various perspectives on chances and challenges, issues and need for action in the field. At the same time, experts from teacher education, engineering, geomatics, life sciences, technology, psychology, arts and design bring together their specific knowledge and new ideas, what fosters the relation of theory with practice and innovative methods. Within the program EduNaT, 18 different projects have been developed. They not only focus on the development of the pre- and in-service teacher technology education and technology didactics in Switzerland. Some projects also address gender equitable approaches for natural science and technology for all ages or work on making STEM subjects more attractive and available for the society. After an introduction about the program EduNaT, the presentation shows three projects, their interdisciplinary work and the experiences with it. One can learn about new instructional methods in pre-service teacher education and the relation of theory with practice in it, and about the development of professional knowledge of teachers by integrating results of interdisciplinary research projects in their studies.

Keywords: Technology education, professional knowledge of teachers, relation of theory with practice

STRATEGIC INITIATIVE EDUNAT

In Switzerland and many other industrialized countries there are different challenges regarding the scientific and technology education. There is a big deficiency in specialized personnel in scientific and technology subjects as science, technology, engineering and mathematics also known as STEM subjects. Additionally, the number of women who study or work in scientific or technology-oriented fields is very low. Furthermore, the majority of teenagers consider most of STEM subjects as difficult and complex. Due to these and other reasons, in the last years schools, universities and the state focus more on scientific and technology education. To overcome these deficiencies and to support the focus on improving STEM education, the University of Applied Sciences of Northwestern Switzerland (FHNW) has developed a program called EduNaT (Education in natural sciences and Technology). The major goal of the program is to promote the interest for natural sciences and technology and to strengthen the education in this field. Another aim of the program is to work interdisciplinary between the different schools within the University of Applied Sciences Northwestern Switzerland. The following six different Universities of Applied Sciences are participating in the program: School of Applied Psychology, School of Architecture, Civil Engineering and Geomatics, Academy of Art and Design, School of Life Sciences, School of Engineering and School of
Teacher Education, which is the leading direction of the program.

**Interdisciplinary work**

To work interdisciplinary means that people from at least two different disciplines are working together pursuing the same goal. When working interdisciplinarily the different specialists can benefit from each other and broaden their minds. Also, the maximum result can be achieved as the specialized knowledges of the scientists and researchers can be combined. There are some characteristics which were defined as good and effective interdisciplinary work:

1. **Common object of research as well as common questions and goals:** It is important to define the research questions and the aim of the collaboration at the beginning. One goal should be to combine the different research fields of the participants.

2. **To agree on the method:** The participants agree on the methods they want to work with and how the integration of the different sub-projects should work.

3. **Integration:** The integration of the sub-projects should not be fulfilled at the end only. Already from the beginning a clear definition on how the different sub-projects suit to each other and how they can be integrated in the entire project is needed.

4. **Research director and team building:** A good interdisciplinary work depends on competent research directors and coordination as well as good teamwork. It would be advantageous if the research director already were experienced in interdisciplinary work.

5. **Common language and communication:** A good communication is very important. Main terms have to be defined from the beginning.

6. **Preparation and processing of the results:** Since there are different scientist form different fields working on a common project, the different results should be described and presented understandable and clear for everybody.

**Aim of the program EduNaT**

Within the program EduNaT 18 different projects have been developed. All 18 projects share the following five main objectives. All objectives concern the content of the different projects:

1. Improve the technology education and technology didactics in Switzerland
2. Develop and improve the knowledge and skills of teachers of every level of education in natural sciences and technology and increase the teachers' confidence
3. Analyze the (interdisciplinary) teaching in the scientific and technology field at the FHNW
4. Implement gender equitable approaches for natural sciences and technology for all ages especially teenagers before their choice of study and profession as well as students
5. Make STEM subjects more attractive and available for the society

On the structural and strategy level there are the following two objectives:

- Connect the six school within the University of Applied Sciences Northwestern Switzerland and their employees by common projects in teaching, research, development and further trainings.
• Establish the FHNW as the leading Swiss institution in the field of scientific and technology education and in long-term in the education of STEM subjects.

**Structure of the program EduNaT**

All involved schools at the University of Applied Sciences were represented in the program control, which met three to four times a year. In the meetings the regulation and control structures have been worked out, the current situation of the program has been discussed, measures have been taken as well as the communication between the schools at the University of Applied Sciences has been ensured. An advisory board of seven people, which met three times as well as a brain trust of four people, which met four times, counselled and accompanied EduNaT.

The draft paper of EduNaT was passed from the program control October 27, 2014. Besides goals, milestones and program organization it already contained a collection of ideas for 21 concrete projects. Out of these, 18 full project applications were submitted in two rounds (April and June 2015). In this process, two experts examined and evaluated every project with the help of given criteria. These reports were an important foundation for the classification of the projects by the program control.

**Outcome of the program EduNaT regarding interdisciplinary work**

Altogether, the projects achieved the expected goals and effects. With 18 projects and about 70 collaborators, EduNaT contributes to a wide and interdisciplinary network within the FHNW with a meaningful exchange and with impulses for the natural sciences and technology education, also after the program is finished.

The majority of the project reports mention positive effects relating to the competence growth, the integration of different perspectives and the increase of the network. In the cooperation between the Universities of Applied Sciences appreciation, openness and enrichment has been experienced. Nevertheless, the additional effort in time and administration, the bridging of cultural and structural differences and some difficulties in orientation should not be underestimated. In addition, not all involved parties have benefited equally from the projects. For example it is difficult to publish papers with focus in education in scientific communities addressed by the School of Architecture, Civil Engineering and Geomatics, School of Life Sciences and School of Engineering. Looking back it is also to discuss how interdisciplinary the projects really were. The planning of the employees in the single projects could have been done more carefully and fairly long-term. As well as the contribution of every faculty should have been described more clearly. There should have been more attention at the selection criteria of the projects and if there was no real interdisciplinarity it should have been corrected.

The program board of control considers an early, intensive and voluntary cooperation as a prerequisite of success.

Nevertheless, the program control noticed the interdisciplinarity as a positive challenge to overcome the described difficulties and to decrease them. It also crystallized that the natural sciences and technology education is a field, which has to be approached interdisciplinarily. The program control is convinced, that with EduNaT a meaningful project for the Northwestern
cantons and for the FHNW has been realized.

Some concrete output including strong interdisciplinary work:

- E-Learning-offers and didactic/ pedagogical material for primary classes with topics about connection techniques are available through a website.
- Two interdisciplinary courses about experiencing, understanding and teaching technology within the degree course primary teacher at the School of Teacher Education for three ECTS (European Credit Transfer System).
- Four completed workshops including teaching materials about concept-orientated exploration of the field 3D-modelation and 3D-print for students of education professions at the Academy of Art and Design and School of Teacher Education.
- Teaching practice for students at the School of Teacher Education through development and realization of eight workshops for 8 to 11 year old kids in cooperation with students of the School of Engineering.
- Application of an open-source-software for didactic support of the programming class in degree courses of the FHNW.
- Three completed tutorials about “particulates in the air”, “micro pollution in the water” and “noise pollution” on an online-platform for secondary teachers.
- Recommendation of actions for political and school authorities for the promotion of general technical education at elementary schools.
- Three courses for seniors to explore natural science and technology with kids. A concept, which combines the promotion of our kids in the STEM field, the lifelong learning and the dialogue of two generations.
- Two 4-days summer camps with workshops on the campus of FHNW for kids between seven and eleven years.

PRESENTATION OF THREE DIFFERENT PROJECTS OF EduNaT

After this introduction about the program EduNaT, three projects are presented to show the interdisciplinary work and the experiences with it. The reader learns about new instructional methods in pre-service teacher education and the relation of theory with practice in it, and about the development of professional knowledge of teachers by integrating results of interdisciplinary research projects in their studies. Finally, a large-scale project of factors of success in technology education will be presented in detail.

Project "Technology education of primary teachers"

With this project the education of primary teacher students of the FHNW School of Teacher Education should get improved relating to technology perspectives. The focus of the project is to develop a lecture about technology and therefore to improve the understanding of technology education on the level of primary school by more relation to practice. To reach this goal the FHNW School of Teacher Education, the FHNW School of Engineering and FHNW School of Architecture, Civil Engineering and Geomatics work and teach together.
Project "STEM interests in preschoolers and primary school children"

The development of vocational interests is an important task in childhood and adolescence. Vocational interests combined with self-efficacy expectations have been established as major factors for future career choices. Various studies show considerable gender differences in interests and self-efficacy expectations in sciences, technology, engineering, and mathematics (STEM). These differences are one important factor to explain the lasting inequalities in the distribution of women and men in STEM majors and STEM occupations. At what age level gender differences in interests precisely occur and whether there are certain sensitive periods for the promotion of STEM interests has not been established. The project therefore wants to investigate these research questions with a longitudinal study with preschool and primary school children.

Project "Factors of success in general technology education"

In Switzerland pupils are educated first at school and, if they do not continue to upper-secondary education at school in order to graduate with a university entrance examination, they do a three-year dual vocational professional educational training (VPET), i.e. they are meant learn practical theory at a school combined with practical training in an enterprise. The current compulsory school system (= kindergarten, primary and lower-secondary school) is supposed to prepare pupils for either of the two tracks. Yet, often VPET teachers complain that school does not provide a solid basis of technological knowledge to smooth the transition from school to VPET. This problem has been tackled in the new Swiss curriculum (so-called Lehrplan 21, D-EDK, 2016). There, technology education is supposed to be taught at a basic level and is now newly integrated in the subject science and technology, besides the subject technical design or information technology. In Figure 1 the problem of coherence in school-to-practice transition is shown. This means, if transition from school to profession is supposed to be coherent, then we need to agree on a basic technology education, based on practical norms as well as professional standards. These standards then have to be implemented in pre-service teacher education.

![Figure 1. The problem of coherence in school-work transition](image)

Research and methodological questions

The central research question in the project aims to get insight into the factors of success in
technology education. So what is "technology education", what is "success" and who determines "success"?

If one takes a look at technology itself, several groups may come to one's mind: professionals, that deal with technology. For example, engineers, architects or technicians; schools and teachers that have to transmit the nitty gritty of technology to students and pupils; and the students and pupils that are the recipients of education and instruction. From our point of view, these key groups need to be considered if one wants to get a comprehensive idea of good technology education.

The project we describe here, aims to evaluate factors of success for school technology instruction. Thus, we ask three major groups:

1. Professionals in technology (e. g. engineers) and professionals with a teaching assignment (i. e. professionals teaching in vocational professional educational training)
2. Teachers in compulsory school (kindergarten, primary and lower-secondary school) and teachers in upper-secondary school

One of the major methodological questions that has to be solved is: How can one generalize factor of success in a heterogeneous field of technology definitions?

In the following section we want to briefly explain the evaluation variables that are used in the study. An overview of the evaluation groups and the most relevant variables is presented in Table 1.

**Levels of evaluation**

The evaluation of professionals in the field of technology as well as VPET teachers (professionals with a teaching position) aims to assess their idea of what technology-oriented content school should teach. This should give an impression of professional demands and standards that should be approached by school education.

Additionally, we ask school teachers about their conception of technology content in school as well as the obstacles they see in implementing technology-oriented instruction. This allows to compare professional standards and educational standards. Evaluating constraints of technology instruction also sheds light on factors of technology instruction implementation. Research projects may build up on these findings and support potential variables.

Another group that is evaluated are pupils and university students. They are asked for their biography and interest in technology in general and about technology content that they experienced during compulsory school. In a questionnaire they are given a content (e. g.: I learnt how a steam engine works.) and had to rate how intense they went through the topic and how interested they were in the topic. The idea is to find out how well school met interests. Also, students and pupils are asked for their "technology idols", i. e. the names of persons on TV, in movies, on the internet, media etc. This item can be used as a proximal indicator for their understanding of technology.
Expected data analyses and results

After evaluation, we will try to correlate quantitative data in an explorative framework. At first, we expect differences in pupils' interest and contents taught at school. Also, with reference to qualitative data, differences are expected in the definition of technology and especially educational standards between professionals and school staff, but also between teachers and pupils at compulsory schools.

Table 1: Overview of groups and variables assessed in the project

<table>

<td></td>
</tr>
<tr>
<td>Professionals</td>
<td>What are essential aspect of a future subject technology?</td>
<td>What is basic knowledge everyone should have in technology?</td>
</tr>
</tbody>
</table>

We expect to find connecting variables that allow to improve the coherence of technological knowledge. Hypothetically, we could approach educational standards from two perspectives: the professional norm and the pupils' interest.

THE ASSESSMENT OF SIMPLE EXPERIMENT BY PRESERVICE PRIMARY TEACHERS

Jan Petr

University of South Bohemia in Ceske Budejovice, Faculty of Education, Jeronymova 10, Ceske Budejovice, Czech Republic, Department of Biology

Inquiry science education is usually accompanied by performing of simple experiments. This empirical study is focused on the investigation whether the pre-service primary teachers are able to design simple experiment oriented on photosynthesis and if they are able to provide formative assessment by the written peer-feedback related to the design of experiment. Pre-service teachers of integrated sciences (n=35) were introduced to the principles of the photosynthesis, respiration and physiology of green plants. After it each pre-service teacher designed his/her simple experiment, which could demonstrate importance of the light for green plants and which was realizable in the classroom. Peer assessment of the experimental design was the second step of the research. The results show that: (1) Experimental design can be useful tool for the identification of knowledge or competence level as well. (2) Pre-service primary teachers are able to prepare relevant experiment but with some mistakes corresponding with lack of the understanding of basic biological principles. (3) This research shows difficulties in the process of formative assessment, lack of experience with assessment and need of better background and support for implementation of formative assessment. Final peer assessment of experiment and additional tasks are often very different in comparison with expected “correct” evaluation.

Keywords: inquiry, primary science, school experiment, peer assessment

INTRODUCTION

The subject Integrated sciences taught at primary level consist from parts aimed on topics related to nature and social sciences. The better understanding of basic natural principles can be supported by inquiry and many studies indicate an effectiveness of inquiry-based instructional practices.

Inquiry is an opportunity to improve students’ understanding of key scientific concepts (Rocard et al., 2007). Inquiry science education is usually accompanied by performing of simple experiments. Some experiments are available in textbooks, books, methodical guidelines, web pages etc. Teachers frequently design their own experiments, which fit the concrete specific conditions of class, school or curriculum.

The main challenge for teacher education is to implement inquiry principles into their preparation and encourage teachers to use simple experiments with students’ initiative activities in their lessons (Hart, 2000, Lord, Orkwiszewski, 2006). Simultaneously, when pupils design their own experiment, teacher should assess rightness and quality of experiment with respect to educational goals and pupils’ motivation.

This research investigates whether Czech pre-service primary teachers are able to design simple experiments and whether they are able to assess experimental design created by their classmates. The photosynthesis was selected as convenient subject matter for this research. It represents one of basic principles of life (Reece, Campbell, 2011). The photosynthesis is
commonly explained as a complex of reactions in which solar energy is converted into the
chemical energy stored in ATP bonds or other organic molecules, namely sugar (glucose). This
process is connected with the nutrition of autotrophic organisms but it is very important for all
organisms as main source of energy circulating in ecosystems (Reece, Campbell, 2011). It is
possible to specify the photosynthesis (and cellular respiration as well) as process which is
associated with systems at multiple biological levels from cells to ecosystems and which
illustrates transport of energy through biological systems (Akcay, 2017). Moreover the
respiration is associated with the photosynthesis immediately.

Only the essential principles of the photosynthesis are appropriate at primary educational level.
Students should understand a conversion of inorganic substances represented by water and
carbon dioxide to organic substances such as sugar and the essential role of the light energy as
well. They should understand uniqueness of this process and its importance for life. The energy
transformations are one of the essentials attributes of the life.

This topic is considered as difficult for teachers and their students (Akcay, 2017). This is
accompanied by some additional effects: (1) the problem of choice of a suitable experiment,
which is simple, illustrative and well comprehensible for students, (2) is it possible to prepare
inquiry lesson(s) and which way, (3) how to asses a students’ work when they design their own
experiments oriented on the principles of photosynthesis or respiration.

**Research questions:**

1) Do pre-service teachers understand basic natural principles? Is it possible to discover it from
their products like the design of the experiments?

2) Are pre-service teachers able to design simple experiments aimed on these principles?

3) Do pre-service teachers assess designed experiment as suitable, illustrative, reliable etc.?

**METHOD**

Pre-service teachers (n = 35) were introduced to the principles of photosynthesis 5 months
before start of the research. They designed simple experiment realizable in the classroom,
which demonstrate one aspect of the plant physiology – the importance of the light for green
plants. Simple drawing in the worksheet was used as a tool for the planning of the experiment.
They used two fields in the worksheet for better readability and easier assessment of final
drawing. There was prepared simple drawing of the plant in the boxes. The experimental design
was presented by sketches and it was accompanied by information about necessary aids,
anticipated results of experiment and some other factors affected plant growth in next three
fields.

In the second stage, protocols were assigned randomly to pre-service teachers in the same group
for the implementation of the peer assessment process with use of evaluative protocol
containing the formative and summative part.

Design (sketch), other answers of respondents and evaluative protocols were coded and
analysed with basic statistical methods (frequency, percentage). Afterwards the additional data
obtained by the questionnaire were also considered in relation to the results of analysis.
RESULTS

The role of the light in photosynthesis was explained by the pre-service teachers (respondents) in the first part of worksheet.

Q: “Why the light is needed by plants?”

Relative large group of respondents (26 %) made mistakes or explained it incorrectly or vaguely. In most incorrect cases, respondents took the light for the respiration as necessary. One respondent considered the oxygen production as main process in the photosynthesis and the light as the essential condition for this. Most incorrect answers laid in an inaccurate formulation within the meaning the light is necessary for plant growth. No answer was referred to basic principles of the photosynthesis, such energy conversion or synthesis of organic substances.

Assessment:

In contrast to this finding all assessors found it as correct explanation (Figure 1). For example assessors did not recognize neutral role of the light in plant respiration. The non-specific answer mentioning the light as condition of life was considered as correct although it do not contain more detailed explanation or reasons. The answers “The light is necessary” or “The light represents one of condition” was found as correct by assessors although it was de facto repetition of the question only. The positive emotional statements were used by all assessors.

Figure 1. The comparison of the explanation of role of the light in photosynthesis stated by respondents (worksheets) and the assessment of assessors (assessment).

Q: “How we can discover that the plants need the light?”

About one half of respondents (49 %) incorrectly defined effect of the light or its deficiency on green plants. For example the flowering or opening/closing of flowers were considered as the phenomenon directly influenced by the light. Some respondents stated the rotation of the flowers or leaves towards the light as the evidence of the light needs not as a result of this. In individual cases respondents connected the light abundance with fruit quality (sweetness) or flower quality (smell), considered visible vaporization (?) as the manifestation of the light
influence. Many respondents (31%) considered the growth or stopping of growth as an effect related to the light.

Assessment:

About 83% of assessors assessed the answers correctly. That means they evaluated correct answers as correct and vice versa. When negative feedback was used, assessor provided information about deficiencies in the answer of respondent.

Q: “Design an experiment which can demonstrate need of the light for green plants. Experiment should be realized in the classroom.”

Respondents used simple sketches for presentation of experimental design. Design of experiment was usually correct when rough draft is assessed. But completely correct design with all required terms was presented in 4 cases only (11%) (Figure 2). Technical quality of the sketches was not assessed. The assessors focused on the content of picture and its items related to the planned experiment.

![Figure 2. Considerable contrast between really correct design of the experiment (worksheets) and the design which was considered by assessors as correct (assessment).](image)

Design of the experiments was very different and varied from incomplete drawings without some necessary details to relative correct drawings with parts which indicate students’ ideas and understanding of the photosynthesis or rather the effect of the light on the plants.

Some sketches represented correct experimental design (Figures 3, 4) and they are representing suitable arrangement but can be incorrect in details. For example flowering or opening/closing of flowers were considered as the phenomenon directly caused by the light. Usually typical can be symbolization of the night or darkness by picture of the Moon (Figure 3). Other sketches contain non-important details on the one hand and crucial items are missed on the other hand (Figure 4).

In several cases, the design/picture included only hint of experimental design. Figure 5 shows experimental design, which represents main idea consisting in comparison of plant lit by the Sun and shaded plant. However, there is not any information about other aids or equipment necessary for the experiment and about condition of the plant.
Table 1. Other factors (except the light) which were considered as important for plant growth (by respondents).

Assessment:

The sketches provide opportunity for recognition of understanding the basic principles of plant physiology connected with the light and allow the easier assessment of the experimental design. But, the assessment is sometimes complicated because it can run into problems with picture quality. At university level, it was not serious problem but demands on skills in reading of the pictures by assessors are important at primary level.

Assessors usually considered design as correct but failed to provide feedback in details, e.g. when necessary aids for plant growing were missing in the experimental design.

In great contrast with number of tiny mistakes, inaccuracies and vagueness most respondents assessed experimental design as fully correct (94%). Nine assessors provided written feedback with additional information, 8 of them expressed positive emotional statement and only one was negative with recommendation of some improvement of the experimental design.

Figure 3. The example of sketch representing suitable experimental design.

Figure 4. The example of sketch representing experimental design with the emphasis on flowerpot, window and light source but without any indication of light effect on the plant.
Figure 5. The example representing incomplete sketch without details.

Q: “Necessary aids for the experiment.”

Respondents presented necessary aids for plant growing. Nobody wrote all needed materials and equipment (Table 2). Respondents considered the light source and shading of the plant as most important but other equipment needed for the experiment was mentioned partly.

It seems that respondents understood main principle of experimental design consisting in comparison of two plants grown in different light conditions but they are not sufficiently careful in details.

Table 2. The overview of necessary experimental equipment presented by respondents.

</table>

Assessment:

Assessors stated presented equipment as satisfactory in 89 % of cases. They frequently ignored some missing equipment. In contrast, when they recommended completing equipment, it was in 10 cases only. Usually assessors recommended to complete water, flowerpot and better shading or blackout.

Q: “Other factors influenced plant growth.”

Identification of next factors, which affect plant growing (except the light), showed varied spectrum of statements. Water (in 91 %) and enough of nutrients (in 63 %) were considered as the most important factors. Some respondents mentioned incorrectly relative problematic factors as enough of oxygen, altitude or air etc. (Table 3). This question was not assessed by assessors and inform in fact about knowledge background or problem understanding.

**DISCUSSION AND CONCLUSIONS**

Designing of simply experiments is very important tool for better understanding of principles of life. Above all, it is crucial part of dynamic disciplines like plant physiology and it is often the best way of instruction for understanding some phenomena. It was found that pre-service teachers are able to prepare simple experiment but with (some) misconceptions.

The answers to research questions stated above are following:

1) Preservice teachers do not understand some basic natural principles correctly. Experimental design could be useful as indicator of understanding of problems by pre-service teachers because they have to apply their own theoretical knowledge in concrete problems or situations. This research supports the assumption that some pre-service teachers work sometimes incorrectly or inaccurately with theoretical knowledge.

2) Especially future primary teachers do not have strong background in science (e.g. biology). Therefore, designing of simple experiments or labs is necessary component of their preparation (at faculty of education). Most of pre-service teachers are able to prepare simple experiment but they are not careful in details and can have problems with correct explanations what happens during experiment and what is the core of the experiment.

3) Assessment of inquiry is not easy and it is impracticable without deep understanding of basic principles and theoretical background of experiments. It is necessary to develop competence in assessment too. This research shows difficulties in the process of formative assessment, lack of experience with this assessing approach and the need for better background and bigger support for implementation of formative assessment in teacher’s future instruction. This statement corresponds with findings of the research realized in the frame of the project ASSIST-ME (Stuchlikova et al., 2015).

REVEALING THE COMPLEXITY OF PRE-SERVICE TEACHERS’ TSPCK: FROM REASONING TO PRACTICE

Elizabeth Mavhunga and Dennis van der Merwe
University of the Witwatersrand, School of Education, Science Education Division, Johannesburg, South Africa

Classroom lesson delivery is generally more complex than lesson planning. In science education, Pedagogical Content Knowledge (PCK) is valued as the teacher professional knowledge for teaching science. However, little is known about how the complexity of classroom delivery from a well pedagogically reasoned lesson plan is exhibited and explained through the lens of PCK, particularly when the topic specific nature of PCK is considered and distinguished as Topic Specific PCK (TSPCK). This study sought to illuminate the complexity of component interaction in pedagogically reasoned lesson plans of (N=4) physical science pre-service teachers and in their subsequent classrooms delivery during a practicum. The pre-service teachers were exposed to a 6-week long intervention targeting the development of the competence to pedagogically transform content knowledge in stoichiometry. On completion of the intervention pre-service teachers were placed in secondary schools where they taught different topics to the intervention. Data collected comprised of lesson plans, lesson recordings and self-review reports. All the data were analyzed for episodes of component interactions using a qualitative in-depth analysis. Findings revealed that (i) more episodes of component interactions were identified in the classroom lessons than in the original lesson plans as could be expected, however more interestingly (ii) original, pre-determined episodes from the lesson plans were identifiable emerging as a cluster of TSPCK episode however with the initial lesson intention retained. Preservice teachers were found to have observed the development. Recommendations for teacher education programmes for explicit attention to component interactions and the clustering effect are made.

Keywords: TSPCK component interactions; enacted TSPCK.

AIM

The gap between theory and practice identified by Korthagen (2007) as a perennial problem in teacher education a century later since Dewey’s (1904) explicit outcry, remains as the today’s (Hennissen, Beckers, & Moerkerke, 2017) “Achilles heel of teacher education” (Darling-Hammond, 2013, p. 12, 12). Other education researchers have framed it as ‘the transfer problem’ (Korthagen & Kessels, 1999), others as the ‘connection or disconnection’ between teacher education and practice (Huang, Lubin, & Ge, 2011). At the heart of the problem is the recognition of the dissonance between preparation to teach and the actual teaching experience. This incongruence talks to the lack of connections between what Aristotle named episteme and phronesis. Accordingly, the conception of knowledge as episteme refers to a body of knowledge about many different concepts. It is similar to what Kislov (2014) called ’knowing that’. Episteme is conceptual and abstract. On the other hand, knowledge as phronesis is used for action in specific situations. It refers to prudence, practical wisdom and what Kislov (2014) called ’knowing how’. The possession of one over another would naturally exasperate the theory-practice gap. In science education the experience is not different to this widely observed trend. Pedagogical Content Knowledge (PCK) has emerged as the theoretical construct that
offers science education practitioners a framework to bridge the theory-practice divide. The key benefit of PCK is the pedagogical transformation (Shulman, 1987) of 'knowing that' to 'knowing how to teach it' with the evidence of learner understanding. By virtue of its theory-practice bridging nature, PCK is in agreement with Dewey’s stand in viewing practicum in Initial Teacher Education (ITE) development programmes as an integration of both the ‘apprentice model’ and the idea of ‘Bildung’ (Nelsen, 2016). In this view both the technical aspects of classroom delivery and the reasoning behind actions are mutually complimentary and informing each other. The challenge within the PCK studies remains however, in capturing and understanding fully how the complexity of classroom practice is reflected by PCK acquired within specific topics as presented in structured courses. In the refined consensus model of PCK (Carlson & Daehler, in press), PCK is acknowledged as having multidimensional nature that could be described by grainsize as PCK generally in the discipline and PCK within specific topics termed topic specific PCK (TSPCK). The model further distinguishes between PCK acquired from the shared knowledge such as from courses based on literature is called collective PCK (cPCK), by reference if acquired within a specific topic as collective topic specific PCK (cTSPCK). The development of PCK in specific topics is highly recommended within science education (Abel, 2008). In this study we sought to illuminate pre-service teachers’ cTSPCK as it develops in a structured course from reasoning about teaching a specific topic into their classroom delivery as enacted personal TSPCK (pTSPCK). Our starting point acknowledged that the classroom teaching process is not simply a transmission of the reasoned plan, nor an additive process but requires the transformation of ‘core practices’ (Darling-Hammond, 2013) that have been displayed in the pedagogical reasoning and planning of the lesson, to be carried into the classroom delivery. We argue in this study that the success towards narrowing the theory-practice gap lies in capturing and understanding how these imported 'core-practices' reasoned-out from a planning perspective withstand and/or change in nature in the face of classroom dynamics.

**BACKGROUND AND FRAMEWORK**

**Core practices in learning to acquire TSPCK**

The key competence in developing the theoretical construct PCK, particularly TSPCK, lies in the 'know how' of drawing interactively on the different content specific components of the construct when formulating teacher explanations and responses. When the knowledge components of the construct are used this way, the resulting effect is evident coherency and depth that promote learner understanding. This 'know-how', interactive usage of knowledge components lead to transformation of content knowledge (Geddis 1993; Nilsson 2008) which is a key benefit of PCK (Shulman,1987) and by reference TSPCK. Thus the mastery of using TSPCK component interactions is key in TSPCK studies. Pre-service teachers are widely expected not to have this competence because of their limited classroom experience as a teacher (Cetin-Dindar, Boz, Yildiran Sonmez, & Demirci Celep, 2018). Many PCK based ITE programmes share the goal of teaching cTSPCK knowledge to pre-service teacher often starting from a reasoning and planning context followed by an exposure to pTSPCK classroom teaching (Chan & Yung, 2015). The rationale is based on Shulman’s (1987) conception that targeting the development of pedagogically sound reasons that would be used as rationale to
Strand 13

classroom teacher actions is as important as the actual delivery. In relation to the theory-practice divide narrative, we argue that assisting pre-service teachers to import the core practice of component interactions developed in cTSPCK successfully into their classroom practice (pTSPCK), given its complexity, will work towards narrowing the current divide.

Strategies to narrow the theory-divide

The persistency of the theory-practice divide problem has evoked a number of different responses from a number of education researchers. Many studies in science education (e.g. (Nilsson, 2014; Rollnick & Mavhunga, 2015) and in mathematics education (e.g. Ball & Forzani, 2009) have offered empirically informed recommendations to the dilemma. Kinyaduka (2017) argued that perhaps the reason we are not winning the battle is linked to what the author calls “Human being Action Theory”. This theory acknowledges that there are always circumstances and acting forces influencing an individual or organization not to act according to laid down plans, beliefs, and/or principles, thus resulting in theory practice gap. As such, the circumstances can be contextual (temporal), and the forces can be from within or from outside an individual or an organization (Kinyaduka, 2017, p.104). This line of thinking may sound like throwing the towel into the ring, however, it borders along that expressed by Nelsen (2016) in the quotation below, where the author advocated teaching methods that explicitly reveal and allow pre-service teachers to feel the tension as actually working towards closing it.

“I purposefully teach my students in ways that widen the gulf between my classroom and those of the public schools around us. I want my students both to understand and feel that gap—that tension between what we are exploring and what they have and most likely will experience when they venture into schools as student teachers.” (Nelsen, 2016, pg. 498)

Nelsen (2016), argued that the practice-theory gap is actually in Deweyen’s terms the growth point. The author points out that Dewey’s work encouraged us not to avoid tensions and the apparent gap but to embrace them and consider them as catalysts for growth. Thus, accordingly, teacher educators are to open up to the tension and exose their students to it. Furthermore, they are to help pre-service teachers to understand how what is learnt in class significantly influences the classroom rather than matching it.

While in this study we see merit in both Kinyaduka and Nelsen’s line of thought, particularly the relief to the painful burden imposed by of the theory-practice divide, we argue that there is however virtue in the purposeful linking of the classroom dynamics and complexity into the strategies of learning how to teach. This does not amount to matching the classroom, as it is naturally impossible, but offers an opportunity to infuse the knowledge for teaching to be learnt in ITE with understanding of the formats and versions of how it looks when in action. We argue that when such versions are fully known they could be made explicit in the first place.

Within PCK studies, the effort to close the practice-theory have been reported in a number of empirical studies where combinations of coursework or structured interventions with practicum is explored. A close review of few cases reporting success, refer to coherency in understanding and using different knowledge components associate with PCK or TSPCK. For example, Nilsson (2008) invetsigated the development of PCK in four (4) pre-service teachers in
Strand 13

mathematics and science in their final year of study who participated in a project teaching physics to students aged 9–11 years. At the time of the project the pre-service teachers had completed their discipline courses and were studying general pedagogy. The findings indicated that through reflection pre-service teachers had begun to develop understanding of the different teacher knowledge bases, particular that are in concert with another and are to be used as an interplay. In a similar case, Hume and Berry (2015) reported on the development of four (4) chemistry pre-service teachers’ PCK through planning using Content Representations (CoRe) (Loughran, Berry, & Mulhall, 2006) and teaching out of it (the CoRe) in a practicum with the assistance of mentor teachers. The authors highlight that the practicum offered the pre-service teachers an opportunity for aspects of their PCK to be explored and expanded upon in classroom settings. Furthermore, they report on pre-service positive reviews and recognition of the transformation of the CoRe into the classroom teaching. Our own research study with science pre-service teachers points to evidence of them importing from a structured intervention, the interactive use of certain knowledge components of TSPCK into the classroom practice, demonstrating transformation of content knowledge (Rollnick & Mavhunga, 2016). These cases indicate potential for narrowing the gap through importing of the kind of knowledge that do significantly influence classroom teaching. However, what is yet to be understood and needed for strengthening the observed potential, is the understanding of how the PCK component interplay observed in classroom action relate back to those seen in the reasoning and planning of the lesson. Furthermore, what factors related to classroom activities influence how the evidence is manifested. These are aspects explored in this study through the research design outline below.

THEORETICAL FRAMEWORK

The study was based on the theoretical construct of Pedagogical Content Knowledge (PCK). According to Shulman, (2015), "PCK is an attribute that teachers develop, and it cannot be found among mere subject matter experts or among those who are good with kids". In his review of PCK, Shulman referred to a realization driven from his earlier projects in the field of medicine and law, that there are ‘Signature Pedagogies’ (Shulman, 2005). These are profession-specific modes of teaching that are associated with that profession, that seem to fit what it means to learn to be a member of that profession. Furthermore, these signature pedagogies are, domain specific. The implication of this was that PCK as the theory for teaching is domain specific, distinct to teaching teachers, and different from teaching layers or medical practitioners. Furthermore, its value is observed when teaching within topics, providing further insight that PCK is topic specific. In this study, we acknowledge both the discipline and topic specificity of PCK. In our earlier studies we defined TSPCK as the knowledge needed to transform content knowledge of specific topics (Mavhunga & Rollnick, 2013). We identified Learner Prior Knowledge, Curricular Saliencey, What is difficult to understand, Repesentations and Conceptual Teaching Strategies as five content specific components of TSPCK. In this study we employed TSPCK within the model of Teacher professional knowledge and skill commonly known as the consensus PCK model (Gess-Newsome, 2015), and explored the link of TSPCK to classroom practice.
METHOD

The study employed a basic qualitative study design, using a case study strategy as described by Yin (2003). Participants were four (4) pre-service teachers who were in their final year of study commonly bound by their desire to complete the teacher qualification. They were drawn from a methodology course that targeted the development of TSPCK in core topics of chemistry and physics. A sample of 4 was purposefully selected based on access to the schools allocated for their practicum. The sample together with a whole class were exposed to an intervention treatment which explicitly introduced the idea of transforming content knowledge (CK) using the ‘different kinds of knowledge’ identified by Geddis and Wood, 1997 as enablers of content transformation. These are within a specific chemistry topic, stoichiometry. Stoichiometry was chosen as it is fundamental in understanding other chemistry topics especially in chemical equilibrium. The key feature of the intervention was explicit discussions on how the constituent components, once understood could be used interactively to transform CK when planning to teach a topic. As a result, the intervention was made up of carefully planned series of explicit discussions on the understanding of TSPCK components that happened over a period of 6 weeks. The 6 weeks period was organized into a total of 12 sessions of about 1 hour each. In each week there were three sessions structured as a single lecture period early in the week and a tutorial double period at the end of the week. On completion of the intervention pre-service teachers were placed in different secondary schools where they taught various chemistry and physics topics as determined by the individual schools. Data were collected from each participant during the practicum. It included various forms of qualitative evidence such as lesson plans, audio recordings of the lessons from the collected lesson plans, and pre-service teacher self-analysis reports. The self-analysis reports were part of an assignment where pre-service teachers were to analyze for TSPCK episodes in their lesson plans and determine how these were visible in their classroom teaching. The self-analysis reports were developed and submitted at the end of the practicum. Analysis entailed authentication of pre-service teachers’ findings reported in self-analysis reports and analysis of their raw data using in-depth qualitative method for TSPCK Episodes (Park & Oliver, 2008). In this approach, two or more components of TSPCK demonstrated in a specific teacher task segment, are first identified and labelled as ‘TSPCK Episodes’. Thus, a TSPCK Episode was operationally defined after Park and Chen (2012) as a teacher task segment that displays the use of two or more components of TSPCK. Each identified TSPCK Episode was then described in detail in terms of (i) what the pre-service teacher had written (in the case of lesson plans) or said and done (in the case of actual classroom lessons), (ii) what components are at play in the TSPCK Episode, and (iii) the nature of the sequence or emergence of the components in an interaction. The identification of TSPCK episodes happened from two video recorded lessons per participant. Two raters analysed the data for TSPCK Episodes following a discussion on rules for coding and a practice run with data from two pre-service teachers in the study.

RESULTS

Key findings about the journey of TSPCK episodes from lesson plans into classroom teaching indicated three salient points. They first is that TSPCK episodes initially identified from lesson plans re-emerged in classroom teaching as clusters of TSPCK episodes where the original
episode was still identifiable. The second observation is related to the first in that new TSPCK episodes emerge in classroom teaching making the number of TSPCK Episodes to increase as compared to the original lesson plan. The final observation was the confirmation that pre-service teachers were authentically able to identify these changes in the journey of TSPCK episodes from their lesson plans into their classroom teaching. In the section below we provide the overview of the findings and a sample qualitative demonstration.

Table 1 presents the overview pattern in terms of quantity of TSPCK episode identified from the planning to the enactment context by the four pre-service teachers in the study. The table also present the extent of qualitativ agreements between the pre-service teachers and the researchers on the quantity and the composition analysis for of the identified episodes. The TSPCK components are abbreviated for ease of reference: Learner Prior Knowledge(LP); Curricular Saliency (CS), What is difficult to understand (DIF), Representations (RP) and Conceptual Teaching Strategies (CTS). The sequence in which the TSPCK components were observed to appear was represented by a forward slash (/) to represent an interwoven sequence and a dash (-) to represent a clear linear sequence. The interwoven nature meant a sense was established that the components appeared integrated in the identified TSPCK episode.

Table 1 indicates a good agreement for all 4 of the participants on TSPCK identification and analysis of composition and sequence in which the TSPCK components appeared in the episodes. It is noted that the quantity of TSPCK episodes initially found in the lesson plans increased when the lesson was enacted out. An example is made with an extract from Zandi’s identified TSPCK Episodes. Zandi taught planned and subsequently taught a lesson on electrostatics. The extract below was lifted up from her planning lesson as a segment of her planning that contained a TSPCK episode. It demonstrated a TSPCK episode with 3 components found interacting.

\[\text{I will introduce the topic on Electrostatic by taking about charged vs. neutral objects. 1 will talk about charged and neutral objects at the same time, comparing their features and use strips of sticky tape placed with the sticky side facing up and, and also use same size of paper strips that are neutral. I will then point the different character exhibited by the sticky tape strips – to stick on the finger while normal paper strips do not. 3 For charged objects this happens because they have gained a charge or lost a charge. I will explain that this is what differentiates charged objects from neutral objects. Charged objects have either an overall positive or a negative charge and therefore, have the ability to attract oppositely charged objects or repel objects charged with the same charge.} \]
```

**DISCUSSIONS AND CONCLUSIONS**

In this study we raised the issue of the practice-theory gap as a continued concern in education generally, and our focus was in science education as an example. We pointed at the fact that the knowledge for teaching, cTSPCK, taught in structured science teacher education programmes courses from a planning pedagogical reasoning perspective, is often taught without reference to how its format changes or withstands classrooms dynamics and complexity. Also that factors that influence its format in classroom situations are not fully understood thus the purpose of the study to illuminate these aspects. The findings revealed that in a classroom context, the initial intentions reasoned –out in a lesson plan as a neat stand alone TSPCK episode, emerge in a classroom context as a cluster of TSPCK episodes that flow into each other to set a scene and support the original intention. The episodes are also seen to expand and increase in quantity responsive to learner interactions. The revelation of the episode clustering effect points to the succinct feature that distinguishes the format in which the learnt knowledge to teach (cTSPCK) emerges in theory vs. Practice (eTSPCK). Learner interactions emerge as a strong visible factor having a direct influence to the manner in which TSPCK episodes emerged. Our recommendations are that teacher educators are to explore for more similar features that shape the format of TSPCK in classroom contexts. For the
understanding of such features will inform the content and emphasis to be explicitly discussed in teacher education programmes working towards narrowing the practice–theory gap.

Gess-Newsome, J. (2015). A model of teacher professional knowledge and skill including PCK: Results of the thinking from the PCK Summit In A. Berry, P. Friedrichsen & J. Loughran (Eds.), Re-
examining Pedagogical Content Knowledge in Science Education (pp. 28-42). London: Routledge.

This article presents the results of an approach applied to - and by - students in initial formation of Licentiate degree in Physics under the theme of Interdisciplinary. Twelve students enrolled in the subject of Methodology of Physics Teaching II at the University of São Paulo and participated in the elaboration of projects guided by the Interdisciplinary Islands of Rationality - IIR (FOUREZ, 1994) model. There were four phases of implementation, which were monitored and mediated by two research monitors and by the discipline/subject teacher. In the qualitative data analysis, the students' arguments - obtained through an online open questionnaire and a semi-structured interview - are explained in relation to: (i) the significant differences of the proposal in contrast to the thematic and strongly traditional approach associated with interdisciplinary school projects; (ii) the development of similar activity in Basic Education and (iii) the potential of this approach on learning and on exploring interdisciplinary in science. The implications of this proposal evidenced that the approach based on Interdisciplinary Islands of Rationality - IIR presents promising elements for the transformation of the didactic culture in the teaching of sciences and a distancing in relation to the reproduction of thematic models of disciplinary approach.

Keywords: initial teaching education, teaching methodology, interdisciplinary.

INTRODUCTION

Interdisciplinarity is a subject that raises many discussions between specialists and scholars in the educational field, besides its definition goes through many perspectives and its importance is justified by the expectation of a greater integration between the disciplinary contents (Morin, 1996; Pombo, 2008). In Brazil, there is a tradition both in research and in teaching about interdisciplinarity. The first publications with interdisciplinary reports appeared in the 1960s (Vieira & Durval, 1965), and in the 1970s more consistent investigations (Japiassu, 1976) emerged in the research scenario, followed by the works published by Paviani and Batomé (1993) and Fazenda (2003), to name some of the most relevant.

The existence of a consistent set of experience and research, however, does not make the task of understanding what is interdisciplinarity intelligible. Perhaps, we can here rehearse, paraphrasing Pombo (2004a, 2004b), something of what we think about interdisciplinarity. The origin of the word lies in the subjects and in the desire to reconstruct the totality of knowledge, it is an "attempt to break with the stagnant character of the disciplines" (Pombo, 2004a: p.4). It can be said that "interdisciplinarity is the place where one thinks of the fragmented condition of the sciences today and, at the same time, expresses our nostalgia for a unified knowledge" (Pombo, 2004a: p5).

Nonetheless, the most friendly feature of interdisciplinarity lies in its ability to establish cognitive and attitudinal relationships. In cognitive terms, it opens the world of sensibilities to complexity, attention to the deep structures of Science and articulation of what initially seems
to us inarticulable. Regarding to the attitude aspect, it stimulates curiosity, appreciation for collaboration and team work (Pombo, 2004a: 16). These are important aspects to resist the exponential trend of Modern Science, which was inaugurated in the seventeenth century, which is specialization.

The adoption of an analytical method that allowed to divide the whole into small parts led to the fragmentation of knowledge, with the underlying idea that it would be possible to recompose this whole and that the whole is equal to the sum of the parts.

Science today continues along this way and we have more and more super specialized areas. In the teaching of science, for example, the didactic-pedagogical difficulties are remarkable in order to overcome the fragmentation of knowledge, which, every day, becomes more intense, due to the result of fragmentation and the development of scientific and technological knowledge. Among the factors is the existence of many topics in a planned curriculum structure with few classes.

The teaching of Physics fits within this curricular structure and, in general, the attempts to insert activities of other disciplines to the physical contents in school projects have contributed little to approximate effectively such areas. In this scenario, we perceive the need to seek for a greater articulation between the concepts of the different disciplines, exploring their potential for integration of the content taught, besides enabling them to understand that knowledge is neither compartmentalized nor "disconnected".

Among the new interdisciplinary proposals to work with while teaching science that were developed over the last few years we have the Interdisciplinary Rationality Islands (IIR), by Gerard Fourez (1994). Such an approach stands out, basically, for two essential points: (a) it does not separate scientific knowledge from technological knowledge (b) integrates interdisciplinary knowledge into its development. Still, according to Fourez (1994), the IIR aims to achieve an appropriate theoretical representation in a precise situation and in function of a determined project.

This means that developing a knowledge by making use of IIR is, in some way, developing a theorization that fits the problem of interdisciplinarity in teaching.

Everything indicates that this approach is a possible way for integration of different knowledges in the construction of a knowledge. Whereas IIRs fall into two categories, namely: (1) those that organize around a concept and (2) those that organize around a project (Fourez, 1994) and this second category has guided a theoretical work developed by Nehring et al. (2000), in which we verified the authors' reflection on the science teaching and the meaningful knowledge. Also, that these in detailing a project proposal based on the IIR approach indicate the need for practical application of the proposal, for its evaluation in real classroom situations. This article, in parts, meets the authors' indication through the application of an activity developed with physics teachers in initial formation, as well as being anchored around the organization of projects following the proposal of Fourez (1994), as well as, the fundamentals of socio-cultural analysis of Sewell Jr. (2005). The following question was asked: What are the implications of the Interdisciplinary Islands Rationality approach in the process of transforming didactic disciplinary culture into Interdisciplinary culture in science teaching?
Transformation and reproduction: theoretical aspects for the study of didactic culture

Sociological theories have been an important path, supported by the concept of structuring, to understand how social practices are produced, reproduced, and transformed. The theory of structuration, which has in Anthony Giddens (1979) one of its main exponents, emerged between the late 1970s and the early 1980s as an alternative to the structuralist-functionalist and interactionist thoughts.

Giddens' formulations on the duality of structures present striking points of dialogue with the theory of Alfred Schutz and Fernand Braudel as they seek to integrate different temporal scales of analysis. A durée, by Schutz to express the daily nature of life and the longue durée, by Braudel in the dialogue with the little variable structures that extend over long periods. The introduction of different temporal levels provides an analytical reflection on how reproduction in the durée's plane contributes to reproduction to the range of the longue durée, in the particularity of the relations between human action and social structure.

Human action by this theoretical bias is characterized as a "continuous flow of conduct." Action and intentionality, however, are separate acts, according to the author "... action does not refer to individuals' intentions on doing things, but to their ability to do these things ..." (Giddens, 1984: 9). Expressed in this way, action is conceived as a "servant of a goal," although without clearly defined intentions in daily life people regularly pay attention to their own actions and the actions of other people. In short, man has the capacity to transform situations, it is precisely human action or agency that allows him to choose between intervening or not doing so. Sewell Junior (1992, 2005) presents an important contribution to the extension of Giddens' notion of the duality of human structure and action.

For this author, structures are mutually constituted by schemes of action and resources, aspects that both enable and restrict social actions, as they tend to be reproduced by these actions. The action is established by structures, both given by the knowledge of cultural schemes, which allows the agency to mobilize resources as well as access to resources that enables the promulgation of schemes (Sewell Jr, 1992). This process reflects the dynamism of human structure and practice. In this point, the author distinguishes Giddens by recognizing that the same structures that shape human conduct are constituted by human beings and are therefore not static, that is, the action that supports the reproduction of the structures is the same that also facilitates their transformation.

In transformation, however, we do not have a disruption, breakdown, but its occurrence comes from the reproduction of the properties of available structures. These theoretical reflections apply to the study of the didactic practice regarding the transposition of action schemes and the mobilization of resources, being pertinent on understanding how reproduction occurs and the transformation of the structure when an innovation is introduced in the teaching activity, for example of the research we analyze here.

METHODOLOGY

The epistemological posture assumed in this qualitative research is interpretivism (Schwandt, 2003). According to which, the researcher, by engaging in data interpretation activities to
enumerate doubts as to what the actors are doing or saying and transforming it into public knowledge, will be assuming theoretical perspectives on what constitutes knowledge, reconfiguring the theory itself and also the objectives that guide it. Thus, the scope of interpretivism is to redraw the self-understanding of historical actors in certain actions, under the participatory / cooperative paradigm and criteria of authenticity (Guba and Lincoln, 1994). In this sense the ways in which actors understand their experience are relevant to the researcher for social scientific understanding, since the ways in which actors understand their actions are also part of this action (Giddens, 1993).

The present study initially involved 52 physics teachers in initial formation, enrolled in the discipline of Methodology of Physics Teaching II at University of São Paulo. Divided into 4 teams, each one received a theme to build the project through the IIR approach. In Fourez's original proposal (1994) eight steps are taken to construct an IIR, namely: 1) Situation Cliché Studied; 2) Spontaneous Panorama; 3) Consultation with Specialists and Specialties; 4) Going to Practice; 5) Opening some black boxes; 6) Global technology outlining; 7) Opening of black boxes without the help of specialists; 8) Synthesis of the Island of Rationality produced. In the developed activity four stages were adequate and integrated to the others, once the project happened concomitantly to the planning of classes and the accomplishment of the obligatory stage to be realized in the discipline. The four stages were synthesized in three moments / class, of approximately 90 minutes each, and two monitors investigated and recorded notes on the research in development.

We selected the project, which was composed of twelve students, and their statements about the execution process, obtained in two intervals: (a) a semi-structured interview and (b) an online open questionnaire for categorization and qualitative analysis of reflections.

**THE DIDACTIC SCHOOL CULTURE AND THE APPROACH IIR**

The teaching of teaching science, as mentioned previously, has some problems regarding to the methodologies adopted to work with and it is often questioned among students by distancing the disciplinary contents in relation to the social issues relevant to learning. Thus, the way the contents are worked and their fragmentation are some of the factors pointed out as a source of discouragement for learning science. The inclusion of broader topics related to everyday life and that stimulate the analysis of society and the possibilities of transforming it signal ways for students to join this knowledge. Pursuing this idea of an approximation between the teaching of science and the field of interest of the students is that the IIR approach was proposed (Fourez, 1994), through the simulation of a public announcement.

The problem to be solved by team 4 in the form of an IIR project was materialized in a Public Notice that included the preparation of a booklet with information on the development and installation of small photovoltaic systems in peripheral neighborhoods of metropolitan regions. With this, it inserts the daily problematic in this application characterized by the use of irregular installations of sources of energy to the physical content.

The execution of the project followed four stages, synthesizing the eight that integrate the construction of Interdisciplinary Islands of Rationality from Fourez's perspective (1994). Being that, after the elaboration of the final product [booklet], the participating students developed a
reflection on their practice that was oriented in the form of a semi-structured interview by the research monitors. The aim of the interview was to make students co-participants in the process by discussing their own difficulties and successes, evaluating the practical implementation of the project step-by-step, in real classroom conditions, and understanding the implications of the IIR approach to disciplinary school culture.

In the interview, Team 4 described the main obstacles to the implementation of the first two phases. Stage 1, called cliché, was the moment that had the greatest difficulty to present the spontaneous ideas about the photovoltaic systems. In his reflections, student 3 states that even though he had read the theoretical article of support to the activity, his actions were guided more by knowing "what we were going to produce [...] 'this is not going to solve' " (Student 3) than to the spontaneous understanding of the situation. The other participants agreed that the rationality that prevailed in their training was preponderant to the exclusion of more open questions and related to daily experience, since they focused their questions on the most relevant hypotheses, understanding that they led them more quickly the construction of the final product. Sewell Junior (2005) contributes to the analysis of the action schemes mobilized during the execution of this stage, while allowing an evaluation in which it is identified in the students' speech that the schemes originated in the training trajectories and these were reproduced in their conduct during practically the whole cliché stage and the first moment of stage 2, of elaborating the spontaneous panorama [both defined in the first lesson]. The students concluded that the approach to the issue of the Notice was also cited as one of the possible causes for the team to discard the initial problematization, important for a first picture of the situation. All of them evaluated that the cliché stage in the execution of the project should not be burned and that the choice of subjects beyond the training area could constitute a more plausible way for the emergence and exposition of intuitive ideas in the group. According to student 5: "The cliché stage is a democratic moment that stimulates the initial debate on the subject" and student 1 complements "[...] it guarantees in part that you have covered the problem from visions different about the proposed situation ". This is considered to be the relevance of these notes, since they are indicative that the choice of a topic mixing knowledge from other areas would concentrate greater chances for the transformation of the action schemes and resources to be triggered by the students, including for stage 2.

Step 2, in the perception of team 4 was also partially impaired, still in the cliché phase these had already proceeded by refinement. This stage, which should still be very spontaneous, was directive and, for the most part, students sought to provide explanations. Subsequently, understanding how and why these difficulties arose to implement the two steps provided a set of information for the composition of the experience of the research monitors, who in the case experienced their first application of the IIR approach. This is a two-way path in which team 4 and the monitors have had and have the opportunity to evaluate their involvement and conduct during production. Several reflections were stimulated to think of suppressing some of the developments in Step 2, but in the end the team concluded that these were essential for the realization of an interdisciplinary road map.

Step 3, from the consultation to the specialists, happened in the second class. The team was less anxious about the first two stages. The students opted for the division of tasks, each pair
Strand 13

was responsible for the visit and consultation of one of the specialists and the confirmation of the rules and legislation in force on the subject. The considerations on this stage were that with the division of tasks among the team members, some of them were dedicated to subjects very close to the training area, damaging the idea of interdisciplinarity, which was the focus of production. This perception only changed when the set of specialists consulted and the relevance of each information for product finalization were scored. As an example, specialists were consulted in: languages, for the production of the text of the booklet; comic book graphic designs, for story illustration; meteorological conditions, to verify the climatic and atmospheric conditions favorable to the use of the energy potential of the supposed region of installation of the photovoltaic and technical systems in installations of the system. It is understood that analyzing the data obtained in this stage is significant for the formation of a holistic view of the process, it also follows that it is necessary to consider and stimulate collective participation at this stage and, if possible, this will depend a lot on the product defined in the edict. It creates means for the visit of specialists in the school. This indicative is largely due to the financial and human difficulties encountered in public schools, in general, for field trips. The team composed of university students did not experience this confrontation, but this was understood as a point to be well thought by the teacher before the execution of the project in high school classes.

Step 4, developed here as the finalization, delivery and synthesis of IIR, resulted in the production of a primer, available at: <https://www.dropbox.com/s/06e1v3jly1ntfia/Cartilha.pdf?dl=0>, with basic and accessible guidelines for the population regarding the criteria and norms for residential installation of residential photovoltaic systems. The plausibility of the IIR produced was registered by the participant team's identification of how the knowledge obtained in each one of the stages presented benefits for the student's autonomy in relation to the decision-making process. Comparatively the approaches of strongly subject school thematic projects often reproduced in school.

Interdisciplinarity, that is, the interlocution with other areas of knowledge, provided a framework of information that, in a way, a disciplinary model would not cover. In short, the practical implementation of the IIR approach with physics teachers in initial training allowed a general assessment of their viability, their mishaps and the need for improvement of the process by the island's producers of rationality in order for it to be effective. terms, thus broadening its potential for transforming subject culture into interdisciplinary culture into scientific education. In the light of Sewell Junior's theory (1992, 2005), the production of the island made explicit the relations between reproduction and the transformation of human action, the generated characteristic of these concepts, which in practice one is necessarily extinct for the other to happen. On the contrary, even the most radical transformation happens framed by the reproduction of the accessible structures.

In addition to the interview, teachers of physics in initial formation were given a second moment of reflection specifically on the implementation of the IIR approach, through an online open questionnaire; eleven students, from the twelve who participated, answered and their answers were organized into categories and subcategories (Strauss and Corbin, 2015), which
are grouped into three frames corresponding to each question. The first question\(^1\) had as objective to verify if the students identified elements of transformation between the school approach of interdisciplinary projects and the methodology of Islands of Rationality, the answers are presented in Table 1, below.

Table 1. IIR approach

<table>
<thead>
<tr>
<th>Category - Perceptions between school approach and the (IIR) approach</th>
<th>Nº Answers</th>
<th>Representative Excerpts</th>
</tr>
</thead>
<tbody>
<tr>
<td>Assign Differentials</td>
<td>9</td>
<td>“...Had a great differential, in relation to projects, where routinely the work is sliced in subjects. In the IIR the various areas of knowledge integrate more naturally” (Student 3).</td>
</tr>
<tr>
<td>Do not assign differentials</td>
<td>2</td>
<td>“No. The part in which I was entrusted with the activity was directed to my subject area and I ended up developing my activity in the same way that I would do in other activities related to physics” (Student 1).</td>
</tr>
</tbody>
</table>

In the subcategory "assign differentials", 82% of students perceived that the consultation of specialists, the range of technical, social, marketing, financial aspects and critical reflection on the stages that required the elaboration of the IIR project distanced them from the school approach which in itself has strongly disciplinary characteristics. According to Fourez (1997), IIRs enhance interdisciplinary dialogue by starting from the notion of a project, characterized by a set of steps to be followed, as well as the integration among several areas of knowledge.

In addition, the activity acquires meaning when related to a theoretical representation presented in a given situation as the initial project (Fourez, 1994).

The subcategory "do not assign differentials", indicated by 18% of the students, was fundamental to think about the development of the IIR, as exemplified by the answer in evidence in Table 1, some of the students attribute to similar areas the extreme difficulty of working in areas that are not yet known, even if they are used to support them in a thematic project. Moreover, this response was significant for the critical reflection of the thematic selection made by the researchers who applied it. be considered by the teacher in the thematic choice, so that it is not so close to the area of knowledge of the participating students, to the point of generating in them the feeling of not being involved in an interdisciplinary culture, as it does not opt for such a distant subject to the point of discouraging student participation.

The intention of question \(^2\) was to evaluate if the future professors of physics wanted to insert in their didactic practice IIR approach in Basic Education (Table 2).

---

\(^1\) Question 1 - In your evaluation did the approach to elaborating Interdisciplinary Islands of Rationality projects provide significant differentials in relation to the thematic and strongly disciplinary approach, which in general guide interdisciplinary projects in the school? What were these differentials?

\(^2\) Question 2 - Do you consider it feasible to apply this approach to high school students?
Table 2. Viability of IIR

<table>
<thead>
<tr>
<th>Category - Perceptions about the viability of IIR in High School</th>
<th>Nº Answers</th>
<th>Representative Excerpts</th>
</tr>
</thead>
<tbody>
<tr>
<td>Consider feasible</td>
<td>8</td>
<td>“The feasibility of the proposal is gained through several factors. [...] In order for the project to be possible, it is necessary that the direction of the school is also in accordance with this new proposal” (Student 6).</td>
</tr>
<tr>
<td>Do not consider feasible</td>
<td>3</td>
<td>“[...] Would not be feasible, since [...] many students want access to the internet, transportation, the means of communication necessary to contact specialists, and the fact that the teacher is pressured by external evaluations [...]” (Student 3).</td>
</tr>
</tbody>
</table>

The "consider feasible" subcategory, weighted by 73% of respondents, gives us an overview of how early teachers interpreted the IIR approach as they emphasized their feasibility of implementation. Factors such as motivation of students with the methodology to develop their classes, topics of interest and possibilities of technical visits characterized their arguments as to the relevance of the proposal. Despite the interest, and to defend their application, contradictorily in their statements many considered the time factor and the teaching structure disciplinary limiting points for the proper development of the project. The disciplinary structure is like a shadow that makes them retroact and rethink their own statements, intimidating the insertion of the new approach into their didactic practice as future teachers.

The subcategory "did not consider feasible" was also justified by 27% of the students, under the arguments: lack of time in class, technological difficulties and access to the network; of the course syllabus of the discipline and of the necessity of extra moments classes for the development of the projects. These answers reveal that part of the students did not understand the IIR proposal in this respect, because in its evaluation the applicability of the proposal would only be possible with the expansion of the time of completion of the disciplines and, in a certain way, fragmenting the project into fairs and/or activities. According to Fourez (1994) changes of this order do not contribute to the central idea of the IIR approach, which consists in the accomplishment of a project following stages of which the greater purpose is the search for the integration of the knowledge.

In structural terms, these statements, when illuminated by Sewell Jr's (2005) theorizing, indicate that the reproduction of disciplinary culture, originating in the formative base of the students themselves, future physics teachers, is so rooted in their practices that interject to the development of the interdisciplinary culture offered by the insertion of IIR in its future didactic practice.

In question 3, we tried to understand how the students in initial formation perceived the IIR's potential for insertion of the interdisciplinarity in the teaching of Sciences.

---

3 Question 3 - What is your view on the development of the Islands of Rationality project for learning and interdisciplinarity in Science Teaching?
Table 3. Implications of IR for learning in science teaching

<table>
<thead>
<tr>
<th>Category - IIR and interdisciplinary learning in science teaching</th>
<th>N° Answers</th>
<th>Representative Excerpts</th>
</tr>
</thead>
<tbody>
<tr>
<td>Positive perception</td>
<td>10</td>
<td>&quot;The work with the IIR develops in the student several skills and competences that traditional or technological classes would not achieve&quot; (Student 3).</td>
</tr>
<tr>
<td>Negative perception</td>
<td>1</td>
<td>&quot;It is interesting, but as I said, I do not know its effectiveness in the short, medium and long term [...], in relation to interdisciplinarity we do not necessarily need to use the islands of rationality&quot; (Student 8).</td>
</tr>
</tbody>
</table>

The "positive perception" sub-category indicated by 99% of the respondents gives an overview of the potential of the IIR approach to the impressions of the trainees, but also of our own findings in the researcher's perspective during the implementation phase of the project. According to the two responses highlighted in Table 3, and reinforced by other students, we have students perceive the differences of this new proposal in relation to "traditional". The students also indicated as a positive point of the approach the construction of a holistic view of the knowledge to be discussed.

On the other hand, the subcategory "negative perception" formed by 1% of the answers, denotes that student 8 is not trusting in this, because it mobilizes other theoretical visions on interdisciplinarity, not based on Fourez's (1994) perspective. The large number of interpretations in the literature on interdisciplinarity may have made it difficult for this student to understand the differences between the IIR-oriented project and the projects generally implemented in thematic-based schools.

**CONCLUSIONS**

In terms of research, our evaluation based on the analysis resulting from the implementation stages of the IIR approach, through the project applied by future physics teachers, revealed aspects about the potential of the proposal for the transformation of disciplinary didactic practice, the basis of the academic training of the students in interdisciplinary practice. From this process, we have also obtained the understanding that transformation is marked by reproduction, these two coexisting throughout the course of production of the book, sometimes emphasizing the schemes of action and resources produced by the area inherent to the formation of students, now being focus action schemes from the new IIR approach.

Which led us to reflect on the transformation as a procedural agent. Therefore, in order to be more aligned to a dialogic perspective with the daily situations of the student intertwined with the technological and scientific knowledge produced in the different curricular and extracurricular areas, it is necessary to insert the IIR in different moments of the student's formation.

Regarding the students' considerations about the potential of the IIR approach to interdisciplinary learning in Science Teaching, they concluded in a contradictory way sometimes indicating the viability of the application, on the other explaining the limits of Basic...
Education and factors such as time and resources emerged as strong barriers to the proposed challenge. This, perhaps, in keeping with Pombo's (2004a: 3) thinking, is related to "the inability we all have to go beyond our own discursive principles, theoretical perspectives and modes of functioning in which we have been trained, educated ".

Finally, we consider that, if we are willing to face our own formative limits and discourses, the IIR approach brings to the light of Science Teaching new ways of thinking about the knowledge taught, enabling discussions and ways of working on a given problem from stages, all adaptable to the reality of each class and levels of schooling, but with one objective: to carry out a given project at a time initially established. In making use of the interdisciplinarity in the teaching of Sciences by the IIR, and more specifically in the present application for the formation in physics, notably was acquired knowledge of other areas on the studied problem.

ACKNOWLEDGEMENT

To physics teachers in initial formation who agreed to cede their statements and recordings in audio and video to carry out this research.

³ Instituto de Química. Pontificia Universidad Católica de Valparaíso, Chile

This exploratory work analyzes five Chemistry Teaching-Learning sequences (TLS) designed by students enrolled in the Master of Science Teacher Training at five Catalan public universities during the 2015-16 academic year. The question guiding the research is: What are the characteristics of the contexts and how are they used in Chemistry TLSs designed by pre-service secondary science teachers? The analysis was oriented around three dimensions: (a) the extent towards activity titles are contextualized, (b) the types of contexts used in the activities of chemistry TLS, and (c) the characteristics and uses of contexts throughout the chemistry TLS. A content analysis of the TLS was performed through a process of progressive segmentation at the level of structure, activity and context. The results indicate that the TLS activity titles are mostly conceptual, and the contexts used within the activities are of a personal nature. Two levels of chemistry TLS have been identified in relation to the characteristics and uses of the contexts, based on the context criteria of authenticity, inquiry, construction, relevance and persistence.

Keywords: initial teacher education, teaching learning sequences, concept and context.

INTRODUCTION

This research focuses on the training of secondary science teachers learning to teach context based chemistry. Its objectives emerge from the difficulties secondary science teachers have in designing chemistry teaching and learning sequences (TLS) from a School Science perspective developed by (Izquierdo 2006; Caamaño 2011). This approach conceives science learning as a process that involves the development, evaluation and revision of models, explanations and theories of natural phenomena. Since the academic year 2009-10 Catalonia implemented a new Master of Secondary Teacher Training (2009-10) which represented a shift in the way to train secondary science teachers towards the promotion of context, inquiry and modeling based approaches to science education. Context-based science teaching is understood as a didactic approach that aims at linking the teaching and learning of science to real-world situation. This situation is used as a central structure to introduce scientific concepts as they are needed and thus develop a better understanding of the situation (Gilbert 2006, King and Richtie 2012). Chemistry education has supported context based chemistry teaching approaches as a way to help secondary students make sense of their learning, improve academic results and feel more attracted to chemistry (De Jong 2008; Parchmann et al. 2006). However, the design of context based TLS in chemistry that facilitates students’ construction of theoretical school science models represent an important challenge for both pre-service and in-service secondary science teachers. There is a need to consider the importance of context in the training of secondary
science teachers and to introduce the context as a necessary dimension when designing chemistry TLS.

The question addressed by this research is the following: What are the characteristics of the contexts and how are they used in Chemistry TLSs designed by pre-service secondary science teachers? Additionally, three sub questions emerge: a) How do the titles of the activities reflect a TLS of contextualized chemistry? b) What kind of contexts are used in the Chemistry TLS’s? and finally, c) What characteristics do the contexts used in the TLS of chemistry have? The present investigation is framed in a qualitative paradigm based on the analysis of texts (TLS).

METHODOLOGY

Selection of pre-service secondary science teachers’ Chemistry TLS

The participating universities included all five public universities in Catalonia offering the one year Master of Secondary Teacher Training program. Twenty-one chemistry TLS were collected during 2015-16 (Table 1) and one chemistry TLS was selected from each university to undertake an exploratory study. Of the TLS collected, one of each university was selected according to the following criteria: (a) existence of a structure in the SEA design, (b) presence of titles of both the TLS and the activities that comprise it, and (c) explicit presence of the activities that the student will develop.

Segmentation of Chemistry TLS

A content analysis of a selected sample of chemistry TLS designed by pre-service secondary science teachers was conducted (Weber 1990). Through a process of progressive segmentation
and the construction of a system of inductive-deductive categories, we proceed to assign meaning based on the activities of the TLS as a unit of analysis. To perform the analysis of the chemistry TLSs, we proceed to segment them into three dimensions: structure, activity and context.

a) The structural segmentation of each TLS is made from the allocation of three phases: beginning, middle and end. The start phase is usually located at the beginning of the TLS and includes those activities designed to present the subject of study, explore the students' previous ideas, and present the objectives of the TLS. The middle phase consists of all those activities designed to develop the competences identified in the objectives of the TLS by the students. Finally, the final phase is made up of all those activities that aim to apply the skills acquired by the students in the previous phase and thus close the TLS.

b) Segmentation by activities is characterized by the identification of the total number of activities that constitute each structural segment of the TLS and by the delimitation of the textual segments of the TLS associated with each activity.

c) Segmentation by context involves the identification of those textual fragments associated with a context within each of the activities identified in the segmentation by activity.

Selection and construction of categories

The selection and construction of categories for the analysis was adjusted to the three sub-questions of the research study as follows:

**TLS activity titles:** Often the title guides a lot about what the TLS will teach and the importance given to context if any. We will consider three categories of titles based on the work of Izquierdo (2005):

- **Conceptual titles,** reflecting the conceptual entities aiming to be taught;
- **Contextual titles,** using a problem or a phenomenon of life for its TLS or activity;
- **Rhetorical titles,** characterized by embellishing the expression of concepts through a language aiming at providing delight, persuasion or move giving written or spoken language the necessary effect to delight, persuade or move.

**Types of contexts:** To categorize the types of contexts that manifest themselves in each of the activities of a SEA, the 4 domains of contexts identified by De Jong (2008) have here been considered, which include the followings:

- The **personal context,** are contexts that make a connection between science and the personal life of the student.
- The **social context and society,** referred to the role of the student in a community and social issues.
- The **professional context** related to the student's career expectation.
- The **scientific-technological context** referred to scientific innovations and discoveries.
Characteristics and uses of contexts: It includes five criteria of a good context in a science TLS adapted from the Context-Based Teaching of Science Criteria developed by the LIEC group (Language and Science Teaching; www.cienciescontext.com) (Table 2).

<table>
<thead>
<tr>
<th>CONTEXT INDICATORS</th>
<th>Authent:</th>

<tbody>
<tr>
<td>Authentic</td>
<td>It raises a situation or a real or plausible problem, which may have meaning or interest for students (Psarros, 1998)</td>
<td>It is socially and personally relevant (or for their professional future) (Parchmann, 2006)</td>
<td>Is the initial context still present throughout the activities? Do these activities make sense in relation to the planned problem? (LIEC, Grup)</td>
<td>It encourages to ask questions and... Wanting to know more? Possible questions that can be valid (from science as well as from action) are specified. (Tamir, García, 1992)</td>
<td>It facilitates the construction of meaningful knowledge of and about science (Roca 2013)</td>
</tr>
</tbody>
</table>

A rubric was constructed to identify the degree of presence in each chemistry TLS of context indicators presented in Table 2. Each indicator was associated to three levels of presence: unsatisfactory (code 1), moderately satisfactory (code 2) and satisfactory (code 3). Table 3 shows the indicators and the meaning associated to each degree of presence. To apply the context indicators each TLS was partitioned in three structural parts (initial, intermediate and final) and a score for each context indicator was assigned to these three parts.

RESULTS

Contextualization of chemistry TLS Activity titles

The titles of the TLS activities selected by the teachers of science in initial training allow us to infer about the use they make of the contextualization in the designed activity. Table 1 shows the global title of each of the five TLSs of the sample and the number of activities included in each of them (between 10 and 30). A first reading of these titles indicates that none of the 5 TLS has a contextualized title that invites the resolution of a personal or socially situated problem.

The descriptive result of the analysis of the titles of the 79 activities that make up the sample of the 5 selected chemistry TLS is shown in the graph in Figure 1. While 85% of the activities have a conceptual title (eg "The density "," Representation of the states of matter "or" Conceptual map "), 10% of them have a rhetorical title (eg" Who is right? ";" Density ... is magic? "or" We know how it works? "). Only 5% of the activities show a contextual title (eg "El Náufrago", "The inheritance of Aunt Agata").

</table>

Figure 1. Titles of the activities of the chemical TLSs (n = 79 titles)
Types of contexts in Chemistry TLS activities

The contexts of the TLS are conveyed through the activities and are materialized from texts constructed with different modalities of the language normally the written one, from narratives of different lengths, or the visual one, from drawings or images. Of the 79 activities analyzed that correspond to the 5 SEA of chemistry designed by the teachers of science in initial training (Table 1) only 28 activities present contexts. These 28 activities present contexts of different typology as shown in the graph of Figure 2. 86% of the activities that use contexts develop them on a personal level which means that the activities have been designed so that the student makes connection between a punctual aspect of science with a particular situation of daily life. Examples of the personal contexts selected by the teachers in initial formation are: History of the Periodic Table, heartburn, oxidation of a bicycle, shipwreck. The activities that develop contexts of social type and society represent 14%.

Figure 2. Types of Contexts used in the activities of the chemical TLS (N = 28 activities)

Characteristics and uses of contexts in Chemistry TLS activities

Table 4 reports on the five chemistry TLS’ characteristics and uses of the contexts. Each TLS was partitioned in three parts (initial, intermediate and final) and a score for each context indicator was assigned to these three parts. These same data are also represented in a line graph shown in Figure 3.

Data collected in both Table 4 and Figure 3 indicate two groups of chemistry TLS in relation to the characteristics and uses of context. One group B and D TLS show a high contextual profile since the TLS perform the highest in most of the contextual indicators. The other group show a low contextual profile A, C y E since the TLS perform the lowest in most of the contextual indicators. The most problematic contextual indicator is Persistence since the scores assigned to the TLS in both profiles are homogenous and the scoring is very different.

**Figure 3. Characteristics and uses of the contexts in chemistry TLS designed by pre-service secondary science teachers from five Catalan universities**

**CONCLUSIONS**

The structures of the chemistry TLSs analyzed are diverse, indicating that there is no uniformity in the way pre-service secondary science teachers structure its design. The TLS activity titles chosen by the pre-service secondary science teachers are mostly conceptual, and the contexts used within the activities are of a personal nature in its majority. In relation to the characteristics and uses of the contexts in the chemistry TLS analyzed, it is worth highlighting the existence of two groups, one of a higher contextualized profile, consisting of two TLSs and one of the lower profile formed by three TLSs. Within the high contextual profile can be found chemistry TLS “D” that use authentic contexts (social, environmental and scientific) which are usually highly inquirer, constructor or relevant, and persists throughout the sequence. These TLS are student centered, allowing them to investigate, construct, reason and argue scientifically about a chemistry phenomenon. In the group of lower contextual profile can be found chemistry TLS “E” where pre-service secondary teachers select and sequence activity titles of a scholarly nature, and focus the goals on the presentation of a concept, the development of exercises, and in some cases the verification of theory through an experimental activity. The exploratory analysis points to the existence of a problem in the training of secondary science teachers in relation to the use of contexts in the design of chemistry TLS that are more authentic, constructive, inquiring, relevant and persistent throughout the TLS.

PROMOTION OF SYSTEM THINKING IN PRESERVICE BIOLOGY TEACHER EDUCATION

Doris Elster¹ and Nicklas Müller²

¹Institute of Biology Education, University of Bremen, Bremen, Germany
²Institute of Science Education, University of Bremen, Bremen, Germany

“INQUIRE for Teacher Students” is an innovative pre-service training course for teacher students of the Master of Education study program biology at the University of Bremen. The goal of the course is to promote inquiry-based science education (IBSE) in the field of biodiversity loss and climate change. Environmental problems are considered to be disease patterns in earth systems that can be investigated using the syndrome approach. This allows the reduction of complex global problems in distinct relations between earth elements in cause-and-effect interactions. As a problem-based environmental context the dramatically loss of the lobster population around the North Atlantic island Helgoland has been chosen. The teacher candidates of the University of Bremen (N=16) conduct an excursion to the island Helgoland. There they investigate the “Helgoland lobster syndrome” supported by science educators, geography educators and the researchers of the Alfred Wegener Institute of Helgoland. Based on their investigations they develop complex simulation games, conduct these activities with school classes of the secondary level and evaluate pupils’ learning. The evaluation of the course is based on various data sources: teacher candidates’ interviews (pre-post), syndrome approaches and concept maps. The findings demonstrate the high potential of the syndrome approach for the promotion of system thinking and subject knowledge in respect to a complex environmental problem.

Keywords: system thinking, syndrome approach, environmental education.

INTRODUCTION

The syndrome approach developed by the German Advisory Council on Global Change (WBGU) is a multidisciplinary analytic tool for identifying unsustainable developments and environmental problems in earth systems by considering them as disease patterns, the so-called “syndromes” of global change (WBGU, 1996). The syndrome approach aims in representing, reducing and returning complex environmental problems to distinct comprehensible relationships (Rempfler & Uphues, 2012). It focuses on the ecological, socio-cultural, and economic dimensions and their interactions in order to foster sustainable development.

Although the new biology and geography curricula reforms in Germany have made explicit the call for teaching system thinking in the science classroom (KMK, 2004; DGfG, 2014) the promotion of appropriate training programs for prospective biology teachers are of minor importance. Therefore, little is known about the impact of specific pre-service teacher training programs in respect to the system competences of teacher candidates and their ability to identify and analyze complex, global (and local) relations and interactions.

This study investigates the impact of the practical course “INQUIRE for Teacher Students” on teacher candidates’ content knowledge and system thinking based on the syndrome approach.
THEORETICAL FRAME

Climate Change and Biodiversity Loss are one of the key issues of Global Change (WBGU, 1996, p.116). They are driven by global transformation processes, which exert profound mutual influences upon each other, unfolding at multiple different scales. The inextricable link between the environment and development plays a central role. Humans and their environment form a tightly intertwined system (Engelhard et al., 2009): “In general, Global Change relates to variations in the key parameters of the Earth’s system [...], the reduction of strategic natural resources, the shift and transformation of large-scale structures and patterns, and the alteration of large-scale processes” (Brand & Reusswig, 2007).

The principle of sustainable development (SD) provides an answer to the challenges of Global Change (Stoltenberg, 2010). SD is based on the simple idea that the earth should be developed into a better and healthier system. To achieve this, we must consider interrelated natural and anthropogenic factors from the perspective of intra- and intergenerational fairness (Hauff & Kleine, 2009). Ecological equilibrium of the earth’s system can only be achieved if economic security and social justice are pursued in equal measure (Cassel-Gintz & Bahr, 2008).

The syndrome approach as a tool for analyzing complex problems

The syndrome approach developed by the German Advisory Council on Global Change (WBGU) is based on the principle of sustainable development (WBGU, 1996). Syndrome analysis may be viewed as a conceptual answer to the transversal character of the problems associated with Global Change. The objective is to understand the interactions between changes in the natural environment and problems associated with development. Based on the findings of syndrome analysis, opportunities for early recognition and prognosis and problem-solving strategies can be derived or developed (Pilardeaux, 1997). Syndromes show us the fundamental mistakes that we should avoid on our path towards sustainable development (Cassel-Gintz & Bahr, 2008). The approach is based on the premise that global environmental and development topics can be reduced to more easily understandable relationships connecting environmental degradation trends (WBGU, 1996). Thus, syndromes are patterns of problematic human-environment relationships, represented in the form of relations between the natural and anthropogenic spheres of the earth’s system (Lauströer & Rost, 2008). The approach can be divided into the two dimensions of analysis and action: after deriving a syndrome-relationship framework from the reinforcing and inhibiting interactions between regional and global trends, research priorities can be defined with the ultimate objective of developing sustainable measures to regulate the syndrome (WBGU, 1996).

The Helgoland Lobster Syndrome

The European lobster (*Homarus gammarus*) is one of the heraldic animals of Helgoland, an island in the North Sea. In former days the lobster fishing was one of the main income sources of the Helgoland inhabitants. Since the 2nd World War the lobster population has dramatically decreased, nowadays the lobster is in danger of extinction.

The development of the “lobster syndrome” (see Figure 1) comprises the following steps: Based on a broad literature analysis system elements are identified and a network of
interconnections of these elements determined. The network consists of six spheres: pedosphere, biosphere, hydrosphere, atmosphere, population and social aspects and, and economy and politics. For the specific analysis of the problem, the key issues of global change “climate change”, “biodiversity loss” and “depletion and pollution of the oceans” are integrated.

In the next step the natural and socio-economic factors of disposition are determined. In respect of the “lobster syndrome” the nature of soil is of great importance as the Helgoland lobster can only live in the cliffy wadden sea. Lobsters are specialists and cannot change their habitat (like fish) if the environmental conditions (e.g. temperature, salinity, or competition) are changing. Especially the overfishing after the 2nd World War, the bombing of Helgoland, and the pollution of the North Sea by shipping traffic, oil platforms, and tourism are possible hindering factors for the constantly decrease of the Helgoland lobsters. Supporting factors for the survival of the heraldic animals of Helgoland is the resettlement program of the Alfred-Wegener-Institute of Helgoland and the tripod of the off-shore wind-parks, where resettlement is possible.

For the analysis of a complex syndrome factual knowledge is not enough (Frischknecht-Tobler, et al., 2008). There is an increased call for promoting system thinking skills when teaching biology and geography (Rieß & Mischo, 2008). In addition, approaches based on system skills have attracted an increasing amount of attention in discussions about educational standards and competency models. The reasons therefore are diverse. In the view of biologists living creatures are remarkable multi-dimensional, and are themselves components of complex systems of populations, ecosystems, and of the biosphere (Campell & Reece, 2003). Animate and inanimate systems are less predictable and cannot be fully controlled by humans. However, humans are able to analyze, influence and even to disturb them (Rieß & Mischo, 2008).

THE INQUIRE COURSE

“INQUIRE for Teacher Students” is a course in the study program Master of Education Biology at the University Bremen. It is based on the European project INQUIRE - Inquiry-based teacher training for a sustainable future (Elster, 2013). In 2015/16 the INQUIRE course took part at the island Helgoland. Goal was the development of IBSE based simulation games in the context of the dramatically decline of the Helgoland lobster (see Figure 2).

- Module 1. Investigation of the ecological background supported by scientists of the Alfred-Wegener-Institute Helgoland and science educators. To gather information about the socio-cultural background, the economic issues (fishery, tourism) and the historical and political development of Helgoland, the teacher candidates interviewed the local inhabitants and visited museums.
- Module 2. Supported by the science educators the teacher candidates conducted IBSE activities and developed the simulation games for the school classes.
- Module 3. The teacher candidates conducted the simulation games with school classes. They evaluated the pupils’ learning outcome. In addition, they reflected on the own professional development and PCK.
Figure 1. Expert syndrome approach (© Müller)
RESEARCH QUESTIONS

The research questions are about: 1) teacher candidates’ content knowledge in respect to the “Lobster syndrome”; 2) teacher candidates´ system thinking based on the syndrome approach (system-related analysis, system organization, system behavior); 3) the self-estimation of teacher candidates in respect to their system competence and working with the syndrome approach.

METHODS OF DATA SELECTION AND ANALYSIS

Sixteen teacher candidates (twelve females, four males) – all of them in the 7th or 9th semester of their pre-service teacher education program (Master of Education for Gymnasium and Oberschule) participate in the INQUIRE course. All of them are studying biology as the first subject.

The methods of data collection are partner interviews with always two teacher candidates (N=16), and the development of concept maps (in teams) and syndrome approaches (in groups of eight participants) in a pre-post-design. In addition the developed materials and simulation games form a further data basis. For the data analysis qualitative and quantitative processes were considered separately.

The interview transcripts are analyzed based on the paradigm of the qualitative content analysis (Mayring, 2010). This allows the building of deductive and inductive categories. The interrater reliability is determined by the Cohen’s-Kappa-coefficient (in average 0,8ĸ). Aggregate scores are calculated for the subject knowledge in respect to biodiversity, climate change, and the interconnection of biodiversity loss and climate change.

The concept maps are analyzed according to their basal structure (Kinchin, Hay & Adams, 2000), the scope and the quantitative interconnectedness (Rempfler, 2010), and qualitatively with the relation scoring method (Clausen & Christian, 2012). The analysis of the basal
structure allows insights in the cognitive thinking of the participants (Clausen & Christian, 2012). The way of connectedness (spoke is mono-causal, chain is linear, net is complex) correlates to the levels of the competence model of Rempfler et al. (2012).

The structural complexity of the syndrome approaches are determined by means of three indices: The scope (U) according to Sommer (2005), the interconnectedness index (VX) according to Ossimitz (2000), and the structure index (SX) according to Bollmann-Zuberbühler (2008). To evaluate the syndrome approaches qualitatively the relational scoring method (Clausen & Christian, 2012) was used.

**FINDINGS**

**Impact of the INQUIRE course on teacher candidates’ content knowledge**

Based on the results of the interviews a distinctive body of prior content knowledge about the consequences of climate change and its influence on the biodiversity was identified. To measure the impact of the INQUIRE course five questions were analyzed (pre-post interview). The questions were about the endangerment of the Helgoland lobster, the attitudes towards the protection initiatives (e.g. of the Alfred-Wegener-Institute), the concurrence with other species (e.g. bio-invasive crabs), the attitudes towards offshore wind parks in the North Sea (e.g. for resettlement of the Helgoland lobster), and the interaction of carbon dioxide emission and the ocean (e.g. acidification). The results demonstrate a high significant increase of syndrome specific subject knowledge (see Figure 3).

![Figure 3. Score of context-specific knowledge of teacher candidates (n=16) in pre-interviews and post-interviews (possible total score: 26) based on five interview questions about context-specific subject knowledge.](image)

**Impact of the INQUIRE course on teacher candidates’ system competence**

The development of the participants’ system competence is analyzed based on the concept-maps developed during the pre-post interviews, and on the syndrome approaches (developed and completed during the ship passage to and from Helgoland).
**Analysis of the concept maps**

The analysis of the basic structure of the concept maps demonstrates the increase of complex structures (pre-interview: two spoke structures, two chain structures, four net structures; post-interview: eight net structures, one chain structure).

The quantitative analysis of the concept maps comprises the scope (U) according to Sommer (2005), the interconnectedness index (VX) according to Ossimitz (2000), and the structure index (SX) according to Bollermann-Zuberbühler (2008). The data show a high significant increase in the scope (all participant teams) and in the VX (seven from nine duos). There is no increase in SX. Table 1 gives an overview about the findings in respect to the indices U and VX.

Table 1. Analysis of the pre-post concept maps. U = scope, VX = interconnectedness index. Master map see Figure 3.

The qualitative analysis of the concept maps is based on the Relational Scoring Method (Clausen & Christian, 2012). The findings demonstrate an increase of the average means of the total score (n=16) from 29.3 (SD 9.1) to 65.3 (SD 2.1). That demonstrates that the INQUIRE course successful in the promotion of the system thinking.

**Analysis of the syndrome approaches**

During their ship passage to and from the island Helgoland (the duration of the passage is about three hours) the teacher developed in teams (duos) syndrome approaches to the Helgoland lobster syndrome (The master syndrome network is presented in Figure 1). We recognized that the average scope (U) of the syndrome approaches is higher than the scope of the concept maps. The mean of the pre-syndrome nets is 54.3, of the post-syndrome nets 100.1. The number of elements increase not so much as the number of relations (pre-mean 15.7 to post-mean 54.1). The comparison with the master syndrome network (see Figure 1) shows that the post-syndrome networks converge to the master map in its complexity. Table 2 shows the indices for scope, interconnection, and structure of the participants’ syndrome approaches.
Table 2. Analysis of the pre-post syndrome networks. U = scope, VX = interconnectedness index, SX = structure index. Master syndrome network see Figure 1.

Impact of the INQUIRE course on teacher candidates´ system thinking

The teacher candidates were asked about the self-estimation of their competences in respect to their system thinking and working with the syndrome approach by ticking a box within a 5-point-Likert scale (not informed – expert). The results demonstrate an change from mostly not informed and beginners to advanced (see Figure 4).

![Teacher candidates’ self-estimation](image)

Figure 4. Self estimation of teacher candidates in respect to their system competence and knowledge about the syndrome approach (n = 16).
DISCUSSION

The findings demonstrate the high potential of the INQUIRE course for the development of teacher candidates’ system competence and PCK in respect to teaching system thinking based on the syndrome approach. System competence can be trained with appropriate learning activities such as the simulation games. We can confirm former research results that show a direct correlation between the learner’s subject knowledge and the system competence (Ossimitz, 2000; Sommer, 2005). In this context the visualisation of the flow path and graphic representations of complex interconnections are of great importance (Sommer, 2005; Rempfler, 2010). The syndrome approach and simulation games can motivate the teacher candidates as well as the pupils for a highly networked view of earth systems.

In discussions about the applicability of the syndrome approach to the context of schools, the potential for providing a systemic representation of complex human-environment systems is often quoted (Cassel-Gintz & Bahr, 2008; Krings, 2013). Since research findings have shown that a certain time investment is required before interventions can measurably influence the system skills of pupils (Rempfler & Uphues, 2012), more long-term and in-depth studies of the syndrome method in schools as well as in teacher education programs would be beneficial.

ACKNOWLEDGEMENT

We thank the Foundation of the University Bremen and the Alfred-Wegener-Institute in Helgoland for funding and support.

RETHINKING LESSON PLANNING –
USING VIDEO VIGNETTES AS CASES
IN E-LEARNING SCENARIOS

Sarah Dannemann
Institute for Science Education, Biology Education, Hannover, Germany

Teachers have to deal with different and very complex situations in everyday practice often without having much time to think about adequate (re)actions. How adequate they act depends on their scientific, pedagogical, and educational theoretical knowledge but also on the repertoire of possible actions they know. Therefore, teacher education needs to provide learning opportunities to experience different learning situations, to reflect on them from the different domain-specific perspectives, and to try out various actions. In science education, students’ conceptions are seen as essential for fruitful learning processes in the context of different theoretical frameworks as constructivism, cognitive linguistics, or conceptual change approaches. If pre-service and even in-service teachers are asked to design learning activities, many of them do not reflect on students’ conceptions. They focus on scientific facts that are often classified as true and the teacher’s activities. In order to support the pre-service teachers’ understanding, we designed and evaluated case-based learning scenarios for science teacher education. A video vignette gives them access to typical students’ conceptions on biological topics. The model of educational reconstruction offered structural guidance and links to relevant theoretical aspects. To evaluate the learning processes 16 bachelor (n = 10) and master (n = 6) pre-service teachers were videotaped. Their performance and their task solutions were analysed using qualitative content analysis and metaphor analysis. The results have shown the learning scenarios as a promising tool to support rethinking processes of theoretical aspects as well as changes in the pre-service teachers’ practice. While bachelor pre-service teachers primarily reconstructed their attitudes and their knowledge, the master pre-service teachers were also able to scale up their diagnostic and design performances.

Keywords: lesson planning abilities, case-based learning, video vignettes

INTRODUCTION

Teachers have to deal with various and very complex situations in everyday practice often without having much time to think about adequate (re)actions. How adequate they act depends on their scientific, pedagogical, and educational theoretical knowledge but also on the repertoire of possible actions they know. These domains are seen as essential in many models of teacher professionalism. Therefore, teacher education needs to provide learning opportunities to experience different learning situations, to reflect on them from the different domain-specific perspectives, and to try out various actions. Looking at the key factors of effective teaching-learning processes individual students’ conceptions have been identified, especially in science education.
UNDERSTANDING THE ROLE OF STUDENTS’ CONCEPTIONS – A CHALLENGE OF TEACHER EDUCATION

For more than 40 years, students’ conceptions have been intensely investigated in science education. They are described for nearly all core subjects of biology to this day. Evidence shows that students’ conceptions need to be considered in class in order to initiate fruitful learning processes (Duit, 1995; Duit, Gropengießer, Kattmann, Komorek, & Parchmann, 2012). Therefore, integrating students’ conceptions in lesson planning is seen as a crucial part of teacher professionalism (e.g. Shulman, 1986; Abell, 2008). Students’ conceptions are often subject of university curricula for science teacher education. Several core skills are addressed frequently: Pre-service teachers ought to know typical students’ conceptions, they should be able to apply methods to not only diagnose students’ conceptions, but also to exploit the learning opportunities these offer. On the other hand it is important to respond to the learning difficulties that occur from everyday conceptions (Reinfried, Mathis, & Kattmann, 2009).

In contrast to this research evidence, students’ conceptions are still not influencing school practice enough (Abell, 2007; 2008). If pre-service teachers are asked to design learning activities, many of them do not consider students’ conceptions. They focus on scientific facts that are classified as true and on the teacher’s actions (Dannemann, Niebert, Affeldt, & Gropengießer, 2014). Many pre-service and in-service teachers lack knowledge of typical students’ conceptions – actually, they often have the same everyday conceptions as their students (Wandersee, Mintzes, & Novak, 1994). Furthermore, some teachers judge students’ conceptions as less or not important for education. Many pre- and in-service teachers classify students’ answers as incorrect or wrong and give feedback accordingly (Aufschnaiter, Alonzo & Kim, 2015; Morrison & Lederman, 2003). Due to this dichotomous thinking, they do not recognize the learning potential of the “wrong” answers for the design of learning processes. They do not mention them as starting points and mental tools for learning (Driver & Easley, 1978). However, even if teachers know about the importance of students’ conceptions for learning processes they lack possibilities to diagnose them or to refer to them in class (Abell, 2007; 2008; Borko 2004; Larkin, 2012).

Referring to this situation, case-based learning scenarios for pre-service science teacher education with video vignettes as core medium were designed and evaluated. They are supplemented with context documents and theoretical as well as methodological information. The pre-service teachers are asked to design learning activities for the students shown in the video vignette. The model of educational reconstruction is used as structural guidance for planning processes. In order to enhance the pre-service teachers’ understanding and handling of students’ conceptions in educational design processes, the scenarios aim at three different dimensions due to the current state of research: attitudes, knowledge, and performance.

THEORETICAL FRAMEWORK

Case-based learning

The learning scenarios are designed as cases. Case-based learning has been used in teacher education for more than 20 years, mainly for pedagogical issues (Koc, Peker, & Osmanoglu,
Two main reasons are assigned: On the one hand, case-based learning proceeds analogically to problem-based learning. Therefore, it is very useful for ill-structured and complex demands like school practice (Zumbach, Haider, & Mandl, 2008). On the other hand, case-based learning is seen as a possibility to bridge the gap between theory and practice (Merseth, 1991). Therefore, a long-term effect of case-based learning is that teachers are able to use and to enhance their knowledge and their performance in future situations (Aamondt & Plaza, 1994). To reach these aims the cases have to meet different general criteria: Many studies point out that an authentic situation is highly important (Merseth, 1991).

**Video vignettes**

Video vignettes are used as core components of the cases. They combine short sequences of a situation and allow an authentic, context-specific, and motivating approach to topics that are relevant for teaching-learning situations (Sherin, 2004). Many video vignettes show typical or problematic classroom situations and focus on general educational aspects. Therefore, they often focus on the teacher (Janik, Minariková & Najvar, 2013). In the current German “Qualitätsoffensive Lehrerbildung” (i. e. “Quality Campaign for Teacher Education”) many projects address this tool in order to reflect on school practice in university courses or to assess pre-service teachers’ competencies.

**The model of educational reconstruction**

To structure design processes for learning activities the model of educational reconstruction was developed (Duit et al., 2012). In this study, the model is adapted focusing on the topic-specific cognitive construct of students’ conceptions in lesson planning (Figure 1). The analytical process consists of three interacting tasks:

1) diagnosing the individual learning potentials, in this study we focus on the central topic-specific students’ conceptions,
2) critically analysing and clarifying the scientific understanding in order to reconstruct the scientific key conceptions, they can serve as basis for the topic-oriented goals of learning,
3) designing learning activities using the results of the other parts.

![Figure 1. The model of educational reconstruction structures design processes of learning activities based on bringing together students' and scientific conceptions](image)
All tasks are linked to each other and performed recursively. The scientific and the students’ key conceptions both are seen as equally important bases when it comes to design learning activities. Students’ conceptions should not be understood as obstacles for learning – a closer look shows links for learning and science-oriented conceptions as well. Therefore, a differentiated diagnosis of students’ conceptions is a central ability of teachers. On the other hand, the scientific conceptions are not judged as “true” – they are seen as the current accepted explanation (Duit et al., 2012). Learning processes need to be reconstructed from an educational perspective. In contrast to Duit et al. (2012), the construction of the cognitive learning goals is here seen as a result of the scientific clarifying process.

In this study, the model of educational reconstruction is also used to structure the pre-service teachers’ learning processes. The individual learning potentials of the pre-service teachers were diagnosed while they worked on the first case. For example we analysed their understanding of teaching-learning processes. The results were compared with educational conceptions and learning activities for the following cases were designed relating to this.

**Embodied cognition and conceptual metaphor theory**

As theoretical framework of the analyses of the students’ and the pre-service teachers’ understanding the theory of embodied cognition was used (Lakoff and Johnson, 1980). Its main assumption is that specific biological phenomena are understood in terms of embodied conceptions. In many cases these explanations are not scientific, but everyday explanations. However, they are meaningful and satisfactory in everyday life. One well known everyday conception is the idea of two or many separated blood circulations in our body: the pulmonary and the systemic circuit (Riemeier et al. 2010). In contrast, biological explanations are often counterintuitive: That the function of our extensive blood vessel system can only be understood as one circulation that links the lung with all cells is hard to imagine. Metaphors as the circulation schema in this case can help us to make sense of abstract and complex biological phenomena. To construct scientifically adequate explanations students need to gain scientific experience and reflect on their everyday explanations. Therefore, the theory of embodied cognition allows for the analysis of understandings and the justification of learning activities and methods (Niebert, Riemeier, & Gropengießer, 2013).

**KEY OBJECTIVES**

We wanted to find out if case-based learning supports pre-service teachers’ diagnostic and design abilities:

- What do the pre-service teachers learn while working with the cases-based learning scenarios focusing on their attitudes, knowledge, and performance referring to students’ conceptions and educational design strategies?
- Are video vignettes helpful tools to initiate the intended learning processes? Which criteria are relevant for determining quality to reach our specific aims?

**DESIGN OF THE CASE-BASED LEARNING PROCESS**

To support the pre-service teachers’ planning abilities we designed a blended-learning course
that consists of a number of cases dealing with different biological phenomena such as blood circulation, nutrition, growth, evolution, microbial spoilage or photosynthesis. The pre-service teachers work individually or together in small groups. The single cases are designed differently due to various purposes:

*Diagnostic case:* The first case consists of the video vignette and context documents (transcript, information on the students and the curriculum). It is used to diagnose the pre-service teachers' individual understanding of planning processes and their performance. Therefore, we ask them to design learning activities for the students in the video vignette.

*Learning cases:* The following case(s) are used to support the pre-service teachers according to their diagnosed learning needs. Often two cases are needed to allow them to reconstruct their own perspectives on learning, their knowledge about the model of educational reconstruction, and diagnostic methods, and even their performance of these tasks. To foster their learning we give them detailed tasks, theoretical and methodological information, and assistance if needed. Subsequently, their proceeding is reflected with a tutor.

*Training cases:* The pre-service teachers have the opportunity to work out other cases that are available on an e-learning platform. They can upload their solution and get double feedback, first from an exemplary solution that is sent to them, and second they can discuss their solutions with a tutor.

**METHODS**

The learning processes of bachelor and master pre-service teachers (N = 16) were videotaped. Their performance and the task solutions were analysed using qualitative content analysis (Gropengießer, 2005) and metaphor analysis (Schmitt, 2005). On the one hand, the coding categories were developed deductively from the theoretic background. On the other hand, they were supplemented by inductive categories that were derived in the analytical process. In this article the focus lies on the perspectives of teaching-learning processes and students’ conceptions. Their analysed learning processes are linked to the learning activities. The following results consist of some of the pre-service teachers’ statements that can serve as anchor citations.

**RESULTS & DISCUSSION**

The development of the pre-service teachers’ attitudes, knowledge, and performance in lesson planning while working on the case-based learning scenarios

*Pre-service teachers’ lesson planning process while working on the first case*

The analysis of the pre-service teachers’ statements (N = 16) before working on the first case shows that they judge students’ conceptions solely as obstacles of learning (Figure 2). Nora and Lara can serve as a typical example for most of the bachelor students (n = 10). Nora states on her performance: “I noted strange aspects or deficits of the student’s thinking.” Nora and her fellow student Lara laugh while watching the video vignette. They write down some students’ statements that they judge as “highly problematic”. A second view of the video vignette or the transcript is rejected. To design learning activities Nora and Lara look through
existing material in scientific textbooks, schoolbooks, or the Internet. They choose material that they judge as scientifically correct, motivating, or well known due to their own school time. All pre-service teachers put the main emphasis on science content in designing teaching activities. Many of the bachelor pre-service teachers used the school- and scientific textbooks uncritically, even if problematic representations were used like the double circulation that was mentioned above: “Double circulation – A circulatory system consisting of separate pulmonary and systemic circuits, in which blood passes through the heart after completing each circuit.” (Reece & Campbell 2011, 11). If the pre-service teachers reflect on reasons for the students’ performance, Mark stated: “If many students do not know this the teacher failed. He didn’t explain it correctly.” This has shown up to be a typical explanation when the pre-service teachers are informed that the students already dealt with the topic in class.

Comparing both sides of Figure 2 emphasizes the pre-service teachers’ learning needs in detail: They do not consider the students’ learning potentials as being important for designing learning activities – even if they are planning for these students. This is in contrast with the constructivist theories that consider learning processes mainly as active processes of the students. The second difference is about the judgment of scientific textbooks. Pre-service teachers regard them basically as correct and, therefore, as material for teaching that can remain nearly unchanged. The theory of embodied cognition points out that they need to be reconstructed consequently from an educational perspective.

![Figure 2. Comparison of the everyday and the elaborated model of pre-service teachers’ design processes of learning activities.](image)

Pre-service teachers’ lesson planning while working on the following cases

Looking at Nora’s and Lara’s planning abilities while working on the third case some differences occur, Nora explains her performance: “It is important to find out the current level...
of the students, what they think, in order to enhance them in a scientific direction.” Nora and Lara watch the video vignette several times and formulate many concepts. They try to classify them as fostering or hindering for learning whereat they often act insecurely. Their classification tends to be inadequate sometimes from a biological perspective. Three groups used provided research articles or compilations of typical students’ conceptions (e. g. Kattmann, 2015) to ease this process. When it comes to designing learning activities, they explicitly refer to some of the diagnosed students’ conceptions but not in a systematic way. Concerning this aspect, the main difference between the bachelor and the master pre-service teachers occurred: the latter are more capable in structuring their lesson planning processes oriented at the model of educational reconstruction and bring together systematically the scientific and the students’ perspectives. They evaluate the model of educational reconstruction as follows: “It is very helpful. We are forced to bring together several layers. First, the students’ perspectives, second, our own perspectives, third, the scientific perspective. Step by step. And then we bring them all together.” (Marleen).

The results show that learning progressions concerning the pre-service teachers’ attitudes, knowledge, and performances took place. The attitudes comprise the perspective on education and, consequently, on the teacher’s performance and the students’ understanding processes. At the beginning, many pre-service teachers think teacher-centred (left side of Figure 2). While working on the cases, the teacher-centred perspective is supplemented by the perspective on the students’ understanding. The perspective on being a teacher also changes: now it is seen as providing learning opportunities. This reconstruction of the perspective on teaching-learning processes tends to be challenging for one pre-service teacher. Even in the third case Marina reflects on this aspect: “The teacher never says it like it is. How should the students know what is right? Just learning material – this is not teaching.” She was in doubt about the sense of the whole learning scenario. Her most frequent argument was that she would have never time enough to perform a diagnosis of the students’ conceptions in daily school practice and to allow them to reflect on their thinking.

The pre-service teachers improve their knowledge on diagnosing students’ conceptions referring to the latter in learning activities. But for many pre-service teachers it is hard to differentiate between scientifically adequate and inadequate conceptions. In six of eight groups the pre-service teachers themselves have everyday conceptions on the topic or were insecure concerning the scientific concept. Some of them also reflect on their perspective on scientific texts and develop a critical disposition from an educational perspective. Furthermore, master pre-service teachers also reconstruct their performance. In many cases the designed learning activities focus on a conceptual reconstruction from the students’ everyday to scientific conceptions. In these cases the model of educational reconstruction offers a helpful structure. In one group the master students begin to discuss further implications of knowing about typical students’ conceptions: “Students’ problems of understanding phenomena are also important to justify the content of instruction and curricula” (Luise). They reflect critically on conclusions on the systemic levels of school, which is a very promising attitude from the perspective of teacher education.
Design criteria of video vignettes for rethinking the role of students’ conceptions in lesson planning

Video vignettes are used as material to scale-up professional development in various ways and with various goals. In this research project they serve as cases. In this chapter, the design criteria are collected that have proven to be decisive for pre-service teachers’ learning processes.

Compared to many case studies that concentrate on multiple perspectives on classroom situations (Merseth, 1991), our video vignettes focus on students’ understanding. Therefore, the video vignettes include short sections of an interview with one or two students about a biological phenomenon. These sections are key scenes that were taken from a longer interview. The interviews ended with an instructional phase. The video vignettes have a dual purpose: 1) they allow the analysis of typical students’ conceptions for different biological topics (status diagnosis) and 2) the diagnosis of learning processes (process diagnoses). Due to these specific goals, the video vignettes have to meet different quality criteria concerning their conceptual and analytical potential (Table 1). We derived them from literature, the analyses of the pre-service teachers’ statements and of expert interviews. The video vignette has to enable pre-service teachers to interpret typical students’ conceptions. Therefore, the most important criteria are an authentic impact and a complexity reduction. The latter has shown to be the crucial condition to make the construct of students’ conceptions accessible for analysis. To reach authenticity the interview atmosphere has to be pleasant to enhance the student’s motivation and to enable him or her to act independently. Both aspect have been described in general but not for the construct of students’ conceptions (e.g. Olson, Bruxvoort & Vande Haar, 2016). The chosen key sequences shall allow an interpretation of the student’s explanation, i.e. they have to be meaningful. This criterion is tested by comparing the conceptions with literature and by discussing the single analyses of biology educators (n = 4). It is also discussed if the video vignettes allow to reflect on theoretically and empirically described characteristics of the construct of students’ conceptions (coherent). These aspects ensure that the video vignette is readable for the pre-service teachers. The representational dimension describes supportive aspects that have been described before (e.g. Blomberg et al., 2013). As the introducing statement shows, it is very helpful for the pre-service teachers to deal with the teaching-learning situations without any need to act immediately.

1888
CONCLUSION

The results of the case study with bachelor and master pre-service teachers (N = 16) indicate that the learning scenarios are a promising tool to address pre-service teachers’ attitudes, knowledge, and performances on the process of lesson planning referring to students’ conceptions. Looking closer at the relationship of these three parts of the overall planning ability, the perspective on students as important parts of teaching-learning processes can be described as a condition for the reconstruction of the other parts. While bachelor pre-service teachers primarily reconstructed their own attitudes and their knowledge on students’ conceptions, master pre-service teachers were also able to scale up their diagnostic and design performances oriented at the model of educational reconstruction. Significant difficulties of the pre-service teachers are a justified differentiation between scientific adequate and inadequate conceptions and, therefore, the ability to assess the students’ learning potential and to address this accordingly in learning activities. The orientation at the model of educational reconstruction also leads to a gratifying side effect as the pre-service teachers include research results on students’ conceptions in their planning processes in all later case processing. From the perspective of a teacher educator, this model is one option to realise a research based lesson planning. This is also an indication for a successful link between theory and practice, i.e. research on students’ conceptions, and the pre-service teachers planning practice.

The results are in line with the findings of other studies. Shulman (1987) describes that the way teachers think about teaching-learning processes is an essential part of their pedagogical content knowledge (PCK). Alonzo & Kim (2015) confirmed this empirically. The results of this study provide that the pre-service teachers understanding of teaching-learning processes could be a condition for the reconstructions of knowledge and performance. As just one student (Marina) did not receive a constructivist perspective on learning processes further research is needed. At the first case processing all pre-service teachers classified students’ answers dichotomous in correct or wrong (comp. Aufschnaiter, 2015; Morrison & Lederman, 2003). This perspective on students’ conceptions may be seen as a typical teachers’ conception. While the case-based learning process all pre-service teachers begin to reconstruct this estimation. An important impulse for this rethinking was the information that the students in the video vignettes already had dealt with the topic in class. In empirical studies, it has been described for several times that the development of PCK depends on the biological understanding (CK) (Rollnick, Bennett, Rhemtula, Dharsey & Ndlovu, 2008; van Driel, Verloop & de Vos 1998; Veal & MaKinster 1999). The results of this study support this relation and account for biological understanding as decisive for diagnostic and lesson planning abilities.

The model of educational reconstruction has been discussed as both a model for planning learning activities for subject matter and for designing teacher professional education settings – but an application was emphasised as missing (Duit et al., 2012). The results of this study indicate that it provides a helpful structure for both tasks: The pre-service teachers who scale up their performance use the model as orientation. Their statements and their performance show that the structure of the MER establishes students’ conceptions as essential parts of planning processes.
The analyses of the pre-service teachers learning processes give empirical hints on some design criteria to develop video vignettes for addressing diagnostic and planning abilities. Most important is that the video vignettes are complexity reduced. They have to make students’ understanding and learning processes visible. In classroom situations, these educational aspects are often covered by e. g. social or pedagogical aspects. The compiled design criteria offer a basis for further developmental studies and research on video vignettes for educational constructs like students’ conceptions.

The case-based learning approach for teacher education is transferrable to other subjects. But it could also be transferred to other science educational themes, such as students’ thinking and performance in doing scientific work or the nature of science. At the Leibniz University in Hannover, case-based learning activities are currently integrated in the university curriculum for science education.

ACKNOWLEDGEMENT
This study is part of the project „Theoria cum praxi. Förderung von Reflektierter Handlungsfähigkeit als Leibniz-Prinzip der Lehrerbildung“ at the Leibniz University of Hannover. It was funded by the Bundesministeriums für Bildung und Forschung (funding code: 01JA1506).

HOW PRIMARY SCHOOL PRE-SERVICE TEACHERS CONSTRUCT AN EDUCATIONAL PROJECT ON A COMPLEX SUBJECT: THE THEME OF TIME

³ Primary School, Comprehensive Institute of Faedis, Udine, Italy

A short formative module on the theme of Time was proposed in meta-knowledge and experiential modalities to a class of Italian prospective primary school teachers. Time was chosen as a multidisciplinary and complex subject since it is a fundamental concept which allows to construct a bridge between common sense and scientific knowledge. Using a rubric developed by the Udine research unit we investigated how pre-service teachers use the proposed elements on the concept of Time to construct an educational project and how they collect and organize the on-fly suggestions received in the context of a specific situation. A marked tendency towards classification and the need to work on the logical connections among concepts are the main interesting indications of this study.

Keywords: prospective primary school teachers, physics education research

INTRODUCTION

Pre-service teachers education arose the interest and work of many researchers in the last twenty years (Pintò 2001, Michelini 2004, WCPE 2014). The Green Paper on Teacher Education in Europe (Buckberger, et al. 2000) recognizes the importance of developing teachers’ skills in constructing educational projects in spite of a limited disciplinary knowledge.

This is particularly challenging in the case of Physics education for Primary School prospective teachers (PPTs). The EU project STEPS-TWO (STEPS 2011) highlighted that there are two models for teacher education in Europe, in which disciplinary and pedagogical aspects are faced either in sequence or in parallel, but always separately. A fundamental contribution was given in this field by Shulman (Shulman, 1986), who funded the concept of Pedagogical Content Knowledge (PCK) and focussed his attention on how the teacher learns, transforms the learnt content into a content to be taught and projects a didatic path about a subject learnt for the first time. In this perspective, innovative educational proposals have been developed based on three main models: Metacultural, Experiential and Situated (Michelini 2004, 2012).

Nonetheless, the issue of a transversal educational approach that offers the opportunity to construct the epistemological bases, in order both to develop the professional competence necessary to re-elaborate a limited, although epistemologically-based, knowledge and to change the learning contexts, is still open.

In this work we studied how future Primary School teachers construct an educational project on the theme of Time, after a short formative module performed in meta-knowledge and experiential modalities. Rubrics were built in order to monitor the identification of key concepts and conceptual knots and, at the same time, to investigate the ways in which PPTs
translate these elements into a rationale that, starting from the identification of the conceptual elements, leads to organize didactic proposals on a naturally transversal theme, such as the theme of Time, which offers different perspectives of discussion and analysis, also in the scientific context. In fact, Time is a multidisciplinary and complex subject as well as a fundamental concept, and, since it is part of anybody experience, it allows to construct a bridge between common sense and scientific knowledge, which is one of the main objectives indicated by the research literature on scientific learning processes (Michelini 2006).

METHOD

A short formative module on the theme of Time was proposed to 21 prospective primary school teachers at the third year of the combined Bachelor + Master Degree Course in “Primary School Education” at the University of Verona in Italy. The intervention included two phases performed in meta-knowledge (two hours) and experiential (one hour) modality, respectively. The first phase was developed as a lecture in which the theme of Time was presented in a multidisciplinary approach inside different contexts (Philosophy, Poetry, Art, Astronomy, History, Physics, Biology) while looking at different aspects: irreversible phenomena, cyclic phenomena, construction and calibration of instruments, sequence of actions in every-day life, duration of time, use of words related to time. In the second phase, prospective teachers explored a set of hands-on and minds-on experiments within the context of the GEI exhibition (GEI - Games, Experiments and Ideas exhibition) organized by the Udine research unit. In this informal context, the activities dedicated to the theme of Time were arranged into 23 stations, in which objects and instruments were introduced and explained through worksheets planned in order to stimulate students’ observation and reflection.

For the present study, rubrics were developed to investigate the following research questions: How do PPTs use the proposed elements on the concept of Time to construct an educational project? Which elements do they indentify as key concepts and which ones do they identify as conceptual knots? How do they collect and organize the on-fly suggestions received in the context of a specific situation? How do they transfer the identified key concepts and knots in the educational project?

PPTs were required 1) to list concepts that they consider as most relevant in an educational path on the theme of Time; 2) to identify related conceptual knots; 3) to write in chronological order the questions and the related activities that they plan to perform in an educational path; 4) to list and map the physical concepts they plan to treat according with the rationale the they chose.

In analyzing PPT answers we looked into 1) the frequency and the order of the listed key concepts 2) the frequency and order of the listed conceptual knots and whether they were or not related to the key concepts 3) whether the indicated concepts and knots were present in the proposed educational path; how students problematized the sequence of conceptual elements into the proposed educational path and how much the problematization affected the construction of a coherent rationale 4) whether the structure of the maps reflected either the structure of the contents or the structure of the educational path and if all the key concepts were present in the maps.
Data analysis was performed following an iterative process of Qualitative Analysis (Miles 2014) by identifying directly from students’ answers a set of categories for each specific part of the rubric (key concepts, conceptual knots, questions in the proposed educational path, activities in the proposed educational path, maps) and by refining it through successive re-readings of students’ reports.

**RESULTS AND DISCUSSION**

**Key concepts**

Students were required to list the concepts that they considered as the most relevant in their educational path on the theme of Time. The order (as colors) and frequency of the listed key concepts are reported in Figure 1.

![Figure 1](image)

**Figure 1.** Key-concepts listed by the PPTs. Colors correspond to the position of the concept in their lists. The abscissa gives the number of students who indicated that element.

Periodicity and cyclic phenomena are treated by all the students, followed by measurement of time and duration. Irreversibility is less cited although it is the one that defines the meaning of time (coherently with what we see at point 6 of the results).

Almost half of the students (9/21) choose the concept of time as the «attack angle»; other attack angles are irreversibility and periodicity (3/21); measurement, duration and sequentiality are chosen as attack angles by 2/20.

The concept of time is considered as separated from irreversibility as well as from periodicity that is listed at the second place by 6/20.

The contextual approach is chosen only by 3/20, as well as the interdisciplinary one; also the evolution of phenomena and sequentiality are treated by a minority (5/20).
As a general comment, we find that contexts are missing. Elements related to the comprehension of the concept of time are not structured in their conceptual organization: e.g. almost all PPTs speak about duration but the concept of instant, which gives sense to duration, is not treated; the same holds for contemporaneity. Although abstract concepts should not be chosen as attack angles but should instead be placed at the end, students make the opposite choice and place abstract concepts at the first place.

**Conceptual knots**

The order and frequency of the key concepts listed by PPTs are reported in Figure 2.

![Figure 2. Conceptual knots listed by the PPTs. Colors correspond to the position of the element in their lists. The abscissa gives the number of students who indicated that element.](image)

Operative aspects (how time is measured, how clocks work) and their relations with mathematics prevail.

Periodicity, cyclicity and measurement of time form a coherent cluster of knots. Measurement of time as related to how clocks work is considered the most important knot by 15/21. This knot is confirmed and strengthened by the fact that 10/21 identify as knot periodicity and cyclic phenomena and 6/21 chronological order and sequentiality.

Another cluster of knots concerns irreversibility and how to reconcile irreversibility and periodicity. Irreversibility is at the first place for the majority of the students: this is a positive indication that they have a clear idea of the need to focus on conceptual issues. Anyway, periodicity and measurements are the most cited.

**Questions/arguments proposed in the educational path**

PPTs were asked to write in a chronological order the questions and the related activities that they plan to perform in an educational path. In most cases, questions were in fact considered as “guide-questions”/arguments and not as inquiry questions. Only in the case of the concept of time the question “what is time” is made to the pupils never to ask for a definition but always to collect their spontaneous ideas. Other single cases where questions are posed to pupils, always to collect spontaneous ideas: which are the words of time (1), how do you measure time (1), which is irreversibility (1), which is the difference between sequentiality and contemporaneity (1), what is periodicity (3).
The order and frequency of the arguments proposed in the educational path are reported in Figure 3, where specific contexts (sun motion, language, poetry), indicated only by 7 students, are reported separately.

The concept of time is placed at the first position as an independent subject by the majority of the students (coherently with what we see at point 6 of the results). ‘What is time’ and ‘if it is possible to go back in time’ are at the same level of interest: there is no contextualization.

Periodicity (mainly a key concept) and irreversibility (mainly a conceptual knot) are placed at the first three places by half of the students after the general concept of time, indicating a significant orientation towards conceptual aspects and towards the distinction between the idea of time and the measurement of time.

At the second or third place 5/21 PPTs indicate chronological order and sequentiality and the knot of the relation between sequentiality and contemporaneity.

The most cited argument is ‘how do clocks work?’ Almost all of PPTs place the measurement of time and the way clocks work at some point of the learning path.
History of time measurement was indicated by 7/21, for half of them at the beginning (1\textsuperscript{st} to 3\textsuperscript{rd} position), for the other half as a final argument (4\textsuperscript{th} to 6\textsuperscript{th} position): narrative aspects are important also when conceptualization could prevail.

Very few students choose to start from the concept of instant to recognize that time is composed by instants.

From these data, it emerges that PPTs have acquired the idea of an approach related to every day experience, but they haven’t acquired an inquiry based learning strategy: they tend to put general concepts at the beginning instead of starting from contexts and reaching the global concepts at the end. They tend to ask for definitions. This is known to be a non effective approach: learning should be contextualized and concepts should acquire a meaning from their correlation inside different contexts. The question ‘what is time’ is of a metacognitive type and should be posed at the end of the learning path.

![Figure 4. a) Listed themes and number of PPTs who chose them either as elements of the educational path (green line) or as key concepts (red line) or as conceptual knots (blu line). b) Relevance of each theme either as an element of the educational path (green line) or as a key concept (red line) or as a conceptual knot (blu line). For each category (argument, concept, knot) the relevance was calculated by dividing the number of students who chose a certain theme in the category by the total number of students who chose the same theme in any of the three categories. The five students who cited the difficulty in conciliating periodicity and irreversibility are considered in both the two themes. Relevance of each element as part of the educational path, key concept or conceptual knot. The synoptical graphs reported in Figure 4a and 4b allow to see how the frequency with which each element is chosen as an argument of the educational path is related to the frequency with which the same element is identified as a key concept and as a conceptual knot. Duration is seen as a key concept as well as a chosen argument, not as a conceptual knot. For the other themes, there is a coherence in their relevance as key concepts, conceptual knots and proposed arguments, except for the case of periodicity, which is replaced by time measurement in the proposed arguments: this could be an indication that measurement of time and periodicity are considered as associated.

The synoptical graphs reported in Figure 4a and 4b allow to see how the frequency with which each element is chosen as an argument of the educational path is related to the frequency with which the same element is identified as a key concept and as a conceptual knot. Duration is seen as a key concept as well as a chosen argument, not as a conceptual knot. For the other themes, there is a coherence in their relevance as key concepts, conceptual knots and proposed arguments, except for the case of periodicity, which is replaced by time measurement in the proposed arguments: this could be an indication that measurement of time and periodicity are considered as associated.
This is also confirmed considering that periodicity and time measurement have the highest relevance as conceptual knots.

Periodicity and duration are relevant concepts as well as the concept of time and the history of the measurement of time. Irreversibility has the same weight as argument, concept and knot. The measurement of time is proposed by the most part of the students although it is considered less important than periodicity and irreversibility.

The concept of time in not critical although important. Chronological order is a critical issue which has to be treated but is not considered of a conceptual type.

**Activities planned for the educational path**

PPTs were also asked to list the activities they plan to perform in the proposed educational path as related to the identified questions/arguments. The frequency of the listed activities grouped by categories and related to the subjects (as colors) to which they were referred by PPTs, is reported in Figure 5.

Answers can be divided into three groups: 1) educational tools (reading, writing, story-telling, organizing previous knowledge); 2) construction and use of instruments for time measurement; 3) exploring phenomena.

In the first group, reading and story-telling are the most utilized educational tools to understand what is time, periodicity and chronological order as well as the distinction between sequentiality and contemporaneity up to the recognition of the correct words of time. Drawings are at the second place, which is quite understandable given the age of the children. Half of the students use images, photos, poster, only 4/21 written materials.

In the second group, all the cited instruments are related to conceptual aspects of time as the wheel of time or hourglasses and pendulum, less frequent is the use of clocks and sundials; most simple instruments such as gnomons, graduated candle, are totally neglected.

As far as the exploration of phenomena is concerned, interestingly PPTs propose phenomena which are or have been historically used for time measurement only as a way for illustrating the concept of irreversibility. Elements of the calendar (seasons, days and months) are the natural phenomena chosen, although by a low number of students (2/21, a little higher, 5/21, in the case of seasons), and have the same frequency as evolution phenomena of a totally different nature such as the motion of fluids and ice fusion (3/21 or 4/21). The measurement of time is only related to a cyclic phenomenon and to periodicity, which in fact is a conceptual conquest due to modern technologies of time measurement. The most common associations to personal experience (birthday, portrait of children, changes due to their own growth or to animal or plant growth) are rare with respect to the choice of stories or technical aspects or seasons.

The relevance of each subject in terms of number of related activities is given in Figure 6, where, for each subject (same colors of Figure 5), the total number of proposed activities (of any category) was weighted by the number of students who chose at least one activity for this subject.
Figure 5. Activities proposed by the PPTs for the educational path. Colors correspond to the questions/arguments for which an activity was proposed. The abscissa gives the number of students who indicated that activity.

Figure 6. For each subject (color) the total number of activities of any category is weighted by the number of PPTs who chose at least one activity for the subject.

The aims of the proposed activities are coherent with the subjects indicated as conceptual knots. Periodicity (31%), and then irreversibility (23%), have the highest weight in the proposed activities, while activities related to measurement weigh only 15% although measurement is the most cited among critical issues and among the proposed arguments. The number of activities related to the ideas of time is comparatively low (8%). Chronological order and sequentiality related to the need of distinguish it from contemporaneity have the same weight.
(6-7 %). The weight of activities related to instant, to the relation between time and earth motion and to the words of time is much more low (2-4 %).

**Concepts and maps for the proposed educational path**

Finally, PPTs were asked to list and map the physical concepts they plan to treat in the educational path. Time is always a pre-existing general concept or entity (19/20), placed at the top (15/20, Figure 7a) or at the centre (5/20, Figure 7b) of the map. Only in one case irreversibility is introduced before the concept of Time. Inside the first group, 9/15 show a conceptual structure where time is organically related to elements which constitute the meaning of time, while 6/15 are organized into proposals of activities. In most cases, maps are collections of disconnected, or only partially linked, items. One student makes a distinction between an objective time connected with its measurement from the perception of time as irreversibility and periodicity.

Periodicity and irreversibility are both cited by 8/20, in all other cases only one of the two concepts is cited. Irreversibility (10/20) is never cited as a property of phenomena, it is always a property of time: in one case, it is defined as ‘irreversible time’. Similarly, periodicity (18/20) is a property of phenomena only in 5/18, it is more often a property of time (13/18): in 1 case periodicity is defined as ‘reversible time’.

The concept of sequentiality (before, during, after; past, present, future) is cited in 9/20, it is related to irreversibility in 2/9, it is related to the words of time in 4/9. The concepts of duration/time interval are cited by 9/20 as related to measurement (2/9), related to instant (3/9), related to periodicity (1/9).

In any case, irreversibility, periodicity, duration, sequentiality are mostly separated, independent, not interconnected: they all are properties, manifestations of time. Measurement itself is independent, it is related only to periodicity and only in 4/18.

![Figure 7. Two typical maps proposed by PPTs: a) Time is placed at the top of the map; b) Time is placed at the centre of the map.](image-url)
CONCLUSIONS

The importance of developing teachers’ skills in constructing learning paths on complex subjects in spite of a limited disciplinary knowledge is well known and recognized especially in Physics Education for Primary School Teachers (Buckberger, et al. 2000). Nonetheless, the issue of a transversal educational approach for PPTs, aimed at constructing the epistemological bases and developing the professional competences necessary to create a learning environment for pupils, is still open. In this context, it is important to understand how future teachers construct an educational path on a complex and transversal subject to identify key points on which to draw attention in PPTs education.

The rubrics developed by the Udine research unit allowed us to monitor the process of construction of a learning path on the theme of Time by twenty one future Primary School teachers at the third year of the combined Bachelor + Master Degree Course in “Primary School Education” at the University of Verona in Italy, and to investigate the ways in which they identify and translate key concepts and conceptual knots into didactic proposals on a multidisciplinary and complex scientific concept, even if not too far from anybody personal experience.

The present detailed analysis of PPT answers gives some interesting indications. PPTs have a marked tendency towards classification (general concepts are placed at the beginning of the learning path and are not constructed as the end-points of the educational proposal; learning is not contextualized; reference to the personal experience or to contexts in the proposed activities is relatively rare; Inquiry Based Learning strategies are not acquired) and are not able to distinguish between physical entities and phenomena (periodicity and irreversibility are mostly considered as properties of time rather than of physical phenomena). It also emerges that much attention is paid in PPT education to methodologies rather than to concepts, thus leading to a strong need to work on the coherent connections among concepts, which are the basis for organizing a coherent learning path (maps are mostly collections of disconnected, or only partially linked, items).

As a whole, these results deserve further study on other classes of PPTs in order to increase their statistical significance and confirm the identified trends.

TEACHING PRACTICES IN PRESERVICE SCIENCE TEACHER EDUCATION

Recent efforts to design and study Pre-service Science Teacher Education have focused on engaging future teachers in teaching practices. This focus on practices comes with an explicit intention to blend aspects of knowledge and doing that has been historically separate in other efforts to teach novice learners practical aspects of their profession. This intention brings particular challenges to EU preservice teacher preparation programs that need to reconsider how to incorporate aspects of practices into their science education courses. These challenges not only emerge from the novelty and interrelated nature of these practices, but also from lack of clear ways of articulating what these practices are and look like across international teacher educational contexts. This paper brings together four EU studies and an international discussant that explore possibilities to embrace and respond to these challenges and being a cross-contextual conversation about science teacher education.

Keywords: teacher education, preservice teachers, science teaching

TEACHING PRACTICES

Preparing teachers to teach science has many complications and challenges. One challenge we face as a field is that we do not have clear and well articulated set of practices defined that could help to inform the design of experiences – both courses and field-based teaching placements – to support the development of excellent science teaching practices. This challenge is exacerbated by the fact that we are working across contexts and levels of practice, in what Windschilt & Stroupe (2017) call the three-story challenge. In order to have conversations across teacher education context we need to not only articulate what kinds of practices we imagine for students in science classrooms, but also the practices their teachers use to create such a learning context, and finally the kinds of practices we as teacher educators need to engage preservice teaching in to develop appropriate teaching practices. In many countries, there are standards or national curricula that define what students are meant to learn (e.g. X The Next Generation Science Standards in the United States, NGSS, 2013; the Knowledge Promotion in Norway, UDir, 2013; KMKK, in Germany, KMK, 2004; The Common Objectives in Denmark, Common Objectives, 2017); however, these standards only recently began to articulate practices that we expect students to engage in while learning science. The lack of clearly articulated definitions of student practices across national contexts means that it is even more difficult for teacher educators to articulate science teachings practice that can lead students to engage with science in productive and disciplinally authentic ways.

For science teacher educators, the challenges in teaching play out in (at least) two instructional contexts, teacher education coursework that happens in university classrooms, and teaching
placements in the field where preservice teachers are working with practicing teachers in some way for some period of time, usually supervision from a university faculty or staff member. There is a large amount of variation across programs about how the balance between these two instructional contexts is struck, and in the particular structures that exist in the courses and in the field placements. All of this complexity makes communication across programs unproductive as we do not have a shared language of practices for us to use when comparing and discussing teacher education contexts.

This paper intends to begin to address that complexity. We hope to begin a conversation across an international group of teacher education scholar/practitioners who are attempting to characterize our own practice(s) and its relationship to the outcomes we have for our preservice teachers, and the outcomes of the K-12 students they teach. Each of the four research groups, a German, a Danish, a Norwegian and a Swedish one, will briefly describe some relevant details of the instructional context(s) or learning environments where these pedagogies and experiences are occurring and then articulate a connected chain of practices cutting across the three layers: 1) a practice students should engage in as part of learning science; 2) a practice teacher educators hope to develop in preservice teachers that is directly linked to the student science practice; and 3) a teacher education practice that teacher educators engage their preservice teachers in, in order to develop the targeted teaching practice, and ultimately student practice. By articulating the reasoning that links this chain of practices, we will make available for discussion our own thinking about how teacher education leads to changes in student learning via changes in preservice teacher teaching practices.

GERMAN – FOCUS ON MODELING PRACTICES

The first study focuses on the second (teacher) and third (teacher educator) layers of the theoretical framework of this paper. However, decisions made while designing practices for these two layers are based on what is expected to happen in the first layer (student), i.e. elementary students developing scientific modeling practices. The connecting principle is problematizing, one of the four principles of the productive engagement framework (Engle and Conant, 2002). The focus is then on teacher educator practices developed to engage preservice primary teachers in learning to engage elementary students in scientific modeling practices by problematizing. I discuss students’ meaningful engagement in scientific modeling (Schwartz et. al. 2012) and examine preservice teachers’ engagements that avoid rote procedures as well as declarative knowledge to learn about these teaching practices. My focus here in one modeling teaching practice: Engaging others in performing a modeling learning goal by problematizing. Understood as an individual or collective action that encourages disciplinary uncertainty, problematizing is a known principle fostering meaningful disciplinary engagement (Engle & Conant, 2002). Here, it will be considered as a key didactical element in articulating supports for preservice teachers learning how to enact scientific modeling practices in their future classrooms. As this teaching practice is new for them, I examine their learning during the re-enculturation process they walk through. Because I want to attend to whether and how the practices are personally meaningful, I include in the research design the idea of “making sense in the doing,” choosing to confront preservice teachers to “do something”
where they attempt to see aspects of the teaching practices they are engaged in rather than make declarative statements about them.

The goal of this study is to better characterize and illustrate the designed modeling teaching practice by understanding what sense preservice teachers make of this practice in the doing. It examines the work of 24 preservice teachers in an integrated science content methods course of a German elementary preservice teacher preparation program. The course lasts two semesters and includes designed supports to make sense of scientific modeling practices, including supports in planning and enactment of short modeling-based investigations, and writing short essays to answer questions about these investigations. Data come from four groups of six students each video recorded during the enactment of their model-based investigations and reflective essays. The analysis follows a constant comparative interpretative procedure among the data sources organized around two analytical dimensions: 1) Epistemic modeling goals; 2) Epistemic modeling considerations, both general and domain-specific, students exchange while working towards epistemic goals. These dimensions are consistent with the Epistemologies in Practices (EIP) framework (Berland, et al., 2015) and highlight the pragmatic context of doing embedded in practical epistemologies supporting learning (Ostman & Wickman, 2014). These analytical dimensions can be distinguished as preservice teachers perform engagements sustained by problematizing. With the characterizations of these performances, the study aims to contribute to our understand of how preservice teachers learn the practice of teaching scientific modeling.

Relevant findings emerged when preservice teachers articulated epistemic considerations performing engagements towards model revisions. I found three patterns. In the first, the modeling goal was performed in three steps: first, through engagements in generating a diversity of ideas about explanatory aspects of the models; second, by working upon this diversity to consider the ideas as alternatives in terms of the different explanations they can produce; and a third, one where preservice teachers engage in justifying the decisions made upon mulling these alternatives. This pattern showed a productive use of problematizing in sustaining engagements for an epistemic goal. In the second pattern I found attempts at problematizing where preservice teachers couldn’t go beyond engaging others in generating diversity of explanatory ideas. In this case, further model revisions were made by direct teaching, telling others “which model revision will be better to explain what was going on,” abandoning the problematizing principle during the performances of the further engagements. The third pattern showed engagements in generating a diversity of explanatory ideas, exchanging these ideas as alternatives in the explanations but with no attempts at mulling these alternatives. This pattern gives the impression that problematizing was left aside in this last track. The three patterns suggest how problematizing was used to sustain engagements, mainly when working towards revising models with regard to the explanatory dimension of modeling. Our challenge then is to use what we learned to inform our own teacher educators practices – belonging to the third layer of this paper set. In this case, this may mean to anticipate the uses of problematizing found to improve our own teaching designs.
The second study focuses on collapsing the three layers of practice to create a teacher education practice where preservice teachers learn to teach interdisciplinary science in authentic teaching contexts. The target practice of this study is preservice teachers' intended practice as future in-service primary science teachers. But rather than just executing pre-scribed teaching activities, the preservice teachers engage in developing and planning interdisciplinary science activities that they will subsequently teach and assess in a real classroom-context. In other words, preservice teachers experiment with interdisciplinary science practices for students in real classroom contexts. The goal of the study is to characterize how preservice teacher experimentation with interdisciplinary teaching practices can support their meaning making about the qualities of interdisciplinary teaching through action learning. As teacher educator, I hope to develop preservice teachers' practices around how to develop, plan, teach and assess interdisciplinary science activities that they will use as coming in-service teachers. The research questions that guided this study are: How can interdisciplinary teaching practices support preservice teachers' meaning making through action learning? Can changes in the preservice teachers' meaning making about teaching interdisciplinary science be mapped with the SOLO-taxonomy?

Training students' problem solving skills in science is considered as a key element in the Danish science curriculum in primary and lower secondary schools. One of the most consistent strategies to learn these skills relates to solving realistic problems in interdisciplinary science activities (Czerniak & Johnson, 2014). In Denmark interdisciplinary science relates the subjects of biology, geography, physics/chemistry and technology. The teaching strategies used in interdisciplinary science are based on inquiry and engineering-based activities.

The context of the research is an interdisciplinary science teacher-training module for primary and lower secondary preservice teachers. Module activities are organized in three projects. In the first project, preservice teachers attend instructional activities and experiment with interdisciplinary teaching the other preservice teachers in the module. The remaining two projects consist of instructional activities, experimental teaching and action learning with 6th grade students in authentic classroom settings. Interdisciplinary science teaching practices are new to many preservice teachers so their meaning making through developing, planning, teaching and assessing these interdisciplinary activities offers evidence for how better to support their learning.

Preservice teachers' reports from the three projects were analysed comparatively using Biggs SOLO-taxonomy (Biggs & Collins, 1982) to map preservice teachers' meaning making of student activities during the experimental teaching situations. Focus in SOLO is neither on what the teacher does nor on what the students can, instead the focus is on what the students do. Learning outcomes are characterized by using verbs to categorize whether student learning is unistructural, multistructural, relational or extended abstract. The cohort consisted of 14 preservice teachers. During the module preservice teachers made three reports. Two of these reports contained reflections and meaning making about student learning in relation to preservice teachers’ teaching of interdisciplinary science in 6th grade science classes. The third report was made without a connected practice situation as basis for the preservice teachers’
reflections in the report. Thus, a comparative study of integration of practice situations in student learning was possible by analyzing the taxonomical levels in the reports. The comparative analysis was supplemented with observations of the preservice teachers in practice situations and group interviews to gain insights into metareflections on their meaning making process.

A recent review of strategies that support teacher professional learning provides evidence that integrating teaching practices into teacher training is a powerful tool for preservice teachers learning processes (Nielesen, 2016). A recent study also indicates that preservice teachers increase their self-efficacy by working with interdisciplinary science in practice situations (Flores, 2015). These findings are supported by the results of the present study. Analysing the preservice teachers’ reports provided evidence about the degree of their meaning making regarding different didactical items: Learning goals, assessment, quality of teaching activities, teacher role, student motivation and contextual factors. The level of preservice teacher reflections in the reports that was made on the basis of integrating action learning in practice situations were, on average, on a higher taxonomical level than the reports that did not integrate reflections from an action learning process. In interviews, preservice teachers argued that their learning outcome was considerably higher when they had experimented with teaching activities in practice situations. As one teacher student argued:

‘When we experimented with the teaching activities in the 6th grade class some of the didactical theory made much more sense. It was easier to write the reports and picturing how e.g. investigating the water quality in a pond relates to biology and chemistry.’

Observations of preservice teachers enacting interdisciplinary science teaching in practice revealed that meaning making was taking place while a group of preservice teachers conducted teaching activities. The group organized themselves in such a manner that half the group were teaching, while the other half were collecting data for their action learning. Data consisted of video recordings of practice situations, gathered artifacts, and interviews with 6th grade students about their experience with interdisciplinary teaching. The preservice teachers subsequently used the data for grounding their reflections on teaching actions in their reports.

The most important finding from this study is that preservice teachers became competent in reflecting on the qualities of interdisciplinary teaching using didactical theory. Experimenting with interdisciplinary science in practice situations proved to be important empiri that the preservice teachers used didactical theory to analyse student learning outcomes. In this sense the evidence from the practice situations was a driver for the preservice teachers’ construction of their own didactical theories about interdisciplinary science teaching. One of the aims in Danish teacher training is to develop preservice teachers to become future reflective practitioners assess and develop the quality of their own teaching practice. For this reason, another important outcome from this study is that through action learning preservice teachers became competent in collecting empiri that subsequently enabled them to reflect on their experimentation with teaching interdisciplinary science in productive ways. A third outcome is that preservice teachers expressed increased confidence in using interdisciplinary teaching in their future teaching practice. These results are interesting because the process of action learning allowed the preservice teachers to connect theoretical understanding about
interdisciplinary science teaching with their enactment in practice situations. The process of collective meaning making and writing the reports were means that enabled preservice teachers to consolidate their experiences and construct their own didactical theory about how to develop, plan, teach and assess interdisciplinary science teaching. Moreover, although the preservice teachers considered experimenting with interdisciplinary science teaching in authentic settings, engaging in action learning and writing reports as a cumbersome processes, the transitions between practices that allowed the preservice teachers to experiment with developing, planning, teaching and assessing interdisciplinary science constitute a way to increase their learning and self-efficacy about becoming competent future in-service science teachers.

**NORWEGIAN – FOCUS ON INQUIRY-BASED LEARNING**

The third study addresses all the three layers of practice from the Norwegian perspective. At the first layer, i.e. in terms of practice students should engage in as part of learning science in K-12, the focus was inquiry-based learning (IBL). Indeed, the latest Norwegian policy reform in the 10-year compulsory school and in upper secondary education (UDir, 2013) embeds a new main subject area in the science curricula: the budding researcher, which models the process dimension of the Nature of Science and clearly features inquiry-based learning (IBL). The central inquiry practices described in the budding researcher bear strong similarities with the scientific practices from the US National Research Council’s (NRC) Framework (NRC, 2012), e.g. asking questions, designing investigations, analyzing data, etc. In Norway, The Norwegian Research Council has developed a guide meant to assist teachers in developing teaching practices that promote inquiry called the Nysgjerrigper Method (Nysgjerrigper, 2006). The Nysgjerrigper Method consists of six steps to research, similar to NRC’s eight scientific and engineering practices, but specially designed for use at primary schools in Norway. The six steps are: 1) I wonder why? 2) Why is it like this? 3) Draw up a plan; 4) Collect data; 5) What we found out; 6) Tell everyone else. Despite the systemic support in Norway (KD, 2016), the PISA+ classroom study reports few enactments of the budding researcher in Norwegian schools (Ødegaard and Arnesen, 2010). Thus, a discrepancy is observed between intention, planning and implementation of inquiry at the classroom level.

One possible way to overcome these obstacles is by developing preservice teachers’ ability to scaffold and teach students science using IBL pedagogy inspired by the Nysgjerrigper Method. This was the focus of the second layer of practice in this study, i.e. the practice we (teacher educators) hope to develop in preservice teachers. Windschitl and Stroupe (2017) describe four principles of instruction they consider good examples of the means by which reform goals for student learning are more likely to be achieved: 1) Provide varied opportunities for students to reason through talk; 2) Treat students’ ideas and experiences as resources to build on; 3) Make students’ thinking visible; and 4) Scaffold students’ writing, talk and participation in activity. In our context, the preservice teachers’ ability to apply these principles is considered an important practice to support students’ science practice as expressed in the Nysgjerrigper Method.

When it comes to the third layer (teacher education practices), Windschitl and Stroupe (2017) state that cycles of preparation, enactment and feedback are a good pedagogy for progressive teaching in teacher education. In our study, we address the third layer of practice by engaging
preservice teachers in using the Nysgjerrigper Method. We asked primary school preservice teachers to use the Nysgjerrigper Method as a support for structuring their inquiry-based lesson plans. In addition, we gave assignments to enact the planned lesson in their practicum followed by reflection with peers, practicing teachers and teacher educators. These pattern of planning-enactment-reflection correspond well to what Windschitl and Stroupe (2017) suggested as good pedagogy in teacher education.

We investigated: which NRC’s scientific practices were preservice teachers able to implement in early primary school when their IBL-lesson plans were based on the Nysgjerriger Method? For the purpose of this paper, we discuss the 2nd layer of practices in light of Windschitl and Stroupe’s four principles. Our particular study is based on two cases, each case consisting of 3-4 preservice teachers, teaching 1st graders (6-7 years old) or 2nd graders (7-8 years old), each in their designated practicum school. In terms of preservice teachers’ application of these four principles, we observed that preservice teachers engaged students in various dialogues (Windschitl and Stroupe’s principle 1), e.g. (a) used children’s’ natural curiosity in a classroom discourse with the aim of setting up research questions in plenary, (b) initiated dialogue to engage students in analyzing and interpreting data, (c) encouraged students to construct explanations, (d) engaged students in building arguments from evidence. Thus, they provided opportunities for students to reason through talk.

Our preservice teachers were also focusing on treating students’ ideas and experiences as resources to build on (Windschitl and Stroupe’s principle 2). The two first steps in the Nysgjerriger Method is “I wonder why?” and “Why is it like this?” which encourage students to set up their own research question and hypothesis, which build on their ideas and preconceptions. Preservice teachers were also using objects that were familiar for the students and activities students were experienced with and were able to adapt to students’ abilities, like offering writing or drawing depending on individual capabilities.

Preservice teachers were making students’ thinking visible (Windschitl and Stroupe’s principle 3), mainly via discourse, and recording of hypothesis and results in writing templates and drawings. Using the Nysgjerriger Method, preservice teachers were also able to scaffold students’ writing, talk and participation in activity (Windschitl and Stroupe’s principle 4). For example, they modelled (role played what a hypothesis is and imitation played what it means to observe), used tables to differentiate hypothesis from results, offered writing templates and drawing for recording of data, and asked questions to make students wonder. During practical activities preservice teachers scaffolded group discourses, ensuring all students active participation and contributions.

In terms of connected chain of practices across the three layers our findings show that the students in lower primary have been engaged in a great range of scientific practices (student layer), since almost all of the NRC’s categories, as well as Windschitl and Stroupe’s four principles were implemented by the preservice teachers (teacher layer). We saw that preservice teachers have given careful thoughts to planning the lessons based on the Nysgjerriger Method and the Method seemed to give them the support they needed (teacher education layer). Different strategies were applied in order to engage students in scientific practices (student layer), and in both cases preservice teachers not only used the Nysgjerriger Method for
themselves as a guide for planning, but also encouraged 1st-2nd graders to learn (1) about the Nysgjerrigper Method; (2) how to use it; and (3) why they should use it, showing some didactic transposition from the teacher layer to student layer of practice. The implemented scientific practices and the strategies employed at the teacher educator layer seem to have resulted in gains in preservice teachers competency for implementing IBL-scientific practices at early primary school.

SWEDISH – FOCUS ON PLANNING TEACHING

The fourth study primarily focuses on the second and third layers of practice, viz., a practice that we, as teacher educators, are hoping to develop in preservice teachers (viz., planning of teaching) and a teacher education practice that we engage in to develop in preservice teachers a certain, targeted practice (viz., microteaching). Thus, unlike the three other studies, here the target practice is not primarily an intended practice for K-12 students, but rather the in-service teacher practice of planning teaching. However, the content of the teaching plans was sustainable development, so this would lie close to the intended classroom practice corresponding to the first layer (student practice) of the theoretical framework. We try to achieve the primary target practice (i.e., planning teaching for sustainable development) by engaging our preservice science teachers in the planning phase of microteaching. Thus, the study focuses on the tension between the preservice science teachers acting precisely as preservice science teachers (focusing, for instance, on “what to do to accomplish the assignment”) and the preservice science teachers, instead, acting like in-service science teachers, actually performing the actions expected by a practicing teacher.

The study was part of a larger research project focusing on science teacher education and how it may be modified and developed in collaboration with science teacher educators. Five groups of preservice teachers taking a one semester course in science and science education, focusing on sustainable development, science education for citizenship and socio-scientific issues, were video recorded as they were planning a 20-minute microteaching unit. The planned unit had to concern a content specified in the syllabus for elementary school viz. human, nature and society in interaction for sustainable development. Each group consisted of 5-6 preservice teachers. Their conversations were transcribed verbatim and analysed, using Practical Epistemology Analysis (Wickman, 2004; Wickman & Östman, 2002). PEA is established method for analysing what purposes people pursue during an activity, how they pursue these purposes as part of a practice and how the practice slowly changes as a result of this.

An interesting characteristic of microteaching is the fact that the preservice teachers need to adopt several different parallel roles, viz., as an in-service teacher, preservice teacher and student (Bell, 2007). Our analyses indicate that preservice teachers regularly moved between a preservice teacher-centered and an in-service teacher-centered practice when they were engaged in planning. The preservice teacher-centered practice was identified through the preservice teachers referring to such things as the instructions, perceived expectations from the teacher educators, or other references to the on-campus context whereas the in-service teacher-centered practice was recognised by being indistinguishable from a conceivable conversation between professional teachers. Overall, the preservice teacher-centered practice was characterized by purposes concerning how to handle and solve the assignment, whereas the in-
service teacher-centered practice consisted of the preservice teachers focusing on details of the unit and how to modify and develop the chosen content and methods. The most important finding is that the preservice teacher-centered practice, as well as the recurring transitions between the two practices, displayed unexpected opportunities for learning. A typical feature of these opportunities was that they offered possibilities for reflection in ways not conceivable within authentic teaching practice. In particular, they allowed a freedom for the preservice teachers to digress into possibilities that are simply not an option in real-life teaching, such as choose the age of their students, what kinds of experiences their students would have had before or where their 20-minute unit should be placed in a larger teaching sequence. In this way, the recourse to the preservice teachers-centereded practice offered a widened space for possible action, allowing the preservice teachers to engage in a kind of “rehearsal of various courses of conduct” (cf. Dewey, 1932/1996, p. 275).

Microteaching is evidently not mirroring authentic teaching practice, nor should it. This study supports the contention by Bell (2007) and others that microteaching should be used in science-teacher education on its own merits and for its own, particular characteristics. In particular, our results point at the potential educative value of the very transitions between practices that preservice teachers recurrently experience. We suggest that this “freedom” from the hard realities of future in-service practice constitutes an important and unique experience offered to preservice teachers through microteaching. By means of this, the preservice teachers’ horizons of action may be widened through their imaginative deliberations into various possibilities which will not be on the table in real-world settings, and which would neither have been considered, should the microteaching task have been rendered more “authentic” by the teacher educators in the first place. Thus, the transition between the two practices seems to constitute a way of increasing preservice teachers’ agency, and a way of handing over the initiative to the preservice teachers.

DISCUSSION

As a focus of the discussion across these international contexts, we use Grossman et al.’s (2009) key concepts around pedagogies of practice: representations, decomposition, and approximations of practice, as a way of attempting to connect commonalities and contrasts in the layers of practice across teacher education, teaching, and student practices in science. It is our hope that this discussion will lead to productive directions for the field in terms of a conversation across contexts in science teacher education.

Table 1 both summarizes the practices identified by the different authors and offers a preliminary effort to extract the key concepts around the pedagogies of practice for each context. For both decompositions and representations of practice, there is little specific detail characterized by any of the authors about the ways preservice teachers do (or do not) decompose practices (i.e. what criteria or sub-practices they use/identify) or what representations of practice are used (beyond a generic notions of a lesson plan) to help support the targeted teaching practice(s) (e.g. scientific modeling, interdisciplinary science, IBL, or civic and socio-scientific engagement).

While there is some degree of consistency at the highest levels of practice across layers, the devil, as they say, is in the details (or lack of specificity). For example, at the student level of practice each context names the practices of students in different ways. The German and Norwegian groups both refer to the NRC’s (2012) eight science practices, though the German group focuses on just modeling, and the Norwegians indicate that there are similarities to the NRC, but that the practices are conceptualized slightly differently. How interdisciplinary science, from the Danish group, and sustainable development from the Swedish group overlap
or map across to the NRC is not clear. Part of this is a function of space for reporting of the research work, but part of this lack of clarity and connection across is a function of a lack of specific focus on communication across contexts.

As science teacher education scholars, we hope to better understand the practices and effectiveness of those practices on some more general level. While it is not necessary for us all to conceptualize our work in the same way, it does seem that some commitment to articulating and specifying our work in more detail would allow for a broader conversation across teacher education contexts. Using Grossman’s (2009) framework might not be the solution, but it does allow for us to talk about our work in ways that encourage connection and cross-talk between teacher education contexts. It is our hope that an on-going conversation across these diverse contexts can develop a framework for communicating practices at all three levels and lead to stronger and more productive science teacher education practice and scholarship.

BELIEFS ABOUT TEACHING AND LEARNING OF CHEMISTRY STUDENT TEACHERS IN CROATIA

Lana Saric¹ and Silvija Markić²

¹University of Split, Split and 7th Grammar School, Zagreb, Croatia
²Institute for Science and Technology – Chemistry Education, Ludwigsburg University of Education, Ludwigsburg, Germany

The importance of beliefs for teacher’s action in the classroom is well known. They influence teachers’ representation of science, science knowledge and organisation of the knowledge and information. Keeping teacher professional developments in mind, student teachers’ beliefs need to be examined and sought out by educators. They should be developed into the direction of teaching chemistry due to recent reforms and teaching and learning theories. Beliefs of both pre- and in-service teachers should be the centre of focus by teacher educators. There are different studies completed in different educational backgrounds and different educational systems about teachers’ beliefs. Due to the political system, culture and religion they are, in most of the cases, not comparable. Since the war in Croatia (the 1990s) there were many changes in the country that influenced the educational system as well. Despite that, there are no studies in Croatia focusing on the teachers’ beliefs or their development. The presented study evaluates Croatian chemistry students teachers’ beliefs about chemistry teaching and learning at the beginning, in the middle and at the end of their university chemistry teacher training program. Participants were instructed to draw themselves as chemistry teachers in a typical classroom situation in chemistry and to answer four open questions. Data analysis follows a pattern representing a range between the predominance of more traditional versus more modern teaching orientations in line with educational theory focusing on 1) Beliefs about Classroom Organization, 2) Beliefs about Teaching Objectives and 3) Epistemological Beliefs. The data depicted mostly traditional and teacher-centred knowledge by all of the participants. Changes are hardly noticeable. The date will be discussed and several implications given.

Keywords: beliefs, initial teacher education, teacher professional development

BACKGROUND, FRAMEWORK AND PURPOSE

Beliefs are defined as psychologically held understandings, premises, or prepositions about the world that are felt to be true (Richardson, 2003). Teachers’ beliefs influence how teachers represent science in general and chemistry in particular in their classrooms and the kinds of opportunities they provide for students to learn (Roth et al., 2006). Beliefs play an important role in how teachers organize knowledge and information and are essential in helping them to adapt, understand, and make sense of themselves and their world (Schommer, 1990). For that reason, teacher education must work with the beliefs that guide teachers’ actions (behaviour) with the principle and evidence that underlie the choices teachers make (Shulman, 1987). In addition, student teachers’ beliefs which are deeply held, need to be sought out by teacher educators to provide chemistry student teachers with ample opportunities to create teaching and learning that is aligned with recent reforms. The student teachers’ beliefs need to be developed into the direction that chemistry should be taught accordingly within recent teaching and learning theories. Fenstermacher (1979) argued that one goal of teacher education is to help young teachers transform tacit or unexamined beliefs about teaching, learning and the
curriculum into objectively reasonable or evidentiary beliefs. For teacher education, pre-service and in-service teachers’ beliefs should be at the centre of focus for teacher educators to challenge the belief systems about teaching and learning.

In the literature, there are different studies about (student) teachers’ beliefs about teaching and learning (e.g. Buldur, 2017; Bursal, 2010; Markic, 2008; Markic & Eilks, 2013). However, those studied are accomplished in different educational backgrounds and different educational systems. The political system, culture and religion are in most of the cases not comparable. Studies like to one from Al-Amoush et al. (2014) comparing chemistry teachers’ beliefs about teaching and learning from different countries show big differences in teachers beliefs in different countries. Similarities are to be shown in the study of Cakiroglu, Cakiroglu and Boone (2005) made among Turkish and American student teachers. Furthermore, studies like the one of Alexander (2001), Markic et al. (2016) or Woolfolk-Hoy et al. (2006) display even differences between teachers from one country but different cultural backgrounds.

In Croatia, there are many political and structural changes since the war in the 1990s which are noticeable in the educational system as well. Also in the last years, a voice of a need for a new educational reform, which is strongly oriented to the western world, has become louder. Chemistry is a mandatory subject in final two years of Primary School (grade 1-8; age 6-14/15) and all four years of High School (Grammar School, grade 9-12; age 15-18/19). In Primary School students gain basic knowledge about the matter, atom, chemical reactions and basics of organic chemistry. Additionally, chemistry in High School is divided into general chemistry (9th grade), through physical and inorganic chemistry in 10th and 11th grade to organic chemistry with basics of biochemistry in the final year. Although there are connections and interweaving of the content, curriculum - especially in High School – is focusing especially on learning by heart and do not make links between the content and e.g. social issues.

In the last few years, the new educational reform (Jokic, 2016) has been presented, however it’s not yet in practice. Chemistry is presented as a mandatory subject in Primary School and first two years of High School. In final two years of high school, chemistry is optional subject for students who plan a career in Science area. The content, as suggested, is divided into three basic concepts: the Matter, the chemical process and changes and energy which are all united by Scientific Literacy. The inquiry-based learning should be seen as the main resource of knowledge and the experiment is the foundation for gaining new knowledge that should be integrated into existing one. The curriculum should be spiral and concepts are to be upgraded every year while the teaching should be student-centred.

Comparing the different way of teaching chemistry in Croatia, however, the question must be allowed, if the future chemistry teachers in Croatia are ready and prepared for implementing such a reform which follows different and – for them – new goals. However, there are no studies in Croatia focusing on the (student) teachers’ beliefs about teaching and learning chemistry and showing how the (student) teachers’ development is comparable to the development of education and new educational theories. Starting from here, the present study is focusing on closing this gap and thus to answer following research questions: (i) Which beliefs about chemistry teaching and learning do Croatian chemistry student teachers hold at the beginning, in the middle and at the end of their university teacher training? and (ii) Are
there any differences and/or similarities in the beliefs of Croatian chemistry student teachers at the different points of their university teacher education program?

METHOD

The participants were instructed to draw themselves as chemistry teachers in a typical classroom situation in their chosen subject and to answer four open questions. This idea relates to the ‘Draw-A-Science-Teacher-Test Checklist’ (DASTT-C) (Thomas, Pedersen & Finson, 2001) supplemented with questions about teaching objectives and prior activities. Data analysis was done following the evaluation pattern as described by Markic (2008). The evaluation pattern is based on three categories representing a range between the predominance of more traditional versus more modern teaching orientations in line with educational theory. Three 5-step scales focus on 1) Beliefs about Classroom Organization, 2) Beliefs about Teaching Objectives and 3) Epistemological Beliefs. The validity of the data was achieved through independent rating and searching for inter-subjective agreement (Swanborn, 1996). The evaluation pattern does not present linear scales. The numbers are the symbols for the descriptions that are made along the data. The short description of the three categories is presented in Table 1.

Table 1. An overview of the three scales (Markic, 2008)

SAMPLE

50 Croatian pre-service teachers in age between 21 and 26 participated in the study. All of the participants were female. Being a teacher in Croatia is traditionally widespread by female part of the citizens. They are coming from three different Croatian universities (University of Osijek, University of Split and University of Zagreb) which are only universities for chemistry teacher education in Croatia.

In general, there are two different programs to become a Chemistry teacher in Croatia:

(a) Studying for becoming only chemistry teacher: on a Bachelor level the focus is only on pure chemistry finishing with a Bachelor of Science (B.Sc.) followed by a 2-year master finishing with a Master of Education in Chemistry.

1917
(b) Studying for becoming chemistry and another scientific domain teacher: on a Bachelor level both subjects studied. This program lasts 5 years and ends with Master of Education in Chemistry and e.g. Biology or Physics. There is no Bachelor Thesis in this program.

Finally, both programs have in common that in the first year of the master, teacher trainees are taking chemistry education module over two semesters. The first semester has a seminar and lecturer character and in the second semester, there are 120 hours of internship included.

In the meaning of a longitudinal study, data were collected by the same group at different points of their teacher education program at the three different Croatian universities. By collecting the data from all the student teachers in that one generation it can be said that, for Croatia, this sample is representative. Those student teachers are future science (chemistry, biology, physics) teachers and were visiting one of the two named teacher training programs (offered at the three universities). They are in the first year of their master degree, where they – next to the pure science courses - start for the first time with pedagogy, didactics and science education courses. Data collection took place before the science education courses started, in the middle of those and at the end of all three science education courses. The first point is chosen to evaluate the students’ teachers’ beliefs on which science teacher educators need to pay attention during their lessons and seminars; the middle because of seminars last more than one semester. The last point is chosen to compare the students’ teachers’ beliefs with the initial beliefs and to evaluate the influence of science teacher educators and courses on the possible change.

RESULTS AND DISCUSSION

The data were analysed considering the three named categories and will be presented here. In general, the differences between Croatian chemistry student teachers’ beliefs about teaching and learning between the three-time points are not big, however, some changes in student teachers’ beliefs during their chemistry education course are noticeable.

Figure 1 shows that majority of future chemistry teachers in Croatia hold traditional beliefs about classroom organisation regardless of the time point of the research. Beliefs about the organization are rather teacher-centred with a slight interaction with the students (-1 stands for rather teacher-centred activities with slight interaction with students). Only a low percentage of student teachers neither have teacher- or student-centred beliefs about classroom organization (0 stands for balanced teacher- and student-centred activities) at all three points of data collection. Just 5.8 % of student teachers have rather student-centred beliefs at the beginning of their science education courses, but no one has it in the middle or at the final point of the study.
Beliefs about teaching objectives (Figure 2) seems to have a more heterogeneous distribution of codes comparing to the last one. However, at the beginning and in the middle most of the student teachers’ beliefs were exclusively traditional and oriented on the content structure (-2 stand for learning of facts is the central objective and -1 stands for learning of facts is in the foreground with some non-cognitive objectives target). At the end of the science education courses, a very slight movement is noticeable towards modern beliefs such as learning of the competencies, problems solving and thinking in relevant context.

Figure 3. shows that Epistemological Beliefs are – similar to the first category – more or less, traditional at all three points of the data collection. There is a slight movement from receptive learning (-2 stands for passive and over-directed learning; dissemination of information) towards over-directed learning with student-active phase (-1 stands for learning followed by storyboard written, organized and directed by the teacher, but conducted by the students). At the end of the science education courses, more than 80% of student teachers hold beliefs that
learning follows a storyboard written by the teacher, conducted by the students, but organized and directed by the teacher means rather teacher-centred.

![Figure 3. Epistemological Belief](image)

We can see a homogeneous distribution (Figures 1 – 3) within all three dimensions. Beliefs about Classroom Organisation, as well as about Teaching Objectives and Epistemological Beliefs, are more or less teacher-centred. This traditional view is not oriented towards problem-solving and gaining competencies for today’s (science) world but toward learning facts and science content structure. The majority of chemistry student teachers in Croatia see learning chemistry as a transmission of knowledge and facts that are strongly organized and directed by the teacher.

To explore the mutual equality of the three categories the combination of coding from each category was made for each participant of the study for each time point of the data collection. At the end, the sum of the combination was made and it is shown in Figure 4. The closer the rating for a student teacher is to the lower, front corner of the diagram the beliefs that student hold are more traditional and teacher-centred.

![Figure 4. 3D- representation of the data from all three points of data collection. The size of the bubbles represents the number of student teachers.](image)
In the beginning of their university chemistry teacher education training, the majority of the student teachers have a code combination in the front lower part of the diagram. This describes that they hold more traditional beliefs about teaching and learning. After one semester of science education courses, a slight movement to the upper part of the diagram is visible. However, the code combinations are still in the front part of the diagram. Thus, only slight change in Epistemological Beliefs is noticeable for the whole group. It is noticeable that the code combinations are more spread in the diagram as before. The 3rd time point of the data collection was the end of the courses. The difference to a prior state is that the group seems to be more homogeneous. The code combinations are about in the middle but still lower part of the diagram. The beliefs are still traditional, however not as strong as before.

In the comparison of the three diagrams some changes are visible but looking to the middle of the evaluation, the direction seems to be not really clear. A possible explanation for this result is the time point – the first semester (seminar and lecturer character) is over and the internship is to begin. At the end (after the internship, lecturers and seminars), although differences to the beginning are visible, Croatian chemistry student teachers hold a view that is less in line with modern theories. It is to be assumed that student teachers are influenced by their experience in the internship and the mentor back to the traditional beliefs.

Finally, Croatian chemistry student teachers` beliefs are very homogeneous, independent of the university they visit. There is a tendency towards more traditional (teacher-centred classroom organisation, content-structure-oriented objectives and receptive learning) teacher beliefs with the slight movement towards modern beliefs in the middle.

Starting from the data it seems that student teachers at the beginning of their teacher training hold beliefs established on their own personal experience from the school. This indicates that the teaching and learning in the majority of Croatian schools was (and probably still is) more teacher-centred so it is no surprise that the beliefs at the start point of the research are, as well, traditional.

Data from the middle and the end of the study show that teacher training seems to have an only small impact on student teachers` initial beliefs. Thus, this impact should be bigger and stronger because after just one semester of internship in school student teachers tend to go back to traditional ways of teaching Chemistry. However, at this point the question must be asked about the content of teacher training in Croatia as well. How much modern educational theories, modern goals of chemistry lesson and newer, student-centred methods in chemistry teaching are the focus of university chemistry teacher training at the Croatian university. This study does not evaluate this; however, it should be the focus of further research.

Additionally, on the one side, pre-service teachers are influenced by the traditionally oriented in-service teachers during their internship. But, on the other side, they need to develop more modern, student-centred and constructivist-oriented ways of teaching chemistry to follow the new education reform. Both sides seem to be paradoxes. Since in-service teachers have an influence on the education of pre-service teachers, the focus should be on in-service teachers` beliefs as well, with followup in-service teacher training.
The study shows that future chemistry teachers in Croatia are not ready and prepared yet for implementing such a reform which follows different and – for them - new goals. Further changes in the education system and especially in university teacher education in Croatia are needed. Teacher education should place more emphasis on making student teachers aware of their own beliefs and change those into a more modern direction. Those must rely on the anticipated goals of the educational reform.

EDUCATIONALLY RECONSTRUCTED EVOLUTION COURSE - EVIDENCE-BASED TEACHING IN THE EDUCATION OF FUTURE GERMAN SCIENCE TEACHERS

Barnd Unger
Institut für Didaktik der Naturwissenschaften, Leibniz Universität Hannover, Germany

At German universities, a teaching student is taught scientific knowledge by scientists who are also scientific researchers in the relevant field of knowledge, i.e. for example microbiology is taught by a microbiologist. The didactical aspects of learning science is taught by science education researchers in specific courses. Typically, there is no cooperation. The presented project is an approach to use synergetic effects in teaching student teachers. The aim of this study is to clarify if and why students' ideas about evolution change while they participate in an educational reconstructed evolution course. The study uses the framework of educational reconstruction. A common evolution course (2015, sample 1, n=114) and an educational reconstructed evolution course (2016, sample 2, n=108) were compared. College students' explanations of evolutionary processes where gathered through open format writing assignments (N=222) and interviews (N=15). Data were analysed by use of qualitative content analysis and systematic metaphor analysis. The analyses of the empirical data are used to achieve an evidence-based improvement in teaching. Several evidence-based changes, developed from the results of sample 1, were implemented and tested in sample 2. The results show significantly more scientific adequate concepts in explanations given by students. E.g. they talk more often about variation of all individuals within a population than about the variation of one individual in an otherwise uniform population.

Keywords: evidence –based teaching

INTRODUCTION

Many questions in biology can be answered without using ideas of evolution: Why is a particular leaf green, how do whales swim, how do birds fly, how do babies come into existence? The understanding of the involving mechanisms is an essential part of biological knowledge. Faced with the unbelievable diversity of life often a new kind of questions comes in mind: Why are there so many different kinds of organisms. With a view to this diversity of species a new question arises: how can the similarities among organisms be explained? The answer of these questions requires a historical context - the answer needs understanding of change through time. We have to ask: what processes has created this extraordinary variety of life. In the mid-nineteenth century Charles Darwin gave an elaborated answer to these fundamental questions.

German science teachers are obligated to teach evolutionary aspects and evolution in several grades – in many german curriculums evolution is defined as the red thread which links the big ideas of biology. Teaching evolution in a science classroom needs a deep understanding of the answers given to both kinds of questions and also a deep understanding of the ideas science education research gathered about how students learn evolution in an effective way. In german universities scientific knowledge is taught to students of teaching by scientists who are science researchers in this specific domain: i.e. microbiology is taught by a microbiologist. The
didactical aspect of learning science is taught by science education researchers in specific courses. Typically, there is no cooperation.

The presented project\(^1\) is an approach to use synergetic effects in teaching students of teaching. The aim of the presented study is to clarify if and why students’ ideas about evolution change by participating in an educational reconstructed evolution course. Different research methods are used to model the subject of research from different perspectives in the sense of an internal triangulation.

**THEORETICAL BACKGROUND**

Research on students’ and teachers’ conceptions and their roles in teaching and learning science has become one of the most important domains of science education research. Many studies show that students hold pre-instructional knowledge or beliefs about the phenomena which are often not compatible with the science views. These alternative conceptions are mostly rooted in everyday-experience and informal learning settings (D. Treagust & Duit, 2008).

In addition to classical conceptual change approaches, the role of metaphors and analogies in teaching and learning science has been evaluated in recent years. Lakoff and Johnson have shown that metaphors are fundamental to human thoughts and provide a basis for mental leaps (Lakoff & Johnson, 1980). The terms metaphor and analogy are used in a variety of ways in the science education literature. From grounded cognition perspective thought is embodied: Our basic categories and conceptions arise out of perception, body movement, and experience with our physical and social environment. We employ conceptions from a source domain and map it onto an abstract target. To analyze the source of the conceptions, we use a theory emerging from the field of cognitive linguistics (Lakoff & Johnson, 1980). The conceptual metaphor theory states that all knowledge is embodied (Niebert, Marsch, & Treagust, 2012). This means that every knowledge we construct about our environment – either direct or indirect – is grounded in bodily experiences. Based on Conceptual Metaphor Theory, we differ between two types of conceptions: physical conceptions and abstract conceptions (Fauconnier & Lakoff, 2013). Physical conceptions are grounded in bodily experiences with the physical and social environments, like perceptions, body movements, and social experiences. Physical conceptions are directly meaningful. Experiences as inside and outside, up and down movements, front- and backsides, and center and periphery relations are conceptualized through schemata. Schemata are conceptualizations of patterns of our perceptual interactions (Lakoff, 1987; Lakoff & Núñez, 2000).

Abstract concepts - which include most concepts in science - are understood imaginatively, drawing on directly meaningful concepts and schemata. Abstract conceptions get their meaning indirectly. They are not directly grounded in experience but draw on the structure of our experience. We get used of our embodied schemata to construct an understanding about abstract phenomena (Riemeier, Niebert, & Gropengießer, 2013; Unger, 2017). Conceptions from a so-called source domain are mapped onto an abstract target domain. Therefore,

---

\(^1\) The LeibnizPrinzip project is being conducted at Leibniz Universität Hannover. The study presented is part of Measure 3: Scientific Reconstructed Science. The LeibnizPrinzip is funded by the Federal Ministry of Education and Research (BMBF).
schemata are the hidden hand that shapes our conceptual understanding not only in everyday life but also in science. Accordingly, scientific understanding, as abstract as it may be, is ultimately grounded in embodied conceptions - we call them grounded cognitions (Barsalou, 2008, 2010).

**RESEARCH DESIGN & METHODS**

The Model of Educational Reconstruction (MER) provides a fruitful framework to study college students concepts and design evidence based learning environments (Komorek & Kattmann, 2008). Using the framework of MER typical stumbling blocks on the way to scientific appropriate concepts of Evolution were analysed. Therefore, studies facing students’ concepts on evolution and evolutionary processes were reanalysed (Zabel & Gropengießer, 2011).

MER as a research program provides three research tasks: clarification of science content, investigation into students' perspectives, and analysis, design and evaluation of learning activities (Niebert & Gropengießer, 2014). Clarification of science content draws on qualitative content analysis of written sources on the subject matter - like leading textbooks. The aim is to clarify the specific structure of concepts about the scientific content from an educational point of view.

A critical analysis is essential because science textbooks address experts and present knowledge in an abstract and shortened way - they are not aimed at the specific learning starting position of novices. Often, scientific terms - which are not reflected by scientists - are misleading if students are to apply them to specific topics. Clarification of science content aims at the accurate formulation of potentially learning supportive ways to talk about specific scientific subject - we call these clarified concepts.

Investigation into students’ perspectives aims at the analysis of the pre-instructional conceptions constructed by students. There is also an interest in the of investigation of the development of these conceptions. Analysis, design and evaluation of learning activities refer to instructional materials, learning situations, and teaching and learning sequences (Kattmann, Duit, & Gropengiesser, 1998; Niebert & Gropengießer, 2014). The design is led by learning capabilities – i.e. interest, cognitive aspect, motivation, previous experience - of the students and clarification of subject specific content.

The college students’ concepts were reconstructed and contrasted with concepts of experienced scientists to identify subject matter clarified concepts. To effectively compare concepts of scientists and students, there is a need to make them comparable first – i.e. represent them in the same grain size. Several studies in the framework of MER have shown that reconstruct concepts in form of conceptions gives a deeper understanding of similarities and differences.

The evolution course is offered as part of the program in 4 semesters of the Bachelor's degree program (interdisciplinary bachelor) – i.e. in the winter semester (Figure 1).
Strand 13

Figure 1. Evolution course as part of the program in 4 semesters

In 2015, the data was recorded with the help of the Conceptual Inventory of Natural Selection (CINS; Anderson, Fisher, & Norman, 2002; german translation), an open-format writing assignment and an interview study after the students had attended a classical - not didactically reconstructed course. The open answer format was based on the surveys carried out by Zabel (2009) among middle school students on ideas about the evolution of whales.

To conduct the interview, the method of guided interviews was chosen. In the interview study, individual learners were asked about their ideas about evolutionary processes based on different phenomena. In addition, it was ascertained which particular aspects of the lecture and the associated seminar were particularly remembered. The students should also describe what they thought the idea of the evolutionary course helped them to understand evolution in particular.

The CINS was evaluated using descriptive data analysis in SPSS. The qualitative data was analyzed using qualitative content analysis (Mayring, 2002) and a systematic metaphor analysis (Schmitt, 2005).

The study was conducted in a pre-post-testing setting. The results of this sub-study were used to successively develop the lecture and the associated seminar in a recursive and cooperative process. The evolutionary course changed in this way was held in the winter semester 2016 (Figure 2). The presentation of the participants in this round was similarly collected and analyzed.

Figure 2. Sub-Study winter semester 2016

CLARIFICATION OF SCIENCE CONTENT

As part of the scientific clarification university textbooks were analyzed. This analysis was conducted in a mediation perspective and aimed at the development of basic concepts needed to understand evolutionary processes. On the other hand, the extent that scientists use terminology in their formulations that could be contrary to a scientifically appropriate
understanding was determined. This article only presents selected results of the scientific clarification. A more comprehensive overview can be found for example in Zabel (2009). It must also be pointed out that the module deals with a large number of evolutionary development concepts that cover a large number of different topics. Thus, not only the classical theory of evolution, but also their extensions and topics such as development of life or evolution of hominids are treated. In the summary shown here (Figure 3) only concepts of the "classical theory of evolution" are presented.

**Figure 3. Concepts of scientific clarification process**

**INVESTIGATION INTO STUDENTS’ PERSPECTIVE: EMPIRICAL DATA**

First, the survey of conceptual knowledge carried out by the CINS in the pre-post-test procedure is presented. The purpose of this test was to determine the general understanding of students of basic concepts of evolution before and after completing the evolutionary course. The results are discussed and related to the results of the questions in the open response format.

Figure 4 shows the results of the pre- and post-test of the cohort 2015 in boxplots. The reliability of the pre-test procedure shows a very good value with a Cronbach’s alpha of 0.87. It can be clearly seen that at the beginning of the module Evolution in the winter semester 2015, students have a high level of conceptual knowledge. With an average score of 11.6 with a standard deviation of 3.2, the average score shows performances comparable to those of other post-intervention studies (Athanasiou & Mavrikaki, 2014; Presley, Gehringer, & Hanuscin, 2017).

The results of the post-test show a massive ceiling effect. With an average score of 17.5 in the CINS answers the students at a very high level. The low variance is reflected in a low standard deviation. Based on this relatively high probability of correct answers by the students, some of the 20 items of the CINS are answered correctly by each of them. This affects the calculation of the reliability of the test, which therefore falls to a value of 0.64 and is therefore only appropriate.
The CINS shows that students are able to recognize the desired conceptual knowledge about evolutionary processes in a multiple choice test. However, it seems to be too simple for the sample, so that no more specific survey of individual knowledge levels is possible. Based on these results, it can be said that the CINS is an appropriate way to measure learning progress in the context of an evolutionary module at university level - but unfortunately not a very good one.

![Boxplots Pre-Post-Test (CINS)](image)

**Figure 4. Boxplots Pre-Post-Test (CINS)**

The results of the open response format show surprising results. Asked to explain how primeval land-living mammals have evolved to the recent whales over millions of years the students gave written answers, which are shown in Figure 5 as an example. These answers were summarized at the concept level with the aid of qualitative content analysis and can be compared descriptively in this way.

![Selected answers of the open writing assignment](image)

**Figure 5. Selected answers of the open writing assignment**

The summary of the results of the 2015 sample (Table 1) shows that significantly more inadequate answers is given by many more students than explanations. Table 1 lists the concepts used by the students in the context of the two figures of thought as causes of variation and types of variation. Thus, 89 of the students in the open answer format indicate mutations as a reason for the variation of individuals within a population. Although this is not a really
wrong answer, it is noticeable that only 10 students use the scientific much more important concept of recombination.

It is also striking that 27 students in their texts represent the concept of Environment causes Variation, which can be assessed as scientifically inappropriate. The concept of Usage of Organs Causes Evolution is also frequently used with 18 mentions, which is not appropriate from a scientific perspective.

A remarkable finding is that this is the same sample that reached an average score of 17.5 in the CINS post-test, which was conducted just before the interview with the open answer format. If one correlates the achieved CINS score with the concepts used in the open response procedure, surprising results are also found here, which are shown in Figure 5 as an example.

It becomes clear that even students with a perfect CINS score of 20 out of 20 possible points, have big problems in the open answer format to formulate a scientifically correct answer. Referring to the sample considered in Table 1, the CINS does not seem appropriate to sufficiently predict the students' answers in an open-answer format to an unknown problem. It can also be shown that for a further development of a course at university level a survey with the help of a conceptual inventory is of limited suitability.

**DESIGN AND EVALUATION: MAJOR CHANGES & IMPACT OF CHANGES**

Based on the findings from the first round, the lecture and the seminar were didactically reconstructed. After most student responses in the open response formats revealed typical technically inadequate thought patterns, typical stumbling blocks were identified in an analysis. Based on these inadequate ideas, three fundamental changes were made in the planning and implementation of lecture and seminar:

1. **The core conceptions**: Conceptions can be understood as the smallest representation of mental processes. In a conception, concepts are related to each other and thus their meaning is specified. The reciprocal determination of concepts is an integral part of any teaching-learning process. As part of the evolutionary course, we have tried in each phenomenon, those conceptions which have been identified in the context of the technical clarification as central conceptions. For this, these core conceptions were repeatedly presented and consistently applied to the different phenomena.
2. **Students alternative ideas:** In the seminar, some additional subjects and aspects were added. In the process of educational reconstruction, the decision was made to add a presentation of widespread alternative ideas on evolution and evolutionary processes found in former science education research studies. The college students were given the opportunity to deal with these scientific inadequate ideas and reflect them under use of the subject matter clarified core conceptions. In this way, it was possible for the students to reflect both the alternative ideas of pupils and in this way to question their own ideas. Through this reflection on the meta-level, students can build a critical distance to their own knowledge and thus develop their own ideas.

3. **Scientific clarified speech:** Based on the separation between the thought and the symbol (Richards & Ogden, 1923), language can be regarded as a window on thought. Thinking expresses itself in language - but at the same time speaking itself has an influence on how we understand certain abstract concepts. Since language in the teaching / learning process represents the crucial interface for the negotiation of meanings, the use of correct and professionally clarified terminology was given special attention. For example, when talking about evolutionary processes, more attention has been paid to the use of passive speech.

The analysis of college students’ answers to the question how recent whales evolve from their terrestrial ancestors’ after participating an educational reconstructed course shows significant more scientific adequate ideas than the sample in 2015. To compare sample 2016 with the answers given in 2015 the conceptual change of core conceptions will be exemplarily displayed: By way of example, the development of scientifically appropriate ideas in concepts *Individuals are different from a uniform population* and *All Individuals in a population are different* can be shown (Table 2).

In a scientific clarified way of explanation college students have to use the conceptions *all individuals in a population are different*. This Variation has its origin in the recombination, and to a smaller part in mutations (*recombination causes variation*). Students often super elevate the role of mutation as most important cause of variation. The comparison of the two samples shows that the college students in sample 1 more often uses scientific inadequate concepts in their explanation. In Sample 2 the scientific correct cause of variation and the idea of full variation in populations itself are used more often.

In open writing in the 2015 sample, many students explicitly write about a single individual who is mutated differently than his otherwise uniform conspecifics. This finding is also supported by the statements in the interview study. Here, the students often speak of a starting population out of mutation a particularly suitable individual emerges, which is superior to all others. So they are more likely to have ideas of saltationism than gradualism. Through the glasses of the theory of embodied cognitions, the learners use the everyday-world idea of an outsider. At the same time, the schemas are an application of the container schema. Here, a container is presented whose content - here the individual individuals of a population - is uniform. Only when certain characteristics are met exactly do the individuals belong in this container. A single individual, which for some reason is different, then does not belong in this container. We call this individual an outsider. The ideas of inside and outside, belonging to it
and not belonging to it, can be experienced in the everyday world - in other words, embodied cognition.

Table 2. Comparison of selected conceptions used by college students after participate in two different evolution courses. Data collected by open format writing assignment. Data analysed by means of qualitative content analysis. Double entries are possible.

<table>
<thead>
<tr>

| Sample 2015_whale (n=114)    | 8 | 27 | 18 | 10 | 89 | 78 | 13 |
| Sample 2016_whale (n=108)    | 5 | 14 | 2  | 65 | 14 | 2  | 87 |

From a scientifically clarified perspective, a metaphorical rethinking - we call that a metaphorical shift - has to happen here. The population container must be thought of as not being filled with uniform individuals, but each individual being different in trifles. It is therefore about the otherwise required typological thinking - as it is important, for example, in classical botany - to expand to a different view on living things.

**DISCUSSION**

It could be shown that the CINS as part of the evolutionary course does not seem to be an adequate survey instrument for this sample and especially for measuring the development of imagination. For the level intended here and the intended transfer of networked knowledge to new, unknown phenomena, the CINS score cannot be used for reliable predictions of answers.

This result contributes to an ongoing debate about what is measured by a conceptual inventory, and how the results of such tests correlate with the learners' actual perceptions (Smith & Tanner, 2010). With a view to the professional future of the target group, whose main task will be to initiate teaching / learning processes in an appropriate way, it should be clear that professional acting as a teacher in the classroom has much more to do with freely formulating answers to open questions, as choosing correct answers from a standardized multiple choice test.

Based on qualitative methods (open writing, interviews) and based on the theory of grounded cognitions, the learner statements could be analyzed in depth. This analysis led to the explication of typical alternative - not scientifically appropriate - ideas about evolutionary processes. These problems of understanding were taken up in the context of an educational reconstruction, in order to arrange the lecture and the seminar so that the students could be given the opportunity to reflect on these lifeworld approaches and to construct scientifically more suitable alternatives. Comparing the results of the 2015 and 2016 samples is problematic in a way because they are two different cohorts with different students who have very different ideas and learning prerequisites. In addition, it is problematic to reduce the described impacts.
of change exclusively to the three changes introduced in the planning and implementation of the event. It must also be remembered that 2015 was a newly designed course with a new lecturer. Here also without didactic reconstruction corresponding improvement in the implementation would have been expected. Nonetheless, it is precisely the results of the interviews presented in case studies that show that the three central changes between 2015 and 2016 were also perceived by the students to be helpful and meaningful for their personal development of more scientifically appropriate ideas.

As a central finding of this study, it can be said that an empirical study carried out as part of a scientific reconstruction is apt to better understand students' specific learning pathways and to use this empirical data to foster fruitful learning. Above all, the implications from the theory of grounded cognition can be used meaningfully.

Based on the presented results general recommendations for the improvement of university teaching can be shown:

1. The use of empirical data for the evidence-based further development of courses provides a deeper understanding of the special learning pathways and is a powerful tool for addressing the needs of learners.

2. The cooperation of research subject didactics and teaching specialists leads to far-reaching synergetic effects. A module developed in a common discourse shows very good results in the promotion of scientifically appropriate ideas.

Strand 14 of ESERA deals with an internationally recognised but not so easily addressed problem: the in-service teacher education and continued professional development of Science teachers. In previous editions of the ESERA proceedings we mentioned that the idea of the value of any educational system depending strongly on the quality of its teachers is perhaps one of the few educational ideas that every educational stake-holder agree upon, from parents to pupils, from teachers to researchers and from political actors to civil society. In this sense, it is not strange that the strand on in-service science teacher education is always one of the most active strands in ESERA.

Despite in-service education and CPD being an old preoccupation and classical theme for researchers in Science Education, each edition of the ESERA conference portray a singular, interesting array of research pieces addressing this problem from sometimes similar, quite often very different frameworks and methodological stand-points that also evolve with time. Comparing with previous editions of Strand 14 of the ESERA proceedings, we found in the selection of papers included here perhaps the most diverse representation in terms of internationalisation. The 10 papers included in this section come from all over the world. There is a European presence with papers from Austria, England, Spain and Sweden. However, the non-European, international presence is stronger, with papers from North and South-America (USA, Brazil, Chile); researches from Africa (two papers from South Africa) and contributions also from Asia (Japan). This gives to this edition a truly international flavour and confirms that including research pieces from all over the world is a trend that is gaining momentum in each ESERA edition. We think the ESERA community would strongly benefit from this global exchange of ideas.

We also found in the selection of papers included here a very diverse representation of pieces of research in Science Education not only geographically, but also regarding richness of approaches and methods. As it has happened in previous editions of ESERA, in Strand 14 PCK both in its traditional and reviewed forms continues to be a prevalent theoretical framework for the design and analysis of Continuous Professional Development. This shared framework, however, does not imply homogeneity of views, uses, methods or results. In the selected papers of this section you will find variation from both qualitative and quantitative researches, analysing teachers’ beliefs to actual content or pedagogical knowledge, using likert questionnaires to vignettes and personal interviews to focus groups, and focusing on teachers’ but also on the development of instruments and curriculum materials.

When reading the selection of papers you will find in this section that interesting issues have emerged. We have noticed less papers devoted to the Inquiry-Based Science Education (IBSE) methodology than in previous editions, with also inclusion of alternative frameworks such as Model-based instruction. We have also identified new contents for Science Education, such as programming, which are related to the STEM (Science, Technology, Engineering and Mathematics) framework. STEM could easily become emerging topic in ESERA and the global
Science Education community in the next years due to the importance that different administrations are giving to this area. We also have noticed a renewed interest in the construction of valid instruments for analysing teachers’ beliefs and competences. These trends identified in this selection are actually trends identified in the Science Education field as a whole.

We would like to finish this short introduction signalling some wishes for the future of the research field in the strand 14. We have seen both at ESERA and particularly in this selection very few research pieces that focus on the actual practice of teachers. We find a lack of observation and analysis of what actually happens in the classroom and how teachers and researchers interpret it. We know these sorts of studies are costly and difficult. They require a great deal of trust and ethics in addition to time and personal investment. In spite of this, as a field we strongly need them. One can argue that, in fact, in research on CPD and in-service education they should be a majority of studies, as improving what happens in the classroom is direct desired outcome of initiatives in this field. We need to see what happens in the different classrooms all over the world as a result of our research and evidence-based efforts. In this sense, we encourage scholars doing research in this field to participate in these sorts of more observational, participatory and impact-focused studies and submit them to ESERA. Our strand and the knowledge on possibilities to transfer research results effectively into practice would benefit immensely from this shift in focus.

Digna Couso and Manuela Welzel-Breuer
The central aim of this research is to improve the understanding of the Nature of Science and Technology. In this paper, we present a Didactic Unit (DU) called "Didactics of the Natural Sciences: a perspective from the Pokémon world ". This DU was implemented in a course of Didactics of the Natural Sciences of a Bachelor's Degree in Education. Students were surveyed through a pretest and post-test, before and after the DU implementation, respectively, comparing with a controlled group. Pokémon are fictitious creatures, which may have physical traits similar to animals, plants, rocks, electrical appliances, stacks, ghosts, fungi or even humans. The use of the Pokémon as a Science, Technology and Society (STS) tool aims at the development of critical thinking through the analysis of analogies, on the one hand, and the conceptual errors presented by the series, on the other. From the statistical pretest analysis, it can be observed that the controlled and experimental groups present small differences in the effect size, and there are no significant differences in attitudinal indices. In both groups, very positive indices have been obtained in some phrases, which would indicate strengths, and some very negative indices in others, which would show weaknesses. Very positive indices were obtained from the interaction between science, technology and society. In the case of weaknesses, in general, the most negative indices are found in naive phrases; for example: the concept of technology since a large part of the respondents considers it as a science implementation. The post-test results show that in the experimental group the treatment effectiveness is high (d = 0.59), while its effectiveness in the controlled group is small (d = 0.17).

**Keywords:** nature of science, pokémon, didactics of natural sciences

**INTRODUCTION**

The central aim of this research is to improve the understanding about Technology and the Nature of Science (NoS&T) of students and teachers in every educational level by means of didactic intervention tools, designed and applied from various contexts. NoS&T is a metacognition set about what science is and how it functions in the current world. The central issue is the construction of scientific knowledge, which includes epistemological matters – philosophical principles that support its validation– and issues as regards the relationship among science, technology and society (STS). NoS&T recognizes itself as the successor of the STS movement and it converges with its own proposals for science and technology education (S&T) in relation to the teaching of the sciences developed several lustrums ago: to improve the public S&T understanding in the current world, which implies understanding S&T impacts and solutions (social, environmental, economic, cultural, etc.), some of the most specialized epistemological topics and the relationship between science and technology. NoS&T presence in the education curricula is justified on the grounds of numerous reasons (cognitive, comprehension, utilitarian, democratic, cultural, axiological); however, certainly, the most comprehensive reason is the aim of achieving a quality S&T education, which fosters S&T
literacy for everyone and develops crucial values and attitudes for public understanding in a world which is, day by day, surrounded by S&T (Acevedo and col., 2005). The reforms carried out by some countries during the last decade of the 20th century have put into operation these education aims as regards NoS&T in the scholar curricula (AAAS, 1993; Department for Education and Employment, 1999; NRC, 1996; NSTA, 2000), which have spread to various countries during the last years, in every level of formal education with a special influence on the obligatory secondary school area (Adúriz Bravo, 2005).

The empirical investigation in Science Didactics repeatedly and consistently shows that students’ understanding about NoS&T is not a proper one. Negative results have been obtained from students in various countries and from different ages (Lederman, 1992), regardless the flaws of instruments, methodologies (Manassero, Vázquez y Acevedo, 2001), nuances and differences found among the students. Numerous authors detect epistemological difficulties as regards the role methodology, theories and hypothesis, models, creativity and temporary situations play in scientific knowledge validation (Acevedo and Acevedo, 2002; Bell and col., 2003; Kang and col., 2005; Manassero and Vázquez, 2002; Vázquez, Manassero and Acevedo, 2006).

EANCYT project uses as an assessment tool the opinions’ questionnaire about Science, Technology and Society, (COCTS by its Spanish acronym) (Manassero, Vázquez and Acevedo, 2001). It is a set which contains 100 multiple option topics whose normal contents comprehend NoS&T dimensions. COCTS issues can be developed to create didactic units, adding the appropriate complements of both resources and activities. In this work, we present a didactic unit (DU) designed within the framework of the project and named "Didactics of the Natural Sciences, a perspective from Pokémon’s world". As part of EANCYT, this perspective fits in the field of Science External Sociology, within the theme about Science and Technology Influence on Society, and Contribution to Social Thinking is a subtheme.

**METHOD**

A didactic unit (DU) named "Didactics of the Natural Sciences, a perspective from Pokémon’s world” was applied in a course of Didactics of the Natural Sciences of the Bachelor's Career in Education of the National University of Quilmes which mainly consists of primary and secondary level teachers who want to improve themselves by aiming at a degree issued by a University. The students had to undergo some pre and post-tests, before and after the DU application, respectively, compared to a controlled group. The selected controlled group was equal to the experimental one in the background variables which define the groups, but in that course the DU was not applied.

To assess this DU, some COCTS aspects were used. The experimental group received treatment, while the controlled group did not. However, both groups were provided with the assessment tool beforehand (pretest) and also, after the assessment was performed (post-test). All of the students were blind in relation to the experience, that is, they did not receive any clue nor information that warned them that the same tool would be used after the treatment. Moreover, the temporal conditions of both moments (pre and post) were the same in order to control the potential participant environmental variables. The time between both assessment
moments is reasonable (four months) so as to avoid the influence any pretest memory can have on the post-test. A statistic data treatment was performed, determining the significant differences between the pre and the post-test and between genders by means of Mann-Whitney U test.

**Didactic Unit**

-Evidence: As regards the DU used in this research, the word "Pokémon" is the Romanized contraction of the Japanese trademark Pocket Monsters (Swider, 2007). The term "Pokémon", apart from referring to the Pokémon franchise in itself, it also refers to the 721 fictitious species that have appeared in the franchise in different ways. Being a Japanese name, the word "Pokémon" is commonly used both in its singular and plural form. The series origin is largely related to the analogies dealt in the DU because its creator, Satoshi Tjiri, got inspired by insects and video games. Pokémon are fictitious creatures which, depending on the type and species, can have physical traits similar to animals, plants, rocks, electrical devices, batteries, ghosts, mushrooms or even humans. Pokémon’s physiology and anatomy allow us to differentiate them in different types. There exists 19 types in total: Steel, Water, Insect, Dragon, Electrical, Ghost, Fire, Fairy, Ice, Fight, Normal, Plant, Psychic, Rock, Sinister, Earth, Poison, Flyer and type "?" (Barbe, 1995). They have powers which are related to the creature's physiology (for instance, one of the abilities a Pokémon Plant has is releasing chemical substances to defend itself) and, in most cases, they can be fantastic. Most of the Pokémon go through an evolution process during their development. This evolution appears upon the wish to do it and to obtain the use of organism structures, due to an environmental influence or by having sufficient power to make it happen. These characteristics are what make Pokémon interesting for a scientific learning with an STS approach. To use Pokémon as a STS tool has as its main goal the development of critical thinking through, on the one hand, the analysis of analogies and, on the other hand, the conceptual errors the series present.

-Competences to be developed: Critical thinking, association capacity, reflection, generalization, creativity.

-Objective: One of the DU goals was to work, together with the students, on competences, critical thinking, association capacity, reflection, generalization, comparison and refutation.

-Work material: The implemented book was *Ciencias Pokenaturales* (Lampert y Ayosa, 2016).

-Lesson development: An expositive and experimental class was conducted in which topics of biology (evolution, taxonomy, adaptations and genetics), physics (energy) and chemistry (properties and transformations of matter) were developed based on Pokémon. Furthermore, different lab practices were done which simulated the Pokémon physiology. The aim was to foster critical analysis of the exposed knowledge, avoiding the theoretical knowledge conception (Davini, 2015) as something closed or static.

COCTS is a survey Likert scale-like in which every phrase can be classified with values that range from 1 to 9. Its translation into attitudinal indexes, which range from -1 to +1, depends whether each of the phrases has been considered as Adequate, Plausible or Naive by an expert committee, and it is conducted according to Table 1:
Table 1. Answer Ratings and Attitudinal Index

<table>
<thead>
<tr>
<th>Agreement grade</th>
<th>Void</th>
<th>Almost void</th>
<th>Low</th>
<th>Partial low</th>
<th>Partial</th>
<th>Partial high</th>
<th>High</th>

<td>0.5</td>
<td>0.25</td>
</tr>
</tbody>
</table>

Therefore, a global index (GB) can be obtained for each of these aspects and, also, an index for each of the phrases (A, B, C... etc.). As pretest and post-test, the following aspects related to COCTS have been applied. These enquire into the students' opinion about:

- 10211. Definition of technology: To define what technology is can be difficult as it is helpful for many things. However, technology is MAINLY:

A. very similar to science.
B. a science application.
C. new processes, instruments, equipment, tools, applications, gadgets, computers o practical devices for daily use.
D. robots, electronics, computers, communication systems, automatism, machines.
E. a technique to build things and a way to solve practical issues.
F. necessary to create, design and test things (for instance, artificial hearts, computers and special vehicles).
G. ideas and techniques to design and create things, to organize workers, business people and consumers, and to help society progress.
H. the knowledge to create things (for instance, instruments, machines, devices).

- 30111. Interaction diagrams among S, T and S: Which of the following diagrams would better represent the mutual interactions among science, technology and society? (The simple arrows indicate a single direction for the relation while the double ones indicate mutual interactions. The thicker arrows indicate a more intense relation than the thinner ones which, at the same time, indicate a more intense relation than the dotted arrows. The absence of an arrow means that no relation exists).

A) Science → Technology → Society
B) Technology → Science → Society
Why do S and T influence our daily thinking? Science and technology influence on our daily thinking since they provide us with new words and ideas:

A. Yes, because the more science and technology you learn, the wider vocabulary you obtain and, therefore, more information could be applied to solve daily issues.

B. Yes, because we use science and technology products (for instance, computers, microwaves, health care products). New products add news words to our vocabulary, and they change our way of thinking about daily issues.

C. Science and technology influence our thinking; HOWEVER, influence is realized by mainly adding new ideas, inventions, and techniques which widen our thinking.

Science and technology are the most powerful influences in our daily life, but not because of words or ideas:

D. Instead, because everything we do and everything that surrounds us has been in some way created by science and technology.

E. Instead, because science and technology have changed our lifestyle.

F. No, because our daily thinking is mainly influenced by other things. Science and technology only have influence upon some ideas.

Influence of Technology upon Society: Does technology influence society?

A. Technology does not have much influence upon society.

B. Technology makes life easier.

C. Technology is part of every aspect of our lives, from the moment we get born to the moment we die.

D. Technology influence society by the way the latter uses the former.

E. Technology provides society the mediums to improve or destroy itself, depending how it is put into practice.
F. Society changes as a result of accepting some technology.

G. Technology provides science the tools and the techniques which make society a modern one.

H. Technology seems to improve life quality at first sight, but, actually, it contributes to environmental decline.

- 40821. Influence of Science upon Society: Does science influence society?

A. Science does not have much influence upon society.

B. Science directly influence only the people who are interested in science.

C. Science is available for everyone's use and benefit.

D. Science trains people to be able to learn about the world.

E. Science has fostered the view of a "modern" world, making society more resistant.

F. Science stimulates society to look for more knowledge.

G. Science influence society through technology.

RESULTS

From the statistical analysis of the pretest, it can be observed that the controlled and experimental groups present small differences as regards the size of the effect and there are no significant differences in attitudinal indices. Very positive indices were obtained in some phrases in both groups which would indicate strengths and some really negative indices in others which would show weaknesses. In the case of weaknesses, generally, really negative indices are found in naive phrases. An example of this is the concept of technology, since the majority of the surveyed people considers it as a science application. As regards this question, the one which obtained a lower index in the pretest (-0.376) was B, naive option, which claims that "technology is mainly a science application". And although in the post-test this phrase is the one which obtains a greater positive difference, $\Delta$ (Post – Pre) = 0.439 (this shows evidence that, after the DU implementation, students agree less with this idea), in the post-test the index is still negative (-0.054).

What is more, many people confuse information with knowledge since they claim that the more science and technology you learn, the wider vocabulary you obtain and, therefore, more information could be applied to daily issues.

Additionally, when the question of the influence of science on society was analyzed, the vast majority pointed out that science is available for everyone's use and benefit which shows that there is still a view of science that is neutral, beneficial and available to everyone.

As regards strengths, really positive indices were obtained upon the interaction among science, technology and society. Comparing the pretest and the post-test of the controlled and the experimental group respectively, the results of the size effect test show that in the experimental group treatment efficiency is high ($d = 0.59$) whereas the controlled group's efficiency is low ($d = 0.17$). Moreover, a Spearman correlation test was performed to determine the relationship.
among the age of the experimental and the control group. The global attitude indices obtained in the post-test, the obtained coefficient, \( r = -0.408 \) (p-value = 0.028 < 0.05) shows us that the elder the person, the lower the attitudinal index in the post-test, that is, the elder the surveyed person, the further the attitudinal indices get from the experts’. A gender analysis of the answers was not developed, since in both groups -control and experimental- all the participants were women.

CONCLUSIONS

Taking into account the obtained results, we can conclude that the application in the class of a DU designed to develop critical thinking improves the opinions teachers have about the nature of science, leading them closer to the opinions experts have on the topic. It is also satisfying that young people are the most positively influenced by the explicit and reflective teaching about the nature of science in class. This highlights the need to improve the understanding students and teachers have about the nature of science in every educational level by means of the design and the application of various tools of didactic intervention.

DETERMINANTS OF SCIENCE TEACHER PEDAGOGY IN ENGLISH SECONDARY SCHOOLS

Peter Taylor
University of Wolverhampton, Wolverhampton, England

This paper outlines a study which investigated how science teachers approach teaching particularly when looking to move their pupils’ understanding of key scientific ideas, on toward more sophisticated ideas nearer to those accepted as accurate by the scientific community, a process referred to as conceptual change. The extent to which approaches modify with increasing teacher experience was considered and further the factors bringing about these changes investigated. This understanding of the constraints and drivers for developing teachers’ practice has enabled recommendations for the professional development of science teachers to be made, hence offering potential for enhancing the learning of children within science lessons as a consequence. This work was set within an interpretive paradigm, and used a ‘learning theory lens’ to consider teachers descriptions of their teaching, obtained through responses to an on-line questionnaire, during in depth interviews and further validated through a small number of lesson observations. This lens was developed from McGregor (2007) and had previously been used to compare the intended pedagogic actions of English, maths and science teachers (McGregor, 2011). A key development in this study however was to attempt a correlation between the evidence of teaching strategies used arising from the learning theory lens with a consideration of the philosophy and pressures underpinning choices made by teachers of science using the context of teaching for conceptual change. Initial findings suggest differences in preferred teaching strategy which depend on both the teacher’s initial teacher training, the number of years they have been teaching and the culture present in their school. This has implications for the structure of both initial and ongoing teacher education.

Keywords: Continuing professional development in teachers, learning theory, culture and education

WHAT FACTORS DETERMINE THE CHOICES SCIENCE TEACHERS IN ENGLISH SECONDARY SCHOOLS MAKE ABOUT THEIR PEDAGOGY?

This paper describes an investigation into how science teachers approach their practice when teaching pupils between 11 and 16 years of age. The extent to which approaches modify with increasing experience was considered and further the factors bringing about these changes investigated. This work had the objective of informing both initial and on-going science teacher education.

This work focused on the practice of current and past participants on secondary science initial teacher education programmes at an English university. It contained three aspects: an e-questionnaire, in-depth interviews and observation of teaching. Analysis of the teaching choices evident through each of these data samples was made through a learning theory lens (McGregor, 2007, pp.50-61), and constraints and drivers for choices made revealed through analysis of descriptions of contexts and experiences.
The research undertaken was set within the interpretive paradigm (Cohen et al., 2007), being naturalistic in approach. The work was constructionist as the knowledge generated was arrived at out of the researchers scrutiny of the world of the teachers communicated through language and observation.

**Theoretical perspective**

The theoretical perspective of this research was interpretivist, as it attempted to describe and understanding complex situations, but this was only possible because the researcher had an underlying understanding of schools, science departments, science classrooms and the intentions of teachers. However the presence in the classroom of this researcher and in discussions with teachers inevitably affected the reality of lessons observed, and views expressed which required careful reflexivity to unpick (Alvesson & Sköldberg, 2000) (Cousin, 2009).

Although the knowledge generated in this research was grounded in the unique contexts and experiences investigated there were however two pre-determined theoretical frameworks applied to this research. These being the a framework of learning theories, covering behaviourist, constructivist, social constructivist and socio-culturalist taken from (McGregor, 2011) which allowed a ‘learning theory’ lens to be applied to descriptions and observations of teaching actions and Hargreaves’ (1994) models for school culture (Figure 1) which provided a stimulus for teachers to describe their context and social interactions.

![Figure 1: Models of school culture. Taken from (Hargreaves, 1994)](image)

**The research questions underlying this work were:**

- What strategies are chosen by science teachers to bring about conceptual change in their pupils?
- To what extent do these chosen strategies change as teachers move through their career?
- What factors influence these teachers’ choice of teaching strategy?
METHOD

The data generated was largely qualitative looking for what Rubin & Rubin describe as the “richness of findings from depth interviews” (2005, p.vii). Observation of lessons was also included for a subset of interviewees as when Abrahams and Millar (2008) researched the effectiveness of practical work as a teaching and learning method it was argued that by the interviewer and interviewee discussing a shared experience the latter’s responses are more effectively anchored in the reality and so produces a higher degree of validity that can be generalized to other settings.

Participants

Teaching alumni from the researching institution were initially sent an e-questionnaire and from this process 90 completed the online questions and of these 40 offered to be involved in interviews and observations. Nine interviews and three lesson observations were subsequently conducted between May 2014 and June 2015. The identified teachers worked in six different schools and had followed two contrasting routes for teacher training, three being school-based, and six the more traditional Post Graduate Certificate in Education (PGCE).

RESULTS

The most common description of pedagogy demonstrated an approach to learning that fitted with social constructivist elements of the learning theories, with twenty-eight examples matching this from seventy-eight identified examples (see Figure 2). Of the teachers who provided mainly behaviourist descriptions of preferred approaches, two of the three were from the same school and had followed school-based teacher training routes. Such teachers demonstrated an awareness of students alternate conceptions, and the need to plan teaching to take account of these, however by offering descriptions which focused on simply ‘correcting’ these displayed an inadequate understanding of how strongly these are held by children. These teachers displayed a strong wish to control behaviour rather than strategize their teaching to promote learning.

![Figure 2. Frequency of descriptions attributable to each learning theory.](image-url)

As was the case where this approach was previously used, socio-cultural learning opportunities “where pedagogical approaches nurture the learners as apprentices learning together in mini-
communities (in true collaboration) and purposely arrange for expert and novice to help each other” (McGregor, 2011), appear to be rare in science teachers’ practice. None of the teachers observed teaching overtly utilised any form of socio-cultural learning, and very few of the larger pool of teachers interviewed described any such activities with only four mentioned in 78 examples. Interestingly of the three interviewed teachers who did describe socio-cultural activities, two were present in the sample also observed, yet they did not utilise any such activities when teaching. This reinforces the suggestion that teachers rarely make use of this strategy an area requiring further investigation. The three other learning approaches, behaviourist, constructivist and social constructivist are though clearly seen in typical science teaching practice.

**Changes in practice over time**

Two-thirds of interviewees were able to articulate ways in which they had developed their teaching over time. The most common change was becoming more pupil-centred or, following the learning theory framework, they identified themselves as becoming less behaviourist. This was expressed in terms of flexibility within lessons so not always following a plan to meet pupil needs. A developing capability and confidence with subject knowledge was also identified as a change over time.

The picture was not though straightforward or clear as more experienced teachers illustrated a large number of behaviourist approaches too, apparently at the expense of constructivist methods. This would seem to reflect what Ewing and Manuel found regarding how the “early idealism of the newly appointed teacher can be buffeted and undermined by …the growing realization that there may be endemic school-based and system-wide challenges” (Ewing & Manuel, 2005, p.7). Interview comments suggested the increase in behaviourist approaches is a response by more experienced teachers to expectations of school managers, to adopt school wide approaches intended to maximise pupil order and compliance, even if this is at the expense of some aspects of children’s learning.

This was balanced by teacher’s comments, which described their practice as changing over time, to become more pupil-centered as they become more confident with subject specific pedagogy. This was even evident in a comment from the least experienced teacher in the sample (at the end of her first year of teaching) who when describing the main development she had made was to become more willing to focus on children’s needs:

“I worry less about trying to pack things in and I pay more attention now to fitting less stuff—I put less stuff in a lesson but I try and teach the kids a concept two or three ways in one lesson, because I’ve found that that’s what the students need.”

**Influences on interviewee’s choice of teaching strategy**

Although interviewees largely described themselves as free to choose their own teaching methods, in all but one case this was followed by a description illustrating some form of constraint. From a science teaching perspective, and of key importance to teacher’s choice of pedagogy when striving for conceptual change in their pupils, flexibility of accommodation, availability of practical facilities and apparatus are highly important. However these were the most common form of structural constraint on day-to-day planning. Many of the schools
involved had been recently rebuilt with insufficient laboratories for all the science lessons timetabled at any one time. Whilst the teachers in this study considered these to both be outside their day-to-day control, they are significant in how these teachers structure their pupils learning. Teacher comments such as “when I first started in this school I was really annoyed that the desks weren’t movable, because I used to love putting the desks in groups in my last school” and “there are not enough labs for the number of scientists we have; we have two rooms in another building but they are just classrooms and we can’t even take demos in there as there isn’t any running water” clearly show the frustration this brings. Piaget (1972) and Vygotsky (1978) took the view that learners construct their own knowledge out of their knowledge and experiences, and this learning is a process involving an interaction between new and existing conceptions. As accepted scientific explanations are often at odds with our everyday experience of the world, science teaching involves a process of proving things to pupils through experiments and evidence (Sutton, 1996). This means pupils need opportunity discuss and to test out these new ideas (Ross et al., 2010). Consequently such physical constraints are significant in preventing teachers from using the teaching strategies that best facilitate conceptual change for their pupils.

A further constraint was revealed during careful questioning: school wide boy-girl seating policies were almost universally imposed yet so ingrained in the experience of many teachers they were often unaware of it being a restriction. This clearly limits opportunity for teachers to set up learning communities based upon individual pupil conceptual development, and to facilitate effective pupil-to-pupil dialogue.

Three groups of people were identified as providing a significant influence on interviewee’s choices of pedagogy. These were in order of frequency: university tutors during initial teacher training, mentioned by six from nine teachers; heads of department, mentioned by three; and departmental colleagues, mentioned by two.

School culture proved to be a clear factor determining the way science teachers operate. It was clear that science departments are highly collegial internally but this either creates, or is a consequence of, a balkanized (silo) atmosphere between different subject areas within a school. There was therefore little cross group working other than that imposed by managers in an attempt for contrived collegiality. This state of affairs, evident across the sample of schools and teachers offers good support networks on a day-to-day basis between subject colleagues, but hinders school-wide change, and cross-team sharing of good practice. It can even perpetuate some practices, such as has been seen where the majority of behaviourist learning practices were seen to be concentrated within one school (the largest). As stated by one teacher “I want to reiterate the pressure from outside; from leadership, it does stifle the way I teach in the fact I would like to branch out into certain ideas that the pupils have… yet I am confined by what leadership let me do”.

The research reported here clearly evidenced this in behaviourist expectations directed by school managers, and evident in centrally imposed lesson structures and grouping mechanisms, reinforced by a judgmental observation regime. The way teacher practice has been shown to change over time demonstrated that teachers progressively comply with these expectations the longer they teach. The challenge for ongoing English teacher education is that as this is at odds
with the Teachers’ Standards which require that a teacher must “demonstrate knowledge and understanding of how pupils learn and how this impacts on teaching” (Department for Education, 2011), and further underlined by guidance which requires that “they have an astute understanding of how effective different teaching approaches are in terms of impact on learning” (Department for Education, 2011).

**DISCUSSION AND CONCLUSIONS**

According to Clarke and Erikson much of the current practice in school science departments reflect “efforts to control classroom practices and to have teachers conform to a set of prescribed behaviours” (2006, p.1). This illustrates the view that teaching is “a process of delivering information and testing students for its reception and retention” (Schön, 1992, p.121). As this is contrary to the strategies espoused in both literature regarding conceptual change (Driver et al., 1994) (Taber, 2009) and in the practice encouraged in science initial teacher education (ITE), it is valuable to demonstrate that such controlling pressures do modify teachers’ practice. Despite a clear view of what strategies support effective conceptual change in pupils even experienced teachers display a need to “comply with prevailing routines, rituals and sub-culture of the staffroom” (Ewing & Manuel, 2005, p.7), it important that ongoing teacher development is able to challenge such cultures.

The learning theory lens has shown itself to be a useful mechanism for exploring teaching intentions and practice. Patterns in responses indicate a change in preferred strategy as teachers move through their careers from behaviourist and constructivist strategies to more social-constructivist and socio-culturalist methods.

As the majority of behaviourist descriptions encountered were concentrated within one school it is clear school culture influences practice. A lack of apparatus and laboratories further limits teaching strategy and those who train under school-based routes are most likely to describe their preferred teaching strategy in a behaviourist manner. These findings are clearly significant for the current trajectory for English teacher training as it moves more and more towards a school based model, and one where facilities are determined by non-specialists. It would seem that there is an increased need for ongoing in-service education to ensure counterbalance the prescriptive cultures prevalent in many schools.

The structured observation format based on learning theory and utilised here potentially offers a useful tool to encourage teacher self-reflection on pedagogy. It offered a mechanism to counter the prevailing judgmental model of teacher performance management, and could encourage further development of teacher peer to peer observation in a form that teachers would value and seek to become engaged in. It is therefore worthwhile restating that:

- We know that teachers learn best from other professionals and that an ‘open classroom’ culture is vital: observing teaching and being observed, having the opportunity to plan, prepare, reflect and teach with other teachers (Department for Education, 2010, p.19).

This provides the opportunity to make use of the collegial culture evident in science departments and so reduces teacher isolation. Increasing the use of peer observation, with a structure such as that developed here, would encourage reflection and debate on teachers’ practice regardless of experience levels, and achieve this in an absence of judgement or
accountability. Such a process of engaging teachers with research into their own practice is a valuable one and as Kind and Taber indicate “being a fully professional science teacher means seeing teaching not only as an evidence-based activity, but also to some extent as a research-based activity” (Kind & Taber, 2005, p.253). As McGregor and Cartwright suggest, professional conversations can encourage teachers to construct their own ideas, but also in order for teachers to learn about their practice, they need to ‘critically reflect’ and importantly to share that teaching experience (McGregor & Cartwright, 2011).

DISCOURSES OF PROGRAMMING TEACHING WITHIN COMPULSORY EDUCATION – FIXED OR CHANGEABLE?

Eva Björkholm and Susanne Engström
KTH Royal Institute of Technology, Stockholm, Sweden

Knowledge linked to programming has recently been extensively strengthened in curricula and syllabi in the Swedish compulsory school. The introduction of this new content requires that teachers have to be trained in programming and programming teaching. The aim of this study is to investigate what content and values that emerge as important in a professional development course and in the participating teachers´ teaching in their classrooms. Data was collected by observation of the teaching sessions within the course as well as in three of the teachers´ teaching, where notes were made continuously. By using a discourse analytical perspective, content and values that emerged as important within the teaching were identified. The findings show that the content knowledge in the teacher training course is taken for granted within the school context, as well as in itself. In addition, normative values and steering strategies have been identified within the teacher training course. In the classroom studies, similar values were identified among the teachers. A potential problem within the teaching practice was found in terms of a lack of progression of the content related to programming, as well as difficulties in relating the use of programming to relevant contexts.

Keywords: technology education, programming, classroom discourse

INTRODUCTION

Knowledge linked to programming has recently been extensively strengthened in curricula and syllabi in the Swedish compulsory school, mainly including the subjects of mathematics and technology (National Agency of Education, 2017). It is argued that this kind of knowledge is needed for students to manage their digital world and deal with their digital tools. In addition, increasing interest in technology in order to get more people into technology training is highlighted (Digitization Commission, 2014). Such a vigorous introduction of new content in school involves substantial efforts on implementation processes in terms of professional development activities for teachers, purchase of equipment, etc. In different areas of the implementation, several actors have interests striving for impact such as university departments of computer science and of teacher training, science centres, non-profit organizations, the business sector financing development project and companies selling digital equipment, and publishers. In this context of the forming of a new topic in school, the culture mediated by the actors becomes crucial for what specific content is emphasized and how it is taught. Previous studies suggest that the content in programming involves decomposition of the problem, abstraction, logical thinking, creating algorithms, and debugging (Jaipal-Jamani & Angeli, 2017; Sullivan & Heffernan, 2016; Yadav et al., 2014). Research related to the use of robotics in K12 education also proposes a learning progression that starts with sequencing abilities, advances to reasoning abilities such as casual and conditional reasoning, and results in greater systems understanding, even though more research is needed to define the extent of learning progression (Sullivan & Heffernan, 2016). At the same time, the teaching of introductory programming is seen problematic, since computing educators within the computing education
community often teach with a narrow focus upon the technology tools, without explicitly taking students’ views and needs into consideration (Berglund & Lister, 2010). The researchers argue that “Computer scientists and academics /../ are parts of, and carry, a certain culture, with its own values and norms. These values and norms need to be made explicit in the discourse of teaching.” (ibid. p. 41). Such studies are, however, sparsely represented; e.g. Barker & Garvin-Doxas (2004) observed the communication climate in introductory computer science courses, concluding that the social environment could be characterized as impersonal, in which it was easy to stay anonymous and socially distant, and very guarded since the students rarely disclosed personal information. Moreover, in a questionnaire-based study, secondary school computer science teachers were asked about the best ways to make the subject interesting (Black et al., 2013). A clear theme emerging from the teachers’ comments was that students’ would be attracted by a feeling of in-the-moment enjoyment - “making computing fun”.

In this paper, we present a study of a professional development course for teachers focusing on programming. The course includes teaching sessions on programming that the participating teachers design and carry out in their classes. The aim of this study is to examine what content related to programming that emerges as important in the teaching throughout the course implementation, and what implicit values concerning this content that are imbedded in the teaching practice. Research question: What content and what values concerning programming emerge as important in the teaching practice in the professional development course and in the participating teachers’ own teaching?

METHOD

Data were obtained through observation of teaching in all course sessions in the professional development course. The course was conducted by a science center, and the teaching was carried out by programming skilled people with experiences in teaching students and teachers, but without any formal teaching training. The course consisted of a total of six training sessions, each lasting a full day. In the course participated 16 practicing teachers (Grades 1-9). The course would result in a small project on programming that the teachers implemented in their own classes, and that was presented and reported at the final session of the course. In addition, three of the participating teachers, teaching in Grade 3, 4 and 7 (students aged 9, 10 and 13 years) respectively, were observed when implementing the project in their classes. The three teachers themselves, at the request of the whole group, reported their interest in being observed while teaching in their classes. Two lessons with the duration of approximately one hour with a few weeks apart were observed for each teacher.

During all the observations, notes were made continuously by two researchers, independent of each other. Immediately after each teaching session, the researchers met and discussed their individual observations, and summarized the analysis. The analyzes of the lessons were based both on identifying what knowledge content in relation to programming that was highlighted in the teaching, and somewhat a discourse analytical perspective (Börjesson & Palmblad, 2015; Gee, 2014) focusing on the values and governance strategies within the teaching practice (Öhman, 2007; 2010). Analyses are thereby directed towards how power, in terms of possible paths of action, appears in individual’s everyday actions (Öhman, 2010). For example, within
a teaching situation, the content that is offered to students contains ideas about which learning and knowledge is important, significant or not (Östman, 1995).

THEORETICAL FRAMEWORK

The theoretical frame of the study is inspired by the notion of “big D” (defined by Gee, 1990); “Discourses are ways of being in the world, or forms of life which integrate words, acts, values, beliefs, attitudes, social identities, as well as gestures, glances, body positions and clothes” (p. 142). We take inspiration in Marie Öhman (2010) as well, and her arguing about school subject’s practices and the relation to power, following Foucault (1982). Öhman (2010): “A school subject’s practices, traditions and customs are often deeply rooted in the teaching practice, and often regard content as natural and obvious. With the aid of [a Foucauldian power perspective], it becomes possible to study how the knowledge, norms and values included in an activity render certain ways of acting more reasonable and others less reasonable and thereby benefit certain ways of acting and being” (p. 406).

When Öhman (2007; 2010) discusses governance strategies within the discourse of the teaching practice, she clarifies the notion based on Foucault’s notion of governmentality. Thus Öhman (2010) places power in relation to a transactional approach: “Placing power in relation to the transactional perspective means not presupposing that power is something given, but something that is examined as it is manifested in a certain context. With the aid of Foucault’s power perspective we can thus explain how students’ actions are both facilitated and restricted in a teaching situation, and thereby determine what these processes look like and how they govern an individual’s way of acting and being” (p. 397). Fimyar (2008) for example, interprets Foucault and describes definitions of governmentality, and she presents a review over how the concept has influenced different studies in education. Governmentality studies explore, by problematizing or calling into question, who can govern, who is governed and how. Fimyar describes how the analytics of governmentality explore the practice of government in relation to ways in which “truth” is produced in social and cultural spheres. Therefore, such an analytic lens could make it possible to seek an open and critical relation to strategies for governing; their assumptions, their exclusions, their regimes of vision and spots of blindness (Fimyar, 2008).

In this present study we lean back on the interpretation in Öhman (2007) when she states: “governance that requires an individual freedom, in such a way that individuals are co-actors within their own governance. In another words: individuals become willing to act in line with the desirable order; an order including knowledge, beliefs and values, accepted within the society, “the normal”. “ (p. 129. translated by the authors). By linking governance and knowledge it becomes possible to study how power operates in the classroom actions, and possible to find such actions that are taken for granted, both in knowledge and in approaches. It is possible to investigate and present a detailed analysis of how students act upon teacher actions and vice versa (Öhman, 2010).
RESULTS

In the following section, we will present the results starting with the analysis of the observations of the teacher training course. This is followed by the results of the classroom observations. Finally, the results concerning the teachers’ presentations of their projects within the teacher training course will be described.

The teacher training course - normative values emerged

(a) The specific knowledge content is seen as something obvious within the school context, and something implicitly obvious in itself

The knowledge content linked to programming that is highlighted involves formulation of well-defined thoughts, organisation of solutions and stepwise instructions, structures of problem solving, i.e., coding. Moreover, the need of an exact language which cannot be misunderstood or interpreted in different ways is essential. The focus is on the logic of programming, and the essence of coding. The code has to be seen separated from the artefact. It is important to learn the “craft” of coding, which is to try and make mistakes, to troubleshoot. You learn through massive practicing.

At the same time, the Blue-Bots, Lego robots seem to be content in itself, since a great focus is on the robots and the controlling of the specific artefacts. Also when Scratch is used, the teachers still focus on the artefacts (the aquaria). The progression of learning starts with using robots (Blue-Bots) to using just the computer. The specific knowledge of coding is not made clearly visible.

(b) The attitude of narrowness, with worship of the nature of programming and its possibilities

The attitude can be described in terms of no unnecessary talking, no discussions, and giving short and quick instructions. There is a “right way” to do things, learning sequences are fast, the aim is to inspire, and to be effective. A great focus is on creative skills aiming to create something new without questioning or problematizing. There is also a playful attitude, showing an uncomplicated approach to related issues, and emphasizing that programming is easy has no limitations. In addition, there is an inviting attitude; it is important to share ideas and programming knowledge - “programming could lead to something without limitations”. Programming skills are highly valued in this context.

The teacher training course - steering strategies used by the course leaders

(a) The strategy of trivializing

Based on the course leaders’ statements, compulsory schoolteachers are seen as programming incompetent. The teachers are spoken to as “How do you feel?” “Do you have fun?” “Do not panic!” “Have fun!” “This is simple, as easy as writing a story.” “Hello, we are going to play with robots!”

The teachers accept the course leaders’ way of talking, and adapt to the expectations on them. They become “pupils”, they applaud, laugh, and trivialize themselves.
(b) The strategy of disjunction

The course leaders distinguish between “we and you”, stating for example “what do we mean by programming?” That is we, who are inside the programming context, unlike you, excluded from that context. The teachers are told “You will get some knowledge”, and “Take some knowledge to your classes”, “Something that make your students positive, interested and engaged”, and “The students must believe that everything is possible”.

(c) The injunction of logic

The course leaders give orders to do everything right and keep to the logic, as for example “Follow the instructions!” “Troubleshoot!” “Be careful and accurate”!

The classrooms - content and values highlighted

The Grade 3 classroom

The knowledge content (the concept of loop, steering Blue-Bots in relevant contexts, and using a code language with consensus) is made clear in the teaching, and the students are given the possibility to learn. However, after a while, the students give up the coding activity, and focus more on constructing of the Blue-Bots’ track. Therefore, the progression of learning fails. The values expressed by the teacher are teaching in focus, aims of the teaching sequence, feedback to the students, and classroom discussions.

The Grade 4 classroom

The knowledge content (decomposing a problem, describing an event, dividing the problem into constituents, different parts will be structured in a specific order - “that is programming!”) is clarified. The students are asked to create a story using the Twine programme. The learning progression dealing with the structure of programming is clear. However, the context of programming is about science, more specifically atoms and molecules, which becomes problematic since the way of using programming related to this content is not logic for understanding science. The students create stories about water molecules acting like humans, and the specific science content is missing. The sequence has focus on learning programming and the science isn’t relevant. Values expressed by the teacher are the importance of a clear structure, a serious approach to programming (talking about useful knowledge, and not only to have fun), repeating the specific learning object, reminding the students what to do, and giving short and explicit guiding.

The Grade 7 classroom

The knowledge content in focus is the artefacts, i.e. the Lego robots, while the programming content is unclear. Instructions are given to students about what to do in detail, without any feedback or discussions. The students are given tasks expressed in instructions and the teacher helps with troubleshooting, and pushing the students forward to problem solving and getting a result. Values expressed by the teacher are short instructions and efficiency, expressed as “Go on!” and “Have fun!” . The teacher wants the students to fulfil the task and feel satisfaction rather than learning how to programme.
Teachers’ presentations – normative values emerged

(a) The knowledge content highlighted in the teacher training course is reproduced, and taken for granted without any critical attitude. The content involves abstract thinking, programming with loops, bugs, trouble shooting, and computational thinking. The teachers also express the importance of explaining central concepts related to programming.

(b) A two-sided approach to teaching is observed; on one hand, programming must be fun, challenging, and raising the curiosity of students (students learn quickly and always want to do more) - on the other hand, it is in conflict with "usual" teaching, since there is no explicit aim, no learning progression, and difficulties with subject integration.

(c) The teachers’ expressed view on students can be described as a clear gender coding in relation to programming. The girls are seen as stronger, more persistent, and precise, while the boys are careless and give up more easily. The teachers have identified programming skills and they see how girls seem to manage in a better way.

Teachers’ presentations – steering strategies

During teachers’ presentations, a communicated strategy is about leaving the responsibility for student learning to the students themselves. This is expressed as “It is possible to release control!” and “The students still learn!” The students are seen as skilled and they manage without the teacher. The programming lesson is summarized by one of the teachers in this way: "It was very successful without me being able to do anything!"

DISCUSSION

In this study we have identified content and values related to programming that emerge as important in a professional development course. The content itself such as decomposition of the problem, debugging etc. was taken for granted, and was similar to content highlighted in previous studies (Jaipal-Jamani & Angeli, 2016; Sullivan & Heffernan, 2016; Yadav et al., 2014). In other words, the consensus of the content that seems to be established appears not to be questioned. At the same time, the artefacts in terms of robots and animations tend to take away the focus from the specific knowledge related to coding. The tools and artefacts seem to stay in focus instead of what students are supposed to learn. This is also found in earlier research, for example in Berglund & Lister (2010). In the professional development course there is an intention regarding learning progression to start with programming robots and then go on to coding with computer, using the Scratch programme. But, when using Scratch the students still focus on the artefact, for example the cat on the display, rather than on the knowledge content related to coding. Developing more complex code knowledge, learning more qualified and efficient commands etc. remains in the background.

Within the teaching practice of the participating teachers, a lack of clear progression in the teaching was mostly identified. Moreover, problems with relating the use of programming to relevant and meaningful contexts were identified (cf. Thuné & Eckerdahl, 2009). We also found that the ambitions concerning teaching programming with a clear learning progression and using relevant contexts were in conflict with the idea that computing must be fun (also found by Black et al., 2013). Moreover, as the content and highlighted abilities are presented
in terms of thoroughness, patience and structure, programming is regarded as suitable for the stereotypical image of a female student.

Within the discourse, there is also an acceptance for the notion that the students can learn by themselves without any teaching. In this way the teachers step away from the usual teacher role, and its’ responsibility for student learning. The idea about stepping aside from the teachers’ main task of promoting learning could be understood as a consequence of the discourse that has been studied and the values identified.

In this study, we want to investigate what content and what values concerning programming emerge as important in the teaching practice in the professional development course and in the participating teachers’ own teaching. The content seems to be obvious and fixed. We have seen how the discourse of programming identified in the teacher training course, both dealing with content and values, is transferred by the teachers to their classroom practice. Norms and values from the programming discourse become more important than the teachers’ professional view on how classroom teaching should be conducted. The overall aim seems to be that the students should find programming fun and interesting. This intention gets a powerful impact within the teaching practice. We find it remarkable how teachers accept the programming discourse values, and abandon their own professional role as teachers.

CONTROVERSIES ABOUT SOME FACTORS INFLUENCING TEACHERS’ RESPONSES TO EXTERNALLY-DRIVEN CURRICULUM REFORM AIMED AT DEVELOPING SCIENTIFIC COMPETENCES: SECONDARY SCIENCE TEACHERS’ OPINIONS IN A FOCUS GROUP

Teresa Lupión-Cobos and Ángel Blanco-López
Science Education, Faculty of Education, University of Malaga, Malaga, Spain

This paper examines certain controversies among a group of secondary education science teachers with regard to the teacher’s role and his/her professional environment, their views being gathered following a training programme aimed at introducing a key competences approach into the Spanish science curriculum. During the programme they were required to design, implement and assess their own teaching unit for developing students’ scientific competences by means of context-based learning. At the end of the programme a representative group of teachers were selected to take part in a focus group in which they discussed the training received and its transferability to the classroom. Their statements were then analysed and categorised in order to identify factors associated with their professional environment (at the level of both school and the wider education system) and the implications they had for classroom practice. The present study focuses on those aspects which generated controversy among the teachers, specifically as regards whether they were seen as facilitating or as an obstacle to the teaching of science via a competence-based approach. The issues of controversy related to the following topics: the approach to teaching, the content to be taught, the views of and coordination with colleagues, the utility of contexts and the need for reflection on one’s own practice. The paper concludes by considering potential reasons for these issues of controversy and the implications they have for a competence-based approach to teaching.

Keywords: curriculum reform, scientific competences, controversies in teachers’ opinions

INTRODUCTION

The current education system in Spain (MEC, 2013) follows the recommendation of the European Parliament and Council regarding the role of key competences in lifelong learning (EU, 2006), this being seen as a way of promoting active learning and scientific and technological literacy among citizens (DeBoer, 2011). The competences listed in the Spanish curricula (MEC, 2015) include basic competences in science and technology (hereinafter, scientific competences).

If one examines different approaches to scientific competences, both those on which the Spanish curriculum is based (MEC, 2015; see, also, OECD, 2016) and those proposed by science educators, a number of core defining features emerge: a) the ability to apply scientific knowledge to everyday problems and situations; b) an understanding of the characteristic features of science; c) an understanding of the role that science and technology play in different areas of our lives; and d) a willingness to become involved, both individually and collectively, in science- and technology-related issues and to show initiative and personal autonomy in making well-informed and responsible decisions.
However, it is one thing to agree that the concept of scientific competences may be defined in terms of these core features, and another to decide how a given set of competences might be taught in the classroom. As Banet (2010) points out, it is easy to agree on the importance of acquiring these competences, but developing a framework for teaching them is a complex matter, and hence there is a risk that curricular recommendations never go beyond a declaration of intentions.

Designing common approaches to science education based on the development of competences poses a number of challenges (Fensham, 2007), since many of what are regarded as key competences are defined in very general terms. Among the various alternatives available, the approach known as context-based learning (Pilot & Bulte, 2006) would appear to provide a useful platform. Together with science-technology-society (STS) approaches (Aikenhead, 2002), context-based learning features widely in the literature on developing scientific literacy (Bennett, Lubben, & Hogarth, 2007; Campbell, Lubben, & Dlamini, 2000), which is the framework in which the development of scientific competences is usually considered (OECD, 2006; COSCE, 2011). Broadly speaking, the aim of context-based learning is to link science with the everyday lives (current or future) of students and to illustrate its relevance to the personal, professional and social spheres. In this respect, King (2012) notes that a context-based approach consists in applying science to a real-life situation around which teaching is structured. Scientific concepts are taught insofar as they are necessary to achieve a better understanding of the situation in question.

Research on the application of context-based teaching shows that students are able to link scientific concepts to real-world situations (Gilbert, 2006; Pilot & Bulte, 2007; Bennett, Lubben, & Hogarth, 2007; Gilbert, Bulte, & Pilot, 2011; King, 2012; King & Ritchie, 2012) and to integrate their knowledge and develop their scientific skills, all of which are important aspects of scientific competence (Fensham, 2009; Lupión-Cobos & Blanco-López, 2016). Furthermore, the evidence derived from evaluations of teaching programmes based on this approach suggests that compared with traditional methods which focus on the transmission of scientific knowledge, context-based programmes are not only better at motivating students to study science but also foster a more positive attitude towards the discipline (Bennett, Lubben, & Hogarth, 2007; De Jong, 2006).

However, the successful implementation of a competence-based approach to learning requires the full support of teachers, and it is therefore important to take their views into account and to consider their existing skills level. The literature in this respect (Kirk & MacDonald, 2001; Leander & Osborne, 2008; Ryder & Banner, 2013; Ryder, 2015) suggests that introducing a competence-based approach to teaching and learning implies changes in the following:

- The way in which the teaching/learning process is conceptualized. Teachers have to act as guides, promoting and facilitating the development of competences among their students. This implies fostering and maintaining students’ motivation to learn by setting them tasks or problem situations that require their active involvement and the use of different types of knowledge, skills, attitudes and values.
-Methods. Teachers need to use active and contextualized methods that facilitate students’ participation and involvement and the acquisition and use of knowledge in real-life situations, and which allow for different learning speeds and styles through individual and group work.

-Design and creation of teaching materials. Teachers need to develop resources that take into account the different levels and learning speeds of their students, thereby enabling more personalized learning processes.

-School organization and culture. There needs to be adequate coordination among teachers in terms of the strategies and methods they use. Hence, they need to work closely with one another and share ideas and experiences regarding the effectiveness of different methods or approaches.

In order to meet these challenges, teachers have to be adequately trained and to have achieved a level of professional competence that enables them to decide what changes they need to make to their classroom practice if they are to successfully develop their students’ scientific competences and, therefore, contribute to their overall education as citizens. Research suggests that a wide range of professional factors influence the extent to which the required changes may be taken on board by teachers (Ryder, 2015); these include personal teacher factors, as well as factors that are internal to schools or linked to the wider education system.

The present study forms part of a broader piece of research (Lupión-Cobos; López-Castilla, & Blanco-López, 2017) that sought to identify the main aspects which teachers believed either facilitated or acted as an obstacle to the development of scientific competences through context-based learning (Fensham, 2009), and to consider the implications of this for science education. The specific aim here was to identify the aspects of the curriculum reform which teachers regarded as posing a challenge to their professional identity (Kirk & MacDonald, 2001; Leander & Osborne, 2008; Ryder & Banner, 2013). This approach enabled us to consider the following questions: (a) What aspects of the teacher’s professional environment generate controversy in terms of their impact on the use of a context-based approach to the development of scientific competences?; (b) Which of these controversial aspects can be considered as facilitators of and which as obstacles to the development of scientific competences?; and (c) What might be the reasons for these points of controversy?

**CONTEXT**

The study was carried out following a wide-ranging training programme (Blanco-López & Lupión-Cobos, 2015) aimed at helping secondary education science teachers to design, apply and assess their own teaching unit (Coenders et al., 2010) for developing students’ scientific competences (Blanco-López et al., 2014). The training focused on classroom practice and the use of an everyday situation that would enable them to work on developing students’ competences, especially those related to science. The programme included both face-to-face and online sessions and it consisted of four stages (Figure 1).
In the face-to-face sessions, teachers discussed the theoretical and practical content that would be needed to meet the proposed objectives. The focus for this was a series of talks given by experts on the topic of ‘What do we understand by scientific competence? and ‘How do we go about helping students to develop it?’, as well as workshops in which teachers were shown examples of existing context-based approaches to teaching science and were offered guidance regarding the design of their own teaching units.

The online sessions, which began in stage 3 of the programme, focused specifically on the design, implementation and assessment (including the writing of a report) of a teaching unit aimed at developing students’ scientific competences. Teachers themselves chose the year group they would work with. The programme concluded with a face-to-face session in which teachers presented their reports and shared both their experience of implementing the unit and their opinions regarding the training received.

METHOD

The sample comprised four teachers who participated in the aforementioned training programme and who were selected so as to provide a diversity of backgrounds (i.e. in terms of how long they had been teaching, their previous experience in the design of teaching materials, and any prior involvement in educational research or innovation initiatives) (Table 1).

Their views and opinions were gathered in the context of a focus group (Callaghan, 2005), a widely used technique in educational research. This method enabled the exchange of information and a comparison of participants’ contributions. Transcriptions of the focus group discussions were subjected to qualitative analysis, with the researchers organizing and categorizing significant fragments of text (units of meaning) in order to identify issues of controversy with regard to the aspects which teachers saw as either facilitating or as obstacles to the teaching of science via a competence-based approach. In order to ensure the validity of this analytic strategy, each member of the research team analysed independently a representative percentage of the units of meaning, chosen at random. The level of agreement in categorization among the three researchers was above 85%.
Table 1. Professional profile of the participating teachers and an outline of their respective teaching units (Lupión-Cobos, López-Castilla, & Blanco-López, 2017).

**RESULTS**

Table 2 shows the results obtained, indicating for each idea and the topic to which it corresponds the teacher who initiated the discussion, whether the idea was seen as facilitating (F) or as an obstacle (O) to a competence-based approach, the number of teachers in favour and against, and the number who expressed mixed views. In addition, each idea is linked to one of the categories established by Ryder (2015) for classifying the factors that influence teachers’ responses to externally-driven science curriculum reforms.

It can be seen in Table 2 that there were seven issues of controversy, four of which corresponded to what Ryder refers to as personal factors and three to factors internal to the school (Ryder, 2015). Two of the controversies (I1 and I6) involved all four teachers.

In terms of their professional experience the four teachers can be split into two groups, one comprising the two more novice teachers (T1 and T2) and the other consisting of their two more experienced colleagues (T3 and T4). From this perspective, it can be seen that only one of the seven controversies (I1 in Table 2) was initiated by a novice teacher (T1). However, these two groups do not appear to hold similar views with respect to all the controversies: while in some cases the two members of a group appear to agree with one another (e.g. T1 and T2 on I6, or T3 and T4 on I1 and I3), in others they hold opposing views (e.g. T3 and T4 on I4 and I5).

</tbody>
</table>
Regarding the role of each teacher in these controversies, it should be noted that four of them were initiated by T3, who appears (see Table 2) to ascribe considerable importance to internal factors related to the working environment (i.e. science department working practices, school and departmental leadership style and perceived audiences for his/her work). The other more experienced teacher (T4) initiated two of the seven controversies, both related to personal factors, and he also took a clear stance on all but one of the others issues. The most recently qualified of the four teachers (T1) also took an active part in the debates, initiating one of the controversies (I1) and taking a stance on three others. Finally, T2, the other novice teacher, played a less active role: she did not initiate any of the controversies and only took a stance on three of the issues.

It is worth considering the nature and direction of the controversies in which the majority of teachers (three or four) participated. One of these (I1) concerned teachers’ ideas and beliefs about the concept of scientific competence in the curriculum and how it could be understood in relation to science education. The teacher who raised this issue (T1) regarded this as a facilitating element, arguing that it was not a complex concept and that it was relatively easy for teachers to implement in practice. The two more experienced teachers (T3 and T4), however, saw this aspect as an obstacle, while the other teacher (T2) had mixed views. More specifically, T3 and T4 considered that competences were not clearly defined in the school curriculum and that there were no guidelines for how they might be transferred to the classroom. Closely linked to this idea is the notion of an awareness of context-based activities (I4), which both these more experienced teachers regarded as a facilitating element.

A similar pattern of controversy, but in the opposite direction, can be observed in relation to I6, the utility of contexts. This idea was seen as an obstacle by the most experienced teacher, T4, who argued that there were better ways of developing competences. This view was not shared by the two more novice teachers, T1 and T2.

In the case of I3, the view of other colleagues was considered to be an obstacle for teachers who wished to implement a context-based approach to the teaching of scientific competences. This opinion was shared by the two more experienced teachers (T3 and T4) and may be representative of a significant proportion of the teaching profession who, for various reasons, are opposed to such an approach.

**CONCLUSIONS AND IMPLICATIONS**

The results of this study show that the use of context-based learning to develop students’ scientific competences is an issue that raises a number of controversies among teachers and that these controversies relate to both the personal and school (internal) level (Ryder, 2015). One potential reason for these points of controversy concerns a lack of opportunities within the ordinary working day for an exchange of ideas among colleagues, that is, a setting in which teachers may reflect on and analyse their own classroom practice. It should also be borne in mind that in order to change their beliefs teachers need time to assimilate new ideas, especially when the proposed approach requires them to reorganize their pedagogical knowledge and to establish clear criteria for incorporating these new ideas into the curriculum and the process of student assessment. Our results highlight the importance of helping teachers to develop their
pedagogical content knowledge (Abell, 2008) so as to avoid the fragmentation of important knowledge areas, a problem illustrated by the controversies we observed in relation to different aspects of teachers’ professional environment.

ACKNOWLEDGEMENT

This work is part of the ‘I+D Excelencia’ project EDU2013-41952-P, funded by the Spanish Ministry of Economy and Finance through its 2013 research call.

CONSTRUCT VALIDITY IN A SCALE OF BELIEFS OF SCIENCE TEACHERS REGARDING QUESTIONS IN THE CLASSROOM

Carol Joglar¹, Marianela Navarro² and Sandra Patricia Rojas³
¹, ³University of Santiago of Chile, Santiago, Chile.
²University of Los Andes, Santiago, Chile.

This study sought to design and validate a scale which had as its objective to measure beliefs held by Chilean science teachers regarding the use of questions during their class-sessions. The sample was made up by 176 biology, chemistry, physics and natural science teachers. A total of 110 items were designed and ordered into a Likert scale. These items were initially validated by means of content analysis enacted by experts in the field of science teaching. Following this, they were subjected to internal consistency and validity construct. In this study both confirmatory and exploratory factor analysis were used. These tests yielded adequate values for three factor-dimensions; which had a high internal consistency according to Cronbach’s alfa. The final scale was made up by 31 items distributed amidst three factors: instrumental use of questions, fostering critical thinking, and cognitive challenge. This study provides researchers and practitioners with a valid and consistent instrument that can be used to better understand beliefs held by science teachers with regard to questions posed during class-sessions. Added, this tool can be used for further studies and/or to identify needs within both pre-service teaching classes as well as continuous instruction courses for in-service teachers.

Keywords: questions in the classroom, teaching of sciences, teachers’ beliefs

INTRODUCTION

Formulating questions within the science classroom, challenges

Posing questions is a distinctive trait of human beings. The aforesaid feature is both an enabler of cultural development as well as being a key factor of scientific endeavors. In essence, without questioning there would be no need to mobilize scientific acumen. Continuing with the same line of reasoning, within science teaching processes, and independently of the specific field of knowledge, questions have a salient role. Regarding scientific content knowledge transmitted within the science classroom, the development of higher-order thinking skills should be a prominent objective; for it would allow students the opportunity to develop scientific competencies, ultimately developing them into scientifically literate citizens. Questioning allows individuals to participate in the world, encourages theory-based reasoning, facilitates the creation of multimodal works and fosters the pursuit of objectives framed within a particular set of values (Quintanilla, Izquierdo and Adúriz-bravo, 2005). Given the pivotal role of questions, queries posed by science professors are of the up-most importance; that is, they predetermine students’ mental processes as well as define pupils’ boundaries of freedom when offering answers (Chin, 2007; Colás, 1983). Id est, they have potential and substantial benefits for learning (Call, 1970; Redfield and Rousseau, 1981).

In spite of their importance, science teachers tend to reflect on what types of questions they employ (verbally and written discourses) during the teaching-learning process in an acritical
fashion. The previously mentioned reality constitutes a challenge for both initial-teacher training and continues instruction of in-service teachers. Without keen questions guiding learning experiences and student evaluations, it is unlikely that scientific activities that foster knowledge, ability, positive attitudes towards development and, ultimately, scientific literacy, will come to fruition. The wealth and breadth of any didactic interaction and/or strategy will hinge in no small measure on the quality of the questions being posed. That is to say that today’s science teachers face two main challenges: a. knowing how to articulate above-par questions within the classroom and, b. promoting learning environments that aid students in the formulation of equally competent questions that will eventually lead to the development of scientific thinking.

**Questions and Chile’s science teaching-staff**

The Chilean System of Evaluation of Teacher Performance has as its objective to strengthen the teaching profession, with a particular focus on municipal schools (Manzi, González and Sun, 2011). It assesses teachers in several aspects, one of which is the quality of in-class teacher-student interactions. Results show that this particular facet of teachers’ activities is characterized by below average outcomes. Aforementioned marks are worsened when one pays attention to the quality of questions being posed within the classroom: 76% of biology and natural science teachers, 72% of chemistry educators and 67% of physics instructors obtained a score of basic or unsatisfactory. According to the (Manzi et al. 2011), questions posed by Chilean teachers are characterized as memoristic and where teachers consent scant time so that students can formulate an answer, thus eventually being answered by the same teacher.

The above referenced situation is of special importance given the fact that the evaluated teachers provide their service to some of Chile’s most socially marginalized and vulnerable student population. In this context it is clear that a difficulty exists within the process of designing and employing high quality questions in Chilean science classrooms (Sun, Correa, Zapata y Carrasco, 2011). As such, before studying how to teach students the “how to” of formulating powerful questions, it is necessary to nurture this ability in teachers. A starting juncture for this endeavor would be to study teachers’ held beliefs regarding the use of questions in their classroom and how these principles affect their teaching models (Bryan, 2003; Pajares, 1992). The latter stated point is sound given the fact that beliefs courier several of their teaching-learning processes.

**Held beliefs about formulating questions**

Studies examining science teachers’ beliefs has seen a spike in recent years. The analysis of the evolution of said beliefs has indirectly contributed to the comprehension of the effects that they impose on students’ learning; even, directing the understanding of theories related to science teachers’ professional knowledge (Quintanilla et al., 2011). As such, research on views and presuppositions acquires a valuable psychological construct for teacher training. Thus, researching beliefs enables a viable, and useful, exploration for education (Pajares, 1992). It is important to keep in mind that explaining a conception does not necessarily indicate how it will be used; this notwithstanding, Martin (2009) argues that verbalizing them can permit one to become conscious and thus give structure and formality to thoughts.
Studies on teachers held beliefs springs from two basic assumptions: firstly, teachers are pensive and rational individuals that take decisions, cast judgements, have beliefs and generate professional development routines; secondly, they self-regulate and guide their behavior. Beliefs are personal constructs, they are directly related with personal experiences, decisions, discourses, achievements and are related with taking action (Da Silva, Mellado, Ruiz and Porlán, 2007). Likewise, they are associated with teachers’ professional world and are readily used to justify and explain decision taken by them, even if aforesaid decisions are irrational. Because they stem from experiences, they are not acquired in a reflexive, critical fashion; rather they are developed through common sense. As such, when they become clearly conceptualized and their meanings consistently detailed, they can be evaluated. The latter would be the simplest and most important construct of educational research (Pajares, 1992).

**Designing of instruments to measure beliefs**

Literature reports the existence of a significant number of instruments for measuring beliefs held by teachers with regard to science, scientific knowledge and scientific models (Vasques et al., 2011; Lederman, 2007). However, when these aspects are considered to be cognitive resources there is currently an absence of measuring tools. Other studies have focused on characterizing teachers’ practices when they formulate questions, emphasizing student participation within the scientific construction process (Benedict et al., 2017). Additional researches link the types of questions being posed with teacher’s gender and how this affects the answers provided by students (Eliasson et. al, 2017). Studies centering on teacher-student interactions have sought to evaluate the influence of specific types of questions on low or high student academic achievements levels (Erdogana y Campbell, 2008). Teachers attitudes and behaviors towards students’ questions have also been analyzed (Eshach, Dor-Ziderman and Yefroimsky, 2014). Lastly, an aspect that has also been studied and reported in literature is the level of complexity of questions employed by chemistry teachers and how this advances knowledge (Nehring, Päßlers and Tiemann, 2017).

According to Rojas (2016), within the Chilean context a substantial amount of research has focused on: intervention models geared towards the improvement of critical thinking skills (Joglar, 2015), the effectiveness of inquiry-based learning (Vera and Rivera, 2011; González, 2008), cyberspaces as learning sites (Suarez, 2013), exploring teachers’ beliefs regarding the conceptual nature of science within preschool (Merino, 2010) and the perception held by youths with regard to science and science oriented professions (Leyton, Sánchez & Ugalde, 2010). Research is also appreciable in areas related with pinpointing the effectiveness of specific teaching methods and techniques (e.g. cooperative learning) and studies exploring the globalization of curriculum proposals with particular prevalence in chemistry (Lazo, 2005; Ríos, Balocchi & Arellano, 2007).

Given the above presented research scene, it is relevant to probe into the beliefs held by science teachers regarding the use of questions within the classroom. As such, the purpose of this study is to validate a scale which measures science teachers’ beliefs regarding questions that arise within the schoolroom. This could be a significant contribution for it would provide adequate tools to better comprehend implicit science teaching-learning practices and processes. Furthermore, by validating the scale this study could provide additional insights when
designing and implementing public policies as well as pre-service and in-service teaching courses (with specific focus on Chilean science education).

**METHODOLOGY**

This study utilized a mix-method approach with a sample size of 176 natural science, biology, chemistry and physics elementary and middle school teachers (34% male and 66% female). The sample was selected by means of a free and voluntary participation system. Thirty percent of the participants belonged to municipal schools, 44% to private-subsidized institutions and 26% to private establishments from Santiago City, Chile. Out of all the participants, 65.6% were less than 40 years old and 69.9% had less than 10 years of teaching experience (S.D. = 10.92).

The scale was initially designed based on the characteristics of the questions posed by constructivist science teachers, according to Chin (2007), and were latter adapted to better suit this study. The preliminary instrument had 122 items, which were grouped in three distinct levels: 1) traditional (i.e. teachers that favor the use of spontaneous closed-ended and descriptive questions, which privilege content-specific and decontextualized knowledge), 2) transition (i.e. teachers that both acknowledge the importance of identifying different types of questions and find it key to use questions that augment cognition, but that use them sporadically within their daily teaching), and 3) catalyst (teachers that recognize, design and incorporate different types of questions in both their verbal and written discourses; furthermore, they foster productive exchanges by means of key inquiries. All the latter by means of copious, discursive and dialogical teacher-student interactions).

The initial instrument was validated by seven experts (teachers of Teaching Strategies for Science Teaching in several Chilean and international universities) who considered three aspects: relevance, clarity and discrimination. Based on this process, 12 items were eliminated because the level of accord between the experts was below 75%. As such, the final instrument had 110 items, for which internal consistency was measured by means of Cronbach’s alfa; the result being 0.832, meaning that the final instrument has a high degree of reliability.

As a second stage, the validity of the construct, as well as the internal consistency of it, was to be tested; and this goal is the objective of this study. The validity was tested by means of two methods: 1) Exploratory factor analysis (EFA), and 2) Confirmatory Factor Analysis (CFA). Regarding EFA, to test how the data adjusted, adequacy was tested by means of Kaiser-Meyer-Olkin (KMO) and Bartlett tests. For CFA oblique promax rotation was employed. In order to select the adequate number of factors, a Scree plot and Kaiser test were used. The following criteria was used to select the values to be kept: ≥ 1values for the factor in question, the parentage of variance explained by each factor and a sound interpretation of the obtained factors. For exploratory factor analysis SPSS version 2.1 was used, for CFA the lavaan package for structural equation modeling (Rosseel, 2012) in R was chosen. The model found via the previously mentioned analysis was then compared with two alternate models, by means of the reason between $\chi^2$ and the degrees of freedom. However, because of the sensitivity of this statistical indicator to sample size (Cumsille, Martínez, Rodríguez & Darling, 2014; Widaman, Ferrer & Conger, 2010), Jöreskog’s GFI (goodness of fit index), the root mean square error of
approximation (RMSEA) and the standardized root mean square residual (SRMR) were also analyzed. The following parameters were set as acceptable: values between 0 and 3 for the ratio between \( \chi^2 \) and degrees of freedom, values above 0.90 for GFI and values below 0.08 for RMSEA and SRMR (Bentler, 1990). With regard to the internal consistency, it was calculated by means of Cronbach’s alfa for the complete scale as well as by how much each item contributed to the total reliability of the instrument.

**RESULTS**

**Exploratory and confirmatory factor analysis**

Out of the 110 expert-validated items, 32 were kept based on the results from the EFA (Table 1). The chosen model has three factorial dimensions: factor 1, *Instrumental use of questions* (15 items); factor 2, *Fostering critical thinking* (11 items); and factor 3, *Cognitive challenge* (5 items). These three dimensions account for 29% of the explained variance. The factors explain 14%, 9% and 6% of the variance, respectively. The CFA gave fairly consistent results when compared to the EFA; however, some items did prove to be problematic. Specifically, items 31 (When planning my classes, it is indispensable to scheme the questions that I will utilize during my teaching session.) and 71 (I feel good when a student takes his or her time in answering a question.). Both of them are ascribed to factor 2 and had loads slightly below .25.

### Confirmatory factor analysis (CFA), model fit

Given the lower loads of items 31 and 71, two alternative models (were these items were eliminated) were tested. Table 2 shows that by eliminating item 31 (When planning my classes, it is indispensable to scheme the questions that I will utilize during my teaching session.) the model fit improves. But, if item 71 is conjointly eliminated (I feel good when a student takes his or her time in answering a question.) the improvement is of less magnitude.

Reliability analysis

The scale showed good internal consistency throughout its three dimensions: 1 (α = .83), 2 (α = .75) and 3 (α = .72). This could indicate that the instrument could be used for future studies integrally or in a subscale fashion.

CONCLUSIONS

The objective of this study was to design and validate an instrument that contributed to the better understanding of the beliefs held by science teachers with regard to questions posed during class-sessions. The final scale was made up by 31 items distributed in three dimensions: 1, “Instrumental use of questions (15 items)”; 2, “Fostering critical thinking (11 items)”; and 3, “Cognitive challenge (5 items)”. In conclusion, through this study a valid and consistent instrument was designed. One that can be used to research beliefs held by science teachers regarding questions used during class-time. For example, the high level of accord between items found in factors one and three show a traditional set of beliefs; and a high concurrence of items in factor two demonstrate beliefs more closely related with a catalyst style of teaching (where questions are used to develop scientific thinking). Given the results of this study, the scale can be a valuable diagnostic tool to be employed for the future development of dialogic didactic strategies centered on question-posing in both pre-service teaching courses as well as for and continuous instruction of in-service teachers.

ACKNOWLEDGEMENT

TEACHER LEARNING SUPPORT IN JAPANESE SCIENCE CURRICULUM MATERIALS FOR SECONDARY SCHOOL

Kazuya Wakabayashi and Etsuji Yamaguchi
Kobe University, Kobe, Japan

Davis and Krajcik (2005) proposed the theoretical concept of educative curriculum materials as curriculum materials that can support teachers’ learning. Although it has been confirmed that educative curriculum materials can support teachers’ learning, it is not yet fully understood whether the existing curriculum materials have the features of educative curriculum materials that can support teachers’ learning. The purpose of this study is to analyse curriculum materials of secondary schools that has yet to be analysed in previous studies. By conducting an analysis of the curriculum materials that are for different stages of schools of previous studies, it is expected to discover curriculum materials that have different features from the ones examined previously. The subject of this study are the curriculum materials published by two of five publishing companies have the highest share in Japanese secondary schools. The science topic is ‘electric current’ that the new content was added with the 2008 revision of the national curriculum. Based on the results, the characteristics of teachers’ learning support provided by curriculum materials in Japanese secondary science were found to be supportive with respect to implementation guidance and PCK for science topics. This is a unique feature that was not found in curriculum materials for elementary or high school science, which were analysed in previous studies.

Keywords: teacher learning, curriculum materials, secondary school

THEORETICAL FRAMEWORK

Teacher learning and teacher knowledge

Teachers need to have multiple types of specialist knowledge (Fischer, Borowski & Tepner, 2012). The main aim of teaching is to develop students’ subject matter knowledge. There are several requirements for teachers to satisfy this aim (Berry, Depaepe & van Driel, 2016; van Driel, Jong & Verloop, 2002). First, teachers must have deep knowledge of the subject matter. Second, they must integrate their knowledge appropriately. Third, they must have the knowledge of how to teach the subject matter, namely, pedagogical content knowledge (hereafter, PCK) (Shulman, 1986).

Educative curriculum materials for supporting teacher learning

Davis and Krajcik (2005) proposed the concept of educative curriculum materials as curriculum materials that can support teachers’ learning. Davis and Krajcik (2005) contended the following three kinds of teachers’ learning that educative curriculum materials can support: PCK for science topics, PCK for scientific inquiry, and teachers’ knowledge of the subject matter.

Davis, Janssen, and van Driel (2016) commented the following as regards curriculum materials’ support for teachers learning specialist knowledge: ‘Curriculum materials serve as a key conceptual tool for science teachers, and better understanding how science teachers use
these tools could help to improve both curriculum design and theory related to teacher learning and decision-making’ (p. 1). Teachers use curriculum materials to provide and plan lessons.

**PURPOSE OF THIS STUDY**

Although it has been confirmed that educative curriculum materials can support teachers’ learning, it is not yet fully understood whether the existing curriculum materials have the features of educative curriculum materials that can support teachers’ learning. Works by Beyer, Delgado, Davis, and Krajcik (2009) and Yamaguchi and Kanamori (2014) are rare exceptions in this regard. Beyer et al. (2009) developed an analytical framework based on the design principles of educative curriculum materials (Davis & Krajcik, 2005) and analysed the curriculum materials of North American high schools. Their analysis highlighted the following two points as characteristics of curriculum materials in North American high schools: (1) regarding teacher knowledge domains, curriculum materials offer much support for teachers’ knowledge of the subject matter; and (2) regarding forms of support, curriculum materials offer much support in relation to educative features. Moreover, using the analytical framework developed by Beyer et al. (2009), Yamaguchi and Kanamori (2014) analysed the curriculum materials of Japanese primary schools. Their analysis identified the following two aspects as characteristics of curriculum materials in Japanese primary schools: (1) regarding teacher knowledge domains, curriculum materials offer much support with respect to PCK for scientific inquiry; and (2) regarding forms of support, curriculum materials offer much support in relation to implementation guidance.

As shown in these preceding studies, by analysing the existing body of curriculum materials using the concept of educative curriculum materials as a theoretical framework, we can find curriculum materials that are effective as educative curriculum materials from the existing body of curriculum materials. To achieve this, it is necessary to engage further with analysis of the existing body of curriculum materials, including different stages of schooling.

This study, therefore, carries out an analysis of curriculum materials of secondary schools that has yet to be performed. More concretely, this study focuses on curriculum materials in compliance with the national curriculum for secondary schools, and investigates whether these curriculum materials have the potential to support secondary school teachers’ learning. By conducting an analysis of the curriculum materials from a school stage different from the preceding studies, it is expected to identify curriculum materials that have different features from the ones examined previously.

In carrying out the evaluations, this study employs the evaluation criteria used in Beyer et al. (2009) and Yamaguchi and Kanamori (2014). The research questions guiding this study are as follows:

1. What is the relative frequency of support of teachers’ knowledge of the subject matter, PCK for science topics, and PCK for scientific inquiry across Japanese secondary science curriculum materials?

2. What is the relative frequency of rationales and implementation guidance supports across Japanese secondary science curriculum materials?
RESEARCH METHOD AND DESIGN

Curriculum materials
There are five publishing houses in total that publish textbooks for junior high school science education in Japan (Shikoshuppansha, Keirinkan, Tokyoshoseki, Dainihontosho, Gakkotosho, and Kyoikushuppan). As of 2016, there were a total of 10,404 junior high schools, including both publicly funded and private ones (Ministry of Education, Culture, Sports, Science and Technology [MEXT] Japan, 2016a). Junior high schools teach according to the national curriculum (MEXT Japan, 2008). The content of the textbooks is created by each publishing house under the supervision of the MEXT through the textbook authorisation system (MEXT Japan, 2016b).

The subject of this study is the curriculum materials created and published by Keirinkan (Tsukada et al., 2012) and Tokyoshoseki (Tokyo Shoseki Co., Ltd., 2012). The science textbooks published by these two publishing houses have the highest share in Japanese junior high schools at over 60% (Watanabe, 2012). The fact that Keirinkan and Tokyoshoseki account for more than half of the textbooks used in science education in Japanese junior high schools is the reason for the evaluation of their curriculum materials in this study.

Science topics
The science topic, which is the focus of this study, is ‘electric current and its use’. The subject matter knowledge that is covered under this topic is as follows (MEXT Japan, 2008): (1) The circuit, electric current, and voltage: by creating a circuit and conducting an experiment to measure electric current and voltage of the circuit, pupils are expected to understand the regularity of electric current going through various points in the circuit and voltage applied to various parts. (2) Electric current, voltage, and resistance: by conducting an experiment to measure voltage and electric current of a metal wire, pupils are expected to understand the relationship between electric current and voltage as well as the fact that there is electric resistance in the metal wire. (3) Electricity and its energy: by conducting an experiment to generate heat and light with electric current, pupils are expected to understand that heat and light can be generated from electric current and that there is a difference in the amount of heat and light generated depending on the amount of electricity. The reason for selecting this topic for the study is because of the new content that was added with the 2008 revision of the national curriculum. It is expected that because there was a newly added content, it is easier to comprehend the characteristics of support for secondary school teachers’ learning in Japanese curriculum materials.

Evaluation criteria
The analytical framework employed in this study follows the design heuristics that Davis and Krajcik (2005) proposed, comprising of three major knowledge domains: PCK for science topics, PCK for scientific inquiry, and teachers’ knowledge of the subject matter. The three domains are further broken down into nine categories. The analytical framework is made up of 9 categories and 25 criteria, drawing from the perspective of forms of support (Beyer et al., 2009).
Roughly speaking, there are two forms of support: implementation guidance and rationale. Beyer et al. (2009) describe implementation guidance as follows:

...implementation guidance is one form of educative support that helps teachers know how to use instructional approaches and activities in productive ways by making explicit their salient features. Implementation guidance also helps teachers adapt these approaches to achieve productive instructional ends (p. 982).

Rational is described as follows:

Rationale is a second form of support that presents explicit justification for using particular instructional approaches by explaining why these approaches are pedagogically and scientifically appropriate. This type of support is educative because it makes the curriculum developers’ pedagogical and curricular decisions visible to teachers. Rationales provide opportunities for teachers to examine the assumptions and agendas underlying the instructional approaches embodied in the curriculum materials (Beyer et al., 2009, p. 982).

Among the three knowledge domains, the categories that belong to the domain of teachers’ knowledge of the subject matter support teachers’ acquisition of knowledge of the subject matter, rather than how to use instructional approaches and activities. Therefore, there is no implementation guidance in the categories that belong to the domain of teachers’ knowledge of the subject matter and there is a particular form called educative feature. This form does not exist in PCK for science topics and PCK for scientific inquiry.

Analysis

Writing contained in curriculum materials were divided into segments according to meaning. As a segment is a coherent unit of meaning, certain segments are made up of a single sentence, whereas others are made up of a few. Each segment was then coded by classifying it into one of the categories of the analytical framework based on its meaning. To secure reliability of the analysis, in accordance with Beyer et al. (2009), about 20% of the entire body of data was evaluated by a third party. The evaluation returned a high match of more than 95%. Where two evaluators differed, a consensus was sought through discussion.

When all segments were coded, descriptive statistics were used to find answers to the research questions. Descriptive statistics showed the frequency of each category of teacher knowledge domains that was supported by the curriculum materials under investigation, and the frequency of each form of support.

As for the comparison between the curriculum materials of two publishing houses, there were similar trends in the frequency of each category in teacher knowledge domains and of each form of support. Consequently, the results reported in the Results section are descriptive statistics that combine both Keirinkan and Tokyoshoseki data.
RESULTS

What is the relative frequency of support of teachers’ knowledge of the subject matter, PCK for science topics, and PCK for scientific inquiry across Japanese secondary science curriculum materials?

Table 1 shows the frequency and percentage of each category of three major teacher knowledge domains: PCK for science topics, PCK for science inquiry, and teachers’ knowledge of the subject matter. To highlight the characteristics of secondary science, which is the focus of this study, results from preceding studies, namely, elementary science by Yamaguchi and Kanamori (2014) and high school science by Beyer et al. (2009), are also shown. A 3 x 3 chi-square test was conducted to compare these results. Residual analysis showed that PCK for science topics is most frequently found in secondary science. It also showed that PCK for science inquiry is most frequently found in elementary science. Moreover, it was revealed that teachers’ knowledge of the subject matter is most frequently found in high school science. This finding demonstrated that the characteristic of the curriculum materials of secondary science is that they are most supportive of teachers’ learning with respect to PCK for science topics.

Following the quantitative results, an example of PCK for science topics is presented. The following example illustrates how Japanese secondary science curriculum materials can support teachers to learn PCK for science topics. This example is a description of the representation of combined resistance in series circuits and parallel circuits.

In the case of a series circuit, it is easy for students to understand, as electric resistance is calculated as a simple sum. There is a strong tendency for students to regard parallel circuits as requiring a complicated calculation formula. Because 1/R is the reciprocal of resistance, when this is interpreted as ‘ease of current flow’, then it can be understood that ‘the ease of the current flow of the entire circuit is the sum of the ease of the current flow of each part’. This holds true with the fact that the resistance of the whole circuit decreases, as the resistors are connected in parallel. (Tsukada et al., 2012, p. 352)

In Japan, elementary school students learn about substances that conduct electricity and substances that do not conduct electricity (MEXT, 2008). However, elementary school students do not learn about electrical resistance; secondary school students learn about electric resistance for the first time in this unit. Secondary school students also learn about combined resistance in series circuits and parallel circuits in this unit (MEXT, 2008). It is more difficult for students to understand parallel circuits in comparison with series circuits. This description calls the teacher’s attention to this. In addition, the description does not merely show a method for expressing electric resistance in a parallel circuit, but it also shows a method of thinking in order to make this expression more understandable for students. This may indicate a representation of scientific phenomena specific to the topic of currents. Furthermore, it appears that this is an example providing support for the use of that type of representation in instruction.

What is the relative frequency of rationales and implementation guidance supports across Japanese secondary science curriculum materials?

Table 2 shows the frequency and percentage of each form of support. As in Table 1, to highlight the characteristic of secondary science, which is the focus of this study, the results from

preceding studies, namely, elementary science by Yamaguchi and Kanamori (2014) and high school science by Beyer et al. (2009), are also shown. A 3 x 3 chi-square test was conducted to compare these results. Residual analysis showed that implementation guidance is most frequently found in secondary science and elementary science. It also revealed that rationale and educative features are most frequently found in high school science. This finding demonstrated that one characteristic of the curriculum materials of secondary science is that they are most supportive of teachers’ learning with respect to implementation guidance.

Following the quantitative results, an example of implementation guidance is presented. The following example illustrates how Japanese secondary science curriculum materials can support teachers to learn implementation guidance. This example is a description concerning the ideas that students are likely to have as to why a light bulb emits light.

In one misconception by students, there is an idea that something flows out from the positive and negative poles and comes into contact in the bulb, resulting in the emission of light. In such a case, the direction of the battery should be irrelevant, but because polarity is related to the direction of rotation in motors, etc., it can be imagined that there is a direction to the flow. In addition, it can be understood that when two miniature light bulbs are connected in a series, it is difficult to think that the current flows out of both poles. (Tokyoshoseki, 2012, p. 235)

In Japan, elementary school students learn methods to connect conductors that conduct electricity and those that do not. They also learn that the direction of the current changes by changing the direction of the battery (MEXT, 2008). However, this does not mean that students have achieved proficiency regarding these topics. This description illustrates such a case. Moreover, it can be considered that this description directs the attention of the teacher to the problem.

There are cases in which the students may have unique ideas. The students may think that something flows from the positive and negative poles and comes into contact in the bulb, causing light to shine. This description shows the concrete details of the students’ unique ideas, and can be considered to be an example that notifies the teacher by suggesting possible problems when conducting lessons.
DISCUSSION

The characteristics of teachers’ learning support provided by curriculum materials in Japanese secondary science were found to be supportive with respect to implementation guidance—‘helps teachers know how to use instructional approaches and activities in productive ways’—and PCK for science topics. This is a unique feature that was not found in curriculum materials for elementary or high school science, which were analysed in previous studies.

Secondary science teachers are required to ‘engage students with tropic-specific scientific phenomena’, ‘use scientific instructional representations’, and ‘anticipate and deal with students’ ideas about science’ not only in Japan but across the world (e.g., van Driel et al., 2002; Brown, Friedrichsen, & Abell, 2013; Luft & Zhang, 2014; Berry et al., 2016). In reference to these needs, the curriculum materials that were analysed in this study can be seen as having the potential to support the learning of junior high school science teachers across the world.

THE ROLE OF CONTENT KNOWLEDGE IN DEVELOPING COLLECTIVE PCK OF CHEMICAL BONDING

Rene Toerien¹, Marissa Rollnick² and Annemarie Hattingh¹

¹School of Education, University of Cape Town, Cape Town, South Africa
²Marang Centre, Wits University, Johannesburg, South Africa

South Africa continues to perform poorly in international benchmark assessments. A possible reason being ascribed to a lack of effective teaching strategies and the poor content knowledge of teachers. There is thus a renewed focus on ensuring high quality teaching in our classrooms. Pedagogical content knowledge (PCK) is unique knowledge held by teachers and is viewed as topic specific by many scholars. Content knowledge (CK) is believed to play a role in teachers’ topic specific pedagogical content knowledge (TSPCK), but the relationship between CK and TSPCK is not completely understood. This study investigates the role that CK plays in developing high quality TSPCK. Sixty chemistry teachers completed a validated measuring instrument for CK and TSPCK of chemical bonding. The Rasch Measurement Model was used to derive and compare teacher performance on the tests and establish the nature of the relationship between CK and TSPCK. An explanatory framework analysis was then used to determine the quality of teachers’ content knowledge before comparing it to their TSPCK. Findings reveal that teachers who use more sophisticated explanatory frameworks are more likely to have high quality TSPCK. This study contributes to building collective PCK for a specific topic, namely chemical bonding, through input from expert teachers.

Keywords: pedagogical content knowledge, content knowledge, teacher professional development

INTRODUCTION

South African learners continue to perform poorly in international benchmark assessments such as the Trends in International Mathematics and Science Study (TIMSS) (Reddy et al., 2016). In the 2015 TIMSS study, South Africa was ranked the lowest performing country for science, and second lowest for mathematics. At a national level, student performance is equally poor, with 60 percent of grade 12 students not able to achieve the prescribed minimum of 40 percent to pass the Physical Science examination in 2016. This trend has been consistent over a number of years. Figure 1 shows a comparison of student performance in the grade 12 Physical Sciences examination from 2013 to 2016 (DBE, 2017).

Poor student performance is, in part, ascribed to ‘shortcomings in the teaching strategies or methodologies applied by teachers’ and ‘the lack of content knowledge on the part of teachers themselves’ (DBE, 2016, p. 6). This situation provides strong impetus for a renewed focus on the quality of teachers’ content knowledge and the need to build collective pedagogical content knowledge to ensure effective teaching of the key topics in chemistry.
Figures 1. Overall achievement in the grade 12 Physical Sciences national examination (2013-2016)

Pedagogical content knowledge

Pedagogical content knowledge (PCK) is unique knowledge held by teachers (Shulman, 1986) and was used as the theoretical framework for this study. Mavhunga and Rollnick (2013) conceptualised PCK as specific to a topic and defined the construct topic specific pedagogical content knowledge (TSPCK) as a transformation of content for the purpose of teaching. Mavhunga and Rollnick’s TSPCK model is shown in Figure 2. They identify five components from which the transformation of content emerges, namely students’ prior knowledge, curricular saliency, what is difficult to teach, representations and conceptual teaching strategies. Content knowledge (CK), which they refer to as subject matter knowledge, is viewed as a separate but related domain.
Collective PCK

Although PCK is often viewed as personal, situation specific, and unique to the individual, a collective body of knowledge exists that is ‘widely agreed upon and formed through research and/or collective expert wisdom of practice’ (Smith & Banilower, 2015, p. 90). This knowledge for teaching is referred to as collective PCK and is canonical and context free. The development of collective PCK for various topics can play an important role in providing teaching support for pre-service and in-service teachers. This is a new research area and this study aims to contribute to the expanding literature on collective PCK for a central topic in chemistry, namely chemical bonding.

Explanatory frameworks

Taber (1998, 2001) conducted an extensive study on the learning of chemical bonding with A-level students in the United Kingdom, and analysed how the students’ views on chemical bonding shifted over a two-year period. He identified four explanatory frameworks that were used by the students, namely an atomic ontology, a full shell or octet view, an electrostatic view, and an orbital or quantum view. These explanatory frameworks are progressively more sophisticated views of the bonding concept, and aligned with how students expand their understanding of bonding models. Table 1 provides examples of each framework from the data in this study.

Chemical bonding in the South African curriculum

The South African curriculum has a spiral design where topics are revisited and expanded upon over time to build understanding. The starting point in grade 8 is an atomic view where ‘an element is made up of atoms of the same kind’ (DBE, 2011b, p.40). Distinctions are made between elements and compounds, and a compound is defined as ‘a material that consists of atoms of two or more different elements chemically bonded together’ (DBE, 2011b, p. 41). In grade 9 the chemical bonding concept is expanded slightly and defined as ‘the force that holds atoms together’ (DBE, 2011b, p.41). For grade 10 chemical bonds are divided into three distinct types strongly underpinned by an octet view. Covalent and ionic bonding is viewed as sharing and transfer of electrons, respectively, whilst metallic bonding is ‘sharing a delocalized electron cloud among positive nuclei in the metal’ (DBE, 2011a, p.25). In grade 11 this is
further expanded upon and a chemical bond is defined in terms of an electrostatic framework, namely ‘the net electrostatic force’ (DBE, 2011a p. 67) between charged entities. The quantum or orbital view is not required at school level in South Africa although teachers would have learned about this view during their teacher training.

When teaching about chemical bonding, teachers need to be able to support learners in expanding their understanding of the bonding concept from an atomic view towards an electrostatic view. This requires well-developed content knowledge and the use sophisticated explanatory frameworks when describing chemical bonds.

This study was guided by the following research question: How are teachers’ content knowledge and use of explanatory frameworks related to the quality of their TSPCK for chemical bonding?

**METHOD**

This study used a mixed method research design (Teddlie & Tashakkori, 2009). A sample of 60 grade 11 chemistry teachers completed a validated questionnaire to measure the quality of their CK and TSPCK of chemical bonding. The CK items probed the nature of chemical bonds, and included questions on the three basic bonding models, namely covalent, ionic and metallic bonding. The TSPCK items were designed using the five components identified by Mavhunga and Rollnick (2013), namely representations (REP), curricular saliency (CS), what is difficult to teach (WDT), student prior knowledge (LPK) and conceptual teaching strategies (CTS).

There were 13 CK items and 12 TSPCK items. CK items were scored with a marking memorandum, and the TSPCK items with a specially designed rubric which converted qualitative responses to quantitative measures. The scoring was moderated by two researchers and inter-rater reliability values, as represented by Cohen’s kappa (κ), were calculated. For the CK items the kappa value was excellent (κ = 0.82) and the average percentage agreement was 88 percent. The kappa value for the TSPCK items was good (κ = 0.72) and the average percentage agreement was 79 percent.

Data analysis took place in two stages. In the first analysis stage, the correlation between CK and TSPCK was determined. The Rasch Measurement Model (Bond & Fox, 2015) was used to convert ordinal raw scores to linear person measures for each of the CK and TSPCK tests. The Winsteps software package (Linacre, 2014) was used to determine the degree to which the variance in TSPCK can be ascribed to the variance in CK.

In the second analysis stage, the teachers’ use of explanatory frameworks was investigated. The teachers’ responses to four of the CK items were classified according to Taber’s (1998, 2001) explanatory frameworks to further investigate the quality of teachers’ content knowledge, and how this influenced TSPCK. Not all the CK items were suitable for an explanatory framework analysis, for example multiple choice items did not provide enough information. The four best suited items were chosen for this analysis and yielded 240 responses for the 60 teachers. Twelve blank responses (5 percent) were coded as ‘no response’ (NR) and not included in the analysis. The four items that were used were ‘What is a chemical bond?’ (item CK2.1), and one question on each of the three types of chemical bonds – covalent bonding.
(item CK3.3), metallic bonding (item CK4.2) and ionic bonding (item CK5.1). The prevalence of the various explanatory frameworks – atomic (AT), octet (OC), electrostatic (EL) and orbital view (OR) – was obtained for the group of teachers and a comparison of the ten highest and lowest performing teachers was made to give insight into the relationship between CK and TSPCK.

**FINDINGS**

The Rasch analysis produced separate person measures for CK and TSPCK. Teachers were ranked according to their TSPCK measures and presented in Table 2. The mean person performance was -0.42 logits (SD = 1.29) for the CK items and -0.18 logits (SD = 1.82) for the TSPCK items. The item means were set at zero for each analysis. A moderately strong correlation of 0.65 (p<0.001, N=60) was obtained between the person measures for CK and TSPCK (see Figure 3).

</table>
The explanatory framework codes for the sample are shown in Table 2 on the previous page and a graphical representation of the findings is included in Figure 4 below.

The two most prevalent explanatory frameworks used by the teachers in the sample were the octet view (44 percent) and an electrostatic view (33 percent). The atomic and orbital views were used less frequently, namely 15 and 8 percent, respectively.

To gain further insight into the links between use of explanatory frameworks and teachers’ PCK, the ten highest and ten lowest performing teachers on the TSPCK instrument were compared. The prevalence of explanatory frameworks for these teachers is included in Figure 5.
It was found that high performing teachers on the TSPCK test answered the CK test using predominantly electrostatic and orbital views (75 percent), whereas low performing teachers on the TSPCK test, used a predominantly atomic or octet views of chemical bonds (82 percent). Low performing teachers also did not use the orbital view.

DISCUSSION AND CONCLUSION

The findings have shown that there is a moderately strong positive correlation between teachers’ CK and TSPCK, confirming findings from similar studies in different topics (for example Davidowitz & Potgieter, 2016). High quality CK is therefore related to high quality TSPCK which means that if teachers are able to improve the quality of their content knowledge, their PCK should also improve.

The explanatory framework analysis, which sheds light on the quality of teachers’ content knowledge, revealed that teachers who scored higher in the TSPCK test had more sophisticated views of chemical bonding. TSPCK is strongly linked to teaching for conceptual understanding and it is therefore not surprising that teachers with higher TSPCK are more likely to have a more conceptual view of the content.

The implication of these findings is that in order to expand teachers’ TSPCK, deeper conceptual understanding of the content, and more sophisticated views of chemical bonding are needed. This study contributes to building collective PCK of chemical bonding by identifying knowledge of sophisticated explanatory frameworks as an important pre-requisite for high quality topic specific pedagogical content knowledge of chemical bonding.

ACKNOWLEDGEMENT

This study was made possible through the financial support from the Sasol Inzalo Foundation.

USING VIGNETTES TO ACCESS PEDAGOGICAL CONTENT KNOWLEDGE OF REDOX REACTIONS

Luciane Fernandes de Goes¹ and Carmen Fernandez¹,²
¹Science Education Graduate Program - University of São Paulo, São Paulo, Brazil
²Institute of Chemistry - University of São Paulo, São Paulo, Brazil

This study aimed to investigate the pedagogical content knowledge (PCK) for teaching redox reactions (RR). Data were collected with 29 teachers with different years of experience. The data collection was done through four written vignettes. These vignettes were developed based on a literature review about the redox reactions content and two pilot studies were conducted. The research subjects answered the vignettes individually. Data were analyzed by the PCK components proposed by Magnusson, Krajick and Borko (1999). Although the answers of the vignettes were focused on content knowledge, it was possible to verify evidence for three components of PCK: Orientations towards science teaching; Knowledge of students’ understanding of science; and Knowledge of instructional strategies. In general, the vignettes have proved to be a PCK access methodology. However, in order to be able to study the other components of the PCK, it is necessary to use more tools to capture teachers’ PCK.

Keywords: pedagogical content knowledge (PCK), redox reactions, vignettes

INTRODUCTION

Lee Shulman (1987) describe “pedagogical content knowledge” (PCK) as a “special amalgam” of knowledge possessed by a teacher. Shulman suggested that PCK comprises “the ways of representation and formulating the subject that make it comprehensible to others” and “what makes the learning of specific topic easy or difficult” (Shulman, 1987). PCK is considered the central component of teachers’ professional knowledge that distinguishes teachers from subject matter specialists (Fernandez, 2015; Grossman, 1990; Shulman, 1987). In the literature, it is possible to find a variety of PCK models (Abell, 2008; Fernandez, 2014; van Driel, Verloop, & de Vos, 1998). Specifically, in the area of science education, Magnusson, Krajcik & Borko (1999) proposed a model of PCK defining five components, namely: orientations towards science teaching, knowledge of science curricula, knowledge of students’ understanding of science, knowledge of instructional strategies and knowledge of assessment for science. The component orientations towards science “refers to teachers’ knowledge and beliefs about the purposes and goals for teaching science at a particular grade level” (Magnusson, et al., 1999, p. 97). This component is more than the simple use of a strategy for teaching certain content. It refers to teaching purposes when using a particular strategy. The nine possible orientations and the characteristics of the instruction are described in Table 1. Instructional strategies are divided between subject-specific strategies, which are more general approaches for teaching science, and topic-specific strategies, which include two type of knowledge: representations and activities. Representations can be explanation, examples, narratives, illustrations, questioning or argument. Activities can be demonstrations, simulations, investigations, or experiments (Magnusson, et al., 1999; Park & Oliver, 2008; Shulman, 1986, 1987).

<td>Academic Rigor</td>
<td>Students are challenged with difficult problems and activities. Laboratory work and demonstrations are used to verify science concepts by demonstrating the relationship between particular concepts and phenomena.</td>
</tr>
<tr>
<td>Didactic</td>
<td>The teacher presents information, generally through lecture or discussion, and questions directed to students are to hold them accountable for knowing the facts produced by science.</td>
</tr>
<tr>
<td>Conceptual Change</td>
<td>Students are pressed for their views about the world and consider the adequacy of alternative explanations. The teacher facilitates discussion and debate necessary to establish valid knowledge claims.</td>
</tr>
<tr>
<td>Activity-driven</td>
<td>Students participate in &quot;hands-on&quot; activities used for verification or discovery. The chosen activities may not be conceptually coherent if teachers do not understand the purpose of particular activities and as a consequence omit or inappropriately modify critical aspects of them.</td>
</tr>
<tr>
<td>Discovery</td>
<td>Student-centered. Students explore the natural world following their own interests and discover patterns of how the world works during their explorations.</td>
</tr>
<tr>
<td>Project-based Science</td>
<td>Project-centered. Teacher and student activity centers around a “driving” question that organizes concepts and principles and drives activities within a topic of study. Through investigation, students develop a series of artifacts (products) that reflect their emerging understandings.</td>
</tr>
<tr>
<td>Inquiry</td>
<td>Investigation-centered. The teacher supports students in defining and investigating problems, drawing conclusions, and assessing the validity of knowledge from their conclusions.</td>
</tr>
<tr>
<td>Guided Inquiry</td>
<td>Learning community-centered. The teacher and students participate in defining and investigating problems, determining patterns, inventing and testing explanations, and evaluating the utility and validity of their data and the adequacy of their conclusions. The teacher scaffolds students’ efforts to use the material and intellectual tools of science, toward their independent use of them.</td>
</tr>
</tbody>
</table>

Although there are many types of research about PCK, its access is difficult. Multiple methodologies are used with the intention to document and portray teachers’ PCK (Fernandez & Goes, 2014; Goes & Fernandez, 2018). Recently, vignettes have been used as a research instrument to capture teachers’ PCK (Chan & Yung, 2015; Kind, 2016; Mavhunga, 2016; Veal, 2004). Vignettes are a short story, in some cases, they are written, in others cases, they are audio or visual representations of a classroom (Boz & Boz, 2008). Thinking about the possibility of analyzing the PCK of Brazilian teachers through vignettes, this study aimed to investigate PCK about redox reactions of chemistry teachers through answers to vignettes. Since experience is one of the factors that can improve teachers’ PCK (Schneider & Plasman, 2011; van Driel, et al., 1998), it was expected to find variance in novice and experienced teachers' answers of the vignettes. Therefore, the second purpose of this study was to investigate the variance in novice and experienced teachers' PCK.

**Teaching the content of redox reactions**

Redox reactions were chosen as the investigated subject matter because its importance related to many chemical processes and its importance in the curriculum for secondary schools (Soudani, Sivade, Cros, & Mèdimagh, 2000). In addition, they are perceived to be one of the most difficult topics, both to learn and to teach (de Jong & Treagust, 2002). The complexity
involving teaching and learning has made redox reactions the object of study for several researchers. Some authors have sought out to identify the main alternative conceptions evoked by students (Garnett & Treagust, 1992a, 1992b; Lee, 2007; Niaz, 2002; Sanger & Greenbowe, 1997a, 1997b). Some studies report the students’ difficulties related to this content (de Jong & Treagust, 2002; Österlund & Ekborg, 2009). Recent studies analyzed the Pedagogical Content Knowledge of teachers on redox processes (Aydin & Boz, 2013; Freire & Fernandez, 2014; Goes & Fernandez, 2016; Rollnick & Mavhunga, 2014). Other studies focus on teaching strategies and practical activities involving redox reactions (Huddle, White, & Rogers, 2000; Niaz & Chacón, 2003; Sesen & Tarhan, 2013). In this sense, the purpose of this article is to investigate the pedagogical content knowledge of secondary chemistry teachers with respect to the content redox reactions. Also, investigate whether there are any similarities and/or differences in teachers’ PCK at their distinct career phases.

**METHODOLOGY**

The vignettes development began with a 17-year literature review (2000-2016) about the alternative conceptions and difficulties of redox reactions teaching. After conducted a literature review, the didactic sequences about redox reactions of two chemistry teachers from two different institutions were recorded. In total, 67 lessons were recorded, totaling approximately 3400 minutes. The instructional strategies used by the teachers were analyzed and served as parameters for the elaboration of four vignettes. A first pilot tested was carried out with 13 chemistry teachers. Then, the four vignettes were revised examining the variation in teacher responses to the pilot test. A second pilot test was carried out with others 10 chemistry teachers. After the second analysis, a final four vignettes were developed. The purpose of these vignettes was to get an idea about teachers’ PCK about redox reactions based on the described class situation in the vignette. For each vignette, teachers were asked to describe what they would do in that specific situation. Twenty-nine chemistry teachers participated in the study. Most of the participating teachers are trained in chemistry teacher education and they have more than five years of experience (Figure 1).

![Figure 1. Characteristics of the participants.](image-url)
Data were analyzed using PCK components of Magnusson and co-workers (1999). Despite being a model of PCK with almost twenty years of the proposition, we consider it an appropriate model and pertinent to our purposes. In addition, it is one of the most used PCK models in science education (Goes & Fernandez, 2018; Kıran & Şen, 2014). Data analysis was performed with a general score. For the component orientations towards science teaching, frequency counting was performed for evidence of any of nine orientations, using definitions in Table 1 for each group.

Overview of the Vignettes

The vignettes used for this study (Figure 2) contain a description of the interacting dimensions found in a classroom about redox reactions. The description of the classroom interaction was mainly based on the classroom observation supplemented with literature review. The first vignette (Vignette 1) presents an image with the row of metal reactivity and then brought a situation in the classroom, questioning what the teacher’s action would be. The second vignette (Vignette 2) deals with phenomena quite described in textbooks, which is the reaction between metallic copper and silver nitrate. It describes a situation in the classroom, where the teacher conducts a demonstration experiment. After the description, there is a short dialogue between teacher and student. In the third vignette (Vignette 3), it also reports a demonstration experiment in which the teacher adds concentrated nitric acid to a copper coin. The students verify the formation of a brown gas and the blue coloration of the solution. In the fourth vignette (Vignette 4), the content of redox reactions is approached by the topic of the production of iron and aluminum.

RESULTS AND DISCUSSION

It was only possible to identify three PCK components. Table 2 presents a synthesis of the data for the component of PCK across the experience levels.

In general, the responses of the vignettes focused more on the knowledge of the content. However, there are also other evidence that leads us to infer about other components. The
responses of the vignettes did not show evidence for Knowledge of curriculum or Knowledge of assessment. Among the nine orientations to teaching science identified by Magnusson et al. (1999), only three emerged from the vignette responses: “Didactic”, “Activity driven” and “Academic Rigor”. Most of the chemistry teachers (26) answered to the vignettes using didactic orientations. This result is compatible with Kind's research (2016), where 50% of responses to the chemistry vignette were coded didactic orientation.

Table 2. The frequency of chemistry teachers’ PCK components shown in answers to vignettes.

In the case of didactic orientations, the purpose of teaching is to transmit the facts of science. Thus, the teacher presents the information usually through lectures. For example:

I would explain the potential standard of reduction of each element. (Teacher with less than a year of experience - Vignette 1).

The metal that has the highest oxidation potential is what will oxidize losing electrons. (Teacher with 1 to 5 years of experience – Vignette 1).

The oxidizer gains electrons and reduces; the reducer loses electrons and oxidizes. (Teacher with 5 to 10 years of experience – Vignette 1).

I would explain that the process to get pure aluminum (electrolysis) is more expensive. (Teacher with more than ten years of experience - Vignette 4).

According to the excerpts above, it is possible to observe that the goals for teaching science include information and concepts.

Activity-driven orientations is characterized by “hands-on” activities, in other words, the teacher wants students to be more active:

I would ask them to research the subject. Let's look at the iron and aluminium production chain to see the differences from a chemical, environmental and energy point of view. (Teacher with 1 to 5 years of experience – Vignette 4).

I would ask them to equate the ionic reactions. (Teacher with 5 to 10 years of experience – Vignette 2).

That this reaction involves the interaction with the nitrate ions in acidic medium, forming a highly oxidizing species. Obviously, this could not be done from a simple explanation; it is a complex subject and could be done in an investigative way. I would ask to the students to write the ionic forms of the substances involved. (Teacher with more than ten years of experience - Vignette 3).
Even with an aim to make the students have a more active position in the classroom, conducting research or equating chemical reactions, it is observed that the objective of teachers is still to transmit concepts and information.

Academic rigor orientation as well didactic orientation involve knowledge verification. The difference is that academic rigor is characterized by challenging students with difficult problems (Kind, 2016). When there are laboratory classes, they are usually used to verify scientific concepts.

First, I would understand the student's conception of dissolving. I would do this by asking what he/she means by dissolving? Then, I would show the real concept of dissolution. Finally, I would present a solution of copper sulfate to the student and say that this solution is also blue and would explain that it is blue due to copper ions. (Teacher with less than a year of experience - Vignette 2).

I would briefly discuss with this student the idea of cost/benefit of the various materials used by a human. I would give some clues as to the “useful life” of iron and aluminum as to the costs of production and the viability of these processes from the way they are found in nature. However, I think that this question must be answered gradually, constructing concepts and ideas that allow the student to understand the completeness of the answer. (Teacher with 1 to 5 years of experience – Vignette 4).

That the above scheme gives a general idea of the problem of reactivity and that if we want to know the differences between metals of the same group, we will need to choose a more sophisticated comparison criterion, using oxidation and reduction potentials. Then, for example, I would show a reaction involving zinc and iron. (Teacher with 5 to 10 years of experience – Vignette 1).

I would ask the student how he/she thinks aluminum and iron are found in nature? This question seeks to develop the idea that metals, in general, are found in the form of oxides and need to be treated for purification. I would question if the student knows the methods how the metallurgies of these metals are made, that is, how they are obtained for use in industry and everyday life. (Teacher with less than a year of experience - Vignette 4).

For the component orientations towards science, according to the excerpts above, it was not possible to verify differences in the purposes and goals of teaching science among teachers with different levels of experience. As it says Kind (2016), the intuitive change of the orientations is still a great challenge, in this sense, teacher training programs should use the orientations to assist the professional development of teachers.

The evidence of the component Knowledge of students’ understanding of science was low, appearing only in the answers of teachers with less than five years of experience. For example, knowledge of students’ prior knowledge can be observed in the following answer:

It is expected that the student has some knowledge about the periodic table. (Teacher with less than a year of experience - Vignette 1).

The knowledge of students’ misconceptions can be noticed in the following statement:
It would be clear that he does not distinguish between the substance copper metal and the substance copper salt, and that each one has very different chemical and physical properties. (Teacher with 1 to 5 years of experience - Vignette 2).

The fact that most teachers exclude students' knowledge of their answers may be related to the nature of the vignette questions. Each vignette presents a classroom situation inviting respondents to address teachers’ actions. That may unintentionally prompt scientific answer.

Among the different instructional strategies reported in the literature, in this research, it was possible to identify five different strategies: explanations, demonstration, questioning, illustration, and examples. Most chemistry teachers (22) answered to the vignettes using explanations as instructional strategies:

- I would explain that aluminum is not found in pure form and there is a chemical process to get it in the pure form that is more expensive. (Teacher with less than a year of experience - Vignette 4).
- I would explain that the reaction occurred because, nitric acid, has high ionization power. (Teacher with 1 to 5 years of experience - Vignette 3).
- I would respond that this series of reactivity is just a form of generalization (grouping in similar reactivity) given the amount of known chemical elements and that is useful when comparing elements of different categories. In order to decide which is the most reactive within the same group, it is necessary to know the reduction potential of the elements/ions. (Teacher with 5 to 10 years of experience – Vignette 1).
- I would show the student the nitrate oxidation potential and would also address that in this case there is no formation of hydrogen gas. (Teacher with more than 10 years of experience - Vignette 3).

Demonstration appeared only in the answers of teachers with more than five years of experience:

- From the oxidation/reduction potential, it would be possible to predict whether the reaction would occur. In the laboratory, this could be tested even before this explanation happens. From the evidence, we could observe the occurrence (or not) of the reaction. (Teacher with 5 to 10 years of experience – Vignette 2).
- From a demonstrative experiment, I would take the student to develop his/her proposition in the sense of perceiving that the blue color is a macroscopic characteristic related to the set of Cu (II) ions and their interaction with the solution and that the nitrate does not play paper in this sense. (Teacher with more than 10 years of experience - Vignette 2).

Questioning was the second most cited strategy by teachers:

- I would do this by asking what he/she means by dissolving. (Teacher with less than a year of experience - Vignette 2).
- We could question whether the metallic copper would turn blue in a solution with sodium chloride. (Teacher with 1 to 5 years of experience - Vignette 2).
- Through the student's response, I would encourage him to try to improve the answer. I would question the answer in the context of redox reactions. (Teacher with 5 to 10 years of experience – Vignette 2).
I was going to propose questions for him/her to reflect: Who would that ion be? How did it become an ion? Are only ions responsible for the color? (Teacher with more than 10 years of experience - Vignette 2).

The illustration appeared as a strategy only for one teacher:

I would try to use an illustration scheme, bringing the idea of the role of ions in this reaction. (Teacher with 1 to 5 years of experience - Vignette 3).

The use of examples appeared more frequently in the responses of teachers with more than ten years of experience:

Within the same group, there are the weakest and the strongest. I would provide some examples to explain this question. (Teacher with more than 10 years of experience - Vignette 1).

I would explain that nitric acid acts as an oxidizer, but not all acids act in this way. I would look for more examples. (Teacher with more than 10 years of experience - Vignette 3).

I could also explore the reaction with the students, performing an experiment and showing the variations of Nox of the species to a better understanding of the phenomenon. (Teacher with more than 10 years of experience - Vignette 3).

According to the excerpts above, there is an expansion in the knowledge of instructional strategies, from novice to experienced teachers. What is observed is that more experienced teachers cite more teaching strategies, this may be a possible indication that teachers considered experienced (more than ten years of experienced) demonstrated more knowledge of instructional strategies than the other teachers did. This result is compatible with the findings of van Driel, de Jong and Verloop (2002), who also found gains in the growth of knowledge of strategies by teaching experiences.

**CONCLUSION**

According to the results, it is possible to observe that the vignettes have proved to be a useful methodology for investigating the teacher's PCK. However, the vignettes used in this study proved to be inefficient for knowledge of curriculum and knowledge of assessment. To investigate these other PCK components, it is necessary to use another methodology together to the vignettes, for example, observing teaching or collecting oral evidence from video analysis. From the answers of the teachers, it was possible to analyze evidence of the strategies that they use in the classroom to teach redox reactions. Experienced teachers showed more variety of strategies, on the other hand, they did not show their knowledge of students’ understanding of science. Concerning teachers orientation, most of the teachers believe that it is essential to transmit the facts of science. There are some limitations of this study. It was used only one data set comprising written evidence and it was investigated only 29 chemistry teachers. Larger-scale studies have the potential to produce results that are more generalizable.

IN-SERVICE PROFESSIONAL DEVELOPMENT IN INQUIRY BASED SCIENCE EDUCATION – OUTCOMES AND CHALLENGES

Christian Bertsch
University College of Teacher Education, Vienna, Austria

National and international reform efforts demand a reversal of school science teaching from mainly deductive to inquiry based methods. However, transforming teacher practice is a long-term project and requires significant and sustained investment in continuous professional development for teachers. Within the project AMGEN TEACH Professional Development sessions on inquiry learning in science including a strong focus on the nature of scientific inquiry were planned, implemented and evaluated. The 20 hour training included concrete teaching tasks to allow personal experiences and time for joint reflection. The PD sessions improved participant’s knowledge of inquiry based science education and their self-confidence in inquiry based science teaching. Teachers reported a strong influence of the training on their science teaching practices. Changing teacher pedagogy cannot be done through short, one-off courses, which currently dominate professional development for teachers in Austria. However, motivating large numbers of teachers for long-term trainings is still a big challenge.

Keywords: inquiry based science education, nature of science, continuous professional development

INTRODUCTION

Inquiry is a central term in the rhetoric of science education reforms around the globe over the last two decades. One goal of these reforms is promoting positive attitudes towards science and learning science. The importance of this promotion is emphasized by the mounting evidence of a decline in young peoples’ interest in science studies and careers in industrialized countries (OECD, 2006). Motivating students to study science is a worthy aim, however the primary goal of science education must not be to produce the next generation of scientists, but to offer an education that develops students’ basic understanding both of the major ideas which science offers and the way it produces reliable knowledge. The aim of science education should be educating students in and about science (Osborne & Dillon, 2009). To achieve this goal we need to refocus science teaching on meaningful learning and conceptual understanding of scientific ideas rather than teaching and learning isolated fragments of theoretical knowledge.

Inquiry Based Science Education, if carried out effectively, is an efficient way to facilitate conceptual understanding and deepen the understanding of the nature of scientific inquiry. Learning with understanding differs from remembering facts such as the names of the planets in the solar system, which particular objects float or sink or the photosynthesis equation (Harlen, Artigue, Dillon & Lena, 2012). Facts alone are insufficient for developing understanding. Understanding means that students can explain why there are four seasons in Austria, why things do or do not float, why plants can’t grow in the dark and which evidence supports these concepts.
Defining IBSE

While Inquiry Based Learning is not especially new in science education it has been increasingly engrossed in reform documents over the last 20 years. In 1996 the US National Science Education Standards declared that inquiry is central to science learning (NRC 1996, p.2). In 2007 the European Commission demanded a reversal of school science-teaching pedagogy from mainly deductive to inquiry-based methods. In 2015 one can find the term inquiry in almost any curriculum in industrialized countries - from primary to higher education. Aside from its raising popularity we still do not have a current unified view of precisely how inquiry should be defined. Some researchers assess its definition as "the most confusing thing about inquiry" (Colburn 2000, p. 42). Part of this confusion lies in the fact that inquiry often simultaneously refers to the learning of both scientific concepts and the skills scientists use to solve problems of the natural world (Magee & Meier, 2011).

Abd-El-Khalick et al. (2004) distinguish between “inquiry as means” and “inquiry as ends”. The former sees inquiry as an instructional approach intended to help students develop understanding of science content, the latter refers to inquiry as an instructional outcome: students learn to inquire in the context of science content and develop epistemological understandings about the nature of science and the development of scientific knowledge, as well as relevant inquiry skills (e.g. identifying problems, generating research questions, designing and conducting investigations, drawing evidence-based conclusions).

One definition that is often referred to within the science education research community is the one given by the US National Research Council (NRC 1996, p. 23). It defines inquiry

“….as a multifaceted activity that involves making observations; posing questions; examining books, and other sources of information to see what is already known; planning investigations; reviewing what is already known in light of experimental evidence; using tools to gather, analyze, and interpret data; proposing answers, explanations, and predictions; and communicating the results.”

The NRC also defines essential features of classroom inquiry and gives variations in the amount of learner self-direction (Table 1).

Within the EU Seventh Framework Programme (FP 7) project “Primary Science Network (Pri-Sci-Net)” IBSE was defined as framework, where the learners

- engage actively in the learning process with emphasis on observations and experiences as sources of evidence;
- tackle authentic and problem based learning activities where the correctness of an answer is evaluated only with respect to the available evidence and getting to a correct answer may not be the main priority;
- practice and develop the skills of systematic observation, questioning, planning and recording to obtain evidence;
- participate in collaborative group work, interact in a social context, construct discursive argumentation and communicate with others as the main process of learning;
- develop autonomy and self-regulation through experience.
Within this framework the teacher scaffolds and guides learning by being a role model of an inquiring learner. The teacher does not perform, in the eyes of the children, as the sole bearer of expert knowledge. Instead, the main role of the teacher is to provide possibilities to negotiate ideas and to highlight criteria for formulating classroom knowledge (Gatt & Scheersoi, 2014).

Table 1: Essential features of classroom inquiry and their variations in the NRC concept (NRC 2000)

<table>
<thead>
<tr>
<th>Essential Feature</th>
<th>Variations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Learner engages in scientifically oriented questions</td>
<td>Learner poses a question</td>
</tr>
<tr>
<td>Learner gives priority to evidence in responding to questions</td>
<td>Learner determines what constitutes evidence and collects it</td>
</tr>
<tr>
<td>Learner formulates explanations from evidence</td>
<td>Learner formulates explanations after summarizing evidence</td>
</tr>
<tr>
<td>Learner connects explanations to scientific knowledge</td>
<td>Learner independently examines other resources and forms the links to explanations</td>
</tr>
<tr>
<td>Learner communicates and justifies explanations</td>
<td>Learner forms reasonable and logical argument to communicate explanations</td>
</tr>
</tbody>
</table>

Interestingly, both the NRC and the Pri-Sci-Net framework see inquiry based learning as evidence-based learning, but they differ in the aim of the inquiry process. In the Pri-Sci-Net framework “the correctness of an answer is evaluated only with respect to the available evidence and getting to a correct answer may not be the main priority” whereas in the NRC framework the “learner connects explanations to scientific knowledge”. What if the students’ findings contradict the current scientific view on a given topic? The NRC framework gives different variations on how to connect students’ explanations to scientific knowledge. It seems to be assumed that students’ investigations cannot contradict scientific knowledge.

Picking two different definitions of inquiry learning, one finds overlaps but also different aspects in these definitions. Looking at other curricula or reform documents I would probably have come up with more definitions, more overlaps and more different aspects. Not all, but
many of these definitions do have a strong theoretical fundament (Abd-El-Khalick et al., 2004). Sometimes the fundament is more epistemological and refers strongly to the philosophy of science. Sometimes the fundament refers to educational theories.

From a scientific point of view a unified definition of inquiry learning by means of clearly defined criteria would ease the access for empirical work in the field. Current meta-analyses on the effects of inquiry learning (OECD, 2015, Hattie, 2010, Minner et al., 2009) are difficult to interpret, because it is not clear what different studies meant when they evaluated inquiry learning.

However, restrictive definitions with the idea, that an endeavor can only be classified as inquiry learning if all the criteria of the definitions are met, have little value for educational settings, because these are highly situated and contextual.

If we want to integrate inquiry learning into daily classroom routines we need to have a clear understanding what inquiry learning is. Based on this understanding we can define curricular goals and develop pedagogical tools and professional development sessions for in-service and pre-service teachers.

However, having a clear understanding of inquiry learning does not mean that we have to follow a unified definition of inquiry learning. Instead of thinking of a generalized definition of inquiry learning in science and assuming it will allow achieving multiple goals (i.e. developing understanding of scientific concepts, helping students to acquire integrated inquiry skills, learning about the nature of science), it might be more useful to think of several dimensions of Inquiry learning that are intimately linked with measurable instructional outcomes.

We see inquiry learning as evidence-based learning, where you can use different methods of investigation to find evidence for defensible conclusions. When planning teacher professional development sessions on inquiry learning in science we have several dimensions of inquiry learning in mind. One dimension is conceptual understanding. How must inquiry lessons be structured to allow better understanding of a given topic? Another dimension is inquiry skills. How can a teacher support the systematic collection of data and fair testing? A third dimension is the nature of science. How can a teacher support the epistemological understanding about how scientists work?

To achieve inquiry based science learning teachers themselves must be aware of how science works and what the characteristics of scientific investigations are. This can only be facilitated if the nature of science is made explicit in the pre-service and in-service training of teachers (Sadler, Burgin, McKinney, & Ponjuan, 2010; Capps & Crawford, 2013).

**IBSE AND TEACHER PROFESSIONAL DEVELOPMENT**

Inquiry based science education requires students to become more independent learners. Teachers must allow students to develop their own ideas taking into account that these ideas can also be wrong at first. Teachers used to teaching science by giving information from text books need the chance to experience, understand and value inquiry based learning if they are to develop the confidence and skills to implement inquiry based education in their classroom.
(Harlen & Allende, 2009). To achieve a change in teaching practices professional development is still seen as the most effective way. Alternative methods, such as policies to support ambitious instructional reforms, have been found to have little impact on basic classroom routines (Suppovitz & Turner, 2000).

Within the project AMGEN TEACH (www.amgenteach.eu) the University College of Teacher Education Vienna, the University of Graz and the Open Labs in Vienna and Graz designed, implemented and evaluated continuous professional development (CPD) sessions on IBSE for more than 300 secondary life science teachers between 2014-2017. The following three dimensions of IBSE were covered within these trainings:

- IBSE and conceptual understanding
- IBSE and inquiry skills
- IBSE and nature of science

Usually teacher trainings in Austria only span one or two afternoons. Evaluation of various projects on the dissemination of IBSE shows that short term teacher trainings do not necessarily lead to a change of classroom routine. Harlen and Allende (2009) concluded in their evaluation of various Professional Development (PD) programs on IBSE

“when teachers learn to use new materials and pedagogy, their needs are similar to those of any learners, particularly the need to communicate with and have feedback from others and to have time for reflection. These are more likely to be provided, and teachers take ownership of their learning, when professional development sessions take place intermittently over a period of time, with opportunities between sessions for teachers to practice what they have learned in their own classrooms and to share experiences with others.” (Harlen & Allende, 2009, p 25)

The developed training lasted for 20 hours and we engaged teachers in concrete teaching tasks to allow personal experiences. Teachers were asked to put into practice what we discussed in the workshops between the training sessions and discuss their experiences with the other participants. We also included a workshop focusing specifically on the Nature of Science into our training.

**EVALUATION OF THE PD COURSES**

The evaluation is focusing on the first year of the project. 60 teachers took part in the three trainings in Vienna and Feldkirch The course was evaluated with a pre/posttest design with questionnaires and interviews. In this article some results of the post-questionnaire will be discussed.

**Impact on teacher knowledge and self-confidence**

92.2% of the participants strongly agree that the PD course improved their understanding of inquiry based science education. 46.2% of the teachers reported a strong influence on their content knowledge of relevant science topics. The focus of the CPD course was on IBSE skills and NOS, therefore we did not expect a strong improvement of content knowledge. 73% strongly agree that the PD course improved their self-confidence in inquiry based science teaching (Figure 1).
Impact on science classroom routine

75% of the participants reported that the PD had a strong influence on their science teaching. 67% strongly agree that they often use the material that was developed during the PD sessions in their classroom. 81% reported that they worked with new methods in their science classrooms (Figure 2). In the literature (Capps & Crawford, 2013) it is suggested that PD on IBSE should contain opportunities for learning through inquiry and learning about inquiry. Therefore one workshop on the Nature of Science was added. Teachers were very enthusiastic about this workshop and in the interviews they mentioned, that this workshop had a strong influence on their own understanding about inquiry. However, only 48% of the teachers strongly agree that they discuss the nature of scientific inquiry explicitly with their students. In the interviews some of the teachers mentioned that NOS is not an explicit topic in the Austrian curriculum and that – due to a lack of time – they did not include it in their teaching so far.

Dissemination of knowledge

Successful PD should empower teachers not only to use new methods in their teaching but also to promote new learning methods at their schools. At the end of the PD course 86% of the participants said that they have discussed content of the workshops with colleagues at school, 81% have shared knowledge and material. 52% strongly and 48% rather agree that they know more about IBSE than most of their colleagues at school. However, only 24% strongly agree that they are able to offer in-school trainings on IBSE for their colleagues (Figure 3).
CONCLUSION

Inquiry based science education has been shown to foster both understanding of scientific concepts as well as understanding of how scientists work when solving problems. Within the project AMGEN TEACH Professional Development sessions on inquiry learning in science including a strong focus on the nature of scientific inquiry were planned, implemented and evaluated. The 20 hour training improved participant’s knowledge of inquiry based science.
education and their self-confidence in science teaching. Teachers reported a strong influence of the training on their science teaching practices.

The major determinant of any education system is the quality of its teachers. If we want a reversal of school science-teaching pedagogy from mainly deductive to inquiry-based methods investment in long-term professional development is crucial. Changing teacher pedagogy cannot be done through short, one-off courses, which currently dominate professional development for teachers in Austria. However, motivating large numbers of teachers for long-term trainings is still a big challenge.

ACKNOWLEDGEMENT

We thank the AMGEN Foundation for its commitment to inspire the next generation of innovators and providing financial support to develop, implement and evaluate teacher trainings on IBSE and NOS for life science teachers.

EXPLORING TEACHERS’ AWARENESS OF MISCONCEPTIONS ABOUT SERIES AND PARALLEL CIRCUITS

Estelle Gaigher
University of Pretoria, Pretoria, South Africa

This paper reports on an exploratory case study, using a new method to probe science teachers’ understanding of learners’ misconceptions as well as their suggestions to address misconceptions. Teachers were questioned about wrong answers they expected from their learners and they were required to explain how they would correct their learners’ wrong answers. Four teachers from South African schools were conveniently selected to participate in the study. Data were collected using an open-ended questionnaire followed up by a semi-structured interview. The instruments were focused on the teaching of series and parallel circuits to middle school learners. Two of the teachers anticipated mistakes related to documented misconceptions about series and parallel circuits. Their answers revealed that they reflect on how learners think about circuits, based on these misconceptions. Another teacher anticipated typical wrong answers but did not show understanding of the misconceptions leading to these mistakes. The remaining teacher did not anticipate any of the typical wrong answers corresponding to wellknown misconceptions about circuits. To address mistakes, all the teachers indicated that they would make use of practical work or demonstrations to illustrate the correct answers, but only two of the teachers referred to concepts that should be developed in order to address the misconceptions. It was clear from their answers that the teachers’ own subject matter knowledge was key to appreciate the importance of scaffolding learners’ conceptual understanding. The technique presented here may be useful in studies of other topics as well as in teacher preparation and professional development programs to sensitize teachers to learners’ misconceptions.

Keywords: misconceptions, electric circuits, science teachers

INTRODUCTION

Students’ misconceptions in electricity have been researched extensively since the early nineteen eighties (e.g. Cohen, Eylon & Ganiel, 1983). It is therefore important that teachers are aware of learners’ misconceptions to be able to design appropriate instruction (Morrison & Lederman, 2003). However, few studies were conducted the teacher’s role in identifying or correcting learners’ misconceptions (e.g., Gunstone, Mulhall & McKittrick, 2009; Morrison & Lederman, 2003). The current paper contributes to closing this gap in the research literature and may ultimately contribute to improved teacher education with regard to misconceptions.

Sencar and Eryilmaz (2004) compiled and discussed a list of common misconceptions from the literature. Quantitative studies showed that many misconceptions occur across cultural and language borders (Küçükközer & Kocakülah, 2007; Shipstone, von Rhöneck, Kärqvist, Dupin, Joshua & Licht, 1988). According to Dupin and Joshua (1987), the weakening current and constant current source models are most persistent. A multi-case study by Gunstone, Mulhall and McKittrick (2009) found that some experienced senior high school teachers and some textbook authors displayed poor conceptual understanding about DC electricity. Morrison and
Lederman (2003) found that teachers not only had poor understanding of preconceptions, but also did not regard the identification of preconceptions as useful. In order to support teachers to address learners’ misconceptions, more research is required. However, teachers may object to such research as they may feel threatened (Pardhan & Bano, 2001). The current paper reports on a part of a larger project (Gaigher, 2014; Gaigher, 2016; Moodley & Gaigher, 2017) which introduced a technique ‘Questions about Answers’ which bypasses possible embarrassment of teachers’ by focussing on learners’ incorrect answers. Two research questions were formulated:

1. How do teachers understand learners’ misconceptions about series and parallel circuits?
2. How do teachers envisage to address learners’ misconceptions about series and parallel circuits?

CONCEPTUAL FRAMEWORK

This study is underpinned by the theoretical construct of Topic Specific Pedagogical Content knowledge (TSPCK, Mavhunga and Rollnick, 2013). Schulman (1986, pp. 9-10) originally described pedagogical content knowledge (PCK) as follows:

“… knowledge of the most useful forms of representation of those ideas, the most powerful analogies, illustrations, examples, explanations and demonstrations ….. also includes an understanding of what makes learning of a specific topic easy or difficult: the conceptions and preconception that learners of different ages and backgrounds bring with them to the learning of those most frequently taught topics and lessons. If those preconceptions are misconceptions, which they so often are, teachers need knowledge of the strategies most likely to be fruitful in reorganizing the understanding of learners, because those learners are unlikely to appear before them as blank slate”.

In the research literature aiming to describe the nature of the PCK, Shulman’s focus on content is often overlooked (Hashweh, 2005; Hill, Ball & Schilling, 2008). Mavhunga and Rollnick (2013) recently introduced the term TSPCK, following earlier authors (Loughran, Mulhall & Berry, 2004; Veal & MaKinster, 1999) who pointed out that Shulman’s original conception of PCK was indeed topic specific. The construct of TSPCK is therefore accepted as a theoretical basis for this study, focussed on the knowledge about teaching series and parallel circuits.

METHOD

Data were collected using an open-ended questionnaire (Appendix 1) followed up by a semi-structured interview. The questionnaire (Gaigher, 2014) focused on two well-known misconceptions, namely current attenuation and the constant current models. These two misconceptions were chosen because these are regarded as the most persisting of misconceptions (Dupin & Joshua, 1987). The questionnaire was based on two multiple choice items, suitable for grade 9 learners. The distracters represented misconceptions, a method proposed by Redish and Steinberg (1999) to investigate learners’ misconceptions. The items were adapted from questions in the DIRECT test (Engelhardt & Beichner, 2004). These two items together with the correct answers were provided to the teachers while they were
questioned about wrong answers they expected from their learners. They were then required to explain how they would correct their learners’ wrong answers. In this way, the questionnaire did not attempt to test teachers’ subject knowledge. Instead, the questionnaire probed two aspects of Shulman’s (1986) notion of PCK, namely knowledge of learners’ understanding and appropriate teaching strategies. The data from the semi-structured interview provided further insight without referring to specific circuits, providing additional information to enhance the trustworthiness of the study. The questionnaire responses and interviews transcripts were analysed by means of content analysis, using predetermined categories from literature as well as categories emerging from the data (Gaigher, 2014).

Four experienced teachers from South African schools were conveniently and purposefully selected to participate in the study. Schools chosen to represent learners from different socio-economic backgrounds in and around a large city. Though all the teachers majored in Physics, it was expected that there would be differences in the depth of their subject matter knowledge in the topic of electricity, related to their different types of qualifications. Richard had a three-year science degree as well as a teaching diploma, Moses had a four-year science education degree, Pete had a two year teaching diploma and Willy also had a two-year teaching diploma as well as a teaching certificate. Richard taught at an elite private school with excellent laboratory facilities and Moses taught at an upper middle class suburban school with a standard science laboratory. Pete taught at an inner city school which had some equipment for learners but no laboratory and Willy taught at a school in a poor township area without a laboratory but with some equipment which he used for teacher demonstrations.

RESULTS

In question 1, a single bulb was connected to a cell and current was measured on both sides of the bulb. The question asked how the reading on the two ammeters compared. Option B represented the weakening current model. The responses to question 1 are summarized in Table 1.

Three of the teachers indicated that they expected that learners would choose B, indicating that this was a familiar mistake. However, only one of the teachers gave an explanation that demonstrates clear understanding the thinking associated with the misconception of weakening current / current consumption. Moses explained: “Because they think current decreases when it has passed through the resistor. Richard’s explanation that A1 is ‘closer to the cell’ may rather be an indication of the empirical rule model (a belief that current decreases according to the length of the conductor as measured from the cell).

To correct the mistakes anticipated in question 1, the participants mostly referred to explanations and measurements. For example, Moses said that learners must understand that current flows because of potential differences in the circuit. The other three teachers indicated that a demonstration or practical should be done to convince learners that the current in a series circuit remains constant throughout the circuit.
### Table 1: Summary of teachers’ responses given to question 1.

<td>Willy</td>
<td>B and C</td>
<td>Because on B, A₁ &gt; A₂ and on C, A₂ &gt; A₁.</td>
<td>D and E</td>
<td>They may think from A₁ to the bulb is zero and from the bulb to A₂ is also zero because due to the distance of the conductors.</td>
<td>Do the connection practically and allow them to connect themselves by giving the simple instructions on how to connect the components.</td>
</tr>
</tbody>
</table>

Question 2 showed a circuit with two bulbs connected in parallel and had two ammeters in the circuit. One of the bulbs was then removed, and the question asked about changes in the ammeter readings. One of the wrong options (E) reflected the constant current source model and another option (C) represented the parallel circuit misconception. The responses to question 2 are summarized in Table 2.

Moses was the only teacher who indicated option E as a first choice, with an explanation showing his understanding of the constant current misconception: “They expect that the current in the circuit stays the same, now all the current passes through A₂”. Richard and Pete chose option C as a first choice; and Pete explained: “Because they think the current will increase as resistance is reduced”, which shows his understanding of the parallel circuit misconception, which amounts to a belief that parallel resistors increases the effective resistance, similar to a series connection.

To correct the mistakes expected in question 2, Moses again suggested an explanation while Pete and Richard suggested measurements. Willy’s choices and explanations were not in line with known misconceptions, and he suggested to correct mistakes by doing calculations.

<th>Second choice</th>
<th>Why would your learners choose this option?</th>
<th>How would you teach learners to understand this circuit?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Richard</td>
<td>C</td>
<td>Because there are less bulbs in the circuit.</td>
<td>E</td>
<td>$A_2$ is already in series and will not be affected by the removal of $Q$.</td>
<td>Do the practical work using circuit boards, voltmeters and ammeters.</td>
</tr>
<tr>
<td>Moses</td>
<td>E</td>
<td>They expect that the current in the circuit stays the same. Now all the current passes through $A_2$.</td>
<td>C</td>
<td>Because a resistor is removed, they think the total resistance decreases and for this reason the current will increase.</td>
<td>The same as the previous experiment.</td>
</tr>
<tr>
<td>Pete</td>
<td>C</td>
<td>Because they think the current will increase as resistance is reduced.</td>
<td>E</td>
<td>Because they think the first ammeter in the connection is gaining more current.</td>
<td>I would teach them the types of circuits and practically demonstrate using ammeters and resistors connected in parallel and series.</td>
</tr>
<tr>
<td>Willy</td>
<td>B</td>
<td>Because $A_2$ is near to the bulb.</td>
<td>D</td>
<td>Because $A_1$ is not near the bulb the electricity won’t flow much at $A_1$.</td>
<td>Give the learners the values of the ammeters so that they can do correct calculations.</td>
</tr>
</tbody>
</table>

During the interview teachers were asked if they knew of any incorrect ideas persisting amongst learners despite teaching. Their answers supported the knowledge they revealed about misconceptions when answering the questionnaire. Richard spontaneously described an idea which may represent either the empirical rule model or the weakening current model, supporting his response in the questionnaire.

“They ... a lot of them ... and even in matric still have the idea that a light bulb closer to the battery has more energy than light bulbs further away in a series circuit. They don’t understand that the current in a series circuit is the same everywhere. They perceive position in a circuit as an indication of how strong the current is rather than whether it is in series or in parallel”.

Moses indicated that “....... they still think that two potential differences in parallel together has to give the total potential difference, that type of thing”. This idea represents amounts to the parallel circuit misconception. Pete indicated that learners often have difficulty calculating resistance in parallel circuit, while Willy indicated that learners do not understand that lightning is a “form of electricity”.

The interview data not only supported answers about misconceptions given in the questionnaire, but also provided insight into teachers’ own understanding of the subject matter and ideas about how it should be taught. Richard revealed that he regarded learners’ involvement in practical work as very important. Moses emphasized the concept of energy when teaching electricity, explaining that “they have to form the idea that we are talking about
the transfer of energy”, and “the operation of a circuit is based on the creation of a potential difference”. He explained that he uses visual aids in the form of different colours for conductors on the two sides of the battery, and explains that the different colours connected to the resistor indicate a potential drop across it. Pete emphasised the algebra about parallel resistors, similar to his answers in the questionnaire. He also revealed inadequate conceptual understanding, when mentioning that learners should understand that “…voltage is actually amount of charge in a, source like a battery.” Willy’s answers in the interview suggested that he lacked fundamental understanding of electric circuits. He focused on physical connections of circuits and gave simplistic explanations of abstract concepts.

**DISCUSSION AND CONCLUSIONS**

Results indicated that two of the teachers, Richard and Moses, understood learners’ misconceptions and reflected on learners’ thinking. From their answers it was clear that they understood the concepts themselves. In correcting misconceptions, Moses emphasized the development of learners’ conceptual understanding, while Richard emphasized the value of engaging learners in practical work. This insight and planned intervention demonstrate relevant TSPCK (Lee & Luft, 2008). Pete anticipated typical wrong answers but seldom understood the misconceptions leading to these mistakes, while Willy did not expect the typical wrong answers corresponding to well-known misconceptions. Answers from Pete and Willy suggested that they did not have a clear understanding of some of the concepts themselves, and they were not concerned about learners’ conceptual understanding. Instead they regarded practical demonstrations, measurements and calculations as a substitute for conceptual understanding, which indicates generic pedagogical knowledge, which has little value if the teacher lacks TSPCK. For this sample, it is clear that understanding of misconceptions is related to teacher qualifications.

The study also pointed out serious gaps in the teachers’ pedagogical knowledge in the teaching of circuits. The teachers focused on teaching correct answers, without confronting the wrong answers, suggesting that they did not consider conceptual change as a possible approach. Also, they did not suggest the use of mental models or analogies.

The conclusions should not be generalized as the study used a small sample in a developing country. Nevertheless, agreement between interview responses and the questionnaire answers supported the trustworthiness of the results. This indicates that the ‘questions about answers’ approach introduced in this study is a promising way to access teachers’ understanding of learners’ misconceptions and their thoughts about how to address learners’ mistakes. Therefore, the method may be useful to explore science teachers’ TSPCK in different topics.

APPENDIX 1

Question 1. Suppose your learners were given the following question in a test:

How do the readings on the ammeters A1 and A2 compare?
A  A1 = A2
B  A1 > A2
C  A1 < A2
D  A1 = 0
E  A2 = 0

The correct answer is A. Please answer the following questions:
1.1 Which one of the incorrect answers B, C, D or E do you think your learners are most likely to choose?
1.2 Why do you think they are likely to choose this answer?
1.3 Which of the remaining options do you think some of your learners might choose?
1.4 Why do you think they might choose this answer?
1.5 How would you teach circuits to help your learners develop the correct understanding about this circuit?

Question 2. Suppose your learners were given the following question in a test:

Suppose bulb Q is removed from the socket, how would the ammeter readings change?
A  A1 decreases, A2 stays the same.
B  A1 decreases, A2 increases.
C  both increase.
D  A1 stays the same, A2 decreases.
E  A1 stays the same, A2 increases.

The correct answer is A. Please answer the following questions:
2.1 Which one of the incorrect answers B, C, D or E do you think your learners are most likely to choose?
2.2 Why do you think they are likely to choose this answer?
2.3 Which of the remaining options do you think some of your learners might choose?
2.4 Why do you think they might choose this answer?
2.5 How would you teach circuits to help your learners develop the correct understanding about this circuit?
MODELING INSTRUCTION AND ITS INFLUENCE ON AUTONOMY, COMPETENCE, RELATEDNESS AND PCK

Kathleen M. Gray¹,², Margaret R. Blanchard² and N. Scott Ragan²
¹University of North Carolina at Chapel Hill, Chapel Hill, NC, USA
²North Carolina State University, Raleigh, NC, USA

Modeling instruction has gained prominence in recent years and has been shown to increase student understanding of unobservable scientific phenomena and potentially influence teacher pedagogical content knowledge (PCK). This study considers modeling instruction through the lens of self-determination theory, addressing two research questions: (1) Were there changes to teachers’ feelings of autonomy, competence and/or relatedness as a result of participation in a professional development program on modeling instruction, and (2) How did teachers report changing their instruction as a result of participation in the program? Thirty-seven middle and high school science teachers in a southeastern state in the USA participated in a year-long professional development program on modeling instruction. Data were collected on participants’ perceived autonomy, competence, and relatedness as well as their content knowledge, PCK and TPCK. Statistically significant increases in feelings of competence were found among participating teachers, with competence defined as self-reported measures of content knowledge, PCK, and technological PCK. Additionally, statistically significant increases in feelings of autonomy and relatedness were found among a subset of teachers with high concept inventory scores. This study provides insight into how professional development on modeling instruction influences the pedagogy of middle and high school science teachers, suggesting that it can improve teachers’ perceived competence, including content knowledge, PCK and TPCK. The study also shows that professional development on modeling instruction can enhance some teachers’ feelings of autonomy and relatedness, potentially contributing to their intrinsic motivation to engage students in modeling.

Keywords: modeling, self-determination theory, pedagogical content knowledge

INTRODUCTION

In model-based teaching (MBT), students use iterative, interactive processes to generate, evaluate and modify cognitive representations of systems, using models to describe scientific phenomena (Khan, 2007). This approach has gained prominence in the United States, in part due to its inclusion in the Next Generation Science Standards (Lead States, 2013). Although published studies are somewhat limited, MBT has been shown to be effective in improving students’ conceptual understanding of unobservable scientific phenomena, such as intermolecular forces and chemical equilibrium (Khan, 2007; Maia & Justi, 2009). With teachers, MBT research has tended to occur in preservice science teacher education courses with small sample sizes (De Jong, Van Driel & Verloop, 2005; Cullin & Crawford, 2003). These studies reported improvements in pedagogical content knowledge (PCK). Research with in-service teachers focused on the potential for MBT to enhance content knowledge and PCK (Justi & van Driel, 2005), but classroom implementation of MBT has been characterized as partial and limited, with key MBT strategies missing or absent (Khan, 2011). Further, teachers’
ability to plan modeling instruction has been shown to be influenced by specific teaching contexts (e.g., setting, resources, discipline and individual preferences).

Minner, Levy and Century (2010) asserted that conceptual understanding was more likely to result from teaching strategies that actively engaged students in the learning process, through scientific investigations. Further, Capps and Crawford (2013) found that even well-qualified and highly motivated teachers struggled to implement reform-based teaching. As a result, the authors identified a need to better understand how professional development programs influence teachers’ views and practices.

**Self-determination theory** (SDT) provides a framework for understanding human motivation and its role in social and cognitive development (Ryan & Deci, 2000); and SDT can provide insight into teacher motivation to adopt MBT. Ryan and Deci characterized a continuum of motivation, arguing that three innate psychological needs—autonomy, competence and relatedness—were central to intrinsic motivation (Figure 1). Autonomy refers to how much control an individual has to initiate and maintain behaviors, and competence is how capable an individual feels to accomplish different tasks. Relatedness refers to how many social connections are made. These needs are believed to exist naturally in all humans and to be influenced by both the individual and her/his environment. Ryan and Deci (2002) asserted that the intrinsic motivation that results from meeting these psychological needs leads to enhanced performance, persistence and creativity.

**Figure 1. Psychological needs that influence motivation, adapted from Deci & Ryan (2000)**

**Research Questions**

Considering modeling instruction through the lens of SDT, this paper focuses on the following research questions: (1) Were there changes to teachers’ feelings of autonomy, competence and/or relatedness as a result of participation in the professional development program? and (2) How did teachers report changing their instruction as a result of participation?

**METHODS**

This research was conducted as part of The Modeling Project, a three-year teacher professional development program implemented in five school districts in a southeastern state in the United States and designed to improve teaching and learning in high school biology and grades 6-9.
physical science classes. Key components included: (a) a 3-week summer professional development institute (with separate biology and physical science tracks) focused on enhancing conceptual understanding of disciplinary content through immersion in a modeling classroom experience, (b) three 2-day follow-up sessions during the school year to extend content knowledge and reinforce modeling strategies, and (c) in-school support from project staff and expert modeling teachers. The conceptual framework of this study is represented in Figure 2.

Figure 2. Conceptual framework for studying effects of teacher professional development on MBT, adapted from Desimone (2009)

Participants
Thirty-seven teachers consented to participate in this study, including 20 biology teachers and 17 physical science teachers. Of these, 25 were female, and 12 were male. All participants were certified teachers or were working on certification at the time of their participation in the program.

Data Collection and Analysis
Data were gathered on each participant using the following instruments: (a) the Teacher Beliefs Interview (Luft & Roehrig, 2007), (b) the Basic Psychological Needs Scale (BPNS Vlachopoulos & Michailidou, 2006,) and (c) concept inventories for biology and physical science. A subset of teachers in each content area also participated in content-specific focus groups about modeling implementation. Additionally, an external evaluator conducted program evaluation, which included self-reported, pre-/post-content knowledge and PCK outcomes for participants and students.

A mix of quantitative and qualitative data were analyzed using a pre-test/post-test design to investigate teachers’ feelings of autonomy, competence and relatedness as a result of participating in the program. Using paired t-tests, pre- and post-professional development BPNS scores and concept inventory scores were compared. The BPNS scores were also broken into component parts, with each participant assigned a sub-score for autonomy, competence and relatedness. Changes to sub-scores were evaluated by final concept inventory score (high score=>80% correct) and by gender. Competence also was measured using self-reported changes to MBT-related content knowledge, PCK, and TPCK. Each participant responded to a series of questions related to these parameters, both before, during and after the professional development institute.
development session. Study procedures were approved by the NCSU Institutional Review Board, protocol #4109.

**RESULTS**

**Quantitative Data**

Across all participants, no statistically significant differences were evident in the BPNS scores ($n=21$) nor in pre-/post-concept inventory scores ($n=16$ for BSCI, $n=17$ for PSCI). However, in both subject areas, teachers with high concept inventory scores (BSCI>23 and PSCI>19, $n=11$) reported statistically significant increases in their feelings of relatedness ($p=0.05$). The biology teachers with high concept inventory scores (BSCI>23, $n=7$) reported statistically significant increases in their feelings of autonomy ($p=0.02$) and relatedness ($p=0.05$). When BPNS sub-scores were analyzed by gender, relatedness increased for female participants ($p=0.04$, $n=12$).

Competence also was measured using self-reported changes to MBT-related content knowledge, PCK, and TPCK. Each participant responded to a series of questions related to these parameters, both before, during and after the professional development session. Using paired t-tests to compare pre/post responses, statistically significant increases were observed on parameters related to content knowledge, PCK, and TPCK, with the largest increases associated with PCK. (See Tables 1 and 2.)

**Qualitative Data**

Qualitative data from the mid-course implementation survey provided insight into how teachers changed their instructional strategies following the professional development program. Participants described their use of a range of MBT strategies, with the following being most common: collaborative work among students (identified by 70% of respondents), assuming a facilitative role (48% of respondents) and white-boarding (48% of respondents). Many respondents also noted that they believed their instruction was more student-centered overall, and other MBT strategies that were mentioned included use of questioning and efforts to explicitly address student misconceptions. One participant noted, “I am better able to spot misconceptions that students may have and how to address them.” Teachers with high concept inventory scores reported that they were more focused on content integration and student understanding, with comments like the following:

*Participation in the modeling project prompted me to analyze how biological topics are linked to form a cohesive unit.*

*The project helped with building the ‘story’ and interrelatedness of units.*

Similar comments were shared in the final evaluation ($N=33$), when participants described how they used their content knowledge differently in their science teaching as a result of participation in the program. A number of teachers described their use of questioning strategies—with one noting that “crafting critical questions” had become part of daily lesson planning. Several participants also described greater integration of their content knowledge across topics. For example, one said,
Strand 14

Developing the ‘storyline’ is one major difference...more connections are being made between the concepts than before modeling. [My] units are being taught as development of knowledge rather than isolated topics.

Another point of emphasis was that participating teachers were more often starting with students’ knowledge and misperceptions. One teacher noted,

I have taken a step back and am more responsive to my students' current knowledge level rather than giving them facts to memorize, regardless of their understanding of those facts. I work much harder at getting my students to proceed from their actual current knowledge level rather than [where] the curriculum says they should be. This works out better for the
students as they are actually weaving the new information in their worldview and looking at the physical world differently because of it.

Comparing pre-/post-responses to questions included in the Teacher Beliefs Interview provided insight into how participants changed their instructional strategies following the program. For example, the following free responses—indicating a shift in feelings of autonomy—were provided by biology teachers with high concept inventory scores, in response to the question: How do you decide when to move on to a new topic in your class?

PRE: [I am] constrained by...the school calendar.
POST: [I] start adding information after students have had time to practice both in small groups and independently.

PRE: I keep with the pacing guide outlined for the county.
POST: When the majority of students are proficient on the objectives, I know it's good to move on.

Some participants’ responses also indicated a shift in feelings of relatedness, specifically in their interactions with expert modeling teachers who assisted them in securing equipment and materials and developing strategies for student assessment.

About 50% of participants (including teachers in both subject areas and regardless of concept inventory or BPNS scores) noted student response to modeling instruction as a core reason for its use. This quote is representative of the reasons cited by participants who responded affirmatively to a question about whether they intended to continue using modeling in the coming school year:

I found that, while modeling takes more time than direct instruction, I enjoy teaching more. Students are more engaged, collaborate, and are asking deeper level questions. I have seen gains in alternative problem-solving skills, the ability to tackle ‘new’ problems, and more openness to taking risks and trying new things.

DISCUSSION AND CONCLUSIONS

Statistically significant increases in feelings of competence were found among in-service teachers participating in a year-long, MBT professional development program, with competence defined as self-reported measures of MBT-related content knowledge, PCK, and technological PCK. Additionally, statistically significant increases in feelings of autonomy and relatedness, as measured with the BPNS, were found among a subset of teachers with high concept inventory scores, suggesting that competence may influence attainment of other psychological needs.

Qualitative data from the mid-course implementation and final feedback surveys and the Teacher Beliefs Interview provided insight into how teachers were changing their instructional strategies following the professional development program. Among the MBT strategies commonly described were collaborative work among students (70%), assuming facilitative roles (48%) and white-boarding (48%). Teachers with high concept inventory scores also emphasized enhanced content integration and improved student understanding, potentially indicating that content knowledge may play a role in teacher adoption of modeling instruction.
Additionally, across the board (in both subject areas and regardless of concept inventory or BPNS scores), about half of the participants focused on their students’ response to the modeling approach as a core reason for continuing it.

Limitations

Several factors may limit the generalizability of these results. First, the study sample only included teachers from a southeastern state in the United States. Second, the overall sample size was small. Finally, some gains in competence may have been missed, due to content knowledge being used as a measure of competence. Specifically, teachers with high pre-scores on the concept inventories had limited ability to increase their post-scores. Interpreting these results in the context of existing literature that examines teacher adoption of MBT should help to counter any biases in this work and inform future research.

Conclusions

This study provides insight into how professional development on modeling instruction influences the pedagogy of middle and high school science teachers, indicating that such professional development can improve teachers’ perceived competence, including content knowledge, PCK and TPCK. The study also shows that professional development can enhance some teachers’ feelings of autonomy and relatedness, potentially contributing to their intrinsic motivation to engage students in modeling.

ACKNOWLEDGEMENT

We thank participating teachers for their time, energy and insights. This project was funded by a grant from the U.S. Department of Education Mathematics and Science Partnership (MSP) Program with state funds awarded by the North Carolina Department of Public Instruction. The professional development program described in this presentation was implemented by The Science House at North Carolina State University.

Strand 15 focuses on Early childhood science education - Science education for children aged between 0 and 8 years of age. It is a growing research field within the science education community, which was reflected by 35 oral paper presentations and many participating researchers at the Special Interest Group meetings at the 2017 ESERA conference. The rapidly expanding research field of early childhood science education now encompasses studies focusing on children’s learning, different aspects of teacher student’s and in service teacher’s pedagogical content knowledge (PCK) as well as different approaches to enhancing our knowledge of learning and teaching processes. The research also covers studies of particular science subject areas as well as broader concepts such as learning and teaching Nature of Science (NOS). In addition, there are a growing amount of studies concerning Science, Technology, Engineering and Mathematics (STEM) education in early childhood education, recently extended with the inclusion of Arts (STEAM education). Thus, early childhood science education now has grown to reflect a vast amount of common topics within science education research, but with a special focus on policy and practice of preschool and primary education.

The following nine papers together reflect the broadness of this research field. They explore a variety of issues based on different theoretical perspectives and give examples of qualitative and quantitative as well as mixed methods. Their authors come from United Kingdom, Greece, Australia, Spain and Sweden.

Five papers concerns research about children’s science learning and how education may scaffold this. Linda Mc Guigan and Terry Russell discusses what science education might be and argue for a more holistic view of contemporary early childhood science. The aim of the paper is to consider the support needed for the entire spectrum of early years staff to include social, communicative and epistemic processes in science practices. Through a review of their own research they describe real possibilities of operationalizing an updated view of science education. Drawing on results from three projects where they have used both qualitative and quantitative methods they present evidence of approaches within existing early years curricula and practices that have potential to offer authentic science experiences to young children through key instructional practices that are consistent with epistemic aspects of NOS; expressing ideas, listening and reasoning with evidence

The implementation of NOS in preschool education is also discussed and explored by Caecilia Tsoukala and Fani Stylianidou. In their paper they present an action research study aiming to evaluate children’s understanding of scientific inquiry and their attitude and knowledge about NOS. Activities were designed to elicit children’s ideas about science and their scientific skills through different types of investigations, activities and material. Children’s drawings researcher’s field notes and memo sheets photos and videos were analysed to draw a picture of children’s understanding of NOS. The results show that children in preschool age or in early childhood can developed an awareness of scientific inquiry skills and processes if they are

2030
familiarized with these concepts through planned activities. There were also evidence that the learning process fostered a positive attitude towards science and a greater appreciation of NOS.

The next paper describes early childhood teachers STEM practices and discusses the inclusion of Art into STEM (STEAM), Coral Campbell, Chris Speldewinde, Christine Howitt and Amy MacDonald presents the results from a pilot survey aiming to understand how STEM education is embedded in early childhood teachers’ programming and planning, pedagogy and knowledge. The survey was distributed to preschools in three Australian states and allowed open answers to questions relating to demographic data and early childhood teachers’ understanding of STEM pedagogy and practice. The results show that STEM formed a part of their regular planning and was supported by intentional planned activities. The STEM pedagogies included working with children’s interests, and prior understanding and learning through play pedagogy. Experiential learning was an important component of all the teaching. The authors conclude that it is critical for early learning in STEM that STEM education training is provided for early childhood educators.

The following three papers each give an example of research where children’s learning of particular science topics are explored. Michael Hasts paper is a review of past and current studies he has conducted with the aim to explore early understanding of rudimentary scientific concepts relating to the everyday world. Specific focus is placed on children’s ideas about what factors they believe to be pertinent to object motion, and what commonsense theories they develop. The first results presented in the paper show that commonsense theories of object motion develop early in childhood, already present by the age of 5 years at the latest. The results also show that underlying tacit knowledge structures around object motion appeared to be stable and that expressed theoretical constructions were subject to change over time without impeding those underlying structures. In follow up studies, now focusing on indication for rise in misconceptions among toddlers aged 2 to 3,5 years, results show that already at the preschool level children are incorporating object variable information in their reasoning about object motion. The author suggest that more consideration may need to be given to preschool educators’ knowledge of scientific conceptions and how their pedagogy may need to be adapted to incorporate exploratory activities.

Marta Cruz-Guzmán, Ana María Criado and Antonio García-Carmona, present part of the results of an extensive study which assesses elementary Spanish children's ideas about water pollution and water saving. The specific objectives were a) to ascertain the children’s ideas about the topics establishing learning progressions and b) to compare preschool pupils’ conceptions with those of primary school pupils. The participants were forty-three 5-7 year-old children from an elementary school in Seville. To collect data the authors used two complementary interviews. The results showed that children are not often aware about water pollution, and if they are, they use to relate it with macroscopic dirt, which could be eliminated with basic physical methods. In general, they do not express any viable ways to save water. The authors suggest that inquiry-based activities should be encouraged in which the children could be guided to discover how humans contaminate and waste water which would help them to value our natural resources.
The research reported by Elena Calderón-Canales, Leticia Gallegos-Cázares, Fernando Flores-Camacho and Luisa Ambrosio-Luz aimed at identifying the representations that preschool children construct about perception, production and propagation of sound.

They conducted a semi-structured interview composed of 15 questions on the above three topics. During the interview children were asked to solve different tasks or situations using several materials: cards with images of objects, people, animals and plants, and cards with images of situations such as for example a child having a box on her head. They interviewed each child individually for approximately 30 minutes. To identify the models that the children built about sound the authors performed a cluster analysis. This analysis provided a complete overview of the types of representations that were built, as it integrated all the elements (perception, propagation, and production). The results indicated that preschool children have the capability of constructing complex explanations of phenomena. The results also indicated the potential of generating educational proposals that help them to expand their repertoire of representations and their understanding of scientific subjects.

Finally, there are two papers describing how teacher training might scaffold teacher students developing teaching skills and self-efficacy, and one exploring how Pedagogical Content Knowledge (PCK) for early years science teachers can be represented.

Drawing on the importance of observation skills for the development of knowledge in science Ann Mutvei, Mikael Lönn and Jan-Erik Mattsson present a study focusing on two questions: How do student teachers perceive the information from observations differently? and Is it possible to train student teachers to increase their ability to observe and enhance their understanding of the contextual dependence? In the study they analyse the quality of written exams and reflections from visits of museums and a greenhouse made by 55 preschool student teachers attending a science course. The quality of the written exams and reflections were analysed using the quality markers 4R’s of Doll’s (Relations, Recursions, Richness and Rigor) and Roland Barthes studium and punctum. Then using classification trees they explored connections between different competences and marks on the questions in the final exam. The results show that training of observation of nature and art combined with making reflections improves the ability to see patterns. The authors conclude that it is important to create many possibilities for student teachers to practice observation, to analyse and to make reflection during their studies. Not only for their own understanding of science, but also in order to understand how teachers may create activities where children can improve their observation skills.

Michail Kalogiannakis and Stamatios Papadakis present an exploratory study which investigates the acceptance of the ScratchJr by pre-service kindergarten teachers as a tool to produce interactive, multimedia, learning content for science teaching as well as a tool for learning and teaching ‘Computational Thinking’. ScratchJr is a programming environment that is developmentally appropriate for young children (5–7 years). As an introductory programming environment that allows young children to ‘discover’ the basic programming concepts by creating projects in the form of interactive stories and games. The authors also investigate the effects of using ScratchJr for future teachers’ attitudes in terms of perceived ease of use and perceived usefulness. The study was carried out at a University Department of
Early Childhood Education in Greece. The results show not only that the use of ScratchJr has a statistically significant increase in pre-service kindergarten teachers’ self-efficacy in ‘Computational Thinking’ but also that they are willing to use it in their future daily practice for science education. Also, the study reveals that pre-service teachers have positive acceptance scores in terms of usefulness and ease of use of ScratchJr.

Helen Tseou presents a work aim of which was the study of theoretical models of PCK on the representational and investigative capacity. For this purpose the concept of PCK was initially investigated at bibliographic level through a critical review of the literature. More specifically the study investigated the following questions: “What are the characteristics and the nature of PCK”? “How is PCK investigated”? The results indicated the existence of disagreement as to the nature and characteristics of PCK as well as to the way of its investigation. According to the results, the need to clarify the concept arose so that it can be investigated in light of its conceptualizations. An operating model of PCK which stemmed from the critical review of the literature was proposed. In order to identify the components of PCK, a synthesis of various models of PCK was performed. The operating model was applied to the empirical field in order to investigate its ability to recognize and detect primary teachers’ science PCK. Two case studies with kindergarten teachers who taught the phenomena of melting and of coagulation were carried out. The application showed that the model can recognize and detect primary teachers’ science PCK in the empirical field through its components and its aspects. The investigation of PCK in bibliographic and empirical levels indicated that the operating model can represent the science PCK of teachers in primary education in order to investigate it properly.

Bodil Sundberg & Maria Kallery
There are currently a number of concerns facing early years education in England. A diverse range of Pre-school settings for 0-5 year olds exists. Those settings in the government maintained sector are required to have at least one qualified teacher whilst settings in the Private, Voluntary and Independent (PVI) sector are not required to employ a qualified teacher. Moreover there is no requirement for a qualification to work in Early Childhood Education and Care settings. While the proportion of unqualified practitioners varies according to setting, about a tenth of adults working in early years in England are unqualified. Moreover, although the majority of settings are graded ‘good’ or ‘outstanding’, there are doubts about the quality of provision, particularly in relation to science. Criticisms tend to centre on practitioners’ knowledge and confidence in relation to science and the quality of science experiences on offer. We argue that views of what constitutes science education and approaches to young children’s learning have developed and changed, with contemporary science adding epistemic and communicative dimensions to longstanding concerns with process and content. Current social constructivist views of learning, together with neuroscientific evidence, point to the brain being primed for social interaction (Hinton & Fischer, 2010). These considerations offer grounds for optimism that changes in emphasis within science education bring the subject closer to developmental perspectives on the education of the whole child. We suggest that the epistemic and communicative elements that are increasingly recognised as authentic and essential to science education can be enhanced by early years practitioners drawing on their existing holistic cross-curricular skills. While acknowledging the benefits of specialist early years training, there are messages to be drawn for all practitioners, including, and perhaps especially, those whose access to training is limited or less than optimal. The fresh perspective we suggest is to bring early years science into closer alignment with wider holistic practices. From this standpoint, we draw on some insights from our research to suggest strategies that combine theory with practical and applied approaches to early years science education. It is striking that the foundations for an epistemic approach can be identified in existing early years curricula and practice and are ripe for more focused attention. Specifically, we refer to the encouragement of multimodal expressive skills, critical listening, and expecting reasons for ideas (or ‘claims’) in dialogic exchanges that increasingly expect evidence in support of beliefs.

Keywords: early years, epistemic, discourse

INTRODUCTION

A recent report by the Department for Education (2017b) claims that 94% of three year olds and 99% of four year olds in England access some government-funded early years education and care (Department for Education (DfE), 2017b). Early years provision is available through a variety of settings including maintained settings (usually nursery school attached to a school or local authority nursery) or through the private and voluntary and independent sector (PVI) which tends to include private and voluntary day nurseries, playgroups, preschools and childminders.
In England, a qualification to work with children in the early years phase is not required. Nutbrown (2012) recommended that by 2022 all staff should be qualified. The data relating to the proportion of qualified staff in settings suggests continuing concerns about the proportions of early years staff having no qualifications. For example, according to Simon, Owen and Hollingworth (2016) a quarter of childcare workers held no suitable qualifications. A report in the same year by the National Day Nurseries Association [NDNA] 2016) claimed the proportion of unqualified early years staff in nursery settings in the UK was more than one in ten. Our aim in this paper is to consider the support needs of the entire spectrum of early years staff, including unqualified personnel, as well as those holding early years and teaching qualifications of some kind.

Notwithstanding the lack of formal qualifications amongst some staff, reports suggest almost all (85%) eligible children receive their early childcare in settings graded as ‘good’ or ‘outstanding’ (DfE, 2017a). In contrast, a recent study of the impact of nursery attendance on children’s learning (Blandon, Hansen & McNally, 2018) demanded greater attention to the quality of teaching and learning. Accumulated international research signals that deficits in the science achievements of young children that persist throughout schooling, across race, ethnicity, gender and socio-economic levels, may influence career choices (Trundle, 2015; Morgan, Farkas, Hillemeier, & Maczuga, 2016; Sackes, Trundle, Bell, & O’Connell, 2011). Criticisms of the nature of early years science education point increasingly to the lack of focus on children’s learning (Sylva, Melhuish, Sammons, Siraj-Blatchford, & Taggart, 2010). This lack is often attributed to low levels of confidence and science content knowledge amongst early years practitioners (Kallery & Psillos, 2001; Garbett, 2003) as well as to an inadequate understanding of the nature of science (NOS), (Bell & St Clair, 2015). Critics of early years science practices point to the absence of effective science instructional techniques (Tu, 2006); and the fewer opportunities available for children to engage with science activities compared with literacy and mathematics (Sackes et al., 2011). Early years activities are widely understood to offer an almost exclusive focus on children ‘doing’ through hands-on activities (H. Inan & T. Inan, 2015) and rarely explore NOS issues (Akerson, Buck, Donnelly, Nargund-Joshi & Weiland, 2011).

The tendency to prioritise low level hands-on activities contrasts sharply with growing evidence that early years children show remarkable capabilities to express and reason about their own ideas and those of others (Piekney & Maehler, 2013; Mercier, 2011; Kuhn, Amsel, & O’Loughlin, 1988; Carey, 2004). Gopnik (2014) acknowledges young children’s capabilities in distinguishing fact from fiction - an important precursor to weighing evidence. Increasing evidence of children’s early capabilities led the U.S. NRC (2007) report to the committee on science learning K-8 to recommend an increase in the quality and the challenge of science experiences offered to young children. They conclude that: ‘All young children have the intellectual capability to learn science. Even when they enter school, young children have rich knowledge of the natural world, demonstrate causal reasoning, and are able to discriminate between reliable and unreliable sources of knowledge. In other words, children come to school with the cognitive capacity to engage in serious ways with the enterprise of science.’ (National Research Council, 2007, p. vii.) Despite this wider recognition of children’s early capabilities, there is continued evidence of a mismatch between capabilities and the learning environment.
In 2015, drawing on evidence of their review of practice and of some of the evidence of children’s emerging scientific reasoning skills, Trundle and Sackes (2015) claimed that: ‘Despite these capabilities, children’s emerging skills usually are not the target of instructional practices in typical early childhood classrooms.’ (Trundle and Sackes, op. cit., p.242). In 2015, the OECD set out the alignment of early years curricula with the goals of primary education (OECD, 2015) in an initiative designed to help children realise their potential.

Historically, in England there has been a widespread acceptance of the notion of science for all and a recognition of the value of science learning for children’s wider development. Science was introduced as part of the core curriculum for the primary years (5-11 years) in 1989 (HMSO,1989) and forms part of the early years foundation stage (3-5years) curriculum within an area of learning entitled, ‘Understanding of the world’ (EYFS, 2012). The curriculum makes explicit that it is through this area that children’s communication and language should be strengthened and applied, so wider curricular links are explicitly acknowledged. Over the years, there has been debate about what constitutes science education and the early debate centred on a tension between the teaching of science processes or content. In more recent years, educators’ views of science have been extended to include an emphasis on social, communicative and epistemic processes as realized in science discourse practices (Duschl & Jimenez-Alexiandre, 2012; Duschl & Grandy, 2013). By making explicit the relationship between communication, language and emergent science, the early years curriculum provides key opportunities for the introduction of early discourse practices and ways of thinking scientifically within high quality social interactions between children and between children and supporting adults. Developments in understanding learning more generally have shifted from behaviourist and information processing perspectives towards dominant views from cognitive psychology about the social construction of learning (De Corte, 2010). The focus on the social nature of learning is further supported by contemporary evidence from neuroscience which describes the brain as being primed for social interaction (Hinton & Fisher, 2010).

In this paper we consider how the development of scientific literacy can be encouraged ‘bottom-up’, using approaches consistent with contemporary developments in science education research and a ‘whole child’ perspective on young children’s learning. This perspective acknowledges the training needs of early years practitioners but suggests building on, rather than the wholesale replacement of, existing skills. We argue that the contemporary understanding of what constitutes science education offers new possibilities for early years practitioners to make significant contributions to an authentic science experience for young children. Our long-standing interest in developmental progression underpins our view that science capabilities can be understood as gradually emerging from more basic, foundational or general skills. Just as children are building up domain-specific ideas about science phenomena, they are also building up ways of communicating, sharing and reviewing those ideas in their early interactions. Learning environments sensitive to these emerging capabilities can promote a culture in which the exchange of ideas is valued and understood as central to learning. We suggest how the encouragement of gradually increasing interactive, reasoning and communicative skills can be nurtured in ways consistent with more current ways of characterising science proficiencies. This strategy requires specification of developmentally appropriate activities that can become central to early years practitioners’ interactions with
young children. In turn, this stance implies the need for a practical agenda that builds on current best practices, and meets the requirements of an updated view of science education. To describe real possibilities of operationalizing this viewpoint, we draw on quantitative and qualitative evidence derived from three relevant projects (children 3-7 years).

**REVIEW OF AUTHORS’ RELEVANT PROJECT ACTIVITY**

Young children’s developmental capabilities relevant to emergent science within early years holistic curricula and practices were explored in a recent assessment project. Construction of the Child Development Assessment Profile (CDAP, Welsh Assembly, 2011) necessitated defining and measuring psychometrically aspects of ‘whole child development’. The developmental assessment criteria that were validated in the first study with a large-scale sample were illuminated by two further pieces of research to which we refer. A second study looked at the qualitative interactions between children and practitioners in settings, drawing on qualitative data from a collaborative exploration of emergent science within the holistic early years practices of 12 settings. Teachers of children 3-7 years worked within their usual holistic approaches with their classes of children, with the authors operating as participant observers. Exchanges between teachers and researchers resulted in the gradual shaping of existing practices towards a focus on the collection of children’s ideas using a variety of modes including action, speech, drawing and 3-D modelling. Once ideas were collected, children were encouraged to listen to each other’s’ ideas and to explain their own reasoning. Data collected included, examples of children’s work, teachers’ journal notes, teachers’ writing and researchers’ classroom visit notes. The study helped to trace in the course of all-inclusive activities, Developmental Learning Progressions between general and emergent science skill proficiencies.

Further evidence of synergy between early years practices and epistemic views of science was found in a third study that explored the ways that children expressed and exchanged ideas and the way they used mathematical tools to collect evidence to inform their thinking. This research-based design project involved ten schools, each focusing on teaching and learning within evolution and inheritance (4-11 years). Here, we draw on some of the qualitative evidence from four of these teachers having responsibility for children 4-7 years. Data collected included, examples of children’s work, teachers’ journal notes, teachers’ writing and researchers’ classroom visit notes.

Evidence from each of these projects’ outcomes helped the identification of approaches within existing early years curricula and practices that have the potential to offer a more authentic science experience to young children.
QUANTITATIVE EVIDENCE OF EARLY YEARS PRACTICES RELEVANT TO AUTHENTIC SCIENCE

The ‘Child Development Assessment Profile’ (CDAP, Welsh Assembly, 2011) was a holistic baseline assessment profile to assess all children (3-5 years) on entry to foundation phase in Wales. A national pilot undertaken as part of the development involved 1195 children in 269 settings. Practitioners trained in the use of the CDAP assessed the children in their care in the course of their usual day-to-day interactions, referring to six Developmental Areas and a total of 114 items, each addressing an observable behavioural criterion. The retrospective review of the criteria identified behaviours of interest to science educators at three levels:

‘General developmental’ criteria accounted for about two-thirds of assessed behaviours. They were defined as those likely to be prerequisites to all learning. ‘Science enabling’ criteria, representing about one quarter of assessed behaviours, were defined as those which would support science related activities without having been nurtured in a context readily identified as scientific. Science-specific criteria (9 of the 114, or 8%) included showing curiosity, giving reasons, explaining how things happen, holding a point of view, describing logical sequences, planning enquiries and empathising with the listener (Russell & McGuigan, 2016a). These latter capabilities are essentially about thinking, reasoning and sharing understanding with others and are congruent with an epistemic view of science. Figure 1 exemplifies the form of item analysis undertaken on all 114 criteria.

Figure 1. Science Specific Item: ‘Gives reasons for why things have happened or are happening’ (age norm 48-60 months)

It is worth emphasising that these nine ‘science specific criteria’ identified as relatively discrete and measurable entities were revealed within a ‘whole-child’ curriculum in which science did not feature as a separate subject. The developmental data confirm that the foundations of an epistemic approach can be found within a broad and balanced early years curriculum in which the focus was child-centred, experiential and play orientated.
QUALITATIVE EVIDENCE: EXPRESSING IDEAS; LISTENING AND REASONING WITH EVIDENCE

The data drawn from the two qualitative early years research projects suggest some key instructional practices that resonate with a simplified approach to argumentation that is both developmentally appropriate and consistent with the epistemic aspect of the Nature of Science (Russell & McGuigan, 2016b). Together, the qualitative studies provide evidence of three Developmental Learning Progressions that help trace the managed emergence of authentic and foundational science experiences for young children. Using illustrative evidence from these studies, three skill areas, ‘expressing ideas’, ‘listening’ and ‘reasoning with evidence’, highlight how all early years practitioners might support children as they make progress towards some of the social and communication skills valued in epistemic views of science.

Expressing ideas

On initial entry to settings, some children may be hesitant to express their ideas. As with spoken language, the conventions governing communication using different formats such as gesture, drawing and modelling have to be learned and their introduction managed by the supporting adult. Gradually children will gain the capability to exploit a range of representational formats and make choices about which best suits their intentions. Barely formed ideas will be developed even as children represent and discuss their ideas. The ability to draw on a range of modes allows the same idea to be represented in different ways; the redundancy reveals nuances that may not be possible in any single mode. The triangulation of different modes is intended to generate richer understandings, not to avoid the oral mode. The value of verbal expression is unquestionable, but can be extended and enriched by multi-modal forms of communicative expression. Amongst the many examples gathered, in one class of six and seven year olds, a teacher invited children to make model pets to show their ideas of pet families (‘babies’ and their ‘parents’). Children used feathers, art straws, paper and sponge balls to make their imaginary pets. They tended to make the offspring smaller than the parents but with the same characteristic eyes, feathers etc. Their 3-D models provided an engaging focus for interactions designed to encourage the expression and sharing of meanings. With the help of a supporting adult, one child mentioned that the young pet would look exactly like its mother only smaller. Others shared this view or thought a boy pet would look exactly like its father. The concrete form of the 3-D modelling helped children keep track of the focus of the discussion. In terms of science discourse, the ideas children expressed whether verbally or in drawings and models could be understood as claims.

Increasingly, children become aware of their own beliefs as ideas to be expressed and shared with others. Children’s tendency to offer the same idea as their peers will be likely to diminish with experience and encouragement. Creating a positive environment in settings, with the expression of ideas being explicitly valued by being praised and drawn attention to, will encourage their further expression.

**Listening to other’s ideas**

Children are normally required to attend to adults when spoken to. Some settings might have a routine to focus children’s responsiveness, for example, children wiggling their fingers in the air and turning to face the adult to signal attention. Similarly, the importance of listening to children and the modes of behaviour required in a discussion must be explicitly introduced to children by the managing adult as an integral part of most activities.

Initially, children tend to think that everyone shares the same idea. Adults can facilitate children’s growing awareness of alternative viewpoints by deliberately drawing attention to the diversity of ideas expressed and by modelling reactions of interest, surprise and valuing any alternative viewpoints. For example, a class of 4 and 5 year olds preparing for a farm visit shared ideas about some of the different animals they expected to see. The practitioner made a class list of children’s drawings and spoken ideas that helped to bring the different ideas to children’s awareness.

A step on from children accepting the diversity of ideas is active listening and responding in ways that demonstrate detailed and thoughtful engagement with the discussion. Active listening within these early exchanges might be revealed as children introduce relevant, albeit different - perhaps opposing - viewpoints as well as additive, supportive expressions of ideas. The supporting adult must make the rules of these exchanges explicit so that children learn to respond respectfully to the ideas of others in what might be described as an early form of peer review. For example, a group of nursery children planting bulbs and deciding what bulbs need to grow (4 year olds) were encouraged to respond to other’s ideas by first saying, ‘I like [Ruby]’s idea but I think…’ All the children adopted this technique of explicitly referring to the name of the owner of the idea and first expressing a liking for the expressed idea before introducing a gentle challenge to each idea or claim. The strategy helped to ensure that children experienced sharing ideas to be a positive, enjoyable process. Once acknowledged by the teacher to be a regular and required feature of children’s interactions, the tactic helped to ensure that children developed the ability to compare ideas and express counterclaims in ways that respected each other’s right of expression.

Approaches which include the encouragement of listening actively to others and an increased awareness of the diversity of others’ ideas constitute an authentic and valid approach to science. In their early interactions with children, supporting adults help children towards productive exchanges in which children become confident enough to express ideas, empathic and respectful in the giving of feedback and resilient in handling others’ feedback. It is these early exchanges which resonate with epistemic science practices. We were reminded of the value of the early and gradual introduction of ‘argumentation’ skills by two year 5 girls (aged 10) who had just experienced a lesson in which they had reviewed and critiqued each others’ ideas for the first time. They had found the requirements to critique and perhaps disagree with others’ ideas unfamiliar and disconcerting.

‘I think it was quite weird arguing with my friends because, ermmm, we all like, agree with them most of the time, so it was a bit weird arguing with them.’ Y5
‘I think it was a bit weird as well because I normally agree with them and then I’m not agreeing with them today.’ Y5

Reasoning with evidence

Encouraging the giving of reasons marks a shift in science thinking towards self-awareness as to what and why a belief is held, rather than an alternative idea. This shift requires children to develop metacognitive skills in which they can reflect upon and manipulate ideas. The shift also requires children to develop the capability to use evidence to support their ideas. Initially, children’s reasoning may take the form of assertions or assumptions of delegated authority, with statements such as, ‘I just know’, or ‘Everyone knows that!’. In these instances, children may think there is general agreement in relation to a particular idea so there is little motivation to seek justifications to support thinking. Yet reasoning is important, because children can be helped to choose between ideas on the basis of the reasons given to back them up. Encouraging children’s regular use of ‘because’ immediately following an idea helps to invite the giving of reasons. The reasons children offer may draw on their own conceptual understanding, first hand experiences or their imagination.

Our evidence suggests that, with practice, children show impressive competency to express ideas, to justify their ideas with reasons and to critique thoughtfully those of others. In this manner, they progress to comparing and modifying their own ideas through consideration of the reasoning and evidence they have heard.

In a class of 5 and 6 year olds, children exploring materials outdoors climbed into an old boat in the school grounds to discuss their ideas about the materials that had been used to make it. The teacher made clear her requirements that children should listen carefully and decide whether they agreed or disagreed with each other’s ideas, and why.

Teacher (T): ‘We are going to listen very, very carefully now and think about whether we agree or disagree with the each other’s ideas about the materials used to make the boat, and why’.
Jo: ‘Screws are made out of metal and the green bit isn’t.’
T: ‘Ok. What is the green bit made out of, Jo?’
Jo: ‘Wood, and screws are not.’
Eleanor: ‘I think Jo’s idea is true but when you paint the metal it looks like it is made out of wood’.
T: ‘Ah! The metal looks like the wood because it is a painted the same colour as the wood.
Nerys: ‘I know why they decided to build it from wood: because, to keep it waterproof.’
T: ‘Ah! So they decided to build the boat from wood to keep it waterproof. So, is wood a waterproof material then?’
(The group responded in unison with either ‘No!’ or ‘Yes!’, suggesting they were divided in their understanding as to whether or not wood is waterproof.)
Erin: ‘No, because it’s not a soft material’.
T: ‘Because it is not a soft material. So are waterproof materials soft?’ (Note the reflecting back of the expressed idea and its reformulation as a question.)
Erin: ‘Yes’.
T: ‘Has anyone else got anything to say about Erin’s idea?’
Anna: ‘I don’t think that that’s true because I only think waterproof materials are made out of plastic.’
T: ‘Anyone got anything else to say about those ideas?’
Nerys: ‘I am beginning to change my mind because actually I think plastic is waterproof.’
T: ‘But what about wood?’
Nerys: ‘Wood can rot in the rain so I don’t think it is waterproof.’
Anna: ‘Plastic doesn’t rot down so I think Nerys’s idea is true.’
T: ‘What do you think about wood then? Do you think wood is a waterproof material?’
Anna: ‘Wood is not, because if you leave it outside for a long time, it will rot down’.
T: ‘Has anyone got anything else that they could say linked to that?’
Harry: ‘If you jump on the boat it will just break because it is plastic.’
T: ‘What do you think the boat is made of?’ (Teacher seems to be checking out the child’s understanding.)
He knocks the boat to check or test his ideas: ‘Out of wood’. (Tapping the boat shows the child is looking for evidence through testing as part of the conversation.) (Russell & McGuigan, 2016b)

In such exchanges, children are being inducted into a process whereby they can explain why they believe one idea in preference to others and importantly, use evidence to support their own view. The supporting adults must be active in probing responses and encouraging children to think about others’ ideas along with their own, and to requiring them to explain their reasons. This process helps to bring about changes in understanding as weaknesses and strengths in ideas are recognised. In the example, we see children exchanging and building on each other’s ideas thoughtfully and showing remarkable capabilities to acknowledge the influence of each other’s ideas on their own reasoning.

CONCLUSIONS

On first stepping out of the home into their early years settings, many children may be reticent in expressing themselves and interacting with others’ ideas. With adult support, they display a developing capability to express their ideas confidently, to listen actively and to critique positively the ideas of others. Through practice routines they gradually learn to adopt strategies that help them to challenge the ideas of others, sensitively and with respect. As they progress, they demonstrate an awareness of how they know and why their ideas have changed, cognitive growth aligned with an epistemic aspect of the nature of science. Our analysis seeks to link general early years practices to these authentic science approaches by tracing Developmental Learning Progressions between general behaviours and the emergence of more science-specific behaviours.

Our collaborative research with practitioners has revealed some of the ways in which these approaches can be supported seamlessly in early years practice. The aim is not to promote heuristics that will encourage disparate, discrete science skills but rather to show how the interactions arising in some of the experiences provided in early years settings might be thought of as enabling of the broader epistemic and communicative view of contemporary science.
Focusing on science education within the whole child framework of early childhood practitioners reveals the potential alignment between early years curricula and practices and current views of contemporary science. While acknowledging the advantages that a specialist training in science confers on practitioners, there are messages to be drawn for all, including those with more limited access to professional development and training. Our research signals some tentative practical guidance for all early years practitioners embedded in the whole child approaches to early years education. The task ahead is to disseminate these possibilities.

REFERENCES

This paper presents an action research study into the implementation of the Nature of Science in preschool education. Conceptualizing the Nature of Science through education could create an enabling environment that offers children the opportunity to think critically about scientific issues. This action research aimed to evaluate children’s understanding of scientific inquiry and their attitude and knowledge about Nature of Science. Activities were designed to elicit children’s ideas about Science and their scientific skills. Children collaborated in different types of investigations, in indoor and outdoor activities, using first and second hand sources, digital and hands-on educational material. Children’s initial drawings, researcher’s portfolio (field notes, memo sheets), digital recorded photos and videos were gathered throughout the research. Analysis used a Classification Scale which ascertained children’s understanding of the ‘Nature of Science’ in each activity. Oral data were analyzed through open and axial coding. All data were combined. Results indicated that, at the start of the study, children exhibited broad and naive ideas about Science, but gradually went on to develop an increasing awareness of scientific inquiry skills and processes. There were evidence that this learning process fostered a positive attitude to science and greater appreciation of the Nature of Science. The benefits of conceptualizing the Nature of Science through educational programs, even in early childhood, could be multifaceted and longitudinal. Its implications could stretch across the early years science curriculum and affect pre-service and in-service teacher training education.

FAMILIARIZING PRESCHOOLERS WITH NATURE OF SCIENCE

Future reality seems to have an immense relationship to Science. In our times scientific accomplishments of great importance happen daily. Nature of Science (NoS) describes how Science factions and refers to the principles and ideas that co-exist in the development of scientific knowledge (Akerson et al, 2009). Conceptualizing of NoS is a component of scientific literature (DeBoer, 1991) and it aims to create the adequate conditions for children to think critically about scientific issues through education.

Researchers claim that it would be useful for Science Education to emphasize NoS even in early childhood (Forawi, 2007). Research findings assert that students do not exhibit adequate understandings about NoS, until the end of secondary education (Bell, Blair, Crawford, & Lederman, 2003). Simultaneously research shows that students do not have received appropriate education to develop relative understandings (Akerson, Buck, Donnelly, Nargund-Joshi, & Weiland 2011; Bell et al., 2003). Preschoolers can grasp NoS conceptions when it is taught through scientific inquiries emphasized in NoS which are meaningful for the children (Akerson et al., 2011).
Based on the above theoretical arguments, a small-scale action-research was designed and implemented in a kindergarten class to study how preschoolers (4-6 years old) contact development with NoS. The action research aimed to investigate children’s understanding of scientific inquiry and their attitude and knowledge about NoS. The focus of the research was on developing children’s questioning and curiosity and providing them with opportunities to express beliefs, to gather and explain evidence, so as to foster their reflection and reasoning and eventually develop critical thinking about NoS.

**METHOD**

Participants: 15 children of preschool age (4-6 years old). All of them had similar socio-economic background, were native Greek speakers and some of them had speech problems.

The Action Research (AR) was accomplished from January to February (1st cycle) and from March to April (2nd cycle). The implementation was taken place for 2 hours through 20’ – 30’ min. activities every week. Children collaborated in different types of investigations, in indoor and outdoor activities, using first and second hand sources, digital and hands-on educational material.

1st activity: “What is this thing called Science?” Every child drew an image of what it believed Science is. It acted as reference point during our conversations and investigations about children’s thinking about NoS.

2nd activity: “Who is a scientist? - Draw a scientist”. All children brainstormed ideas and definitions. Every child drew an image of its own idea about scientists and their work.

3rd activity: “Hello Mrs Science”. Teacher/Researcher brought a hand-made puppet into the classroom. The puppet had a long conversation with children about Science and Scientists and asked children about what scientific issues they would like to learn more with her assistance.

4th activity: “Can children record and collect data for our trees and plants outdoors investigations?” They observed real plants and flowers outdoors to see what they could find out at first hand. End of 1st AR cycle.

5th activity: “Record of outdoor activity”. Children and teacher created a diagram/conceptual map of what children know, what they wanted to learn and how they would be able to achieve it. Start of 2nd AR cycle.

6th activity: “Planting seeds”. Children were given different kinds of seeds to plant, using visual instructions to direct them. They had to take in mind factors affect growth.

7th activity: “Keeping data in ‘Scientist’s Book’”. Children were motivated to express their ideas and opinions about keeping data process. Every child took his own “Scientist’s Book” and made an image of his/hers first action (planting) and later every 2-3 days observed its plant, identified evidence about it, recorded data and kept notes (including images) in his/her own ‘Scientist’s Book’.

8th activity: “Making predictions and experiments”. Children in small groups made predictions and experiments of the factors needed for seeds to growth (humidity, light, air and ground). They recorded their evidences and fulfilled classroom’s learning wall.
9th activity: “Researching Books and Internet”. Children researched questions they could not answer at first hand through printed and digital educational material. In small groups they tried to answer questions searching science books and Internet websites. The focus was on information we could not readily answer in the classroom (e.g. photosynthesis).

10th activity: “Constructing Plants’ Models”. Children collaborated to make 2D models of a flower/tree, named its parts and communicated their explanations.

Reflection Activity: Teacher/Researcher asked children to bring in mind everything about this learning process and express their thoughts.

Data were collected by means of a) children’s initiative drawings, b) researcher’s portfolio (field notes, memo sheets), c) digital recorded photos and videos throughout the research. All data were analysed separately and in combination. Children’s drawings were analysed through a Classification Scale depending the understanding of ‘Nature of Science’ concept they represented (No – Naive – Sufficient Scientific Understanding) per each activity. Oral data were analysed through open coding using in vivo codes of children’s answers and teacher’s notes. Classification of understanding was applied in oral data by axial coding. All data were combined aiming to answer the research questions.

RESULTS

Children’s understanding of scientific inquiry and their attitude and knowledge about Nature of Science are presented by specific examples (Table 1) during the sequence of activities implemented. Classification of children’s scientific understanding presented in drawings (Table 2) offers a focused insight, while the analysis on the evolution of children’s scientific understanding (Figure 1) draws a broader answer to the research question.

3rd activity: “Hello Mrs Science”.

“She is a scientist and will help us learn things about Science”

“She is wearing glasses and she has a magnifier in her bag”

“She has a ruler too”

“…. and a book”

“What scientific issues would you like to learn more about?”

4th activity: “Can children record and collect data for our trees and plants outdoors investigations?”

“Do you have any questions from what you see outside?”

“Why there are so many green plants?”

“Trees seem so tall, they can reach the sky. Can they?”

“This flower seems like a clock. Can it really count time?”

5th activity: “Record of outdoor activity Conceptual map”

“Let’s write down what you already know, what you want to learn and how you could do it”

“We know things, but...”

“But... there are many things to find out”

“We can really become Scientists and learn and investigate things about plants and trees”.

6th activity: “Planting seeds”.

“Do you know how can we plant??”

“What do we need?”

“Yes, I know … I have planted flowers with my mum”

“We will put seeds in soil”

“We should follow the instructions”

Figure 1. Evolution of Children’s Scientific Understanding

DISCUSSION AND CONCLUSIONS

Results presented in Table 1, indicate that children started by having broad and naive ideas about Science, mainly in relation to technological artefacts, and rather stereotypical ideas about NoS and the work of scientists (1st and 2nd Activity). Puppet ‘Mrs Science’ in the 3rd activity motivated them to start thinking about science in more personal terms. During their initial explorations in the outdoors and based on their observations on the field (real plants) they started developing their own questions for investigation (4th activity). More controlled investigations helped them experience a number of inquiry processes, develop inquiry skills and experience first-hand the empirical nature of science (5th, 6th activity). The use of multi-modal ways of recording, representing, searching for, interpreting and evaluating evidence in the ‘Scientist’s Book’ (7th, 8th activity) and when working in teams enhanced their experience of science as a creative endeavor, while at the same time re-enforced their self-concept as ‘scientists’ (9th, 10th activity). Finally, their reflections on their learning, during the last activity, gave them a first-hand experience of the tentative nature of science at they had to explain their ideas and be confronted with alternatives.
The classification of children’s scientific understanding, presented in Table 2, shows they had no scientific (7/15), or naïve scientific ideas (7/15) about NoS in the beginning of the research (14/15). During the learning process children developed more scientific ideas (13/15). They talked explicitly about key features of working as scientists – for example the importance of making observations, thinking about and checking results. They showed curiosity and began to recognise that science involves asking questions and testing predictions. They suggested new ideas, gave reasons for every decision they made and reflected on their learning. Their ideas and explanations seemed plausible and creative. At the end of the research results show children had developed a growing awareness of scientific inquiry skills and processes (14/15). Children’s increasing awareness about science is obvious in Figure 1, where the evolution of their scientific understanding is presented. ‘No scientific’ line begins from point 6 and decreases during the main activities. On the contrary ‘ naïve scientific’ line starts from the same point (6) and increases during learning process. Its lower point (9), during the activities, happens at the same time with the highest point of the ‘scientific’ understanding. In the reflection activity the majority of children’s understanding is either on ‘ naïve’ or ‘scientific’ line.

All these results show that children in preschool age or in early childhood can assimilate NoS conceptions when it is taught through activities and scientific inquiries emphasized in NoS which are meaningful for them as Akerson et al. argue about (2011). Children seemed to develop their questioning and curiosity; they expressed beliefs, gathered and explained evidence. They seemed to recognise that in spite of their actions, scientists would face new questions to answer, as long as they know how and where to search, keeping in mind Science evolves constantly. Children fostered their reflection and reasoning and eventually they appeared to develop critical thinking about NoS.

There were evidence that this learning process fostered a positive attitude to science and greater appreciation of the Nature of Science. The benefits of conceptualizing NoS through science educational programs, even in early childhood could be multifaceted and longitudinal (Forawi, 2007). Its implications could lead to a reshaping of the early years science curriculum and affect pre-service and in-service teacher training education.

ACKNOWLEDGEMENT

This research was implemented as part of Curriculum material in Creativity in Early Years Science Education (CEYS) project, funded by the Erasmus+ (2014-1-EL01-KA201-001644). The CEYS project aimed to develop a professional development and innovation course curriculum addressed to teachers, school leaders and teacher educators to be used in European programmes of Initial Teacher Education and (science-specific) Continuous Professional Development to promote the use of creative approaches to science in preschool and the first years of primary education, in the frame of inquiry-based educational environments.

² University of Western Australia, Perth, Australia
³Charles Sturt University, Albury, Australia

In 2016, a pilot survey was conducted in Australia to understand how Science, Technology, Engineering, and Mathematics (STEM) education is embedded in early childhood (EC) teachers’ programming and planning, pedagogy and knowledge. Emerging research signals that laying foundations for future STEM learning needs to occur in EC years, as meaningful STEM experiences have been found to increase young children’s STEM self-efficacy and early development. EC STEM pedagogies are informed by play-based approaches which are child-instigated but with purposeful intentional teacher scaffolding. A survey was used, allowing open responses and consisting of questions relating to demographic data and EC teachers’ understandings of STEM pedagogy and practice. An analysis was undertaken and responses scrutinised for common themes. Findings indicated that EC teachers acknowledged that STEM formed part of their program and was embedded in regular program planning - supported by intentional planned activities. STEM pedagogies included: working with children’s interests, working from children’s prior understanding and learning through play pedagogy. Findings from this research help to articulate STEM learning foundations in early childhood and can assist EC teachers to better understand STEM pedagogy and methods to engage children in STEM learning.

Keywords: Early childhood, STEM, pedagogy

INTRODUCTION

International attention in science, technology, engineering and mathematics (STEM) has increased significantly in recent years as a result of the declining interest in STEM-related occupations and the expected impact of this now and in the future. Australia is dependent on life-time engagement with STEM education (Chubb, 2013). Declining STEM participation in schools and in higher education pathway choices, provides the challenge to teachers to meaningfully embed STEM-related content into teaching and learning to engage students at all levels of schooling (Marginson, Tytler, Freeman & Roberts, 2013). There is increased interest among educators and researchers on investigating contexts that support children’s learning in science, technology-based, engineering and mathematics (STEM) as a result of great concern to educators and policymakers in improving mathematics and science education (Brenneman, Frede, Stevenson-Boyd, 2009; MacDonald, & Carmichael, 2017). Literature suggests that STEM education needs to embrace key principles: engagement through hands-on exploration (enquiry), meaning-making that is facilitated through discourse scaffolded by the teacher and the effective use of resources.

As well as “core subject knowledge” STEM education is described as covering “skills of collaboration, critical thinking, creativity and problem solving” (Education Council, 2015) which promote more focused STEM practices to be introduced into pedagogy. Stated goals of general STEM literacy include a “strong foundational knowledge in STEM” to achieve “a
fundamental level of STEM literacy that enables them to engage with, and succeed in, the world beyond the school gate” (p. 5). There is a need to clarify educators understand as STEM in education and how this can be transferred into curriculum and pedagogy across all stages of education. Yet despite this need, there is an acknowledgement that research into science education and learning in kindergarten and pre-school settings is extraordinarily scarce (Moomaw, 2012). This pilot survey focuses on understanding EC teachers’ current pedagogy and practice in STEM education. Future research will investigate demands and affordances specific to EC education (covering from birth to five years) as a vehicle for achieving quality foundational STEM outcomes.

BACKGROUND - THE STEM IMPERATIVE IN EARLY CHILDHOOD

The first five years of life have been identified as crucial in shaping a child’s ability to learn and think creatively (Council of Australian Governments [COAG], 2008). Research has shown that the quality of EC experiences can stay with children until adulthood (Sylva, Melhuish, Sammons, Siraj-Blatchford, & Taggart, 2010) highlighting the importance of this stage of education. As mentioned previously, there have been limited examples of research in the field of EC STEM although due to attention in recent years research output has been increasing. Despite the limited research in the area of STEM learning in early childhood, it has been shown that children begin learning from birth and that children engage in enquiry from their earliest years (Moomaw, 2012; 2013). Emerging research signals that early childhood years are essential for laying the foundation for future learning in STEM (Ricks, 2013; Hunting, Mousley & Perry, 2012; Benson, 2008). For example, early meaningful experiences of science for young children have been found to enhance self-belief in their ability to learn science and to promote greater interest in science (Patrick et al., 2009); such experiences trigger an appreciation for science and its value to everyday life (Fleer, March & Gunstone, 2006). One element of that early STEM learning includes mathematics which has been shown, if successfully introduced at an early age, to be a predictor for later academic success and employment prospects (Chesloff, 2013). An account of the benefits of introducing STEM at an early age has been incorporated into reports alerting government policymakers to issues such as the strengthening of STEM education training for early childhood educators (Brown, 2010; Wolfe, 2014) and the benefits to longer term teaching and learning and economies of scale. At the micro level of local school policy, there is evidence beginning to surface of school’s incorporating STEM experiences and attainment of excellence into their written plans for student learning (Maitles & McAlpine, 2012) and further awareness of the importance to the individual’s development in STEM.

Within the space of the early childhood centre opportunities exist for children to becoming fully engaged in learning through hands-on activities, cooperation and decision making (Bottini & Grossman, 2005). With the availability of this opportunity, the integration of STEM into existing hands-on activities which may not have had the focus of STEM learning in the past, will provide an opportunity for integrative methods to be applied to early childhood learning (Lyons & Treadwell, 2015). Early childhood centre directors bear the responsibility of providing ongoing professional learning for their staff (van Oers, 2013; Colmer et al., 2014)
and within this requirement is an underlying expectation that environments are created for enhanced learning, creativity and exploration (Steg et al., 1994).

While in Australia policymakers are still to fully embrace the importance of STEM education in early childhood education, and there is evidence in Western countries of wide variances in national STEM education policies between nation states. Strong evidence of STEM in early childhood education (ECE) can be drawn from welfare state policies across Scandinavian countries (Karila, 2012). There has been a recognition in these countries of the need to move away from disparate teacher education programmes to one teaching degree that integrates all levels of education including ECE. This direction of the ‘Nordic model’ confirms a holistic, child-centred approach directed towards participation and autonomy that reflect those welfare policy areas integrating the social, the family and education. This approach, more wholly, incorporates STEM into an integrated curriculum.

Evidence of the application of STEM in ECE contexts and how they both contextualise STEM for early learners and scaffold further learning has been shown through the application of technology (Lyons 2015) and engineering (Dietze & Kashin, 2013). Robotics (Bers, Seddighin & Sullivan, 2013), wooden blocks and construction (Wise Lindeman, McKendry & Anderson, 2015; Bagiati & Evangelou, 2015) and web-based learning including interactive media (Paulsen & Andrews, 2014; Lyons & Tredwell, 2015) to develop understanding of STEM are all recent examples where early childhood learners can apply their understanding of simple STEM concepts to practical examples. The extension of STEM learning to STEAM, through the inclusion of Arts, adds further complexity to the integrative approach allowing young children to express their STEM learning and to support teachers find alternative delivery methods of building STEM into the curriculum. Wooden blocks, also viewed as technology, added to activities such as music and painting, can be added to STEM to create STEAM (Sharapan, 2012). Ricks (2012) provides a mathematics focus with STEAM, applying it into a discussion on the integration of social constructivism mathematics instructional practices, practical, hands-on tasks, and performing arts such as music and movement practices. The fundamental frameworks of kindergarten instruction and the application of these social constructivist practices of mathematics were shown to have a greater positive influence of student achievement and motivation in mathematics than did more hands-on, tactile mathematics activities which are more associated with early childhood learning.

Although some science, technology and engineering (STE) focus is apparent, research into ECE mathematics (M) has gained the most attention (Cross, Woods & Schweingruber, 2009). Cross et al (2009) note that competent mathematics learning is ‘not realised,’ despite a potential for that learning to occur in the early years by all children. Mathematics teaching and learning is overlooked in both everyday experiences in homes and communities as well as the early childhood educational settings which is reflective of the systemic issues of deficiency in mathematics education within broader childhood education system. When given the opportunity to use for example, graphs, mathematical reasoning in the EC experience, children have been shown to make connections with their thinking (Larson & Whitin, 2010). There appears to be a lack of knowledge and confidence to effectively teach mathematics and more
broadly STEM (Ford & Strawhecker, 2011). Mathematics remains the dominant element in ECE at the expense of STE.

Research has indicated that EC teachers’ attitudes towards incorporating STEM subjects such as science and mathematics are relatively positive (Campbell & Jobling, 2010; Edwards & Loveridge, 2011). Teachers are interested in investigating contexts and teaching approaches that support children’s deep learning in relation to STEM skills and processes, including creativity, problem-solving and critical thinking (analysing, synthesising and evaluating). The holistic nature of EC education where imagination and play are privileged makes EC a powerful context for further investigation of STEM pedagogy. There has been insignificant consideration of the notions of integrated teaching within an early childhood setting. The focus is upon the teaching pedagogy of the EC educator rather the outcomes to the child itself. Again, the intent here is to consider the teacher and how an integrated approach to teaching practice supports children to think and learn naturally. What has become apparent in the EC setting is that some teachers have been allowed greater professional autonomy, responsibility and autonomy in planning their curriculum (Maitles & McAlpine, 2012). In short, the volume of literature pertaining to an integrated teaching methodology within early childhood contexts is growing but there remains the potential for further consideration of this subject material.

Given the essential nature of these years, research is needed to inform both theory and practice around effective STEM pedagogies in EC. This pilot survey will provide some initial answers and help focus future research in the most appropriate and effective way. This survey was designed to generate theoretical knowledge about forms of pedagogies in EC STEM education by examining teachers’ responses to a number of questions associated with the play-based, holistic, and integrated pedagogy common to early childhood.

Research Question: In what ways is STEM education embedded in EC teachers’ programming and planning, pedagogy and knowledge, and conceptualisations of learning?

THE RESEARCH PROJECT

Methodology

This research is part of a larger project which used a mixed methods approach to gather data on early childhood educators’ STEM pedagogy through professional learning and case studies. These multiple methods of data collection (surveys, observations, interviews, document analysis) provide a means for triangulation or a systematic convergence of data sources which strengthens the validity of the data while reducing biases or weaknesses with any one method (Creswell, 2014).

The initial phase, reported in this paper, involved the use of a survey administered electronically. Surveys can provide quantitative or qualitative data relating to a numeric description of trends, attitudes, or opinions (Creswell, 2014). In the initial design of the survey we considered many factors, but essentially wanted to ensure that the survey responses provided a breadth of data around the key questions of the bigger research project and that our survey data could provide a snapshot of a population (EC Educators) by studying a sample of that
population. As a cross-sectional survey, the survey was required to provide a broad response, so it was necessary that the survey was sent to all educators in a number of geographical sites with the intent of generalizing from a sample to a population (Fowler, 2008). In addition, we were aware that the response rate could be lower than expected, so we followed a procedure to ensure maximum participation. The four-phase process followed included:

- An initial short advance-notice email to all potential participants informing them of the research and including brief details.
- The second email contained the actual link to the electronic survey and was distributed two weeks after the first notice.
- The third email was a follow-up, sent to all potential participants about two weeks after the initial survey. It contained link to the electronic survey.
- A fourth email was sent to all potential participant just before the closure of the survey, thanking them for participation and providing the response rate. As the survey was anonymous, we could not just target the respondents. Overall, the survey and collection of data took six weeks.

**The Survey Instrument**

The survey employed both likert-style responses and open-ended sentence answers (without pre-determined responses). It included provided some questions relating to the demographics of the educators (quantitative data) as well as qualitative data relating to the STEM pedagogy. An anonymous online survey was distributed to preschools in three Australian states (New South Wales, Victoria, Western Australia) with an expectation of responses from about 100 educators. Based on similar national surveys (Lyons et al, 2006), the expected response rate was 20-40% and the survey achieved a 30% response rate (i.e. 30 educators completed the survey). The survey's purpose was to elicit responses regarding demographics of EC teachers and their STEM education pedagogy and growing conceptualisations of STEM. The demographic questions were included to ensure that the population of the sample could be considered representative of a bigger population. In other words, we wanted to ensure that there were no unusual aspects to the group who participated. The STEM questions were adapted from our larger research area which outlined the following areas: (i) teachers’ pedagogy and knowledge of STEM as a learning area, (ii) teachers’ beliefs regarding children’s deep learning through engagement in STEM, and (iii) teachers’ planning and programming practices in relation to STEM. The survey was developed using Qualtrics software and consisted of likert-style response questions and open-ended questions, generating qualitative data.
Strand 15

Survey Questions

Demographics:
1. Indicate your age: 18-29, 20-29, 40-49, 50-59, 60 +
2. Number of years teaching, 0-5, 6-10, 11-15, 16-20, 20+
3. Your formal qualifications: text entry
4. Institute attended: text entry
5. Number of educators working at your kinder? 1-2, 2-3, 4-5, 6 +
6. The number of three year old kinder groups conducted each week at my kinder is: 1, 2, 3, 4 or more
7. The number of four year old kinder groups conducted each week at my kinder is: 1, 2, 3, 4 or more
8. The total number of children that participate in all sessions at our kinder is: 0-20, 21-40, 61-80, 81-100, 100+
9. The location of our kinder is: suburban, urban, regional, rural
10. The socio-economic profile of our kinder community is best described as: low socioeconomic, medium socioeconomic, high socioeconomic.
11. The number of years our kinder has been operating is: 1-5, 6-10, 11-15, 16-20, 21+
12. In the past five years has the number of children attending your kinder: increased, decreased or remained stable?
13. In the last 5 years, I have participated in PD in science, maths, design/construction, ICT: Yes/No

STEM questions
1. What is your understanding of STEM?
2. What teaching practices do you use for STEM learning?
3. Describe how you enable/encourage/foster children’s learning in STEM areas.
4. How do you ensure that children’s STEM learning is meaningful and significant in the child’s world?
5. How does your strength in the STEM discipline areas promote children’s learning?
6. How do you highlight a concept or process to draw children’s attention to a STEM related idea in the kinder setting?
7. How do you include STEM in your programming & planning?
8. Are there particular issues you have encountered as you plan and / or implement STEM practices and how have you overcome these?
9. What is available in the kinder environment that provides opportunities for exploration related to STEM e.g. setting, materials, people?
10. What resources would you like to have to further enhance STEM learning?

DATA AND ANALYSIS

Responses from the demographic data were presented in graphic form with percentages assigned to the number of responses in a given question. For the purposes of this paper, where responses were evenly spread across the scales, these were recorded as representative of a normal spread. If any single response generated more than 50% of the responses or presented with a percentage gap of greater than 30% these were considered as important to note.

</table>

Demographic data indicates that across the items chosen:
- Age range of educators from 18 years old to over 60 years old.
- Work experience in kindergartens from 0-5 to over 20 years.
- Predominantly Bachelor degrees and Diplomas
- Half the kinders had more than 6 educators, most others have between 2 and 5.
- Kinder attendance - range from small groups of 21-40 to large groups of more than 100.
- Most kinders indicated as middle SES (14), others high SES. No low SES. (response?)
- All kinders are well established, most having operated > 20years,
- Over 80% of educators have participated in some form of PD in Science, maths, design/construction, ICTs in the last five years.

**STEM Question responses:**

Question responses were compiled on a grid. All responses were read and re-read by the researchers to assimilate the information. This allowed for the development of a continuum of educator responses graded from minimal response to complex response. For this paper, the data were aggregated and roughly attributed to three categories:

- **Response One** - complex response which indicates an understanding of STEM or some of the STEM fields, and teaching strategies
- **Response Two** – Simpler answer which indicates some understanding of STEM
- **Response Three** – Incomplete or answer indicates minimal understanding.

</thead>
<tbody>
<tr>
<td>What is your understanding of STEM?</td>
<td>My understanding of science is all things that are living within the world we live,… technology refers to our world of computers and machines. engineering to me means often things we can't see like all the plumbing that goes on under the ground to take water away for instance, building structures, railway lines, roads, construction sites, etc. Mathematics beginning with the understanding of numbers and their relationship to quantity. Graphs, statistics, finances, areas, multiplication, subtraction, dividing</td>
<td>Stem is ensuring that your program provides the opportunity for children to experience science, technology, engineering and mathematics across the program</td>
<td>I have never heard of the acronym STEM.</td>
</tr>
</tbody>
</table>

Themes which arose from the STEM question data included:

1. What is your understanding of STEM?
   - STEM is not a term which is commonly understood
   - Technology understood to mean technological devices such as computers
   - Some educators had a broader interpretation of STEM

2. What teaching practices do you use for STEM learning?
   - Some disciplinary responses, several mentioned integrated
   - STEM experienced though discussions, play experiences, research questions, intentional teaching activities, incidental learning activities

3. Describe how you enable/encourage/foster children’s learning in STEM areas.
   - Group learning, teacher-led, demonstrations followed by children experimenting, guided interaction, inquiry-based activities, questioning.

4. How do you ensure that children’s STEM learning is meaningful and significant in the child’s world?
   - Start with children’s interests and prior understanding, listen and observe and build from there

5. How does your strength in the STEM discipline areas promote children’s learning?
   - science background - so passionate, using inquiry learning, children’s attitude/engagement important, exposure to these areas will impact on the children learning later in life.

6. How do you highlight a concept or process to draw children’s attention to a STEM related idea in the kinder setting?
   - Teacher-led activities, building on children’s interests, project work. Scaffolding play. Teacher excitement leads to children excitement

7. How do you include STEM in your programming & planning?
   - Specific inclusion of discipline areas, regularly/fortnightly, investigation table, Interwoven in program

8. Are there particular issues you have encountered as you plan and / or implement STEM practices and how have you overcome these?

2060
• Planning is difficult - following children’s interests; own knowledge and experience limited; equipment not adequate

9. What is available in the kinder environment that provides opportunities for exploration related to STEM eg setting, materials, people?
   • The setting (natural, bush); Adults with interest; support from other knowledgeable adults

10. What resources would you like to have to further enhance STEM learning?
   • Further PD on how to integrate; extra materials and parent support.

Analysis

The data provided critical insights into how EC pedagogies align with, and can provide the foundation for, deep STEM learning. STEM pedagogies described by the teachers included how they worked through children’s interests. “I always try to follow the children’s interests - for example adding PVC pipes to the sandpit when the children were experimenting in how the water flows and making lakes”. Generally this meant being able to add value to a child instigated activity and being able to act promptly. Teachers would need to feel confident in their own understandings of the content to be able to do this effectively. Teachers indicated that they often worked from children’s prior understandings and were able to build on this through co-learning with the children or through purposeful, intentionally development of activities, “Children's views are sought and built upon, open-ended questioning and activities”. Finally teachers commented on play pedagogy and how they built on children’s play “Learning happens with their play. Use scientific words. Listen to children and follow them. Scaffold their own ideas and mine - new learning. Play along with children and explore concepts with them”.

In returning to the original research question embedded in the survey design, we can draw on our data to answer:

In what ways is STEM education embedded in EC educators’ programing and planning, pedagogy and knowledge, and conceptualisations of learning?

The analysis of the results indicated that all EC teachers reported that they incorporated STEM education into their daily informal and formal activities through regular program planning - supported by intentional planned activities. However, their definition of what constituted STEM varied and tended to indicate discipline-based approaches, although some were attempting to work holistically.

CONCLUSION

This pilot research survey investigated early childhood educator STEM pedagogy. Based on an understanding of some earlier work in this area, we were specifically looking at what educators commented about holistic or integrative methods (Lyons & Treadwell, 2015) as applied to STEM learning and found that this was acknowledged but not always practised. Experiential learning was an important component of all the teaching, enabling children to become becoming fully engaged in learning through hands-on activities, cooperation and decision making (Bottini & Grossman, 2005). A final aspect which was clearly articulated
through the survey responses and is critical for early learning in STEM, is the need to provide STEM education training for early childhood educators (Wolfe 2014). In conclusion, the educators were heartened by the responses from the educators and are anticipating that the follow-up research will provide further understanding into EC STEM pedagogy.

DEVELOPING COMMONSENSE THEORIES OF MOTION: 
THE EMERGENCE OF MISCONCEPTIONS

Michael Hast
St Mary’s University, Twickenham, UK

How developmental psychology underpins our understanding of knowledge formation and conceptual change in early science education has been of concern for some time now, fostering a strong partnership between the two disciplines. In particular, there has long been interest in the development of knowledge that stands in conflict with accepted scientific views, often posing challenges for educational instruction. To explore this, the work presented here is a review of past and current studies I have conducted in the field of early understanding of rudimentary scientific concepts relating to the everyday world. Specific focus is placed on the construction of so-called commonsense theories of motion and the role played by object and motion dimension properties in contributing to this early conceptualization. Further, consideration is given to some of the nonverbal underpinnings of such constructions by addressing recent work into tacit knowledge and the role of relative object weight in preschool search tasks. Potential implications for educational practice are discussed, as well as relevant directions for future research.

Keywords: early science, object motion, object properties.

CHILDREN’S CONSTRUCTIONS OF THEORIES OF MOTION

My research over the last years has been influenced by some of the oldest philosophical discussions around the laws that govern the physical world, leading all the way back to Aristotle, if not further. Many of these so-called commonsense theories that are based on personal experiences result in conceptions that are misaligned from accepted scientific views, and these often persist into adulthood. Based on this, I have been particularly intrigued to explore children’s ideas about what factors they believe to be pertinent to object motion, and what commonsense theories, as a result, they develop. To date, this has focused on two key elements in their reasoning – the role played by various object variables and the understanding of different motion dimensions. These are aspects of physical science that many school curricula cover during early stages of education, providing a clear justification for exploring at what level and in what way intuitive knowledge about object motion and accepted scientific views in the classroom meet.

By initially working with primary school children aged 5 to 11 years it became evident that their understanding of object motion was dominated by the particular concept of object weight, more so than any other type of variable – for example, heavy objects, by virtue of their heaviness, are deemed to fall faster than lighter objects, but lighter objects are believed to roll faster along horizontal surfaces because of their lightness (Hast & Howe, 2012). Continued research also unveiled that object weight also impacts on children’s understanding of speed change (Hast & Howe, 2013a). A central question at this stage was also whether ideas about object motion in the three dimensions are interrelated or independent from another in children’s thinking. Both above studies indicated that the same children reason differently when it comes to considering objects’ behavior in fall, along horizontals or down slopes. What is more, when
using the same objects children consider the central role of object weight to still matter but to be constrained or facilitated according to the particular dimension in which the objects move (Hast & Howe, 2013b; also see Figure 1 for a summary of some of the main results). Consequentially, the notion was developed that children’s constructions of commonsense theories of motion begin early, that these theories have a certain degree of robustness to them, and that they outline an understanding of the laws of the physical world that is incommensurate with accepted scientific views – thus presenting a challenge for the science classroom on a number of levels.

Figure 1. Apparatus used for “incline” condition in Hast and Howe (2013b), left, and overall predictions made by children in each condition about which ball would be faster, right.

However, subsequently it became clearer that children’s reasoning is not informed by three separate dimensions but merely by two – noted through absence or presence of surface support – and that children appear to use these theory fragments either independently or in interaction with one another (Hast, 2014a, 2016). Collectively, this work was able to show that commonsense theories of object motion develop early in childhood, as they are present by the age of 5 years at the latest, and that these theories are constructed on the basis of both motion dimension and object variables. This certainly has implications for early science education, since one of its core purposes is to engage with and, where necessary, challenge the knowledge that children bring into the classroom. For instance, it raises questions about in what order certain topics should be taught, how conceptual change can be facilitated, and when this should be done. An answer to the first question might be that aspects of fall and horizontal motion should be taught first, and then of motion down inclines (cf. Hast & Howe, 2013b). But is there opportunity to foster conceptual change, and when should this be addressed?

TACIT RECOGNITION OF OBJECT MOTION

To begin addressing the notion of the nature of the commonsense theories outlined above – which includes their potential malleability in the context of conceptual change – my work has examined children’s underlying understanding of object motion. That is to say, based on a plethora of studies with nonverbal infants there seemed good indication that children could potentially verbally state one prediction yet could, underlying, hold models that represent
something else about the same phenomenon. Different studies that I conducted, again with 5- to 11-year-olds, have thus shown that there is indeed a difference between expressed beliefs about object motion and recognition of dynamic events (Hast & Howe, 2015, 2017; also see Figure 2 for a summary of the results). Children would explicitly predict one outcome – such as that heavy objects will fall faster than light ones because they are heavier – but would be able to accurately identify this as incorrect if shown through simulated events (and pick out those events that actually corresponded to the correct outcomes, even if these had not been predicted).

Figure 2. Overall outcomes of children’s predictions and recognition of objects in fall (Hast & Howe, 2015), left, and of objects rolling down inclines (Hast & Howe, 2017), right.

Most notably, the predictions that children make in such tasks are clearly informed by their rigid beliefs about object properties, yet their ability to recognize and reject dynamic events to a high degree of accuracy suggests an intuitive grasp of such dynamic events does not draw on such object property beliefs. The work has given rise to the proposition that underlying tacit knowledge structures around object motion are stable, quite possibly from infancy onwards, but that expressed theoretical constructions are subject to change over time without impeding those underlying structures. This was particularly notable in the exploration of children’s understanding of motion down inclines (Hast & Howe, 2017). In the context of education it is worth examining this in more detail. I devised a dual pathway model outlining the relationship among knowledge representations, with the significant difference being external contributors such as discourse, education and personal experiences (Hast, 2014b; also see Figure 3), but further research would do well to examine the specific contributor processes in more detail.

Applications of the theoretical work to classroom practice have already shown that utilizing underlying knowledge recognition principles has significant potential in promoting conceptual change in this field when working with primary school age children, and even adults (see Howe, Devine, & Taylor Tavares, 2013; Howe, Taylor Tavares, & Devine, 2016). However, it is important to not only consider the direct implications for child learning but also for classroom teaching. A recent qualitative examination of generalist primary school teachers’ perceptions on the use of such intervention tools to guide conceptual development in the early science classroom (Hast, 2017a) has shown positive attitudes embedded within a model centered on trust and responsibility of learning. However, it also raised some concerns about the feasibility
of incorporating such tools into practice, especially for teachers who lacked the necessary knowledge or confidence to teach physical science topics. Addressing these concerns will require a deeper understanding of teaching practice but also a clearer view of the underpinnings of the conceptions children bring to the classroom.

Figure 3. A dual pathway of reasoning about object motion (adapted from Hast, 2014b).

**INDICATION FOR RISE IN MISCONCEPTIONS AMONG TODDLERS**

More recently my work has, as a result, turned to examining potential beginnings of scientific misconceptions that may contribute to a clearer understanding of the development of commonsense theories of motion. To do so, I turned to working with toddlers aged 2 to 3½ years (Hast, 2018). Past work has consistently demonstrated a so-called gravity bias during this age: When a ball is released into a tube that goes down not in a straight line but in a curved shape, then they will search for the ball immediately beneath the tube rather than where it actually is. To illustrate, using the image on the left in Figure 4, if the ball is dropped into entry A at the top, then the ball will end up in drawer 2 at the bottom, but younger toddlers will be more likely to start searching in drawer 1 immediately beneath entry A. By 4 years of age they typically overcome this bias. But does having information about the relative heaviness or lightness of a ball influence toddlers’ search behavior in any way – does the gravity bias, as outlined above, stay for longer or disappear sooner, and do they make fewer or more gravity error searches?

The results of this particular experiment showed that giving toddlers relative information about objects – that is, they are given both a heavy and a light ball to handle – impacts their search behavior. Most notably, they make more search errors guided by a gravity bias when they have relative information about the heaviness of an object and fewer errors in the context of relative lightness (see Figure 4) – but not if the relative information cannot be established. This pattern
also only started to show significant effects with toddlers aged around 3 years and above, rather than sooner.

Figure 4. Apparatus used in Hast (2018), left, and overall outcomes of search behaviour, right.

A further study that I then conducted with toddlers aged 2, 2½ and 3 years (Hast, 2017b; see Figure 5) similarly showed that relative weight of objects impacted toddlers’ search behavior in a task where they could not visually follow the motion. As in the gravity task above, toddlers were more likely to search incorrectly if they had information about the relative heaviness of the ball, and more likely to search correctly if they knew of the relative lightness, but only among the 3-year-olds. For the 2-year-olds this did not play any role. For the 2½ -year-olds only relative lightness mattered.

Figure 5. Apparatus used in Hast (2017b), left, and overall outcomes of search behaviour, right.

Both of these recent studies show that already at the preschool level children are incorporating object variable information into their reasoning about object motion. Taken with the previous studies covered in this paper there is thus good indication that children develop explicit understanding, either expressed in their reaching or in their verbal responses, that may give rise at early stages for some of the misconceptions around commonsense theories of motion that dominate the early science education literature. Importantly, while among 5- to 11-year-olds
conceptions already seem to be fairly stable and therefore more likely to be resistant to conceptual change, their development seems to begin in the preschool phase and is a gradual process. Understanding this gradual change at the preschool level may not only have implications for the primary science classroom but for the engagement with basic scientific concepts in preschool settings – and, consequentially, for the practitioners in such settings.

CONCLUSION AND FUTURE DIRECTIONS

The various findings outlined in this paper collectively outline the complexity of scientific commonsense theory formation in early childhood that present a challenge in the science classroom. However, they also highlight the positive viewpoints provided through developmental psychology research that demonstrate potential for working towards more effective conceptual change approaches in the early science classroom. In particular, we see that the aspect of object weight plays an early role in the conceptualization of knowledge about motion, and that this already begins at the preschool level. Future research currently in planning is hoping to consider even earlier insight into the nonverbal understanding of conceptual knowledge in this domain, to more fully understand the emergence of misconceptions and, consequently, to move towards more targeted intervention approaches, but it seems clear that the external contributors identified in my dual pathway model (Hast, 2014b) already matter at some point in early development.

In the more applied context of education, this array of research – particularly the more recent developments – may have implications for preschool education. There is no suggestion that science education should be more formalized at that stage. However, more consideration may need to be given to preschool educators’ knowledge of such scientific conceptions and how their pedagogy may need to be adapted to incorporate exploratory activities such as the gravity task. In allowing the targeting of conceptions at such an earlier age, misconceptions at the primary school level could potentially be more accessible in and amenable to conceptual change approaches. Future research, in a psychology-education coproduction, must attempt to address this matter.

WHAT DO SPANISH 5-7 YEAR-OLDS SAY ABOUT WATER POLLUTION AND WATER SAVING?

Marta Cruz-Guzmán, Ana María Criado and Antonio García-Carmona
Science Education and Social Science Education Department, Seville University, Spain

This paper presents some of the results from a more extensive study, to assess children’s ideas in a Spanish elementary school about water pollution and water saving. Data were acquired using two complementary interviews. The results allowed us to identify the children’s main ideas on both topics. Children are not often aware about water pollution, and if they are, they use to relate it with macroscopically dirt, which could be eliminated with basic physical methods. In general, they do not express any viable ways to save water. Water consumption in children’s households is very present in their lives; so ways to avoid wasting and polluting water at home should be highlighted. Inquiry-base activities could be encouraged in which they would be guided to discover how humans contaminate and waste this resource. This could help them to value our natural resources.

Keywords: education for sustainability, children’s ideas, elementary education.

INTRODUCTION

Education for Sustainability in the early educational stages

Education for Sustainability (EfS) as a focus at the preschool level has been argued persuasively in the literature for at least a decade (Davis, 2015). Various research groups throughout the world have been studying in this field. Martínez, Ull and Aznar (2014) have provided a brief recollection about it. Such studies conclude that it is important for the child to appreciate the fact that living things respond to and feel the changes in their environment, since this will develop attitudes of conservation and respect. Therefore, EfS should begin in a child’s early years (Taylor, Quinn, & Eames, 2015).

There is an important body of literature on experiences and projects related to EfS at the first levels of education. In Spain, the majority of schools let their pupils interact with natural materials from their environment – logs, rocks, sticks, pine cones, and even scrap or recycled materials – with the firm intention of promoting values such as respect for the environment (Flecha, 2013; García, 2010). For instance, Álvarez et al. (2004) shows experiences at preschool and primary education levels, such as school environmental proposals to participate in the collection and sorting of waste. In these experiences, not only scientific knowledge of the surrounding world is promoted, but also an understanding of how to act in order to preserve it. The aim is also to encourage internalization of conservationist attitudes, and an awareness and appreciation of the reasons behind conservation. In sum, this project stresses the acquisition of values as the basis for EE.

Garrido (2007) stresses the importance for the pupil to appreciate the fact that living things respond to and feel the changes in their environment, since this will develop attitudes of conservation and respect. To understand these interactions, we believe it is necessary to go beyond presenting children with natural resources in isolation, outside of their natural systems,
but instead to view these systems from within allowing children to see the multiple relationships among the members where they make sense.

**Studies of Children’s Ideas in Environmental Education**

Knowledge is built on the foundation of the student’s mind as new experiences and new information interact with their misconceptions. According to Cubero, Cubero, Santamaría, Saavedra, and Yossef (2007), we need to know our students’ preconceptions and worldviews before starting a learning-teaching process with them. Then it is possible to construct a shared meaning and educators are able to adjust their intervention in greater depth.

As mentioned above, the literature includes several examples of Environmental Education (EE) related activities in preschool classrooms. In every case, EE should be connected with the children’s environmental conceptions, in order to improve this type of education (Rodríguez, Kohen, & Delval, 2015). Reid and Scott (2013) show that it constitutes a whole field of research within EE.

EiF should be connected with the children’s environmental conceptions, in order to improve this type of education. Different authors have studied preschool children’s thinking about different environmental topics (Kerr, Beggs & Murphy, 2006; Palmer, Suggate & Bajd, 2004; Saçkes, Flevares, & Trundle, 2010), though different authors state that there is a research deficit in early childhood science teaching (Cantó, Pro & Solbes; 2016; Kambouri, 2016). There are fewer studies on early childhood children’s prior ideas than on those of pupils at other educational levels.

**Goals of this communication**

The focus of this study is to assess the ideas of preschool and primary school children about water pollution and water saving. This one involves the following specific objectives:

- a) to ascertain what children’s ideas about the topics, establishing learning progressions;
- b) to compare preschool pupils’ conceptions with those of primary-education pupils.

**METHOD**

**Participants**

The participants were forty-three 5-7 year-olds at an elementary school in Seville (Spain). They were chosen by convenience. Children had had no prior lessons at their school about these environmental issues (water pollution and water saving) when we interviewed them. They formed into two groups: twenty-one 5- and 6-year-olds in their final year of preschool education; and twenty-two 6- and 7-year-olds in their first year of primary education.

**Phases of the Research**

The methodology is structured and can be summarized in the plan shown in Table 1. In the design of the instrument, some of Payne’s (2010, 2014) suggestions were followed: (i) qualitative (and descriptive only) data were collected ethnographically from young children via ‘philosophical’ conversations (in classroom) and art works (outside in the playground) about a
range of topics freely chosen by the children about children's conceptions of (local and experiential/existential) nature and environment; (ii) how young children experience and investigate highly local/proximal-temporal environmental problems were highlighted; (iii) how the 'social ecology' of families/homes has an intergenerational impact on how young children behave themselves, were endeavored. However, due to space limitations in this paper the details about the design and validation of the instruments to detect children’s ideas on environmental issues are not shown.

### Table 1. Outline of the Phases of the Research

<table>
<thead>
<tr>
<th>Phase</th>
<th>Sub-phase</th>
<th>Facts</th>
</tr>
</thead>
</table>
| I     | Design of the first version of the data collection instruments | A Interview with the usual format of questions (QFI)  
B Interview with format adapted for young children: "complete the story" (CSFI) |
| II    | Validation of both instruments | First Apply pilot trials of (A) and (B) to individual children  
Second Analysis of results  
Third Amendment of (A) and (B) to give their final versions |
| III   | Application of the final versions of (A) and (B) to children in groups of three |
| IV    | Recompilation of the new data, and analysis of the final results |
| V     | Conclusions |

In accordance with Littledyke (2004), we acted as non-judgmental active listeners, since our questions were designed to simply draw out and clarify views. We encountered the same limitations; i.e., lack of confidence in speaking out, shyness, lack of attention, language limitations, etc. The interviews were all digitally recorded and transcribed.

A qualitative analysis of the data was performed by open response categorization, suitable school science responses\(^1\). To ensure the reliability of the design of the category system and the subsequent allocation of responses to each category, we followed an inter-rater strategy of analysis (Padilla, 2002). Thus, after their independent analysis (Creswell, 2007), the researchers reached an almost unanimous agreement on all the codes (99% inter-coder reliability) and they met to form a consensus on both establishing the definitive categories and how to allocate the uncertain responses.

### RESULTS

The responses were grouped into categories (at least three tiers) that progressively approach school science that is appropriate for these ages, which are meant by levels in learning progressions (Roth, 2014). Especially we present figures where best responses are displayed first, medium answers next, etc. The percentages of the responses given to each question by participants from the last year of preschool education (21 children) and the first year of primary education (22 children) will be given as entries in Figures 1 and 2.

\(^1\) **Suitable school science** means 'right' science suited for this children level of knowledge.
We will now present the different sections that analyze the responses, and compare the preschool children’s ideas with those of the primary education children. In these comparisons, it should be taken into account that, in general, a pretty percentage of primary education pupils did not provide answers to some questions and therefore there was a higher overall response rate from the preschool pupils. We can only think of two aspects that can explain this fact. Firstly, it may simply be due to oscillations of the small samples used in our inquiry. Secondly, it has been reported that preschool children are more unconstrained than primary children, who feel inhibited to answer on topics they have not mastered (Delval, 2002).

**Figure 1.** Majority categories for questions 6 and 7 about Water pollution (Q6. What we mean by the water being polluted?; Q7. What could we do to make their friend Flop happy?).

**Figure 2.** Majority categories for question 8 about Saving water (Q8. Ideas on how to use less water – can you think of any?).

**Water pollution** (Question 6). The vast majority of the pupils (62% PSE, 68% PE) do not know about water pollution, and 38% PSE, 27% PE relate it to macroscopic dirt and rubbish that might be found in rivers or seas. In the same sense, Littledyke (2004) concluded that many primary children identified pollution as litter, visible items, and few had a clear concept of chemical pollution: ‘When my dad is out fishing and they throw litter in the water, we could poison the fish and kill them’ (p.228). He also showed that pollution issues became more significant among older children.
Rodríguez et al. (2015) found that 9- and 10-year-old students knew three predominant epistemic structures about the pollution process: (1) pollution as innocuous; (2) dirt and apparent features; and (3) local, direct and immediate impacts. In our case, PSE students knew about only two of them, and first-year students were beginning to acquire the third one, because only 4% of the PE pupils are aware of the chemical pollution of water which can render it impossible for certain aquatic animals to inhabit. In this sense, Garrido (2007) places PE as being the period in which students learn that every kind of living being adapts to life under certain specific conditions, and that their development can be limited by a change such as pollution. As a chemical general wide concept (its causes and consequences), pollution is too abstract for them (Rodríguez et al., 2015). However, children can understand some specific and evident examples, as dead birds or fishes while been covered by a black film of thick fuel dumped in the sea. In fact, Evans et al. (2007) found there was high concern (82%) in first- and second-year students about the water pollution from industrial dumping.

**Remediation of water pollution** (Question 7). In keeping with the above responses, the majority of the PSE pupils (57%) do not know how water is decontaminated or cleaned. The others (43%) would clean the water with very rudimentary, physical means: with shovels, brooms, glasses, etc.

The percentage of PE pupils who did not know how water is cleaned is similar to the PSE case (59%). Some 27% would do it domestically using physical means. However, 14% of the pupils stood out for having heard about severe cases of pollution, such as oil spills, and were aware of the need to clean them up. Kahn (1997) found that the majority of the 2nd grade students understood that oil spills negatively affected the local environment.

It is important to appreciate that the majority of the students do not care about water pollution and its remediation. Similarly, Lea and Hilmo (1998) observed that ‘Clean drinking water is taken for granted by children in Norway, but for children in many countries, polluted water will be the first environmental issue young children are concerned with’ (p.54).

**Reducing water consumption** (Question 8). Although children aged 9 may know some ways of saving water (Arozarena et al., 2012), most of our pupils (76% in PSE and 77% in PE) ignore this aspect. The others (24% in PSE and 23% in PE) describe just a single way (turning the tap off, washing things less). According to Kruse (2010), the situation becomes real for preschool children when they personally experience it. In order to develop water saving habits, Siguráardottir (1998) proposes that one day all the water should be turned off in the preschool, so that it was not possible to have water to drink or for washing hands.

**DISCUSSION AND CONCLUSIONS**

**Discussion**

In general, results are in concordance with what is expected from their developmental growth in conceptual understanding. In general, children are not able to think of ‘non-perceptible-phenomena’, they have ‘evident-focused thinking’ (Delval, 2002). In the next paragraphs we discuss these features in relation to the specific ideas investigated.
When water pollution and its treatment are addressed, again their unawareness can be explained by their aforementioned ‘evident-focused thinking’. Harlen (2008) claims that for children it is difficult to understand abstract concepts like the pollution influence on the environment if they do not have prior perceptible experiences with concrete cases in their lives. For instance, pupils can dirty the water in a goldfish bowl and compare how fishes live there and in a clean one (although we think it could have ethical concerns, because we are injuring animals). According to our results, older pupils were not able to define ‘pollution’, although they could describe certain contaminating actions (Pérez, Galache, & Camacho, 1996).

At last, most of our pupils ignore any viable ways of saving water. Ching-Yuan and Pei-Yu (2016) reported a similar case. They develop effective activities for 5 and 6 years old children that did not know how to use less water in Taiwan, in fact they often did not know how to cherish water resources.

In comparing the two educational levels, unexpectedly, we found that a greater proportion of PE pupils did not answer compared to the PSE pupils. This relatively greater inhibition of children one year older may be due to a particular feature of the sample, as it has been explained. Beyond this, many of the items studied showed the same trends in the two levels. There were also other cases in which the higher level of education presented better levels of formulation of knowledge (as might be expected). For instance, there were greater percentages of pupils who are aware of the process of recycling and its purpose. In the higher level, (even though a small percentage) it also emerged who knows about the chemical contamination of water and its impact on the lives of certain aquatic animals, and who recall severe cases of contamination of water such as oil spills and are conscious of the need to clean them up.

Conclusions

This study shows the children’s formulation of two environmental topics at the earliest stages of education, which were identified through an instrument, CSFI. Different levels of learning progressions were established while grouping the responses. Similarities and differences between the two educational levels, preschool and primary education, were also determined.

In synthesis, we could describe the common conceptual features that we found as follows: (a) they are not often aware about water pollution, and if they are, they use to relate it with macroscopically dirt, which could be eliminated with basic physical methods; (b) in general, they do not express any viable ways to save water.

The acquired results compare children’s ideas about specific environmental issues of preschool and first-year primary children and report that general features of preoperational thinking likely lie behind these responses.

From the analysis, we are able to establish a number of proposals for the improvement of the teaching of these topics. Therefore, we think that activities for humans taking care of nature should continue to be insisted upon, but through showing pupils their chance to choose not to participate in harmful activities. Fostering autonomy and responsibility in their decision-making will make their involvement more effective and help them assimilate the worthiness of their acts.

2076
We would also suggest providing specific examples (e.g., the consequences of specific types of contamination, such as water pollution, on the living conditions of specific forms of life). This should constitute the backbone of the teaching and learning process. In this sense, water consumption in pupils’ households is very present in their lives; so ways to avoid wasting and polluting water at home should be highlighted. This implies that tasks in which the children can be made aware that water used at home ‘travels to natural surroundings’ should be included. Inquiry-based activities (Peterson & French, 2008) could be encouraged in which they would be guided to discover how humans contaminate and waste this resource. This could help them to value our natural resources.

Finally, this study has also limitations mainly due to the small sample of children. Two complementary instruments were used (although only the results of one of them have been reported in this paper), and both were piloted previously in order to improve their validity and reliability, and the data were analyzed using an inter-rater strategy. In addition, suggestions based in Payne (2010, 2014) were followed in the design of the instruments, as mentioned above.

ACKNOWLEDGEMENT

This study was supported by the Ministry of Economy and Competitiveness (Spain) under Grant EDU2013-41003-P.

REFERENCES

Recent research has shown that early age children construct ideas of complex phenomena, the acoustic phenomena are an example; however, this topic and this educational level have received little attention from researchers. The aim of this paper is to identify the representations that preschool students construct about perception, production and, propagation of sound. A semi-structured interview was used to address children ideas. From the analysis, two representations about the sound were identified, the representations differ mainly in the ideas about production and propagation of sound. In representation 1, production of sound is explained only by the actions people do, while in representation 2 sound is considered a characteristic of the subject. In representation 1, propagation of sound is explained by the idea that sound is a kind of substance, while in representation 2 it is considered that sound cannot be propagated. From the results, it is possible to recognize that preschool children have the possibility of constructing complex explanations of phenomena and it also shows the possibility of generating educational proposals that help them to expand their repertoire of representations and their understanding of scientific subjects.

**Keywords**: preschool, science education, sound

**INTRODUCTION**

Three decades of research have shown that children, regardless their culture and having received explicit instruction on some topic, construct representations about the world around them (Driver, Guesne, and Tiberghien, 1985; Inagaki and Hatano, 1993; Gallegos, Flores, and Calderón, 2008, 2009). These representations are essential for children since it allows them to interpret new information and experiences, to establish regularities, to make predictions and to solve problems. In this sense, representations are functional elements that guide or limit the type of answers given to a specific problem.

Although there is an extensive repertoire of research, it is necessary to emphasize that until the decade of the nineties just a few investigations were conducted with very young students (Hadzigeorgiou, 2015).

The case of acoustic phenomena is an example of this, possibly because it is a complex issue to investigate with children under 6 years of age. Among the few studies are Piaget (1973), in this research Piaget found that the understanding of sound goes through different stages. The first idea is that nothing happens between an object that produces sound and the ear of a person (4-5 years old); on the second stage, children believe that the sound leaves the object and passes to the ear of the person, but then returns to its point of origin (5½ - 6 years old); later, between the 7 and 10 years old, children think that the sound moves in a straight line and in all directions
(7-10 years old). Finally, the sound is a kind of blow that resonates and that it expands in the air (11-15 years old). Driver, Squires, Ruschworth, and Wood-Robinson, (1994) analysed the ideas about sound of students between 4 and 16 years old. Among its main findings are that production of sound and the actions that the subjects perform to produce it are linked, the sound is part of the object and also that sound travels by air.

For Mazens and Lautrey (2003), children (6-10 years old) begin to conceive sound as an object and as they grow older, diminish some of the properties of matter that they assign to sound, such as permanence, weight and trajectory. They also identified five mental models: Model 1, sound has properties of substance and cannot pass through solids; Model 2, sound can pass through materials because they have holes; Model 3, sound goes through when it is stronger or harder; Model 4, the sound is transparent, invisible and different from other objects; Model 5, the idea of vibration or resonance appears. For these authors, children’s knowledge of sound shows a certain degree of structure and coherence and the conceptual change from one model to the other is slow and gradual.

Sözen and Bolat (2011), studied primary school student’s misconceptions about sound transmission analysing their drawings. They found that most students think that the sound is heard by reflection, the sound is transmitted by vibration, and causes the particles to move, the sound is heard through vibration and explains that matter moves in the same direction in which sound is transmitted.

Finally, it must be considered that, in the specific case of sound, these initial representations do not seem to depend on concrete or perceptually apparent properties (Gelman, 2006), whereas in the eyes of children the sound may be invisible or non-obvious, therefore, this construction of representations is part of the actions that subjects realize or perceive and that allow them to construct explanations that do not depend on the explicit instruction. Given the above, the objective of this research was to make an analysis that allowed us to identify the representations that preschool students, 4-6 years old, construct on the perception, production and propagation of sound.

**METHOD**

The participants were 23 students, 10 of second and 13 of third year of preschool (mean age 4.6 years old), of three different preschools located in the Sierra Norte de Puebla in Mexico.

A semi-structured interview of 15 questions was conducted on three topics: perception, production and propagation of sound. During the interview children were ask to solve different tasks or situations using several materials: cards with images of objects (e.g. table, chair, balloons), people, animals (e.g. whale, dog, snake) and plants (e.g. tree), cards with images of situations, for example a child with a box on her head; other kinds of materials such as boxes of different materials (e.g. wood, glass), a metal triangle, a hose telephone among others. The children were interviewed individually for approximately 30 minutes. Ethical considerations were discussed and approved by the principals of the schools.
Data analysis

All interviews were transcribed and analysed to identify the categories for each of the dimensions described. Classifications of student responses within the categories helped to organize the representations that students built about the sound. A cluster analysis was performed to identify the models that the children built about sound. This analysis provided a complete overview of the types of representations that were built as it integrated all the elements (perception, propagation, and production). The categorization was performed by two independent judges.

RESULTS

From the analysis of the responses of the children 6 categories were identified, these categories describe children’s ideas about the production of sound. The categories correspond to different levels of complexity, which is indicated by the level of the first column. Table 1 summarizes the categories and also shows some examples of the type of answers given by the children that correspond to the category described.

<td>Produces sound when you speak, say letters, blows or whistles Babies produce sound when they cry</td>
</tr>
<tr>
<td>4 Sound is produced by subject’s action over objects (hitting or moving objects)</td>
<td>You can produce sound by hitting an object You can produce sound with a bicycle if you drive it</td>
</tr>
<tr>
<td>5 Sound is produced by specific actions determined by the characteristics or qualities of the object</td>
<td>To make a sound with a guitar you need to pull the strings</td>
</tr>
<tr>
<td>6 Some objects produce sound in interaction with something</td>
<td>Rain produces sound when it hits something plastic Trees make sounds when the wind moves them</td>
</tr>
</tbody>
</table>

The percentages of responses of the categories are shown in Figure 1. It can be seen that the highest percentage correspond to the category 4 (20%), *Sound is produced by subject’ action over objects (e.g. by hitting or moving objects)*. Secondly, the idea that some specific objects (like some toys or a disc) and the idea that the sound comes from the mouth (for example when you talk) share the same percentage of response (17%).

In the theme of sound perception, three categories were identified. Table 2 describes the categories and shows an example of the type of response given by the students. Figure 2 shows the percentage of responses for each category. It can be observed that the idea that the
perception of sound depends on the characteristics of the material or subject (75%), is the most popular idea among students.

Table 2. Response categories about perception of sound.

<table>
<thead>

<tr>
<td>1 Perception of sound depends on the characteristics of the subject or material</td>
<td>Dogs can hear because they have ears</td>
</tr>
<tr>
<td></td>
<td>You can listen with ears covered because your hands have holes</td>
</tr>
<tr>
<td>2 Perception depends on the characteristics of the sound: volume, travels, goes through materials</td>
<td>You can listen even if you have a box in your head because the sound is strong and it goes through the box</td>
</tr>
</tbody>
</table>

Figure 2. Percentages of answers for perception of sound.
Students’ responses on the propagation of sound were grouped into 4 categories (Table 3). In Figure 3, it is observed that the idea that is used most often correspond to category 2, the sound propagates but has the quality of substance. In second place (20%) are students who believe that sound can be propagated but this propagation depends on having certain properties. With this same percentage, we also find students who believe that sound does not spread. It is also important to mention that, although in very low percentage (8%), some students consider that air is involved in the propagation of sound.

Table 3. Response categories about propagation of sound.

<table>
<thead>
<tr>

</thead>
<tbody>
<tr>
<td>0</td>
<td>I don’t know</td>
</tr>
<tr>
<td>1</td>
<td>Sound does not propagate</td>
</tr>
<tr>
<td>2</td>
<td>The sound propagates, but it has properties of material substance</td>
</tr>
<tr>
<td>3</td>
<td>The sound propagates when it's intense or the material is thin or transparent</td>
</tr>
<tr>
<td>4</td>
<td>Sound propagates through the air</td>
</tr>
</tbody>
</table>

Based on the themes and categories identified an Euclidean distance-based cluster analysis was performed to group students’ answers. The objective of this analysis was to identify different groups of responses and to infer or identify different models or representation about sound. From the analysis two groups were identified, each group corresponds to a representation.

- Representation 1 (N=12) is composed of four students of 3rd grade and seven of 2nd grade.
- Representation 2 (N=11), is composed of nine students of 3rd grade and two of 2nd grade.

Figure 3. Percentages of answers for propagation of sound.
The main difference between the two representations (Table 4) is on production and propagation dimensions. In Representation 1 (R1) the production of sound is explained, mainly, by the actions that the subject exerts on objects, while in representation 2 it is explained by the sounds that mouth produces. In R1 subjects are focused on their action and by considering sound as an object (material substance) external to them, they have the possibility to confer it other properties (able to move or be moved, able to be contained by something). In Representation 2 (R2), the sound is a characteristic of the subject itself, the sound, in this case, cannot be a foreign element and is therefore likely to have characteristics that allow it to behave as an object. Finally, in R1 the propagation is explained by the substance characteristics that are given to the sound, while in R2 the sound cannot be propagated.

The representation of sound in R1 is composed of an ontological belief about objects (substance idea) that is interconnected with causal mechanisms (the sound is heard because it travels, the sound is not heard because it stays inside something). While in R2, although there is also this ontological belief (the idea of substance), there are no causal implications on the phenomenon (sound is finished, the sound is in your ear).

Table 4. Differences between representations 1 and 2.

<table>
<thead>
<tr>
<th>Representations</th>
<th>Production of sound is explained, mainly, by the actions that the subject exerts on objects.</th>
<th>Production is explained by the sounds that mouth produces.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Propagation is explained by the substance properties (Eshach and Schwartz, 2006) that are given to the sound (sound is containable, sound is consumable, etc.)</td>
<td>The sound cannot be propagated.</td>
</tr>
</tbody>
</table>

**DISCUSSION AND CONCLUSIONS**

The data obtained from the analysis reveal that preschool students have a wide knowledge about the world, the objects that surround them and how these objects behave. It is also evident that children from this educational level are able to construct explanations of phenomena as complex as sound.

We can also infer that children seem to start with a representation of sound as a feature that is part of objects, for example, when they say that sound is the lyrics or crying, and then develop a representation of sound as a substance, that is, the idea that sound is a kind of object that possesses certain properties or characteristics. Children build their representations from perceptual elements and, from their interaction with all the thing that surrounds them, gain some understanding of objects and phenomena and expand their representations so that it is possible to use that information to interpret and represent the phenomenon from another perspective, one more sophisticated or abstract (Baillargeon, 2006; Wellsby and Pexman, 2014).

Finally, the analysis described shows us, on the one hand, the process of construction of physical knowledge and on the other, contribute with some elements to consider when generating educational proposals that help children to expand their repertoire of representations and thus to improve its understanding of scientific themes.

DEVELOPMENT OF OBSERVATION SKILLS IN SCIENCE EDUCATION FOR ENHANCED UNDERSTANDING

Ann Mutvei, Mikael Lönn and Jan-Eric Mattsson
Södertörn University, School of Natural Sciences, Technology and Environmental Studies, Huddinge, Sweden

Observation is a skill necessary for the development of knowledge in science and is used, e.g., in studies to notice patterns and connections between abiotic and biotic factors, or in laboratory experiments where detailed observations are necessary to achieve understanding. Observation does not only include viewing details but also hearing, smelling and tasting to get all available information from the senses. How students perceive the information depends on their previous personal experiences. It is therefore essential for students to practice the ability to observe and to understand the contextual importance for learning. Here we present a study where 55 pre-service preschool teacher students attended a science course for 10 weeks with a variety of exercises. Late in the course they visited a Natural History Museum, a greenhouse with plants adapted to Mediterranean climate conditions and an art museum. Evaluation of written reflections after the visits were done by using the quality marker 4R’s of Doll’s (Relations, Recursion, Richness and Rigor) for the Natural History Museum and the greenhouse and Roland Barthes concepts studium and punctum for the art museum. Our results showed that the students described their experiences from the visits in a personal way with high quality. The variation of activities was important for the students’ ability to observe and to understand how to design pedagogic activities for children in preschool.

Keywords: observation, pedagogic activities in museums, pre-service preschool education,

INTRODUCTION

Perception may be “the ability to see, hear, or become aware of something through the sense” while observation is described as “the action or process of closely observing or monitoring something or someone” where observe is to “notice or perceive (something) and register it as being significant” (Oxford University Press, 2018). Thus, observation is a more complex action where it is necessary to interpret the input by perception and to put it into a context by cognitive processes.

Small children develop knowledge of their surroundings by observations, experiments and repeated training. For example, the understanding of shadows may be a result of the child’s repeated inquiries by itself which finally gives the experience that their own shadow with the aid of light is a projection of an image of the child itself.

Observation is also a skill necessary for the development of knowledge in science and is used, e.g., in studies to notice patterns and connections between abiotic and biotic factors, to understand nature and the interaction of animals and plants in a wide context, in laboratory experiments where detailed observations are necessary to achieve understanding, or to detect technology in our surroundings. Observation does not only include viewing details by the naked eye but also by hearing, smelling and tasting in order to get all the information from the senses. It also depends on experience and understanding of the situation (Pugh & Girod, 2007, Kohlhauf, Rutke, & Neuhaus, 2011). Therefore, training of observations of details in different
situations is necessary in order to understand complex situations. Observation competences of children are primarily dependent on their previous knowledge based on experience and not so much on their language skills (Kohlhauf, Rutke, & Neuhaus, 2011). The observation skills can be divided into three levels, incidental, unsystematic and systematic observations with three dimensions: describing, scientific reasoning and interpreting (Kohlhauf, Rutke, & Neuhaus, 2011). In order to promote knowledge in science the teacher should create conditions and situations to enhance the achievement of understanding starting from the student’s own experiences (Pugh & Girod, 2007). These activities should be diverse and promote students to inquire and explore. They include training of the observation skills of the students in order to detect details and to create understanding by connecting the observations with their previous experiences. Learning is also enhanced in a sociocultural environment where children communicate their understanding to each other, thus demonstrating different perspectives. To verbalize the process of learning and to make knowledge visible are other important issues enhanced by working in groups (Johnston, 2009).

In the goals for development and learning in Swedish Curriculum for the Preschool science education is pronounced:

The preschool should strive to ensure that each child
– develop their interest and understanding of the different cycles in nature, and how people, nature and society influence each other,
– develop their understanding of science and relationships in nature, as well as knowledge of plants, animals, and also simple chemical processes and physical phenomena,
– develop their ability to distinguish, explore, document, put questions about and talk about science (Skolverket, 2011, p. 10).

This means that the education of pre-service preschool teachers has to involve training of skills to help them to make observations and recognize the process of using it in order to understand complex situations in science. Here we present a study on the development of the scientific content knowledge and the pedagogic content knowledge of pre-service preschool teachers during a science course.

OBJECTIVES

As shown above it is not sufficient for the teacher to carry out demonstrations in order to create understanding of scientific relations. The demonstrations will be perceived differently by the students, primarily depending on the large variation of their previous experiences. Here we focus on two questions. How do the students perceive the information from observations differently? Is it possible to train students to increase their ability to observe and enhance their understanding of the contextual dependence?

COURSE DESCRIPTION

During a 7 weeks course in science (biology, chemistry and physics), 55 pre-service preschool teacher students were given a variation of exercises including experiments and excursions as well as creating pedagogic activities for children. All exercises where carried out in groups of
5–6 students. During the course students wrote four scientific reports where they described the exercise, the goal, their observations, questions and reflections of their own learning processes. These reports where commented by students or teachers in order to further develop the student’s understanding of the exercises and their connections to the development of the students. After six weeks the students visited the Natural History museum in Stockholm to study dioramas with plants and animals typical for Sweden and the Edvard Anderson Conservatory, a greenhouse in Bergius Botanic Garden in Stockholm, to investigate vegetation in four different regions of the world (Mediterranean, South Africa, California and Australia) and tried to find out how plants are adapted to these different areas with Mediterranean climate. They wrote reflections from the visits of the Natural History museum and the greenhouse about their own personal experiences and made a pedagogic plan of how to use the museum and the greenhouse in pedagogic activities for children in preschool, including the aim with the visit, what to do during the visit, how to document it, and how to follow up (evaluate) the visit. Two days later the students went on an excursion in the city of Stockholm trying to find out the special features of different places selected by the teachers and to create personal relations to these places. This exercise created experiences of different spaces. They also visited the Museum of Modern Art in Stockholm in order to train their ability to observe, analyse, make reflections, and make documentations of the exhibition "Life itself" and art work by Alexander Calder, Niki de Saint Phalle or Jean Tinguely. In order to promote this and increase the quality of their reflections the students received a short instruction how to analyse the art work based on the concepts studium and punctum by Roland Barthes (Wikipedia, 2017).

After seven weeks the students had a written exam with three different tasks (Table 5). They had to give examples of the scientific content and phenomena in preschool environment (question 1), the importance of scientific discovery (question 2) and how to describe nature and its cycles (question 3). All three questions have to be approved for the final mark “passed” and for the “high mark”, at least two questions had each to be assessed “high mark” and one question with “passed”.

METHODS

The quality of written exams and reflections from the visit in the Natural History Museum and Edvard Anderson Conservatory was made using the quality markers 4R’s of Doll’s, Relations, Recursions, Richness and Rigor (Doll, 1993). Doll’s 4R’s were compared with the evaluation of the reflection of the artwork using Roland Barthes studium and punctum (Table 1).

Barthes described punctum and studium as two ways to experience images. Punctum as an unconscious personal feeling that something in the image pierces the viewer creating a wound or a scar and studium, opposite punctum, the meaning and explanation the image describes. (Barthes, 1981). The quality markers had three different levels in each category used in the analysis (Table 2) and the studium four different levels of quality (Table 3) (Mutvei, Lönn,

Table 3. Rubric for the assessment of art work reflections (Mattsson, Lönn, & Mutvei, 2017).

| Punctum | 1 | Refers to a touching detail establishing a direct personal relationship. |
|         | 4 | Refers to personal experiences not shown in the related art work.       |
| Studium | 3 | Refers to strong emotions related to the art work.                       |
|         | 2 | Explains the personal choice of art work (recognition)                   |
|         | 1 | Description of the art work                                              |

Associations between marks of the different questions in the final exam and the quality marker of 4R’s and studium were analysed and visualized using classification trees (package rpart) and generalized linear models using the mark (high mark/not) response assuming a binomial error using the R statistical program (R Core Team, 2017).

RESULTS

Analysis of studium and punctum showed a high level of quality on the reflections about the artwork. More than half of students referred to strong emotions in relation to the art work (Table 4). Among these, half of the students referred to important personal experiences outside the context of the art objects. Almost all students explained their personal choice of art work. Only 9 students referred to a touching detail establishing a direct personal relationship. The result of the written examination showed that 32 students passed, 14 had higher mark (Table 5) and 9 failed or did not attend (not shown).

Examples of answers from students

Here some examples of students’ answers and the results of the assessment using *studium* and the quality marker 4R’s of Doll’s are presented.

**Studium, level 4, in art work, referring to personal experiences not shown in the related art work.**

The art "Kunstformen der Natur" is by a German biologist, Ernst Haeckel showing the symmetry of natural things (https://en.wikipedia.org/wiki/Kunstformen_der_Natur).

“The illustrations are so beautiful that I'm happy to look at them. […] They give me the same feeling as when I watch the forest or the sunset in the bush of Zambia – a sense of wonder about life and a gratitude for living. In such a moment, complicated questions about life do not matter to me. […] Perhaps it is not necessary to answer questions like “what is the meaning of life”? It may be enough to have a sense of wonder that you even live among all this beautiful and fascinating. When I've had trouble in life, that's the feeling that helped me. At such an instant, complicated questions about life do not matter to me.”

Another example is describing art by Joseph Beuys representing seven rusted metal barrels in different size.

“When I looked at this artwork, I get the feeling of hard work. I'm thinking of milk churn, how milk farmers worked hard to carry milk churns with only their own power. I have relatives who have a farmhouse. I have memories of my childhood when I saw how they carried the milk churns uphill several times a day. […] I know how heavy these barrels were because I did not even manage to lift one up the hill. Even though I know there are other methods today, I only get a sad feeling about the hard work done for each liter of milk and yet it's so cheap to buy in the stores. I know how much pain in the back my relative has today so this piece of artwork mediates the feeling of pain and made me experience memories from my earlier life.”

**Recursions 2, in written reflection from the visit in the Natural History Museum and greenhouse referring to learning out of previous experience.**

“I have been several times before to the museum when I was a child and what I like mainly
are the big areas that allow children to actually move even though they are in a museum. I also like that the museum use senses to create curiosity to the children and especially the touch.”

**Relations, level 3, in written reflections from the visit in the Natural History Museum and greenhouse which describes the process.**

“When I left the museum, I felt I had brought something from my visit. Knowledge. Knowledge that I did not have before the visit. When working in a group, one learns from each other and that I felt was fun. That I learned and maybe even learned to someone else.”

**Richness, level 3, in written reflection from the visit in the Natural History Museum and greenhouse, which uses several approaches (perspectives, dimensions).**

“By the reaction of my classmates from the regions, they have done a very convincing job of creating a little Greece just north of Stockholm. Right now, there are many children forced to leave their homes in the Mediterranean region, and perhaps get very strong memories from home. This may be far-fetched, but it may be worth thinking that smell can make us travel in memories through time and space. Maybe someone gets sad without explaining why”.

No students showed **Rigor** in their texts leaving the framework totally and enter new contexts.

**STATISTICAL ANALYSIS**

Statistical analysis showed that students with high quality in their reflections from the Natural History Museum and greenhouse had a high probability to get high mark in question 1 of the final exam. The analysis showed that students having high scores of **studium** had a high probability to get high mark of question 2 of the final exam (Figure 1).

![Figure 1. The effect of the total score of 4R’s on the marks of question 1 (left) and **studium** on question 2 (right). The mark (high mark/not) was used as response in two generalized linear models with Total score of 4R’s or **studium** score as explanatory variables and the significances of the effects are from ANOVA analyses of the models. Question 1: Total score of 4R’s from the texts of the Natural history museum and the greenhouse (p=0.041*) and question 2; **studium** scores from the texts of the Modern art museum (p=0.011*).](image-url)
Using classification trees, it is possible to see the connection between different competences and marks on the question in the final exam. The analysis of question 1 in classification tree showed the distribution of students that passed or had high marks. The largest group of students that did not express *Recursion* in the text passed (G). However, students expressing *Recursion* (>0.5) and *Relations* (>0.5) in the texts of the reflections from the Natural History Museum and green house and *studium* (> 2.5) in the texts of the Modern art museum had probability to get high marks (V) on question 1 (Figure 2) (60% in the group had V of the group representing 12% of all students).

When a classification tree was done using marks on question 3 as response, also *Recursion* (>0.5) was important. In addition, *Richness* (>1.5) was indicating higher marks (V). In this group consisting of 38% of all students, 2/3 of them had high marks (V) (Figure 3).

These analysis show that different competences are often necessary in order to be able to perform well on exams with questions of different kind.

This shows how different competences are needed in answering even fairly open questions compared to the open task to reflect on art work that the student chooses by themselves. This is in agreement with our previous results showing that students show better understanding when answering open questions (Mattsson & Mutvei, 2015).

![Classification Tree Diagram](image)

*Figure 2. A classification tree (rpart in the R programme) sorting students on marks at question 1 of the final exam sorted by *studium*, *punctum*, *Recursion* and *Relations*. The representation of marks for the largest group of the students is indicated in the box (G=passed, V= higher mark). The percentage indicate the proportion of the students in each group and the decimal number the proportion of the group that has the high mark (V) in the box (15 % of group had high marks). The left branches show the result if the criterium at each node is fulfilled and the right branches if it is not (exemplified with yes/no at first node).*
Figure 3. A classification tree (rpart in the R programme) sorting students on marks at question 3 of the final exam sorted by Recursion and Richness. The representation of marks for the largest group of the students is indicated in the box (G=passed, V=higher mark). The percentage indicate the proportion of the students in each group and the decimal number the proportion of the group that has the high mark (V) in the box (52% of group had high marks). The left branches show the result if the criterium at each node is fulfilled and the right branches if it is not (exemplified with yes/no at first node).

DISCUSSION

The ability to see pattern by the analysis of observations of different kind is important for learning. This is supported by our results and connection between different factors and ability to answer open questions. Training of observation of nature and art combined with making reflections improves the ability to see patterns. Therefore, it is important to create many possibilities to practice observation, to analyse and to make reflections during the education of pre-service preschool teachers. Not only for their own understanding of science but also in order to understand how teachers need to create learning situations where children can get new experiences. These will improve children’s competence to observe factors affecting nature, make observation when working with scientific method and to deepen understanding. In addition, teachers have to design pedagogic activities to give children possibility early to develop qualifications for learning. Furthermore, working with open questions and observations in different contexts will enhance the development of knowledge of the student in their own personal way.

A PROPOSAL FOR TEACHING SCRATCHJR PROGRAMMING ENVIRONMENT IN PRESERVICE KINDERGARTEN TEACHERS

Michail Kalogiannaki and Stamatios Papadakis
Department of Preschool Education, Faculty of Education, University of Crete, Greece

The innovative educational programming environment called ScratchJr offers young children the possibility to program their own interactive stories and games. This study aims to investigate the acceptance of ScratchJr by pre-service kindergarten teachers as a tool to produce interactive, multimedia, learning content for science teaching as well as a tool for learning and teaching Computational Thinking. Also, the effects of using ScratchJr for future teachers’ attitudes in terms of perceived ease of use and perceived usefulness are explored. The study was conducted during winter semester of the academic year 2016-2017 at a university department of early childhood education in Greece. The results show not only that the use of ScratchJr has a statistically significant increase in preservice kindergarten teachers’ self-efficacy in Computational Thinking but also that they are willing to use it in their future daily practice for science education. Also, the study reveals that pre-service teachers have positive acceptance scores in terms of usefulness and ease of use of ScratchJr. Additionally, no significant difference between the acceptance scores of the participants in terms of programming background, and their studies in high school they graduated from as indicators of programming experience was found. Preliminary analysis of the data shows that ScratchJr is an appropriate educational environment for pre-service kindergarten teachers to learn programming basics as well as a platform for the development of educational resources to support the learning of science teaching.

Keywords: ScratchJr, preservice kindergarten teachers, computational thinking

INTRODUCTION

Computer Science (CS), Programming (Coding), and Computational Thinking (CT) have recently been introduced to the primary school curriculum in several western countries (Duncan, Bell, & Atlas, 2017). Other countries are in the middle of changes regarding school curricula as they see the value of introducing topics such as programming and Computational Thinking (CT) (Bean, Weese, Feldhausen, & Bell, 2015; Duncan, Bell, & Tanimoto, 2014). Computational thinking is typically associated with coding and computer programming, but the fact is that, CT has clearly become an interdisciplinary concept based on, but not limited to Computer Science (CS) (Saltan & Kara, 2016). Computational thinking is more than that, involving “solving problems, designing systems, and understanding human behaviour”, according to the Carnegie Mellon University (Balanskat & Engelhardt, 2015, p.4). Seymour Papert in his seminal work “Mindstorms: Children, Computers and Powerful Ideas” (Papert, 1980 as cited in Bers, 2017, p.10), shares his big ideas about how children can become better learners and thinkers through coding.

As a result, learning programming as well as the development of CT is a teaching subject in many departments of tertiary education, which are not necessarily related to CS or Technology directly (Fesakis & Serafeim, 2009). This trend has informed a variety of new introductory computing courses at the undergraduate level that focus not on specific programming skills for
a computing major (Papadakis, 2018; Papadakis, Kalogiannakis, Orfanakis, & Zaranis, 2017), but on developing general CT skills for non-majors, or cross-discipline connections to computing (Sherman & Martin, 2015, p.54). Among these, the departments of education, in which pre-service teachers get acquainted with programming and CT are included (Papadakis & Kalogiannakis, 2017a). The goal for pre-service teachers is either to teach children the basics of programming or to utilize the knowledge gained for the creation of interactive and multimedia-enhanced learning material, or to teach other subjects such as Science Education.

However, there are risks for teaching programming: if a student is taught programming by a teacher who lacks confidence, there is a possibility that the student will create a negative impression of the subject (Duncan et al., 2014; Bean et al., 2015). For that, it is necessary pre-service teachers not only to develop CT but also a positive attitude and a strong degree of interest and confidence in using programming into their teaching. At the same time most of the primary teachers are unlikely to have the appropriate skillset to teach this new technical subject (Benton, Hoyles, Kalas, & Noss, 2017, p.2).

The present study investigates the effect of familiarity with ScratchJr (Scratch Junior) in pre-service kindergarten teachers’ opinions and attitudes regarding the usefulness and ease of use of ScratchJr. For this study, ScratchJr as a programming environment was used. ScratchJr is a developmentally appropriate tool which is inspired by the rich tradition of constructionist learning environments initiated by LOGO (Bers, 2017). Additionally, it investigates the contribution of ScratchJr in pre-service teachers’ self-efficacy in CT as well as the acceptance by pre-service teachers of the use of ScratchJr as a tool for learning and teaching CT and Science Education.

MOBILE DEVICES IN PRESCHOOL EDUCATION

Digital technology has become an everyday part of young people’s lives both at home and in the classroom (Moffett, Gray, Dunn, & Mitchell, 2017; Papadakis, Kalogiannakis, & Zaranis, 2017, 2018). Tablets, computers, iPads and smartphones are part of a modern family’s daily life (Pervolaraki et al., 2016, p.450). New technologies have also facilitated multimodal learning in the 21st century. Multimodal experiences are linguistic, spatial, visual, gestural, aural, and tactile activities (Yelland & Gilbert, 2017, p.2). Smart mobile devices permit very young children to engage interactively in an intuitive fashion with actions as simple as touching, swiping and pinching (Lovato & Waxman, 2016). Recognising the educational potential of this mobile technology, many schools have prioritised the integration of tablet devices into their classrooms (Moffett, Gray, Dunn, & Mitchell, 2017). Teachers ought to follow the rapid increase of technology and incorporate digital devices in their classrooms (Papadakis & Kalogiannakis, 2017b; 2017c; Pervolaraki et al., 2016, p.456).

At the same time, many researchers and educators have indicated that teachers play the dominant role in using various aspects of ICT in the formal educational context (Papadakis, 2016; Papadakis & Kalogiannakis, 2010). This is due to the fact that teachers’ teaching behaviors are influenced by their beliefs, confidence and motivations for teaching. Teachers with higher confidence in technology are likely to succeed in technology-related tasks effectively and significantly (Hsu, Tsai, Chang, & Liang, 2017, p.136). Many studies
demonstrate that kindergartens compared to other grades do not fully exploit and derive benefit from the role of digital media on children’s learning. Teachers need to attend seminars on digital media use and effectiveness and search for apps that can really foster different cognitive and literacy skills (Pervolaraki et al., 2016, p.456). Thus, early childhood teachers need information on the use and the implications of using these tools in teaching young children (Papadakis, Kalogiannakis & Zaranis, 2016a; Pervolaraki et al., 2016, p.457).

**THE SCRATCHJR PROGRAMMING ENVIRONMENT**

The term CT became mainstream in education with the ideas of Papert as he intertwined the learning power of engaging in personally meaningful creation with the use of computer-aided design tools (Smith & Burrow, 2016, p.121). Seymour Papert (1980, as cited in Bers, 2017) believed that of the best uses of the computer was for children to become creators and producers of their own projects through programming. The reason is that “coding enables children to think in systematic and sequential ways while encountering powerful ideas from computer science and other domains of knowledge” (Bers, 2017, p.10). Research shows that engagement in a structured computer programming environment aids young children’s number sense, visual memory, and language skills (K–12 Computer Science Framework, 2016, p.271).

Nowadays there is a growing number of available programming environments and robotic kits have been developed, such as ScratchJr, Hopscotch, Cargo-bot, Codeable Crafts, Daisy the Dinosaur, Lightbot Jr, Robozi, Run Marco!, Sushi Monsters, The Foos, Tynker, Beebot and Kodable that allow novices to engage more easily in authentic programming and computational thinking activities (Dwyer, Boe, Hill, Franklin, & Harlow, 2013). Drag-and-Drop environments have become very popular for teaching programming to young children and novice programmers (Orfanakis & Papadakis, 2014; 2016) as they do not require knowledge of programming syntax but provide an environment where compile-time errors are nonexistent (Duncan et al., 2014). The advantages of visual programming and drag-and-drop environments are:

- students don’t need to learn syntax and cannot create syntax errors;
- students can see what blocks (instructions) are available;
- blocks often hide complex logic or operations in a single block.

Programming education typically has been provided in a computer environment. More recently, mobile platforms with advanced features have been used as well (Gedik, Çetin & Koca, 2017). ScratchJr takes advantage of the popularity of mobile devices since it is available as a free application (app) both for smart phone devices with iOS or Android operating systems and screen sizes up to 7 inches (Papadakis, Kalogiannakis, & Zaranis, 2016b). With ScratchJr, coding happens on the mobile device screen (Bers, 2017, p.11). ScratchJr was first launched as a freely downloadable app on iPads in July 2014, and has since been released for use on several other platforms including Android tablets, Amazon tablets, and Chromebooks (Leidl, Bers & Mihm, 2017, p.116).

ScratchJr is a programming environment that is developmentally appropriate for young children (5–7 years) (Bers, 2017). As an introductory programming environment that allows
young children to ‘discover’ the basic programming concepts by creating projects in the form of interactive stories and games (Figure 1). ScratchJr approach is inspired by constructionism (Papert, 1980). Constructionism asserts the belief that hands-on design activities can provide personally meaningful contexts for “learning by making” because the learner builds their own knowledge during the process of creation (Smith & Burrow, 2016, p.120). ScratchJr, as a developmentally appropriate version of Scratch, helps children learn to think creatively, reason systematically, and work collaboratively (Kalogiannakis & Papadakis, 2017). The interface is entirely symbolic and contains only a third of the original Scratch instruction set because young children can struggle with several levels of decomposition (Rose, Habgood & Jay, 2017, p.299).

Figure 1. A screenshot of the ScratchJr app.

ScratchJr teaches children to program their own interactive stories, games and animations. Applications (projects) are built by combining visual blocks (Karachristos et al., 2017) (Figure 2). Using ScratchJr does not require the ability to read or write (Bers, 2017, p.11). The ScratchJr interface allows children to use blocks that control motion, looks, sound, character communication, and more (Leidl, Bers, & Mihm, 2017, p.116). In environments such as ScratchJr coding can become a playground. Children work in an environment which enables them to be creative, to express themselves, to explore alone and with others, to learn new skills and problem solve. An environment to explore powerful ideas (Bers, 2017, p.11).

To date over six million young children all over the world are using ScratchJr to create their own projects and it has been translated to several languages (Bers, 2017, p.11). With ScratchJr
young children can work with a specific set of computational thinking skills such as algorithms, modularity, control structures, representation, the design process, and of course, debugging.

Figure 2. A screenshot of a ScratchJr script (blocks).

CURRENT STUDY

Study purpose

The purpose of this study was to investigate pre-service kindergarten teachers’ acceptance of ScratchJr as a tool for learning and teaching CT. The research questions for this study were as follows:

(1) To what extent has ScratchJr contributed to pre-service teachers’ self-efficacy in utilizing CT within their future teaching endeavors in programming and Science Education?

(2) To what extent do pre-service teachers accept the usage of ScratchJr for learning and teaching CT and Science Education, in terms of perceived ease of use and perceived usefulness?

(3) Is there a difference in acceptance of ScratchJr related to programming experience, and the High School direction (Humanities, Science and Technology) pre-service teachers graduated from?

This study was carried out in mixed-methods design. In this research design, researchers collected a multitude of qualitative (e.g. semi-structured interviews) and quantitative (e.g. questionnaires) data aiming to capture as many aspects of the students’ ScratchJr use as possible and to view the topic from their perspective. In the course of the research, every effort was made to comply with the ethical guidelines mandated by the University of Crete. Ethical principles relating to basic individual safety requirements were met with regard to information, informed consent, confidentiality and the use of data. All identifiable information was removed prior to analysis.

The sample

The study was conducted during winter semester of 2016-2017 at the department of preschool education of the University of Crete in Greece. The sample was comprised of 122 female pre-service kindergarten teachers. The students had registered for an optional IT course and voluntarily participated in the study. The ScratchJr was chosen as the programming environment. The intervention was carried out in an amphitheater where students sat together in small groups (2-4 persons) using tablets, and could observe one another succeeding at in the
task. The first 10 lessons were divided into two parts. In the first part, the students were engaged in an open activity with ScratchJr, which introduced a new programming concept or a new ScratchJr characteristic. In the second part, the students were engaged in group work and were supervised by the teacher.

We carefully selected experiences from the science field that would be both attainable and challenging, and arranged them in increasing complexity. Students used those experiences to approach problems and focus on tangible actions: Debugging by finding and fixing errors, Tinkering by experimenting and playing, and creating by designing and making things (Duncan et al., 2017, p.66). The students were informed that the last three courses would be dedicated to the development of three open-ended design-thinking projects from the fields of science and mathematics. Projects were designed to reinforce and train abilities like sequencing, understanding of causality, and problem solving while engaging in open-ended creative projects (Bers, 2017).

**Instruments**

For data collection, participants were asked demographic questions, open-ended questions, and likert-type questions, on a 5-point Likert scale, which ranged from "strongly disagree" to "strongly agree". To evaluate the first research question, we adapted a simple survey instrument - Teachers’ Self-Efficacy in Computational Thinking (TSECT) from Bean et al. (2015). This instrument is intended to capture a sense of the student’s self-efficacy in utilizing programming and CT within their future teaching endeavors in teaching science education. The scale had good reliability as the Chronbach’s Alpha was 0.95. This survey was given as a pre- and post-test before and after the intervention. Also, to investigate to what extent pre-service teachers accept the usage of ScratchJr for learning and teaching CT and Science Education, in terms of perceived ease of use and perceived usefulness, we followed the research approach of Saltan & Kara (2016). We used a questionnaire adapted from David’s Technology Acceptance Model (1989) (perceived usefulness and perceived ease of use). The second instrument was given after the end of the intervention. The data from each questionnaire was coded and entered into SPSS software for statistical analysis. Copies of the ScratchJr projects pupils created during the lesson were collected. The students’ interviews were intended to identify what they learned during the lesson, what problems they experienced, and the strategies used to overcome them.

**RESULTS**

For the first research question a t-test of the pre and post-survey scale revealed a statistically significant increase in pre service teachers’ self-efficacy in CT from pre \((M =12.80, SD = 9.22)\) to post \((M = 30.59, SD = 4.77)\), \(t(121) =11.48, p < .0001\). Cohen’s effect size \((d = 1.42)\) indicated a large positive effect.

For the second research question the participants were asked to respond to 14 items with answers ranging from 1 to 5 on a Likert-type scale which evaluate two factors of the TAM model; namely, “Perceived usefulness” and “Perceived ease of use”. Overall, the “Perceived usefulness” factor had a mean score of 4.12 \((SD = .87)\) and the “Perceived ease of use” had a
mean score of 3.99 ($SD = .51$). The mean scores of the items show that participants have positive and similar acceptance ratings for the items and the factors in the scale.

For the third research question, the results from independent samples t-tests showed that there was no significant difference between the perceived ease of use and the perceived usefulness mean scores of the participants regarding their direction at school as well as their experience from IT-based university courses (Table 1).

</tbody>
</table>

After completion of the teaching intervention one of the researchers conducted a focus group interview with a structured interview form (Kalelioglu & Gülbahar, 2014). Below are some of the questions that were asked to the students:

- Did you have difficulty with the software?
- What was your favourite aspect of the software?
- What was your non-favourite aspect of the software?
- Do you like programming?
- What do you want to learn more about programming?
- How confident did you feel teaching this topic?
- Would you recommend ScratchJr to your colleagues as a tool to teach CT?
- What expectations did you have at the beginning, and have they been met?

Similar to other studies, students were engaged and satisfied. The students considered that the course had been funny; useful and interesting, they had loved this way of working and had understood the activities; wanted to learn more about the subject (CT - programming), and they had done them working in groups as they engaged in social interactions with each other, including peer-to-peer communication and cooperation (Duncan et al., 2017; Mishra, Balan, Iyer, & Murthy, 2014; Pinto-Llorente, Martín, González, & García-Peñalvo, 2016; Smith & Burrow, 2016). In general, students were enthusiastic about introducing the tool, and they mentioned that they were able to adapt its use in a variety of contexts. Like other research, students in their majority noted that they liked ScratchJr, flexible design (Strawhacker, Lee, & Bers, 2017).
To sum up, our study and its results have proved the potential of the software ScratchJr in the subject of natural sciences to promote the computational thinking, and to engage preservice teachers in programming, and problem solving (Pinto-Llorente et al., 2016).

LIMITATIONS

This study was intended to be exploratory in nature, and the design has limitations which should be acknowledged. As Gedik, Çetin, & Koca (2017) point out, the small duration of the study was insufficient to explain whether their interest was derived (and to what degree) from the novelty effect, that can be caused by the presence of tablets for the first time in the “classroom”. Moreover, the group sizes limited the study. One of the most salient limitation in terms of the data is lack of diversity among the sample. This is partly due to the method of recruitment, which resulted in a self-selected sample of pre-service teachers curious about and experienced with technology (Strawhacker, Lee, & Bers, 2017).

Furthermore, as noted by Rose, Habgood & Jay (2017) ScratchJr itself had some limitations which could have affected the outcome of the study. As a result, it was observed that many participants completed levels using non-optimal solutions.

DISCUSSION AND CONCLUSIONS

Coding continues to play a prominent role in the education agenda (Balanskat & Engelhardt, 2015). The importance of learning programming languages goes beyond coding with fluency. The biggest issue is that it makes people to thing in a very different way, in an algorithmic manner, to use abstraction to understand complex systems and how these interconnect, to decompose them to smaller ones and next solve them to provide a solution to the bigger one (Karachristos et al., 2017, p.294). At the same time as Computational Thinking, will be a new topic for the majority of primary school educators and preschoolers, resources will be needed to support them and this new curriculum. To prepare teachers to develop logical thinking, algorithmic thinking, problem solving and coding skills in the lessons, professional development and support must be given (Seow, Looi, Wadhwa, Wu, & Liu, 2017, p.167).

However, in preschool education, the fluency of programming software is limited, and the use of tools is regulated in formal education (Sung, Ahn, & Black, 2017, p.445). ScratchJr seems to positively contribute to the development of pre-service kindergarten teachers’ self-efficacy in utilizing programming and CT within their future teaching endeavors in teaching science. From the consideration of research data, it also seems that ScratchJr is useful for helping pre-service teachers’ use computational constructs, engage in programming processes, acquire programming skills and motivation, and develop positive attitudes toward programming and usage in teaching Science Education. Importantly, the positive experience that the teachers had will encourage them to adopt Computational Thinking as a subject through intrinsic motivation, rather than feeling it is a topic imposed on them (Duncan et al., 2017).

In this study, ScratchJr allowed students to practice sequencing, logical reasoning, and problem-solving skills, along with positive behaviors such as collaboration and communication. Also, study’s results, revealed that pre-service teachers have positive and similar acceptance of ScratchJr in terms of usefulness and ease of use regardless of the school.
direction or their experience in IT university courses. Based on these findings, we believe that ScratchJr is appropriate to function as an introduction to basic programming concepts and CT as well as the development of educational applications from kindergarten teachers. ScratchJr can be used by teachers to help pre-school children to develop problem solving and logical thinking skills through play. One of the reason is that ScratchJr makes it easy to get started but provides room to use more complex concepts (low floor and high ceiling), it allows many pathways and styles of exploration (wide walls), ideas can be incrementally developed through experimentation (tinkerability), the interface is friendly and playful (conviviality) and it can be used with a wide range of learning outcomes (classroom support) (Rose, Habgood, & Jay, 2017, p.299).

Especially in Greek settings, poor government funding is the main reason for low use of digital tools in Greek kindergartens (Pervolaraki et al., 2016, p. 456). The BOYD policy (Bring Your Own Device) with the combined use of developmentally appropriate tools such as ScratchJr could be used to facilitate productivity in preschool education.

ACKNOWLEDGEMENTS

The authors would like thank all the students who took part in this study.

SCIENCE PEDAGOGICAL CONTENT KNOWLEDGE (PCK) IN PRIMARY EDUCATION: HOW CAN WE REPRESENT IT?

Eleni A. Tseou
AUTH, Greece

The aim of this work was the study of theoretical models of PCK on the representational and investigative capacity. For this reason, the concept of PCK was initially investigated at bibliographic level through a critical review of the literature. The results indicated the existence of disagreement as to the nature and characteristics of PCK as well as to the way of its investigation. According to the results, the need to clarify the concept arose so that it can be investigated in light of its conceptualizations. An operating model of PCK which stemmed from the critical review of the literature was proposed. The model was theoretically based on the combination of radical and socio-cultural constructivism. In order to identify the components of PCK, a synthesis of various models of PCK was held. Additionally the inquiring differentiation of the aspects of PCK (knowledge, perceptions and practice) was proposed. The operating model was applied to the empirical field so as to investigate its ability to recognize and detect primary teachers’ science PCK. So we used two case studies with kindergarten teachers who taught the phenomenon of melting and coagulation. The application showed that the model can recognize and detect primary teachers’ science PCK in the empirical field through its components and its aspects. The investigation of PCK in bibliographic and empirical level showed that the operating model can represent the science PCK of teachers in primary education in order to investigate it properly.

Keywords: PCK, science education, primary education

INTRODUCTION

The importance of the role of science in education as well as the role of teachers in teaching and learning have led to the creation of teachers' knowledge models on the teaching and learning of science. One of these models is PCK, which was defined as the blending of content and pedagogy in the teaching of specific issues of science, and in particular the way in which they are organized, represented, adapted and presented to students (Shulman, 1986b). Since its introduction, the construction of PCK has received many interpretations which have led to the creation of various models.

The initial review of the literature has shown the value of the construct of PCK (Loughran, Mulhall & Berry, 2004) as well as the points of agreement on it, like certain key components. At the same time, the problems of its conception from the existing theoretical models have arisen. One of the most critical problems with PCK concerns the process by which the other categories of teacher knowledge are involved in its creation (Kindt, 2009b). According to the transformation process, knowledge categories like content knowledge, are used in the formation of PCK but are not included in it. On the contrary, according to the process of integration, knowledge categories are not only used in the creation of PCK but they are also found in it (Gess-Newsome, 1999).

The two different processes of the formation of PCK are linked to different epistemological theories. These theories can be placed in a continuum spectrum. The left end of the spectrum
is occupied by the theories of realism, according to which knowledge of the real world is objective and independent of human ideas. The right edge of the epistemological spectrum is occupied by the theories of idealism, according to which knowledge is subjective and is built by humans (Hein, 1998). The most extreme position of idealism is expressed by personal or radical constructivism, which does not deny the existence of absolute reality but only the possibility of knowing it (von Glasersfeld, 1989). Between the two extremes of realism and idealism are several intermediate epistemological positions, such as Dewey’s (Hein, 1998), who is considered to be the main representative of instrumentalism and pragmatism, and considers that knowledge derives from experience through reflection (Dewey, 1938b/1969). Another intermediate position includes the idea of critical consciousness, which is unified with reality and leads to critical action (Freire, 1985).

According to Shulman, the concept of PCK (1987) is based on Dewey. However, Dewey's views cannot support the separation of content into pedagogical and non-pedagogical, nor the transformation of content by the teacher, as the only transformation needed concerns the world in which the child acts. Additionally, the adoption of the transformation process in the creation of PCK is based on objectivist epistemology as teachers have to transform the knowledge of academics which is objectively true (McEwan & Bull, 1991). So knowledge is not built up by teachers as it is considered stable and external (Banks, Leach & Monn, 2005). Against the existence of objective knowledge, very strong arguments have been expressed, such as the existence of a large number of theories which, while initially were accepted, were subsequently rejected as well as the use of the same data in different theories, etc. (Kuhn, 1970).

On the other hand, the adoption of integration process in the creation of PCK is associated to constructivism since the knowledge categories, as internal, are constructed by the teachers themselves (Cochran, DeRuiter & King, 1993). The different interpretation of nature and society by humans according to their background and their experiences leads to the inevitable acceptance of the theory of constructivism (Hein, 1998). However the individualism of personal constructivism with the relativism that it entails, leads to disuse the evaluation of different ways of producing knowledge, which can only be addressed by recognizing the dependence of individual knowledge on public knowledge (Matthews, 1994). The sociocultural constructivism emphasizes that knowledge is socially constructed through cultural tools, provided that it is in the zone of proximal development of the individual (Vygotsky, 1978).

Another problem as regards PCK concerns its assessment as the difficulties that characterize the evaluation of teacher knowledge extend to it (Kagan, 1990). Many methods are used such as Likert type self-reference scales, conceptual maps, multimethod evaluations, etc. (Baxter & Lederman, 1999). The selection of methods is related to the adoption of an integrative or transformational model of PCK (Kindt, 2009b).

The intense criticism of the concept, combined with its ambiguity problems and the difficulties of its evaluation that emerged from the initial review of the literature, created the need for a rethinking of this concept. Moreover the presence and use of various models of PCK create the need of their evaluation. For this reason aim of this work is the study of theoretical models of PCK on the representational and investigative capacity.
METHOD

A key research question is: "What theoretical proposal for PCK can represent teacher knowledge in science teaching so as to investigate it in the appropriate way?" Initially, it was assumed that existing theoretical models show ambiguities and discrepancies in the nature and characteristics of PCK. To test this hypothesis, the first inquiry question was investigated: «What are the characteristics and the nature of PCK? » The confirmation of the initial hypothesis led to the creation of a second hypothesis. Specifically, it was assumed that the theoretical ambiguity is transferred to the research field. So the investigation of the second inquiry question was decided: «How is PCK investigated? » The confirmation of both cases led to the creation of a third hypothesis according to which the operating model of PCK, emerged from the literature review, can recognize and detect teachers’ PCK in the empirical field, through its components and its aspects respectively. To test the hypothesis, the third question was investigated: «How is Kindergarten teachers’ PCK recognized and how is it detected in the empirical field during the teaching of melting and coagulation in kindergarten?

A critical review of the literature was used to investigate the first two questions. The collection of data was carried out by searching the electronic sources of Hellenic Academic Libraries Link (heal-link) through the library’s website of Aristotle University of Thessaloniki (see http://www.lib.auth.gr/). In particular the search was conducted through the alphabetic index, the publishers (Wilson, Elsevier, etc.) and the bibliographic full text databases (Jstor, ProQuest κ.α.) using the term "pedagogical content knowledge" or related terms, like subject-specific pedagogical knowledge, etc. The analysis and synthesis of critical review data was carried out using grounded theory (Eaves, 2001).

In order to investigate the first inquiry question "What are the characteristics and the nature of PCK?" the sample of the research was composed by the articles dealing with theoretical issues concerning PCK. The sample selection criteria were as follows: i. The theoretical treatise, ii. The concept of PCK, iii. The publication of the articles in the English language, iv. The publication period of the articles (1986-2009). A total of 25 articles were found. The purpose of the investigation was to seek out the theoretical models proposed in relation to PCK, the existence or non-existence of theoretical foundation of the concept, the process proposed for the participation of the different knowledge categories in PCK, the criticism of the concept and its components.

In order to investigate the second question "How is PCK investigated?" the research material was consisted by the empirical research articles on primary teachers’ science PCK. The sample selection criteria were as follows: i. Empirical study, ii. The concept of PCK, iii. The publication period of the articles (1986- 2009), iv. The publication of the articles in the English language, v. The inclusion of the study in the field of Primary Science Education. A total of 45 articles have been identified. The investigation was aimed at search of models that are used in the mapping of teachers’ science PCK in studies of primary education, the components which are investigated, the relations explored between its components and the way of its methodological investigation.

The investigation of the third question, "How is Kindergarten teachers’ PCK recognized and how is it detected in the empirical field during the teaching of melting and coagulation in
kindergarten?" was aimed at investigating the way in which Kindergarten teachers’ PCK is manifested during the teaching of melting and coagulation in Kindergarten and confirming or not confirming the basic components as well as the dynamic character of PCK’s operating model.

As a method, the case study was used in the constructivist / interpretative paradigm in which knowledge is co-built by the researcher and the participants in the study (Stake, 1995). This method was chosen because of the personal nature of PCK and its theoretical foundation in the combination of radical and socio-cultural constructivism. Moreover, the recognition of the context as a decisive parameter is common between the case study and the concept of PCK as the latter is defined in the operating model. In the present study the combination of qualitative and quantitative data is selected to highlight not only the knowledge, perceptions and practices of Kindergarten teachers when they teach the melting and coagulation phenomenon but also the predominant ones.

Two case studies were used to allow both in-depth investigation and comparison of findings. The sample selection criteria were: i. The teaching experience, ii. The frequent teaching of melting and coagulation in kindergarten, iii. The willingness of kindergarten teachers to participate in the study. The first two criteria were investigated using a written questionnaire while the third criterion was investigated through personal contact and oral communication. Data sources were the questionnaire and the written planning of a teaching, the videotaping of this teaching and two interviews, one before and the other after the teaching. The subject of the lesson was the phenomenon of melting and coagulation due to its frequent teaching in kindergarten. As an analysis tool, the operating model of PCK was used.

The validity of the study has been assured by a variety of ways at the design stage, at the data collection and analysis stage and at the presentation stage. The reliability of the study was ensured by the pilot study, the data triangulation, the peer review and the members' control.

RESULTS

The results of the investigation of the first question "What are the characteristics and the nature of PCK?" are outlined below. In particular, the search for models on PCK led to Table 1:

Table 1. Theoretical articles on PCK

<table>
<thead>
<tr>
<th>Articles that propose a new model</th>
<th>Articles that don’t propose a new model</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>15</td>
<td>10</td>
<td>25</td>
</tr>
</tbody>
</table>

As can be seen in Table 1, a wide variety of models are proposed for PCK (n = 15), such as by Shulman (1986, 1987), Cochran et al. (1993), Carlsem (1999), Magnusson, Krajcik & Borko, (1999), Morine-Dershimer & Kent (1999) etc. Regarding the process of participation of teacher knowledge categories in PCK, the results are shown in Table 2:

Table 2. Processes proposed for the participation of teacher knowledge categories in PCK

<table>
<thead>
<tr>
<th>Models of PCK</th>
<th>Transformation</th>
<th>Integration</th>
<th>Other process</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>7</td>
<td>8</td>
<td>6</td>
</tr>
</tbody>
</table>
As can be seen from Table 2, there is a strong debate about the process of involving teacher knowledge categories in the formation of PCK. Specifically, it seems that some models support the transformation process (n=7), while other models support the integration process (n=8). Furthermore, a number of models is observed which support other processes (n=6) e.g. 'Filtering' etc. The results on the theoretical foundation of articles dealing with theoretical issues concerning PCK are shown in Table 3:

**Table 3. Theoretical foundation of PCK in theoretical articles**

From Table 3, most of the articles dealing with theoretical issues concerning PCK as theoretical foundation of the concept adopt the paradigm of pragmatism (n=15). In a small number of articles, the constructivist paradigm is adopted (n=3). The paradigm of critical theory appears only once (n=1). Significant is also the non-reference to the theoretical foundation of PCK in several articles (n=6). As an example, the model of Magnusson et al. (1999), does not include any epistemic or didactic / learning theory (see Hein 1998) on which the concept of PCK is theoretically based. The introduction of PCK by Shulman (1986, 1987) is considered to be the starting point of the model by Magnusson et al. The results of the investigation on the criticism of PCK, as defined by Shulman (1986, 1987), are presented in Table 4:

**Table 4. The key criticisms in the original proposal on PCK (Shulman, 1986, 1987)**

</tbody>
</table>

As can be seen in Table 4, criticism was mainly brought to PCK ‘from the inside’ (n = 13), with the aim of adding or modifying certain components. In several articles, criticism was made ‘from an intermediate position’ (n = 6), in which the concept itself is not questioned, but only the way is used. Some articles criticized PCK ‘from the outside’ (n = 4) in order to reword or reject it. An example is Turner-Bisset’s article (1999), which criticizes the skill model, but the latter is separated from PCK as defined by Shulman (1986, 1987). Concerning the components of PCK, the results of the review are summarized in Table 5.

As shown in Table 5, various components are proposed, some of which appear more often such as student knowledge (n = 13), knowledge of representations (n = 11) and knowledge of content.
(n = 11), while others appear more rarely as knowledge of self (n = 4). The results of investigating the second question "How is PCK investigated?" are displayed below. In particular, the findings of the study on the mapping models of primary teachers’ science PCK are presented in Table 6.

**Table 6. Models on mapping science PCK of teachers in Primary Education**

As observed in Table 6, various models are used in the mapping of primary teachers’ science PCK, while the models by Magnusson et al. (1999) (n=7) and Shulman (1987) (n=4) are the most frequently used. In most studies (n = 29) no model of PCK is stated. e.g. Dickerson, Dawkins & Annetta (2007) do not state which concept of PCK is adopted in their study, although various interpretations of the construct are described. In addition, some articles report that they agree with two PCK’s models. The results as regards the components of science PCK that are investigated in studies of teachers in primary education are presented in Table 7:

**Table 7. Components of science PCK investigated in Studies of Primary Education**

</table>

In Table 7, it is observed that various components of PCK are being investigated with a great difference in the frequency of their investigation (cf. knowledge of students, n=19, knowledge of assessment, n=3). Also, the investigation has shown that it is often unclear what is included in each component. For example, Gee, Boberg, & Gabel (1996), indicate that, in relation to PCK, the implementation of appropriate pedagogy will be investigated, without specifying what is included in it. The results obtained as regards the investigation of the relations between the individual components of science PCK are presented in Table 8:

**Table 8. Investigation of relations between components of science PCK in studies of Primary Education**

In Table 8, it appears that the relationships between the individual components of PCK are rarely investigated (n=4). For example in Davis’s study (2003) the relation between content knowledge and knowledge of teaching representations is explored. The results obtained by the investigation of methodological approaches that are used in studies about science PCK of teachers in primary education are shown in Table 9:

Table 9 shows that the methodological investigation of PCK is carried out in all three paradigms. However, the qualitative paradigm (n = 31) is used more often, followed by the mixed (n = 12) while the quantitative paradigm is very rare (n = 2). In addition, various types of research are used in each paradigm. Of these types, some prevail as case study (n = 21) while others like action research are used rarely (n = 2, see Goodnough & Hung, 2009).

The results of the investigation of the third question "How is Kindergarten teachers’ PCK recognized and how is it detected in the empirical field during the teaching of melting and coagulation in kindergarten?" are presented below. In particular, the results as regards the way of manifesting kindergarten teachers’ PCK about the teaching of melting and coagulation in Kindergarten as well as the confirmation of the basic components of PCK’s operating model are shown in Table 10:

Table 10. Ways of manifesting Kindergarten teachers’ PCK during the teaching of melting and coagulation

Note: Components and faces of PCK marked with v are confirmed

The above table shows that the two kindergarten teachers’ science PCK on the teaching of melting and coagulation are manifested through a variety of components (content, class, context, curriculum, pedagogical and assessment) and aspects (knowledge, perceptions, practices). In addition, it appears that the basic components as well as most aspects of the operating model are confirmed. Further processing has shown that new sub-components of PCK appear in the assessment component and specifically the knowledge, perceptions and practice of teachers regarding the types, procedures and results of students’ assessment. The results as regards the connection between the components of PCK are shown in Table 11.

Table 11 shows that the components of the operating model are linked together. For example, a link between content knowledge and context knowledge of a kindergarten teacher is appeared in the table as she uses the 'language' of the children in defining the phenomenon: "When the flame is turned off and the "juice", the liquid becomes solid, it is again such a candle, then it is called coagulation." The connection between the components of the two Kindergarten teachers’ science PCK confirms its dynamic character.
DISCUSSION

Concerning the first research question "What are the characteristics and the nature of PCK?" the results showed disagreement among researchers on theoretical level as regards PCK despite the existence of some points of agreement. Specifically, there are various models that differ regarding the theoretical foundation and the components of PCK as well as the process by which the teacher knowledge categories are involved. Moreover, the concept of PCK as originally defined (Shulman, 1986, 1987) has faced severe criticisms.

Concerning the second research question, "How is PCK investigated?" the results showed that the theoretical discrepancy is also transferred to the research field. In particular, the researchers do not agree about the appropriate model of mapping primary teachers’ science PCK as well about the components being investigated and their significance. In addition, it seems that there is a lack of exploration of the relation between the components of PCK and a wide variation in its methodological investigation. These differentiations are associated with a different conceptualization of PCK.

The investigation of both the first and second research question has shown the need to clarify the concept on a theoretical level so that it can be investigated in connection with its conceptualization (Tseou, Tsitouridou & Pandidos, 2014). Additionally, the critical review of the literature, through the grounded theory method, has led to the creation of an operating model of PCK. The operating model, starting from the model by Cochran et al. (1993) is theoretically founded on the combination of radical (Von Glasersfeld, 1989) and socio-cultural constructivism (Vygotsky, 1978). According to the operating model, the teacher knowledge categories participate in PCK mainly through the integration process without rejecting the transformation process. In order to address PCK in a comprehensive and specialized way, the starting model is combined with the models by Magnusson et al. (1999), Morine-Dershimer & Kent (1999) and Turner-Bisset (1999) only in terms of defining and processing their components while their theoretical foundation, which is often implicit and has strong influences from objectivist or instrumentalist epistemology, is not adopted. Furthermore the model emphasizes the need of all three aspects of PCK to be considered and specifically the knowledge, perceptions and practices of teachers (Baxter & Lederman, 1999). However their research separation, instead of identification which usually takes place between knowledge and perceptions seems necessary (Smith & Siegel, 2004).
With regard to the third research question "How is PCK of Kindergarten teachers recognized and how is it detected in the empirical field during the teaching of melting and coagulation in kindergarten?" the results showed that the operating model of PCK, which emerged from the literature review, can recognize and detect science PCK of teachers in the empirical field. In particular, it has been shown that Kindergarten teachers’ PCK during the teaching of melting and coagulation in the Kindergarten is manifested through a variety of components and aspects. The basic components of the operating model are confirmed, its aspects are modified, its sub-components are enriched and their significance is specified. The components and subcomponents of PCK are presented below:

1. The content: i. The substantive content: content definitions, basic-principles or objectives, conceptual frameworks, ii. The syntactical content: educational purposes or orientations, iii. Other content.
2. The class: i. The learners and their learning: requirements of learning, differentiated learning approaches depending on the age, motivations, learning style, developmental level, previous knowledge and the difficulties of the students, ii. The self: strengths and weaknesses of teaching.
3. The context of the learning: i. The social context, ii. The political context, iii. The cultural context, iv. The physical context
4. The curriculum: i. The goals, ii. The general pedagogical guidelines, iii. The activities and programs, iv. The materials and media, v. The vertical curriculum
5. The pedagogy: i. Class organization and management, ii. Communication and speech, iii. Instructional strategies of specific subject, iv. Instructional strategies of specific topic
6. The assessment of the students: i. The dimensions, ii. The methods, iii. The types, iv. The procedures, iv. The results

The aspects of PCK, through which the above components are manifested, are as follows: i. Knowledge, ii. Perceptions iii. Practice. Only the subcomponents of the syntactical content and the self are not manifested through practice.

Moreover the results showed the existence of connections between the components of PCK. So the dynamic character of the construct is confirmed. Thus, the schematic representation of teachers’ science PCK arises (see Figure 1). In this figure PCK is illustrated as a circle that represents its integrative nature. Six cycles are embedded in the circle, indicating the same number of PCK’s key components. All components are connected together, as shown by bidirectional arrows with which the cycles are linked. Within each cycle, the aspects of PCK’s components are displayed. As a way of representing the integrative nature of PCK the overlapping of its components is not used as by Cochran et al. (1993) and Otto & Everett (2013), in order the parallel transformation process to be simultaneously represented.

The model of PCK proposed in this study is distinguished from the other models of PCK as follows: PCK is treated as a set of components linked to each other. In this way the dynamic nature of PCK and its integrative nature is recognized as opposed to most models that emphasize only the transformation of certain components. This finding has important implications for the education and training of teachers. Specifically, the components of PCK should be "well structured and easily accessible" to be integrated in teaching (Gess-Newsome
(1999, p.13). For this reason both the separate and the integrated teaching of the components of PCK are required (Cochran et al., 1993).

PCK acquires a synthetic and comprehensive view since it includes as components the knowledge of content, the context and the pedagogy as opposed to transformational models in which they are not considered to be components of PCK. This eliminates the risk of de-professionalization teaching and its reduction to mere imitation of good practices (Gess-Newsome, 1999). At the same time, PCK does not lose the element of specific issues, which makes it distinct from the other knowledge categories of teacher’s (see Loughran et al., 2004).

PCK includes the self knowledge, a component not included in most of the models of PCK. The particular component enables the teacher to reflect on his teaching (McIntyre, 1993) and it cannot be omitted by a constructive model (Kinsella, 2006). Furthermore, combining self knowledge with students’ knowledge into one component, the component of class, brings the educational dyad back at the core of the teaching / learning process (Carlsen, 1999).

PCK treats students’ assessment not only as being composed of appropriate dimensions and methods, but also by procedures, types, and evaluation results. In this way, the operating model is linked to the achievement or otherwise of student learning and the feedback of teaching. This finding is in line with the findings of the 2nd Conference on PCK, which took place in December 2016 in the Netherlands (Berry, Nilsson, Van Driel & Carlson, 2017).

PCK is not faced as mere knowledge of a list of components, as in most studies, indicating a static conceptualization of PCK and an epistemology of objectivism. On the contrary, in the present study PCK is linked to the teacher’s reasoning and practice, referring to the epistemology of constructivism (Tseou, Tsitouridou & Pandidos, 2014). In addition, the three aspects of PCK, i.e the knowledge, perceptions and practice of teachers, are differentiated in research rather than being identified as in most studies (Smith & Siegel, 2004).

In addition, the proposed model is theoretically based on the radical (Von Glasersfeld, 1989) and socio-cultural constructivism (Vygotsky, 1978) as opposed to most theoretical models of PCK which do not include theoretical foundation or are based on objectivist epistemology.

In particular, the proposed model of PCK differs from the starting model of Cochran et al. (1993), as it is enriched with new components and sub-components and is methodologically differentiated with the research separation of the aspects of PCK. After the implementation of the operating model, the significance of the component of students’ assessment, which is completely absent from the starting model, is emphasized. In addition, after its implementation the model is schematically differentiated from the starting model as the connections between its components are highlighted.

The above features that differentiate the operating model from the other models of PCK indicate a significant part of the contribution of the model to the research on PCK and science education. At the same time, the limitations of the model are recognized, because a theory, as a human process of constructing meaning, cannot include everything connected with this phenomenon. The further use of the operating model in research and science education can lead to its improvement, modification or rejection.

STRAND 16: INTRODUCTION

SCIENCE IN THE PRIMARY SCHOOL

Strand 16, Science in the Primary School, attracted the submission of 37 papers, one symposium and five posters to the conference, reflecting the diverse subject matter and theoretical interests of science educators from ten or more countries including some cross-national collaborations. While the majority of papers were from countries in the European Union (France, Germany, Greece, Spain, Sweden and the U.K.), papers from Turkey and the South American continent (Brazil, Chile and Mexico) were also contributed. Of these submissions, 23 papers, one symposium and seven presentations as posters were accepted for inclusion in the conference. Eight of the above – two each from Germany and the U.K and one each from Portugal, Spain, Slovenia and Brazil - were submitted for inclusion in this e-publication, met the technical requirements and are reproduced in the following pages.

Graça S. Carvalho, Paulo Mafra and Nelson Lima (Portugal) report children’s alternative conceptions on microorganisms and health before the formal education of this content (5th grade) and two years after (7th grade). A questionnaire consisting of closed questions was applied to 439 pupils. Most pupils associate microorganisms with disease and recognize the reasons they should be vaccinated. Contrary to results in other studies, pupils associate vaccines with disease prevention rather than disease cure. Also, the beneficial aspects of the microorganisms are little recognized by the pupils. The writers consider that textbooks and teachers should give greater emphasis to the justification of personal hygiene and the beneficial aspects of microorganisms.

Sarah Rau-Patschke (Germany) describes a project focusing on how the quality of teaching ‘Sachunterricht’ (a subject which combines natural and social sciences in German primary schools) develops over the time of teacher education in general and with regard to several criteria for good science lessons. To address these questions, the practices of twelve prospective teachers were explored, the lessons of twelve prospective teachers were videotaped and analysed during the teacher education process. The results suggest that time has no effect on the development of several aspects of the quality of Sachunterricht, though the several aspects differ significantly on every point of measurement. A qualitative typology shows specific progressions in terms of development over time. Both qualitative and quantitative results provide indications of improvement for teacher education.

Ben Dunn, Irina Kudenko and Tom Lyons (UK) study the problems of teaching STEM (science, technology, engineering and maths) subjects in school in order to engage and inspire young people for STEM study and careers. It has been asserted that the effectiveness of an industry’s educational outreach initiatives can be maximised by offering a comprehensive package which includes professional learning for teachers and specially trained industry champions (STEM Ambassadors), who combine STEM industry knowledge with educational expertise. This multi-interventionist approach has been tested in the UK’s Tim Peake’s Primary Project (2015-17), which uses the British astronaut Tim Peake’s mission to the International Space Station to promote the use of space as a context for science learning in primary school. This report examines evidence from the project and discusses its effectiveness and benefits.
Azula Oier, Julen Barriuso, Jenaro Guisasola and Kristina Zuza (Spain) describe an initiation workshop for science that has been implemented in the Langile Ikastola of Hernani (Gipuzkoa, Basque Country) in 3rd grade of primary. This workshop was developed during school hours and within the school facilities but in a non-formal context. A student report/notebook has been designed that has served both as a guide for students and as an instrument for collecting research data. Despite the acknowledged limitations of the work, the results suggest that school activities outside the formal context can help the students to gain understanding of scientific procedures at the same time as they improve their understanding of the concepts that are studied.

Gregor Torkar and Luka Praprotnik (Slovenia) examined preschool and primary school learners' knowledge about animal diversity on different continents as related to their interest in biology. Additional aims were to find out the influence of gender and age on their interest in biology and knowledge about animals on different continents. Altogether, 198 young learners from Slovenia, aged 5 to 12, were interviewed. The study findings show that participants revealed relatively high interest in biology, but no significant correlations were found between their interest in biology and the total number of known species, or for the number of known species on any of the continents. Significant positive correlation between learners’ interest in biology and knowledge about bird species diversity were identified, but no correlations between learners’ interest in biology and knowledge about mammals, reptiles, amphibians, fish and invertebrates.

Maria Tsapali, Connor Quinn, Michelle R. Ellefson, Anne Schlottmann and Keith S. Taber (UK) examined how young children understand liquids (water) and solids (sugar) and their composition, and how these understandings progress through primary school. A sample of 108 children drawn from four different year-groups in the United Kingdom was interviewed, using a structured interview protocol. The findings suggest that young children start understanding materials in terms of their perceptual properties and their functions and properties in daily life. As they grow older, they attend to materials’ composition and chemical properties. They developed a better understanding of water, progressing from a continuous view of matter to the view that it is composed of invisible pieces of different shapes and sizes. Even within the same year-group, there was significant variability in students' understandings of materials and their progress in understanding did not appear to be linear.

Lenir Abreu, Valter Forastieri and Nelson Bejarano (Brazil) analyze the development of a teaching and learning sequence (TLS) performed by the teacher of a class of ten year old children. The research aims to answer the research question: What evidence does the application of the TLS for ‘energy transformation’ by the teacher provide about her learning of how to teach science in an investigatory perspective? The analysis uses an analytical tool that characterizes the ways in which teachers interact with students to promote understanding in the social context of science classes. Before performing the TLS with her pupils, the teacher had the opportunity to become a student in a training program conducted by USP researchers. The research found that, in spite of not having had initial training in science, the teacher performed all the six interventions described in the analytical tool. This experience contributed to the
pupils’ ability to develop their ‘scientific narrative’ for the subjects studied, as well as learning about approach scientific methodology.

Lisa Rott and Annette Marohn (Germany) describe a project which combines concepts from science education and special needs to create, test and evaluate the teaching concept ‘choice2explore’ for inclusive science education in primary schools. Within the framework of design-based research the aim of this study is to focus on conceptual development as well as collaborative learning with third grade school groups from different locations. Accessible learning materials could be developed, subject to ongoing revisions. Accompanying qualitative content analyses describe conceptual development and characterize the learning situations according to cooperation/collaboration, revealing how the learners work with particle models.

_Petros Kariotoglou and Terry Russell_
CHILDREN'S CONCEPTIONS ABOUT MICROORGANISMS AND HEALTH

Graça S. Carvalho¹, Paulo Mafra¹,² and Nelson Lima¹,³

¹ CIEC, University of Minho, Braga, Portugal
² ESE, Polytechnic Institute of Bragança, Portugal
³ CEB – Centre of Biologic Engineering, University of Minho, Braga, Portugal

Children’s alternative conceptions on microorganisms and health are little studied in the literature. Several international studies have shown that these conceptions are incomplete, divergent from scientific knowledge and resistant to change, often even after formal education. This study aimed to identify children’s conceptions about microorganisms and health before the formal education of this content (5th grade) and two years after (7th grade). A questionnaire consisting of closed questions was applied to 439 pupils. Most pupils associate microorganisms with the disease and recognize the reason they should be vaccinated. Contrary to results in other studies, pupils associate vaccines with disease prevention rather than disease cure. Some children do not directly associate behaviours related to their hygiene and the need to disinfect wounds with the elimination of undesirable microorganisms. Also the beneficial aspects of the microorganisms are little recognized by the pupils. Statistical analysis showed significant differences (p <0.05) between the two groups in some answers. It is necessary to improve the approach to microorganisms right away in primary school. Textbooks and teachers should give more emphasis on the justification of personal hygiene and the beneficial aspects of microorganisms.

Keywords: microorganisms, alternative conceptions, health education.

INTRODUCTION

The issue of alternative conceptions has been studied in several areas by many researchers in the last 20 years. However, with regard to microorganisms, the subject is poorly studied, although there are several works that constitute an excellent contribution to this area, such as Nagy (1953), Maxted (1984), Vasquez (1985), Prout (1985), Freitas (1989), Bazile (1994), Leach et al. (1996), Kalish (1996, 1997, 1999), Au and Romo (1996), Au et al. (1999), Simonneaux (2000), Inagaki and Hatano (2002), Byrne and Sharp (2006), Jones and Rua (2006), Byrne et al. (2009), Byrne and Grace (2010), Byrne (2011), Mafra (2012), Mafra et al. (2015), Ruiz-Gallardo and Paños (2017). In general, all these studies demonstrate that children's conceptions about microorganisms are often incomplete and divergent from scientific knowledge.

Considering the relationship between microorganisms and health, many children associate the cause of the disease with environmental factors, such as bad weather, air pollution or the ingestion of contaminated food (Piko and Bak, 2006), however, one of the children’s most common ideas is the link between microorganisms and disease. This is referred to in older studies such as Nagy (1953), Maxted (1984), Prout (1985) and Springer and Ruckel (1992), who emphasize the pathogenic view of microorganisms as a dominant idea in all ages. More recent studies, as Byrne (2011), report that children in early elementary school consider that all microorganisms are potentially pathogenic, highly infectious and dangerous, and are the only cause for the onset of the disease. Simonneaux (2002) adds that most children have the notion
that diseases have a purely exogenous origin, that is, a healthy individual becomes ill when he/she is "attacked" by microorganisms. The same author points out that this concept may later interfere with pupils' understanding of diseases, such as those of genetic origin, and may create learning obstacles when teaching these contents at higher levels of education. Byrne (2011) also points out that younger children tend to think that the presence of microorganisms is enough for disease to occur, and older pupils associate infection with behaviour such as touching, coughing or sneezing towards others, or eating contaminated food. In fact, the mechanism of infection is not well understood by children, especially the younger ones, and the vast majority have naïve ideas about the notion of disease and its transmission.

These ideas often remain even after addressing the issue in formal education (Kalish, 1999, Inagaki and Hatano, 2002). Au et al. (1999) also suggest that children between 8 and 9 years old understand the biological cause of diseases through the model of infection that is transmitted by common sense. Thus, Byrne and Sharp (2006) report that some pupils consider environmental conditions alone as a factor that cause diseases. On the other hand, older children associate it with poor hygiene conditions or dirty places, considering that under these conditions the microbes "gain strength" or are more likely to cause infections.

Finally, it appears that only a limited number of children recognize the benefits of certain microorganisms, e.g., those used in the production of vaccines and antibiotics (Byrne et al., 2009). The anthropomorphic attribution identified in drawings of microorganisms done by children (Byrne and Sharp, 2006; Byrne, 2011; Mafra, 2012) exhibit "good feelings", indicating that some understand that not all microorganisms are dangerous. However, although some children report the use of antibiotics to cure diseases, many are not aware of how they are produced and how they work. Similarly, Byrne (2011) states that children think that both vaccines and antibiotics are designed as medicines, i.e., both acting as curing diseases; being placed in the same therapeutic class makes the concept of prevention through vaccination difficult.

According to the above, in this study it was intended to identify the conceptions of two groups of children (one before the formal teaching about microorganisms; the other two years after) about the relation between microorganisms and health and verify if there are statistically significant differences between groups.

**METHODOLOGY**

This is an exploratory study in which two groups of pupils were studied: one group was in the 5th grade (10-11 years old) who had had no formal teaching on microorganisms; and the other group was of the 7th grade (12-13 years old) who had had formal teaching on this issue. They were enrolled in schools of Bragança town, in Portugal.

A questionnaire with closed questions was given to 439 pupils. The questions focused on: the importance of washing hands before meals and brushing teeth after meals; food hygiene; the perception of the role of vaccines; knowledge of the various types of disease transmission, the importance of wound disinfection and the role of microorganisms. The frequency analysis of answers was estimated and Pearson’s square statistical analysis was used to determine statistically significant differences between the groups analysed, using a significance level of
The ethical requirements were followed in accordance with Portuguese legislation for this purpose, and formal authorization was obtained for the development of this study.

**RESULTS AND DISCUSSION**

Results are presented on the pupils' answers to the questionnaire. In some questions they could only choose one alternative, but in others they could choose more than one, as indicated in each Table.

For the question **"the most important reason for washing hands before eating is ..."**, it was found that 63.7% of pupils said they should do so to avoid getting sick and 34.6% because their hands may be dirty (Table 1). The attribution of disease to this behaviour may be associated with microorganisms and evidence that children know that they have them in the hands.

</tbody>
</table>

We found statistically significant differences (p <0.05), with a decrease in the answer "...to avoid getting sick" from 5th to 7th grade. According to Mafra and Lima (2009), in the 5th curricular programme and corresponding textbooks, all contents related to hygiene are presented as recommendations to comply with or rules of good conduct without explaining the reason for the behaviours. This incomplete approach can contribute to the strengthening of alternative conceptions and make difficult the learning of these contents at higher school levels.

In the question, "the most important reason for washing your teeth after eating is ...", the large majority of pupils (95.1%) considered prevention of dental caries (Table 2). There were no significant differences (p> 0.05) between the 5th and 7th grades.

The preventive behaviour of tooth decay is a topic widely discussed in schools and broadcasted through the media, therefore it is rooted in children’s perception. However, although they recognize the importance of brushing their teeth after meals and the consequences of not doing it, they may be unaware of the cause of the problem (Mafra, 2012).

On the question of food hygiene, "the most important reason for washing fruit before eating is...", 62.5% of pupils said they should "do it because it may be dirty" (Table 3). The second most chosen option was "do it because it can hurt your belly" with 34.5% of the answers.

There are significant differences between the 5th and 7th grade (p = 0.001). More importance was given to the problem of dirtiness by the 7th grade pupils, in line with the formal teaching at this level. These results show that more importance was given to the possible "dirtiness" and suggests that the pupils assume these procedures as a norm or rule to fulfil without, however, valuing the scientific justification to this behaviour.

Regarding the nature of vaccines, 72.6% of the pupils reported that "they are substances that protect us from certain microbes" (Table 4). However, there were significant differences between the 5th and 7th grade (p = 0.001) in that 7th grade gave more importance to protection given by vaccines. This difference can be justified by the fact that in the 7th grade the vaccines are part of the curricular programme and textbooks.

Following this theme, it was asked "the reason why we should be vaccinated ...", where the majority of pupils (77.2%) presented a scientifically correct conception related to prevention, especially the pupils of the 7th grade (Table 5), with significant differences between the two grades (p = 0.011). Thus, in contrast to the results obtained by Byrne (2011), the preventive vaccine is well recognized by the pupils of this study, with only 20% of them seeing vaccines as a "cure for the disease", "killing microbes ".

Concerning the question "When you hurt yourself, why should you wash the wound?", 83.8% of pupils considered "to kill the microbes" (Table 6), presenting a scientifically correct notion. There were no significant differences between the 5th and the 7th grade (p > 0.05). However, it should be noted that in both 5th and the 7th grades there were pupils who thought disinfecting a wound aims "to remove dirt." Regarding this option, and considering the 5th grade, this result is in the curricular programme and textbooks. In fact, the first aid topic in textbooks includes
the disinfection of wounds, which are presented as a mere cleaning procedure, presenting no reason explaining why this procedure must be done.

Regarding how diseases can be transmitted, most children chose "when you sneeze to someone without putting a hand/arm to the front of the mouth" (88.7%, Table 7-A), and also "when you eat after playing on the soil" (61.5%, Table 7-C), both responses with significant differences (p <0.05) between the 5th and the 7th grade. In the case of the response "when you eat spoiled food" (69.9%, Table 7-H) there were no significant differences (p> 0.05) between the two groups. These responses show the recognition of two forms of disease transmission: aerial (mostly recognized by the children of the 7th grade) and oral (recognized by both groups).

With regard to the places where one can find microbes, it was found that the answers "in the mouth" and "on the skin" only 17.9% and 31.4% of the answers, respectively, were found (Table 8-D and -E), with no differences between the 5th and 7th grade (p> 0.05). This is to say that in both groups there is poor knowledge of the presence of microorganisms in these human body areas. Despite being a content addressed in the 7th grade, most pupils keep a non-scientific conception, resisting to change. This result shows an incomplete or inadequate teaching-learning process regarding mouth hygiene (brushing teeth) and body care.

Pupils’ answers to the above questions denote a strong negative connotation towards microorganisms, which is in agreement with those results described by Byrne and Grace (2010), Byrne (2011) and Mafra (2012). This may be related to the approach to microorganisms in the textbooks of primary school, where microorganisms are only and exclusively presented as associated with disease and pollution (Mafra and Lima, 2009). Also hygiene content is addressed as recommendations to comply or rules of good conduct, without explaining the reasons for the advised behaviours (Mafra et al., 2015).

Most children recognize why they should be vaccinated and associate vaccines with disease prevention rather than with "cure for disease," which are in agreement with results found by Byrne (2011). The percentage of pupils who consider the vaccine as a "cure for the disease" may be explained by the fact that in primary school this issue is quite valued, in particular the vaccination (as a rule) and the vaccine compliance with a timetable (Mafra, 2012).

Most children identify air and oral disease transmission, which generates the following reflection: on one hand, pupils indicate the air and food they eat and drink as places where there are microorganisms, suggesting they are aware of the ways of air and oral disease transmission; on the other hand, only a few identify the mouth and skin as places where microorganisms exist. The latter matches the reflections by Mafra and Lima (2009) who discuss the sections of the primary school programme and textbooks which address body hygiene (brushing teeth, bathing, etc.) but that do not explained why children should adopt these hygienic behaviours. In fact, pupils devalue, or do not know, that they have microbes in their mouths and skin. If they knew, it would be more likely that the recommended hygiene behaviours would be more understood and accepted, and would not be taken as a merely fulfilment of a socially correct procedure.

Most pupils recognize why children should disinfect wounds, but some associate the process to the need to simply remove the dirt from the wound. This result may be related to the way
the topic is presented in the primary school curriculum programme, where there is no explanation for the reason of disinfecting wounds.

The results also show that when referring to the beneficial aspects of microorganisms, even after they have had the formal teaching on this topic, pupils retain little of certain microorganisms’ benefits, in particular in favour of humans.

The results as a whole, also indicate that there are scientifically incorrect conceptions prevailing in the 7th grade pupils, even after this topic is taught in formal teaching.

This leads to the identification of conceptions resistant to change and to a reflection on how the contents should be treated in the teaching and learning process, in the perspective of an effective conceptual change. It is important to make children know and understand, from an early age, the reason why they should adopt certain behaviours associated with their personal hygiene, giving them scientific significance and thus contributing to the increase their scientific and health literacy.

CONCLUSIONS

Most pupils associate microorganisms with disease and recognize the reason they should be vaccinated by associating vaccines with disease prevention rather than disease cure.

Some children do not directly associate behaviours related to their hygiene and the need to disinfect wounds with the elimination of undesirable microorganisms. Also pupils, in general, do not recognise the beneficial aspects of microorganisms.

It is necessary to change the teaching and learning process of microorganisms at the level of the Primary School. Should the textbooks and teachers give more emphasis to the explanation of personal hygiene as well as to the beneficial aspects of microorganisms?

LEARNING TO TEACH NATURAL AND SOCIAL SCIENCE AT PRIMARY SCHOOL

Sarah Rau-Patschke
University of Duisburg-Essen, Essen

The performance in class is a basic ability for teachers. Ideally the performance strives to reach the criteria for good lessons. It is assumed that lessons considering those criteria effect pupils’ achievements. It is widely unknown how prospective teachers learn to perform in class with regard to the criteria of good lessons. This also applies for primary school teachers teaching Sachunterricht, a subject which combines natural and social sciences at German primary school. In conclusion, this project focuses on the questions, how the quality of teaching Sachunterricht at primary school level develops over the time of teacher education in general and with regard to several criteria for good science lessons. To answer these questions twelve prospective teachers were investigated. During the time of teacher education Sachunterricht lessons of these twelve prospective teachers were videotaped and analysed. A multi-factorial ANOVA was conducted to compare the effect of time during teacher education on the quality of conducting Sachunterricht. The results show that time has no effect on the development of quality of Sachunterricht. In addition, time has no influence on the several aspects of quality of Sachunterricht, though the several aspects differ significantly on every point of measurement. Furthermore, a qualitative typology shows specific progressions in terms of development over the time. Both qualitative and quantitative results provide indication of improvement of teacher education.

Keywords: primary school, practical phase, quality of conducting lessons

FOCUS OF THE STUDY

The ability to perform in class mainly develops during practical phases in teacher education (Stronge, 2007). Teacher education in Germany is divided into two phases. The first phase focuses on theory-based knowledge. In the second phase, prospective teachers have to transfer their pedagogical and subject-specific knowledge into actual teaching conditions (Viebahn, 2003). Teaching Sachunterricht requires a broad subject-specific knowledge as it combines both social and natural sciences in primary school while dealing with one topic. This means Sachunterricht is a very challenging subject for teachers. They do not only have to gain a broad content-knowledge and pedagogical content knowledge in all these subject areas, but also have to gain Sachunterricht-specific knowledge (GDSU, 2013).

Based on the assumption that teacher education has a positive impact on pupils’ achievements (Niemi, 2011) the present study traces to what extent prospective teachers learn conducting quality-orientated Sachunterricht. Only by knowing about developmental processes, are teacher educators able to improve their education.
THEORETICAL BACKGROUND

Teaching Quality – Different Perspectives on Teaching Goals

Teaching Quality depends on normative political and social expectations as well as current research results. There is a broad agreement in describing Teaching Quality by learning scenarios, which have a positive impact on cognitive and social learning success (e.g. Ditton, 2009; Helmke, 2009; Reusser & Pauli, 2010). This learning success can be categorized into content-based achievements, general key competencies and values or attitudes. To ensure learning success, Berliner (2005) differentiates between Good Teaching and Effective Teaching: Good Teaching refers to normative expectations of society. Therefore, teachers should, for example, encourage their students to learn independently, regardless whether we know if this has a significant effect on the students’ knowledge or not. It is more about the general autonomy of the individual. In contrast, Effective Teaching is related to reaching learning goals, e.g. knowledge. Direct instructions, as a contrast to independent learning, is highly effective although society would not expect that (ibid.). Berliner summarizes that a high-quality teacher shows evidence of different aspects of Quality Teaching (2005).

Quality teaching is often described by different models or catalogues, e.g. Brophy (2000), Helmke (2014), Meyer (2009), Walberg & Paik (2000). They use different structures and labels but share similar content. On the one hand there are aspects of good teaching, which effect learning outcomes indirectly e.g. adaptivity, good classroom climate or arrangement of the learning-environment. On the other hand there are other aspects of effective teaching like cognitive activation, student-orientated environment, classroom management. But, what most of these catalogues are missing, are the subject specific requirements.

Most studies using those catalogues focus on subjects of secondary school or other primary school subjects, e.g. Mathematics, German language or only the physical aspects of Sachunterricht. Quality of Sachunterricht as a combination of social and natural sciences is not sufficiently described yet.

As already stated by Pietsch (2010) aspects of Teaching Quality can be represented in four hierarchic levels, as shown in Figure 1:

![Figure 1. Four phased model to classify the quality of teaching (Pietsch, 2010)](image-url)
The School inspection of Hamburg constructed and validated a four-stepped model (Pietsch, 2010). For further information, see Windt et al. (2016).

This model is valid for professional teachers, so it might be more difficult to teach on Level 3 and 4 than on Level 1 and 2. Furthermore, it might be that aspects of structuring and organising lessons develop earlier.

Teacher Education: Learning to Teach with high Quality

How prospective teachers learn to conduct lessons with high quality is widely unknown (Niemi, 2011). This also applies for Sachunterricht. Therefore studies with a focus on other subjects than Sachunterricht and other school types, e.g. secondary school, have to be taken into account. Prospective teachers at secondary schools generally profit from learning opportunities in preparation programs (Schmidt et al., 2007). Especially their beliefs and knowledge were impacted. Furthermore, general aspects of teaching quality, e.g. efficiency of instruction, cognitive activation, improve over time during practical phases in different subjects (Baer et al., 2011). Furthermore, different research groups pointed out, that not every aspect was develops equally (Baer et al., 2011; Döbrich & Storch, 2012; Guldimann, Smit & Helfenstein, 2013). Different research groups found out that some aspects of quality of teaching increased more, for example efficiency of instruction, economic use of time and cognitive activation (Baer et al., 2011; Döbrich & Storch, 2012). However these related to teachers of all school-types and were not related to specific subjects. Therefore, it is not fully clarified yet, which effects of the second phase of teacher education has on the teaching abilities of prospective Sachunterricht-teachers.

RESEARCH QUESTIONS & HYOTHESES

The given background leads us to the following questions: How does the quality of conducting the subject Sachunterricht develop over time during the second phase of teacher education (1) in general and (2) with regard to the several criteria for good Sachunterricht-lessons?

It is assumed that the quality of conducting Sachunterricht increases over time during the second phase of teacher education. Furthermore, it is hypothesised that several aspects of quality of Sachunterricht differ in their amount and in their period of increment. Aspects of structuring and organising a lesson develop priorly in the first half of teacher education while aspects concerning the individual level of students develop in the second half.

MATERIAL, METHODS & DESIGN

During the time of the second phase of teacher education, twelve prospective teachers, 25 years ($SD = 1.168$) in average, were investigated. Three Sachunterricht-lessons of each prospective teacher were videotaped at the beginning, middle and the end of the second phase of teacher education. In addition, every person involved in the education, evaluated the quality of each Sachunterricht-lessons as well as the prospective teacher him- or herself.

As there is no common understanding of what quality of Sachunterricht looks like, a manual was developed and validated by experts (Windt et al., 2016). The six criteria of quality of Sachunterricht can be divided into two groups:
(a) Aspects of structuring and organising a Sachunterricht-lesson
- Classroom-Management
- Clarity and Structure
- Arrangement of the Learning Environment

(b) Aspects of individualisation:
- Activation
- Handling Heterogeneity
- Supportive Classroom Climate

Each criterion is described by a different number of facets. Each facet is rated either dichotomously or on a four-point Likert scale. For each criterion, the average value of all related facets is calculated.

Every videotaped lesson was analysed by this instrument using the software MAXQDA (Version 11), which allows a qualitative content analysis (QIA) of videos. The QIA provides a more open interpretation of the data. To ensure inter-subjective verifiability, the data collection was standardised by guidelines for videotaping the lessons as well as for making pictures of additional material in the classroom. Ratings of the videotaped lessons were standardised by deductive category application with definitions, examples & coding rules (Mayring, 2000).

The inter-rater agreement ranges between acceptable and perfect: \(0.545 < \kappa < 1.0\).

RESULTS & INTERPRETATION

As Figure 2 (left side) shows, the general Teaching Quality of Sachunterricht only marginally develops over time. A multi-factorial ANOVA with repeated measures (right side of Figure 2) shows that – contrary to the expectations – the quality of Sachunterricht does not develop significantly over time, \(F(2,22) = 2.160, p = .139, \eta^2 = .164\).

Figure 2. Development of Teaching Quality in general over the time.
Furthermore there is no interaction effect between time and group of criteria, $F(2,22) = 1.521$, $p = .242$, $\eta^2 = .121$, see Figure 3. As expected, the groups of criteria differ from each other. Aspects of organising and structuring were conducted significantly higher than the aspects of individualisation, $F(1,11) = 53.197$, $p = .000$. Due to the fact, that the samplesize of twelve is very small, the non-parametric Friedman-tests was calculated as well. These calculations support the results.

![Figure 3. Interaction between Group of Criteria and Time; blue = aspects of teaching on the structuring and organizing level; orange = aspects of teaching on the individual level of students](image)

To acquire a deeper understanding of the data a qualitative typology was conducted additionally. Three groups of development of conducting *Sachunterricht* can be extracted: positive development, negative development and stagnation (Figure 4).

![Figure 4. Three different groups of development: positive development (green), stagnation (orange) and negative development (red); scale abbreviated.](image)

Within the group of positive development two types could be identified as shown in Table 1.
Table 1. Characteristic of the identified types

</table>

The general Teaching Quality of Sachunterricht may only develop marginally (see Figure 2) as there are different types of development. Some prospective teachers show a positive development in the first half of the second phase, while the Teaching Quality of others develops in the second half. Both types struggle with the criteria of individualisation. This also fits to the comparison of the groups of criteria, where aspects of organising and structuring were conducted significantly higher than the aspects of individualisation (see above).

DISCUSSION & CONCLUSIONS

The results show, that quality of conducting Sachunterricht does not develop consistently during the time of teacher education. The hypothesis can not be verified statistically. Medium or even large effects are not significant. There is a high variation of the individual developments as we can see in the typology. Due to the fact that the different aspects of quality of Sachunterricht differ significantly, it may be assumed that structuring and organising a lesson is easier to learn than to conduct a lesson on the individual level of pupils.

The results can not be generalised due to the small sample size. Videotaping often leads to an opportune sampling. There might be a much higher variation of types of development, which cannot be found by the given sample. Although the results do not represent the whole population of prospective teachers, who learn to teach Sachunterricht, the quantitative as well as the qualitative findings give us hints towards possible improvements within teacher education. As the aspects of structuring and organising seem to be easier to conduct, it might be helpful to strengthen prospective teachers’ knowledge about organising and structuring Sachunterricht already during the first phase of teacher education. It is probable that this knowledge frees up capacities to deal with the requirements of individualising Sachunterricht intensively during the second phase of teacher education. Therefore, it might be helpful to have a closer look at the first phase of teacher education and diagnosing the prospective teachers’ abilities at the beginning of the second phase more detailed.

As the Teaching Quality of Sachunterricht refers to aspects of Good Teaching and Effective teaching (see Berliner, 2005) the understanding of Teaching Quality may change in time. This leads us to the third phase of teacher education. Professional, examined teachers are obliged to attend continuous and further training to expand their knowledge about different aspects of Teaching Quality as well as to strengthen their competence to reflect on conducting Sachunterricht-lessons.

EFFECTIVE USE OF STEM INDUSTRY INITIATIVES FOR ENRICHING PRIMARY SCIENCE

Ben Dunn¹, Irina Kudenko¹ and Tom Lyons¹, ²

¹STEM Learning, York, UK
²ESERO-UK, York, UK

Contextual teaching of STEM (science, technology, engineering and maths) subjects in school can engage and inspire young people for STEM study and careers. With schools lacking this expertise, STEM employers’ contribution is invaluable, but often comes as stand-alone educational resources, which teachers are not confident to use, or as one-off engagements with STEM professionals, who often have a poor grasp of educational settings and curriculum learning. It has been asserted that the effectiveness of an industry’s educational initiatives can be maximised by offering a comprehensive package which includes professional learning for teachers and specially trained industry champions (STEM Ambassadors), who combine STEM industry knowledge with educational expertise. This multi-interventionist approach has been tested in the UK’s Tim Peake’s Primary Project (2015-17), which uses the British astronaut Tim Peake’s mission to the International Space Station to promote the use of space as a context for science learning in primary school. This research examines evidence from the project and discusses its effectiveness and benefits.

Keywords: primary science, contextual learning

INTRODUCTION

Research Background

The ability of school educators to enrich their teaching with real life examples and industry contexts brings multiple benefits for learners, positively affecting their engagement, subject learning and aspirations for STEM careers (Klassen, 2006). Stanley and Mann (2014) identify three distinct ways employer engagement can support subject teaching and learning in school: it can supplement the conventional teaching and learning processes, complement them by offering alternative ways of learning, e.g. mentoring, and add additional value by offering learning outcomes in addition to conventional learning outcomes as recognised by qualification, e.g. employability skills.

A recent meta-review of the international research on the value of employer engagement in education concluded that engaging employers in the educational system can often be expected to provide beneficial educational and economic outcomes for young people (Mann, Rehill & Kashefpakdel, 2018). These outcomes are associated with the enhanced capacity of young people to engage in education and navigate progress through schooling into ultimate employment. The review also identified four broad areas in which young people benefit from school collaboration with industry specialists and other members of economic community. Such partnerships can: 1) enhance pupil understanding of jobs and careers; 2) provide the knowledge and skills demanded by the contemporary labour market; 3) provide the knowledge and skills demanded for successful school-to-work transitions; 4) enrich education and underpin pupil attainment. In primary education, this practice is particularly instrumental in
developing pupil knowledge and skills and influencing attitudes and aspirations, while in secondary school there is a bigger focus on achieving economic outcomes.

However, most schools have limited knowledge and expertise in using cutting edge knowledge and industry examples to enhance their teaching practice. Equally, many teachers don’t feel confident to use real life practical or other enrichment activities to contextualise teaching and learning of STEM subjects and career education (SCORE, 2013). In terms of teaching scientific inquiry skills, Kelley and Knowles (2016) argue that teachers have misconceptions about practical activities with many believing that hands-on learning simply equates to scientific inquiry. Instead, students should be encouraged to formulate their own questions and investigate through experimentations and draw conclusions which relate to and sometimes verify established scientific theories – this is scientific inquiry. In order to ensure scientific inquiry skills become more widespread in the classroom, teachers must have improved pedagogical content knowledge and have experienced authentic scientific inquiry themselves (Kelley & Knowles, 2016)

Not surprisingly educators are keen to engage with STEM employers, who can make science ‘real’ for children, developing valuable skills and a passion for STEM. In a recent study of educational initiatives in Europe developed by STEM employers, Kudenko, Simarro, and Pinto (2017) identified a number of systematic gaps and barriers that may hinder school-industry collaboration and subsequently reduce its effectiveness and impact on young people. The study demonstrated that STEM employers’ support for education comes in two main forms: provision of learning resources and access to industry experts, so-called STEM Ambassadors. Although both are useful engagements, to become successful they need to be coupled with continued professional development (CPD) for school educators and STEM Ambassadors. CPD helps teachers to use new learning resources effectively, while STEM Ambassadors, who, as a rule, are not familiar with the world of education, need to learn how their expertise could be best deployed to facilitate STEM curriculum and career education in schools.

**ESERO-UK programme description**

STEM Learning is the UK’s largest provider of CPD and resources to STEM educators; supporting schools, colleges, teachers and others in science, technology (including computing), engineering and mathematics. They work closely with many STEM employers, developing STEM enrichment resources and supporting STEM educators with professional learning. STEM Learning operate the National STEM Learning Centre and Network; providing support locally, through Science Learning Partnerships across England, and partners in Scotland, Wales and Northern Ireland; alongside a range of other projects supporting STEM education, including ESERO-UK.

ESERO-UK (European Space Education Resource Office in the UK), also known as the UK Space Education and Resource Office, aims to help teachers use the context of space to open doors for young people by delivering engaging, world-class teaching in STEM. ESERO-UK is based in the National STEM Learning Centre in York. Working alongside STEM Learning, ESERO-UK is able to provide influence, funding and services to improve the teaching of
STEM subjects in schools and colleges, and inspire young people through engagement and enrichment activities.

This research looks at one of STEM Learning’s recent projects, the Tim Peake Primary Project (TPPP). Delivered by ESERO-UK, the TPPP uses the British astronaut Tim Peake’s mission to the International Space Station (December 2015) to promote the use of space as a context for science learning in primary schools. TPPP has been funded by the UK Space Agency and the English Department for Education with further support from the European Space Agency (ESA).

TPPP offers participating schools space-themed learning resources, teacher CPD and access to space-industry champions, known as Space Ambassadors (SAs), who receive bespoke pre-project CPD on space resources/activities and how they can be best integrated in primary science teaching to engage pupils and support their learning. They are then able to act as consultants regarding the effectiveness of the activities undertaken within a school. SAs attend schools on a number of occasions providing CPD to teachers and also carrying out activities with pupils. The TPPP concluded in June 2017, having run for 3 academic years. The first phase ran in 2014/15 as a pilot study at 47 schools in the UK, engaging over 1700 pupils in upper primary school. The second phase began in 2015 with over 650 UK schools taking part in the first year and over 750 in 2016/17 (Figure 1).

![Figure 1: Over 1400 UK schools engaged in the TPPP – red markers on the map show those engaged on 2015/16 and green markers show those engaged in 2016/17.](image)

The TPPP aimed to:

- increase pupils’ enjoyment and engagement in science, numeracy and literacy
Strand 16

- increase pupils’ confidence in learning science and working scientifically
- increase pupils’ knowledge of career opportunities available to them if they study science and mathematics subjects
- increase pupils’ attainment in science
- increase teacher confidence in teaching space topics.

Using the data from this project, this paper explores the effectiveness of using a multi-intervention approach (i.e. combined provision of CPD, resources, STEM industry experts) in helping to contextualise teaching and improving teaching and learning of primary science. More specifically, we aim to find if and how this combined model increases the uptake and impact of new enrichment activities and novel ways of teaching primary science.

**METHOD**

The research employs quantitative and qualitative methodologies to analyse various types of data collected in phase two of the project. TPPP schools are asked to provide two milestone reports: a pre-project action plan stating their intended outcomes and actions and a post-project impact survey reporting on the achievement of those outcomes and impacts.

Action Plans (N = 854) were completed online, with SAs supporting schools in their plans for using resources and organising SA-led activities. Completed action plans were submitted directly to ESERO-UK. Impact surveys (N = 453) were completed online, independently of the SA, and allowed schools to reflect upon whether the planned outcomes in the action plan had been met. Impacts surveys also included more in-depth data on how engagement with the TPPP impacted on pupils, teachers and the school. Results presented here are based on the content and narrative analysis of all 854 action plans and 453 impact survey responses collected from schools.

SAs submitted post-project school reports, which highlighted the number of schools and teachers engaged, activities undertaken and their general feedback on the programme delivery. In a number of cases, SAs chose to provide their own evaluation data such as quotes from teachers and pupils, samples of pupil work or feedback from the activities. Qualitative analysis of the additional data submitted by SAs was undertaken and presented below.

Further evidence of impact comes from the TPPP online community group hosted on the STEM Learning website. Schools and SAs were encouraged to use the community group to share evidence of their engagement, ideas and examples of best practice. Community group posts included photos, samples of pupil work, success stories and teacher resources.

In addition, long-term follow-up surveys assessing the sustainability of the project were sent to schools in the 6-12 month period post-project. For those schools participating in the first year of the TPPP, the follow-up survey was sent 12 months after the project. For those participating in the second year of the project, a follow-up survey containing a number of similar questions was sent 6 months post-project as part of a forthcoming independent external evaluation of the project.

Finally, interviews with involved teachers, science coordinators and SAs were undertaken by an external evaluator, with evidence from the interim report being used below.
RESULTS

The TPPP was very successful in meeting the stated aims of the project. First, the data collected shows that the TPPP has been very successful in achieving and exceeding its aims for engagement of teachers and pupils. Table 1 shows how the TPPP exceeded the targets set as part of the first year of the main project (2015/16).

Table 1. TPPP key achievements across a range of agreed project deliverables during the first year of the project.

Teachers and students were pleased and excited with the resources, activities and support offered by the programme, so many schools opted to implement more than they originally planned. A comparison of project activities that schools intended to do (outlined in the action plans) and those reported as completed (in the impact reports), shows a 12% increase in whole school events and a 10% increase in teachers implementing ‘other’ activities related to the TPPP, e.g. visiting planetariums, organising Space Camps, and holding community based events. There was also a 6% increase in teachers’ uptake of the online library of TPPP resources (Figure 2).

Figure 2. Proportion of teachers who planned (action plan, N=854) versus completed (impact survey, N=453) outcomes as part of the TPPP
The qualitative data from SA reports, impact surveys and samples of school evidence from the online community paints an equally successful picture of the project’s impact on educators, learners and the wider community.

“The CPD session was excellent and the children all enjoyed the Space Ambassador led activities. Staff have felt confident in delivering their own Space activities from the resources. Science club is now over-subscribed. Pupil Voice for science has identified the visit from Space Ambassador to have been a highlight of the term. The children have been highly engaged on twitter and following the adventures of Tim Peake.” – Teacher

“I don't usually enjoy teaching this aspect of the curriculum but I now feel really inspired and can't wait to use the great resources. Thank you!” – Teacher

“Really enjoyed the CPD course. It was very informative and the speakers most knowledgeable. Super to have great resources and Teacher's pack which is suitable for different classes. Thank you very much.” – Teacher

“This was the best CPD session we have had. All staff were motivated and enthusiastic and keen to incorporate it into our creative curriculum. We are confident that our pupils would thrive with activities and the projects. As a school we are now planning a Science Space Week and half-termly topics using our Space Ambassador to lead and guide us.” – Teacher

The evidence also shows that SAs often played a very significant role in ensuring both the take up of the programme activities and the success on such a wide scale. A vast number of teachers commented on the high quality of support received from SAs.

“Robin [Space Ambassador] was both inspiring and informative. [He] provided excellent CPD for staff when teaching this topic. Robin gave clear information about the next steps in the project and was happy to answer all of my questions.” – Teacher

One of the main benefits of having access to a SA was that it increased the authenticity of the experience for young people who were very inspired by the fact that an ‘expert’ had come in to talk to them:

“The space ambassador was amazing. She is just so inspirational and brought in lots of really good resources and the children really, really loved her. She was fab with them and her coming to do the CPD for us as well was really good for the teachers. It gave them a bit of confidence...It created a real buzz.” - Teacher

Similarly, working alongside an industry-based expert has helped increase the confidence teachers have when using the context of space and the TPPP resources to implement cross-curriculum activities. Indeed, a follow-up survey issued to schools in the 6-12 month period after engaging with the TPPP showed how schools highly valued the support of the SA, with 80% stating that SAs were crucial or very important to the success of the project. Similarly, the
CPD session delivered by SAs was also seen as valuable with 79% of respondents stating the session was crucial or very important to the success of the TPPP (Figure 3).

“Having our Space Ambassador come and talk to the children was amazing. He had so much actual experience to share and could answer trickier questions with absolute certainty. He also inspired the children to consider STEM as a career - including less able children who have low self-confidence.” – Teacher

Figure 3. A Space Ambassador undertakes an activity with pupils

School responses to the impact surveys (Table 2) show in more detail how engaging with the TPPP positively impacted pupils’ learning, for example 99% of respondents stated an increase in enjoyment and engagement in science and 96% saw improvements in pupils’ science attainment.

Table 2. Teachers’ feedback on the impact of the TPPP representing 453 schools and over 60000 pupils

<td>75</td>
<td>24</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

Furthermore, the responses highlighted the positive impact on both teachers and the school as a whole, with 100% of respondents citing an increase in confidence when teaching space topics, and 97% acknowledging the role the TPPP played in increasing the profile/priority of science in their school.
“[TPPP] has helped us to raise the profile of STEM subjects across the school. The increase in children’s curiosity, engagement and enjoyment of science and space topics has been evident for all staff to see.” – Teacher

“We had a whole school Tim Peake day where staff planned cross-curricular work, had an assembly and took part in workshops. This improved staff confidence in teaching in this way.” – Teacher

There is also evidence that engaging with the TPPP provides sustainable, long-term impacts and that to a great degree this sustainability was due to a bespoke support from an industry champion, who coached school teachers and inspired their students through the programme activities. The follow-up survey showed that 95% of schools continue to use space as a context for teaching on a regular basis, with a further 2% stating they plan to in future (Figure 4). Of those schools currently using space as a context for teaching, 98% state they use space as a context to teach science and 82% use space as a context to teach other curriculum subjects (i.e. literacy and numeracy). Qualitative analysis shows that the TPPP has encouraged schools to use space as context for teaching numerous other subjects beyond science, numeracy and literacy, i.e. art, PSHE, DT, PE, ICT, music, history, geography and modern foreign languages.

“We have it as a topic each year now for a whole term. Covering the entire curriculum” – Teacher

Figure 4: Proportion of schools continuing to use space as a context for teaching since completing the TPPP

The feedback collected on long-term impacts was also very encouraging; respondents agreed that since completing the TPPP, pupil enjoyment and engagement in science continued to increase (95% agreed), and further increases were seen in confidence when learning science and working scientifically (75% agreed).

“I learnt that you can do anything no matter if you are a girl or a boy.”
– Pupil

Similarly, teachers continued to show positive long-term impacts, including increases in confidence teaching space topics (83% agreed) and ability to enrich teaching with real-life examples (65% agreed) (Table 3).

“One teacher in particular has changed the way practical science is taught in her class after observing the organisation during the session on working scientifically.” – Space Ambassador

However, there was some evidence of cases when SAs were not successful in establishing long-lasting and productive relationship with schools and teachers. Sometimes this led to complete disengagement from the programme after the initial meeting with SA, although a more likely scenario was when schools continue to participate in the programme activities and use programme resources while choosing to opt out of CPD and SA-led activities. Feedback from SAs and teachers show that in most cases this was explained by differences in school contexts, e.g. school culture, their experience with previous similar projects and their level of STEM expertise. One teacher interviewed stated that their school has established a high level of STEM expertise already and therefore felt that classroom activities undertaken by the SA were not as impactful as they had hoped:

“I did feel a bit like the activities delivered by the space ambassador was science by numbers. It felt very prescribed and very let’s do this now, do this, do this, do this, which isn’t really the way I tend to work with my class, but I understand that when you’re coming in working with children that you don’t know you have to be a lot more structured.” – Teacher

DISCUSSION

The evidence collected to date shows that the comprehensive, multi-intervention approach adopted by TPPP (see Figure 5) allowed the project to meet (and exceed some of) its aims of supporting STEM enrichment in primary school, improving the quality of science teaching and learning in primary schools and increasing outcomes for young learners.

The TPPP shows that training SAs to develop equally strong knowledge of space industry context and educational environment significantly improves their effectiveness as STEM industry champions and CPD coaches in schools. Their dual expertise in both fields of space and education enable them to engage with teachers developing their confidence and teaching skills and with learners providing enthusiastic and impactful activities. Importantly, attending the school on multiple occasions gives SAs the opportunity to form an ongoing relationship with teachers and pupils. Face-to-face interactions with SAs allow pupils to learn more and get more excited about career opportunities in STEM, while the collaborative approach (i.e. working alongside SAs) gives an additional impetus to teachers’ learning.
The qualitative data shows that teachers allowed SAs to lead during many activities, which then provided teachers with a number of ideas on other relevant activities. It also added the novelty value that having an ‘expert’ guest speaker has on the engagement of children. The ongoing relationship between SAs and schools gave teachers the opportunity to discuss with an SA the best ways to use the resources, and then share these ideas with colleagues. The results show an increase in the uptake, dissemination and embedding of enrichment activities. The evidence collected in the follow-up surveys shows that using the multi-intervention model and particularly engaging STEM industry champions in programme delivery – after they received additional training as CPD coaches and activity presenters, has resulted in the increased sustainability and higher level of impacts for all participants.

Overall, we conclude that SAs are an effective agency that help increase school engagement with STEM enrichment programmes, build up their internal expertise in teaching STEM subjects and provide additional benefits to learners. However, for this approach to work well SAs have to be upskilled and have good understanding of both worlds – the world of industry and the world of education.

At the same time, different schools and teachers face different circumstances and this appears to influence the importance as well as the impact of a SAs’ input. Using the evidence from this study as well as evidence from other research (e.g. Archer, 2014) we conclude that the following have particular influence:

- pre-existing expertise in teaching STEM subjects
- previous experience of working in partnership with employers and using STEM enrichment resources, as well as
- socio-economic background and science capital of their students.

Schools with high level of experience and expertise may choose to work independently on the programme, engaging with activities and resources and embedding new practices.
Most of primary schools in the UK are not in this position and can benefit greatly from a bespoke support provided by a trained SA. This, however, depends on the ability of the SA to engage with the school and establish a good relationship with its educators. Should this relationship not develop, this may result in disengagement and/or suboptimal outcomes. This is a perhaps a ‘weak link’ of this delivery model that requires monitoring and timely intervention from the programme leadership team.

INTRODUCING SCIENCE: A NON FORMAL WORKSHOP IN PRIMARY SCHOOL

Azula Oier¹, Julen Barriuso², Jenaro Guisasola¹ and Kristina Zuza¹
¹University of the Basque Country, San Sebastian, Spain
²Langile Ikastola, Hernani, Spain

The paper presented describes an initiation workshop for science that has been implemented in the Langile Ikastola of Hernani (Gipuzkoa, Basque Country) in 3rd grade of primary. This workshop was developed during school hours and at the school facilities but in a non-formal context. A student report/notebook has been designed that has served both as a guide for students and as an instrument for collecting data for research. In addition, the sessions have been recorded. The data analysis has been performed according to the objectives of the research using the case-study technique. Despite the limitations of the work, the results point out that school activities outside the formal context can help the students to know the scientific procedures at the same time as they improve the understanding of the concepts that are studied.

Keywords: primary school, workshop, non-formal teaching

INTRODUCTION

This paper describes the design and implementation of a workshop for 3rd grade of primary in the school but in a non-formal environment. The process of scientific learning is developed from a young age, so it is important to address it as early as in primary education, both in conceptual learning and procedural skills. Studies have shown that the approach to science from a non-formal perspective helps students to engage it more passionately (Pedretti, 2004), since students have the ability to use aspects of scientific methodology from an early age (Gelman and Benneman, 2004). The workshop has been designed to analyze the following objectives: i) how students are confronted with the scientific method, ii) how the concept of force evolves and iii) how the concept of density evolves during the workshop. The analysis of the implementation and the data obtained has been analyzed through the case study.

THEORETICAL FRAMEWORK

There are many works that speak about the places or contexts in which learning takes place. Although learning is something continuous, in general, this learning is cataloged as 'formal' or 'non-formal' depending on whether learning takes place in or out of school (Guisasola and Morentin, 2007). However, we must consider that it would not be right to relate an obligatory learning context to formal learning methods, with which, we must also differentiate the contexts of the methods (Garmendia and Guisasola, 2015). With these premises, non-formal learning may occur in compulsory school contexts in ways that enrich formal school science with other aspects (Banks et al., 2007).

Different researches have shown that simply presenting interesting and/or spectacular proposals does not have to lead to learning. It may be that the situation presented to students seems abstract and/or they may feel an inability to interpret the phenomenon presented to them and this could generate frustration in students and feed the feeling that science is difficult.
Therefore, it is necessary to look for a relationship between the scenario and the content (Kortland, 2007). Taking this reference, two concepts were chosen that are present in the primary curriculum (Curriculum Vasco Heziberri, 2016), the concept of force and the concept of density.

In this non-formal school context, a science initiation workshop has been designed and implemented in the form of a scientific inquiry for 3rd grade on force and density, which we describe in more detail below

**METHODOLOGY**

**Design and implementation of the workshop**

The workshop was developed in the Langile Ikastola of Hernani. The participation of the families is key in the development of the objectives of this school. Families are invited to participate in some workshops together with teachers. The workshops are held on Friday afternoons, during school hours and have a duration of 1.5 hours. In the 2015-2016 academic year in the 3rd year of primary education, 7 workshops were held simultaneously (with 7 repetitions) in which all the students of the course participated, three groups (72 students). The tutors made 7 heterogeneous groups of 10 or 11 students, made up of students of the three groups with the same number of girls and boys. The workshop was led by a researcher of the group and the tutor of one of the groups of 3rd grade who participated in the workshops. Similarly, the teacher made 3 subgroups for each intervention.

Each group worked independently following the report. This, in addition to be the guide of the workshop, served as a workbook and was collected as evidence for the subsequent analysis of the intervention. Also, a voice recorder collected the interventions of each of the working groups. The teacher and the researcher guided the work through guiding questions explanations of practical but not with conceptual questions, with the aim of encouraging the argumentation.

The guide that was given to the students had two distinct parts, one about the nature of force and the other about density. Both parts contained the same sections, detailed in Table 1.

| Table 1. Sections and contents of the guide / student's book of the initiation workshop to science. |
|---|---|
| **WHAT CAN I DO TO MOVE SOMETHING?** | **HOW MUCH FORCE DO I HAVE TO DO TO MOVE SOMETHING?** |
| **Objective** | The force appears in pairs (it is exerted on one body by another) | The force that must be done to move an object depends on its weight, not the volume |
| **Before starting** | - Can I move something without touching it? | - It orders from major to minor by the force necessary to move the boxes. |
| | - ¿ If I kick the air, I do a force? | |
Preparing the experiment

Build small boats with masts of metal and wood.

Familiarization with the dynamometer, the balance and the table as an instrument to take data.

<table>
<thead>
<tr>
<th>Force to move</th>
<th>Weight</th>
</tr>
</thead>
<tbody>
<tr>
<td>Green (Big)</td>
<td></td>
</tr>
<tr>
<td>Orange (medium)</td>
<td></td>
</tr>
<tr>
<td>Red (small)</td>
<td></td>
</tr>
</tbody>
</table>

Doing the experiment

Although the magnet has approached all the ships have not all reacted equally, why?

In search of an explanation. Is the hypothesis confirmed?

- Has the hypothesis been confirmed?

Conclusions

- Is one magnet enough to make a force?
- If you are playing football, but you fail, and you do not hit the ball, have you exerted any force?
- What do you need to move something with a force?
- The size of the boxes has any relation to the force that must be exerted on them to move them?
- What do you have to fix to predict how much force you must do to move something?

To validate the design, in addition to considering the theoretical framework and selecting concepts based on the curriculum, the researchers designed an initial version of the workshop choosing some activities already validated in previous researches (Morentin, 2010). The first sketch of the design was presented to a group of primary teachers of the school, who proposed changes. In addition, the first two sessions were used to verify that the procedure was correctly understood, and the times were adjusted.

The case study

The analysis of the data has been qualitative and based on the case study. Voice recordings and written reports from four groups of 21 groups have been analyzed. Taking into account that all groups were heterogeneous, the groups with the highest number of interventions were selected from each of the sessions from the 3rd to the 6th, in this way it has been possible to obtain as much information as possible from four cases (Stake, 1994). The first two sessions were
discarded, since they were used to make adjustments in the design of the intervention and the last one because it was a special session and a little out of the usual because it was the last one.

The data have been examined and ordered according to the three initial objectives of the investigation and in relation to these, the description of the cases and conclusions has been developed (Yin, 2003). The presented data has limitation taking into account that the data has not been submitted to a statistical analysis (Devetal, Glazar, & Vogrinc, 2010). This study presents an explanatory approach that describes the process according to the objectives (Bryman, 2004).

RESULTS

The data were collected from the reports, the transcriptions of the recordings and the notes of the implementations. In the first section we will study how the students approach the scientific methodology, in the second, how the understanding of the concept of force evolves and finally, how they identify the concept of density.

How do you deal with scientific methodology?

Students have had difficulties formulating hypotheses; either they were afraid of doing it wrong or after seeing that their hypothesis was not fulfilled, they changed the initial hypothesis. The important thing for them, is usually that the answer is right and wait for the teacher.

Group C, in the second part of the workshop when they have to check if the density hypothesis has been met:

Teacher- Then your hypothesis has been fulfilled?
C1- no, because I have said that "you cannot know".
C2- Can I change it?
C3- option c, has not been fulfilled because we have said that "you cannot know".
Teacher - but you said it depends on the weight.
After a time, the group again calls the teacher and the researcher
C1- so, what do we have to put here?
Teacher - If your hypothesis has been fulfilled?
C2- yes
Teacher - you said you cannot know.
C2-yes, but…
Researcher - after deleting it ... Is not that cheating?
C2- excuses…
Teacher - But what have you put?
C1- you cannot know
Teacher - you have said that you cannot know although it is true that you have argued very well later.

Some of the experimental procedures have been new, for example, the use of dynamometers or tables to collect data.

Using the dynamometer to measure. The researcher asks how much force they have made, and they begin to become familiar with reading on the metric scales.

D3- Look how easy it moves, with super little force
Researcher - But how much? I have not told you much or little. You must see where the red line is when the box starts to move
D3- cero.
Researcher- I do not think so ... proof again, where the line is when it starts to move.
D3- Umm... Here
Researcher - Where is “Here”
D3- between 0.5 and 1

**How does the concept of force evolve?**

The evolution of the concept of force has been studied by analyzing the first part of the workshop (column 2, Table 1). Before explaining about the experiment, all groups state that 'something can be moved without touching it’ in the form of hypotheses, although only the first group refers to magnets. The rest of the groups put wind as an example, giving it immaterial character.

Group A answers the question: can we move something without touching it?

A1-yes
A2- yes with the air.
A1- yes with the wind yes, with the wind if you do puff (blows)
A2- look at a rubber eraser without doing anything ... (and it blows)
A4- yes, with the wind.

Once the task is explained, all groups can identify that boats that have pins to hold the sails are going to interact with the magnet. It is significant that while group A and C say that they are going to move, group B and D express that the ships are going to fly. Likewise, they say with total certainty that the ships planned with wooden masts will not move.

Group B are discussing whether their initial hypothesis has been met
Researcher- so, do these boats move?
B1- Yes, the boats with metal move.
Researcher - And the others, those who do not have the needle?
B1, B2- No.
Researcher - So?

B2 - What I said will happen (she refers to the previous hypothesis).

Researcher - Okay, so some of them approach and the others do not, why do you think that's the case?

B1, B2 - Because they have a magnet.

Researcher – explain me what happens?

B1 - the boat goes up.

When the groups begin to look for the explanation of what happens we observe that the evolution on the concept of force is unequal. While groups A and D have found it more difficult to conclude that force appears in pairs, groups B and C have been able to come to generalize more. This has been reflected in two questions. When asked if a magnet was enough to make force, all groups have clearly seen no, that the magnet-iron interaction was needed. When attempts have been made to generalize this to the case of kick and ball, groups A and D have had more difficulties. In the end, everyone has come to a satisfactory conclusion.

Researcher - It is possible to make a force only with the magnet or only with the leg.

D1 - yes

D2 - no

Researcher - you must give an explanation. What is necessary to move something according to a force?

D2 - two magnets

Researcher - two magnets, or

D4 - two legs

Researcher - and for the ball and the leg. What happens?

D2 - aiming?

Researcher - just aiming! you must give ball no?

D3 - I’m going to write aiming.

D2 - aiming and force.

Researcher - are both needed? The magnet and the needle, the leg and the ball...

D1, D2 - ok

D2 - if I write, that the magnet and the needle both are needed is it ok?

Researcher - for example.

How does the concept of density evolve?

As far as the density concept is concerned, an experiment has been proposed where objects of different sizes are used with weights that do not agree with the size. They have then been asked
to move them and to measure the force by means of a dynamometer (column 3, Table 1). In the beginning, only group C has been able to indicate the correct hypothesis. Group A on the other hand, although it has indicated that they will need the same force, uses valid arguments, since to their understanding all have the same weight. Finally, the other groups have been carried away by the size of the boxes and in their arguments, they do not speak of the weight.

Group A are discussing about which box will need the biggest force to move.

A1- The same, because at the end, although the boxes are different, and this is bigger, the same weight could have what is inside.

A2- Could be...

A1- All boxes have the same thing inside, therefore, even if the box is larger. The necessary force is the same.

A2- then what have we to write?

A1-The option all the same, because they are all the same.

Once the experiment is done and the measurements are carried out, all are able to conclude that the force required to move the boxes depends not on their size but on their weight. In turn, they have concluded that without measuring the mass of an object one cannot know how much force must do to move it.

Group D answers the questions with the help of the teacher

Teacher- Now the experiments done and looking the three boxes in front of you, you believe that the force will have to be: Big force for the big box, medium force for the medium box and small force for the small box?

D1- It is true that medium size box needs medium force.

Teacher - Okay, but how did you classify the others?

D2- (small (biggest force), medium, large (smallest force)) That's what we've put.

Teacher - And why do we need more force to move the small box.

D1- Because it has a ball inside.

D2- Because it has a lot of weight inside.

D3- Because it has more weight inside.

Teacher - Okay, perfect, write it down.

CONCLUSIONS

In reference to the objectives that were stated at the beginning and following the analysis of the data obtained in this case study, the following conclusions can be drawn.

In general, these activities of the workshop (not formal in the school context) have led the students to approach the scientific methodology and begin to know scientific skills and data collection and/or use of material. Although this approach has helped them to evolve positively,
they have shown some difficulties, especially in the formation of hypotheses according to previous studies (Guisasola, Ceberio, Zubimendi, 2006).

In all groups, with more or less difficulties, there has been an evolution in the understanding of the concept of force. The experiment has brought students to understand the key concept, the need for the interaction of two objects, to advance their understanding of the concept of force.

Regarding the concept of density, students have been able to relate directly the force necessary to move an object with the mass it has. Students have understood that the size of the object is not directly related to the mass they have and therefore, the force necessary to move it.

Despite the limitations of this work, it seems that the design and implementation of research-based workshops, they can help the students to know better the scientific procedures besides to improve the understanding of the concepts. The results suggest that this type of non-formal intervention can be an important support for the work of teachers in formal education.

INTEREST IN BIOLOGY AND KNOWLEDGE ABOUT ANIMAL SPECIES DIVERSITY ON DIFFERENT CONTINENTS AMONG YOUNG LEARNERS FROM SLOVENIA

Gregor Torkar and Luka Praprotnik
University of Ljubljana, Faculty of Education, Ljubljana, Slovenia

Preschool and primary school learners’ knowledge about animal diversity on different continents was examined in relation to their interest in biology. The additional aims were to find out the influence of gender and age on their interest in biology and knowledge about animals on different continents. Altogether, 198 young learners from Slovenia, aged 5 to 12, were interviewed. The study findings show that participants have relatively high interest in biology, but no significant correlations were found between their interest in biology and the total number of known species, neither for the number of known species on any of the continents. Results show significant positive correlation between learners’ interest in biology and knowledge about bird species diversity and no correlations between learners’ interest in biology and knowledge about mammals, reptiles, amphibians, fish and invertebrates. No gender differences were detected. Older learners named more animal species than younger ones. There were no gender or age differences in their interest in biology.

Keywords: interest in biology, knowledge, animal species

INTRODUCTION

At the present time a significant number of animal species are in danger of extinction. There are multiple causes for this threat to biodiversity, but human indifference to the situation and negative attitudes towards at least some species are undoubtedly among them. It has been estimated that from prehistoric times to the present, humans have probably eliminated more than 10% of animal species, and a similar proportion of existing species are currently in danger of extermination (Wilson, 1993). Teaching about species diversity is important to raise public awareness about conservation of nature (Barney Mintzes, & Yen, 2005). Biodiversity is defined as species diversity, species variations or genetic factors, as well as variations in the occurrence of the living organisms depending on their habitat, ecosystem and the ecological complexes in which they occur (Convention on Biological Diversity, 1992). The United Nations General Assembly (UNGA) declared 2011–2020 the United Nations Decade on Biodiversity to support and promote implementation of the objectives of the Strategic Plan for Biodiversity and the Aichi Biodiversity Targets, with the goal of significantly reducing biodiversity loss (UNGA, 2011).

A comparative case study from four European countries showed that primary school teachers integrate at least some information on the scientific aspects of biodiversity, but they rarely include the controversial nature of biodiversity conservation in relation to economics, ethics, social and political concerns (Lindemann-Matthies, Constantinou, Junge, Koehler, Mayer, Nagel, Raper, Schuele, & Kadjí-Beltran, 2009). van Weelie and Wals (2002) emphasized that biodiversity is an abstract and complex construct that is difficult to teach, and so teachers give preference to species diversity as their focus when teaching about biodiversity. It is important
that children and adults possess knowledge and experience of organisms and their environments. In this study, Slovene young learners’ knowledge about animal diversity on different continents in relation to their interest in biology and animals was addressed. In the following literature overview, we discuss these aspects.

LITERATURE REVIEW

Interest in Biology and Animals

Researchers recognized interest as one of the most powerful variables in explaining achievement and motivation in learning (Hidi, 2006; Schiefele, Krapp, & Wintelar, 1992). Interest is also an important aspect of intrinsic motivation (Deci & Ryan, 1985). Klose (1997) pointed out that learners interested in a thing more easily acquire new knowledge in their attempt to integrate it into already existing. Interest is therefore a condition and an objective of successful learning processes. Studies in science education revealed that students are usually more interested in biology than other science subjects (Osborne, 2003; Ramsden, 1998). Ramsden (1998) reported that there are differences in pupils’ attitudes toward physical and biological sciences, with physical sciences appreciably less popular than biological sciences. Uitto, Juuti, Lavonen and Meisalo (2006) report gender is an important factor predicting Finish pupils’ interests and attitudes towards science, with boys being more interested in physics and girls in biology. In addition, the grades of girls in biology and geography were significantly higher than those of boys, but the reverse was found in physics (Uitto, Juuti, Lavonen, & Meisalo, 2006). Interest in animals fades as children get older (Lindemann-Matthies, 2005; Prokop, Prokop, & Tunnicliffe, 2007; Prokop, Tuncer, & Chudá, 2007; Prokop & Tunnicliffe, 2010) and girls express a greater interest in biology than boys (Dawson, 2000; Prokop, Prokop, & Tunnicliffe, 2007; Prokop, Tuncer, & Chudá, 2007; Uitto, Juuti, Lavonen, & Meisalo, 2006). Uitto, Juuti, Lavonen and Meisalo (2006) found that girls were more interested in biology, especially in the context of human biology and health education. Only in the context describing basic processes in biology (i.e. functions of cells or food web) did more boys find interesting. However, some studies found no gender differences in the interest in biology (Uşak et al., 2009). Some studies were investigating students’ interest in specific groups of animals, like amphibians (Randler, Ilg, & Kern, 2005) and birds (Prokop, Kubiaková, & Fančovičová, 2007a; Hummel, Ozel, Medina-Jerez, Fančovičová, Uşak, Prokop & Randler, 2015), or sub-disciplines, like zoology and botany (Baram-Tsabari & Yarden, 2005; Randler, Osti, & Hummel, 2012). For example, a cross-cultural study (Hummel et al., 2015), including countries from different continents, showed that girls had consistently higher interest in birds than boys. High interest is believed to lead to high academic achievement (Hummel & Randler, 2012; Randler & Bogner, 2007). But Hummel et al. (2015) found that factual knowledge about birds is not a necessary prerequisite for interest in birds.

Knowledge about Animal Species Diversity

Examining the acquisition of learners’ subject knowledge is important for designing an appropriate range of learning experiences (Palmer & Suggate, 2004). Children, from their earliest years, gain their knowledge and experience of the animals in the everyday environment where the children live and attend school. This knowledge is not necessarily gained from
formal education (Kellert, 1985; Tunnicliffe & Reiss, 1999, 2001), which may serve simply to amplify and extend existing knowledge (Tunnicliffe, 2011). Children notice animals in the real world, in the media, both electronic and paper forms, as well as in representations in household items such as wallpaper for children and soft toys (Tunnicliffe, Gatt, Agius, & Pizzuto, 2008). Children have various relationships with animals in their everyday lives. Experience obtained in interactions with pets (Prokop, Prokop, & Tunnicliffe, 2008; Geerdts, Van de Walle, & LoBue, 2015), domestic, farm, and exotic animals, and through school field trips to museums, farms, zoos, and field/nature centres (Tunnicliffe, Gatt, Agius, & Pizzuto, 2008, Tunnicliffe & Reiss, 1999; Tunnicliffe, Lucas, & Osborne, 1997). Tunnicliffe, Lucas, and Osborne (1997) report that when children look at animals as exhibits remark out loud about the salient features of the animals they see, such as a leg, a shape, bits that stick out and colour, as well as any behaviours observed at the time. Moreover, children also acquire understanding and knowledge from the society in which they live: from caretakers, various artefacts, and the media (Russell, 1993).

Genovart, Tavecchia, Enseñat and Laiolo (2013) found that children recognize exotic species better than local ones. Similarly, Yli-Panula and Matikainen (2014) reported that Finish secondary school students knew the best animal diversity of the savannah. Children in developed countries know exotic species well, because they come in contact with them in zoos and outdoor centres (Patrick & Tunnicliffe, 2011). Palmer and Suggate (2004) examined UK children’s responses to the question about what might live in rainforests and polar places. They found that children have some knowledge about distant environments as early as 4 years of age and there was a general increase in the number of children able to demonstrate accurate knowledge about animals living in distant environments of about 10% per annum. The average number of correct animals per child increased from 1.6 for the 4-year-olds to three for the 10-year-olds. In another study, Prokop, Kubiatko and Fančovičová (2007) showed that 7–15-year-old children’s knowledge about birds is inconsistent and that many of them have various misunderstandings about bird biology and systematic. Huxham, Welsh, Berry and Templeton (2006) found that boys had higher wildlife knowledge than girls. On the contrary, Randler (2008) reported slightly higher level of animal knowledge in girls.

**Education about Animals in the Slovenian School Curricula**

Slovenian primary and lower secondary education is organised in a single-structure nine-year school for students aged 6 to 14 years. In the educational system children in kindergarten, pupils and lower secondary school students are mainly taught about animals native to Slovenia and to some extent about animals that live in exotic ecosystems. Children are taught about the basic grouping of organisms in school (taxonomy). In addition to the study of the ecosystems and species diversity in relation to their living ecosystem, also conservation of species is in focus. In primary and lower secondary schools described learning objectives are mainly achieved in the school subjects Environmental Studies (Years 1-3), Science and Technology (Years 4-5), Science (Years 6-7), and Biology (Years 8-9). There is a lot of emphasis on hands-on activities in these subjects, including fieldwork, experimental and laboratory work. In addition, elective school subjects (offered to students in Years 7-9, 35 hours each) upgrade and expand the knowledge and experience students have acquired during compulsory science
subjects. Among biology electives the Organisms in Natural and Artificial Environment subject is the most popular one.

AIMS AND RESEARCH QUESTIONS

In previous work, we showed that Slovenian learners know best animal species living in Africa and Europe. They possess several misconceptions about animal species ranges, such as those of penguins and tigers. Boys named reptiles more often and amphibians less often than girls (Torkar, & Mavrič, 2016). The aim here was to report the Slovenian learners’ knowledge about animal diversity in Europe, Africa, Asia, Oceania, South and Central America, and North America in relation to their interest in biology. In literature overview no study was found focused on their interest in biology in relation to knowledge about animal specie’s area of origin. The research questions that guided this study are as follows: (1) How is young learners’ interest in biology related to their knowledge about animal species diversity on different continents? (2) How is their knowledge of specific group of animal species related to their interest in biology? (3) Does gender and age affect their interest in biology and a total number of named animal species on different continents?

METHODOLOGY

Quantitative studying of young learner’s perceptions is difficult, especially when trying to compare results with older children and adolescents. This study, therefore, should be regarded as explorative and tentative.

Participants

Because of its exploratory character, this study did not include a random sample of Slovene preschool and primary school children. Altogether, 198 young learners from Slovenia participated in the study. The participants were between 5 and 12 years of age. Of the participants, 99 were boys and 99 girls. The children attended a variety of preschools and primary schools in central part of Slovenia.

Data Collection and Instrument

Participants were interviewed via a questionnaire in preschools and schools. They were asked to name three species of animals for each of the six continents (Europe, Africa, Asia, Oceania, South and Central America, and North America). The second part of the questionnaire consisted of five items designed to reveal their interest in biology (i.e. visiting natural environments to observe animals and plants, watching documentaries and reading books about animals, visiting farms and zoological gardens to see animals, and learning about animals and plants in (pre)school, and dislike plants). These items were selected according to the findings of previous studies (e.g. Barbas, Paraskevopoulos, & Stamou, 2009; Prokop, & Tunnicliffe, 2010; Uittov, Juuti, Lavonen, & Meisalo, 2008) and developmental characteristics of the participating learners aged 5 to 12 (i.e. reading literacy).

In addition, learners were asked to name their most frequent source of information about animals and some demographic questions. Closed- and open-ended questions were used. The questions were presented in Slovenian. The face-to-face interviews were carried out by
university students (from Faculty of Education, University of Ljubljana) during their teacher training in preschools and schools. The questionnaire took approximately 10 minutes to complete. Interviews took place in winter 2012–13. The ethical rules in social science research were considered. Rules of confidentiality, information, autonomy and voluntary participation were followed.

Data Analysis

Descriptive and inferential statistics were used to answer research questions, employing the Spearman’s rank correlation coefficient, the Shapiro-Wilk W test of normality, and the Mann–Whitney U test. SPSS 20 was used for statistical analyses.

FINDINGS

The descriptive data regarding learners’ knowledge of species from different continents is presented in Table 1. Animals from Africa and Europe were the best known among learners. Almost one-third of them did not give answers listing animals from South and Central America. Altogether, participants named in 2299 animals, mostly mammals (75.9 %), followed by reptiles and birds (Table 2). Figure 1 presents three most frequently mentioned animals from each continent. For more detailed analysis about their knowledge of animal species by continents and misconceptions see Torkar and Mavrič (2016).

Figure 1. Most frequently mentioned animals from different continents.

Participants showed high interest in animals and biology (Table 3). Most of them agreed with the statements that they like to visit farms and zoological gardens to see animals (89.4 %), to learn about animals and plants more than other school topics (93.8 %) and to visit grassland, forests, rivers and lakes where they can observe animals and plants (94.3 %). Next, 82.5 % of learners like watching documentaries and reading books about animals. The lowest was their support of the statement that they do not like plants (17.5 %).

The main aim was to find out if young learners’ interest affects their knowledge about animal species diversity on different continents. Internal consistency for five described items representing interest in biology (Table 3) using Cronbach’s alpha was poor (α = .51), therefore, the effect of each individual statement representing their interest in biology was analyzed. No significant effect was found between their interest in biology and the total number of known
species ($r_s = .077, p = .279$), neither for the number of known species on any of the continents: Europe ($r_s = .043, p = .562$), Africa ($r_s = .034, p = .636$), Asia ($r_s = .037, p = .654$), Oceania ($r_s = .051, p = .497$), South and Central America ($r_s = -.008, p = .928$), and North America ($r_s = .111, p = .171$). From Table 2 is clear that participants do not know all the groups of animal species equally well. It could be expected that this is correlated to their interest in specific groups of animals and that this would result in higher number of listed species from that group. However, results show significant positive correlation between interest in biology and knowledge about bird species diversity ($r_s = .138, p = .027$), and no significant correlations for mammals ($r_s = .084, p = .240$), reptiles ($r_s = -.086, p = .229$), amphibians ($r_s = .019, p = .795$), fish ($r_s = -.088, p = .218$), and invertebrates ($r_s = .059, p = .408$).

The Shapiro-Wilk W test showed that the variable distributions are different from normal. The nonparametric test for independent samples (Mann–Whitney U test) was to measure the effect of each of the five items representing learners’ interest in biology. Statistically significant effects are presented in Figure 2. Results show that learners interested to go to natural environments to observe animals and plants named more animal species from Africa and Oceania. They also named more bird species than learners less interested to go to natural environments to observe animals and plants. Secondly, those who disliked plants named less bird species. Next, participants visiting farms and zoological gardens named more amphibian species. Lastly, those who prefer to learn about animals and plants more than other school topics named more reptile species.

![Diagram of continents and interest in biology](image)

**Figure 2.** Results for the nonparametric Mann–Whitney U for independent samples showing the significant effects ($\alpha = .05$) of learners’ interest in biology (codes are presented in Tables 1, 2 and 3). Significant positive effect = full arrow / negative effect = dashed arrow.

Next, gender and age differences for interest in animals and knowledge about animal species diversity on different continents were investigated. The nonparametric test for independent samples showed no statistically significant differences between boys and girls in their interest in biology ($MW = 4085.50, p = .080$) and total number of named species on different continents ($MW = 4659.00, p = .546$). Age of participants was in no significant correlation to their interest
in animals \((r_s = -0.059, p = .412)\) and in weak correlation to the total number of named species on different continents \((r_s = .374, p < .001)\), in favour of older learners.

**DISCUSSION AND CONCLUSION**

A literature review reviled that interest in biology and other scientific fields is an issue frequently studied in recent years because of its important role in learning process. Research findings show that majority of interviewed learners agreed that they like to visit farms and zoological gardens to see animals, they like to visit grasslands, forests, rivers and lakes where they can observe animals and plants, and they like watching documentaries and reading books about animals. Most of the learners also agreed with the statement that they like to learn about animals and plants more than other school topics. Similar studies in science education revealed that learners are usually more interested in biology than other science subjects (Osborne, 2003; Ramsden, 1998).

In the first research question the effect Slovenian learners’ interest in biology has on their knowledge about animal species diversity on different continents was examined. Learners had relatively high interest in biology, which was measured with above described five items. No significant correlations were found between their general interest in biology and the total number of correctly named animal species, neither for the number of named species on any of the continents. This could be explained with high percentages of interviewed young learners interested in biology. More detailed analysis revealed that young learners interested to visit grasslands, forests and other natural environments in order to observe animals and plants named more animal species from Africa and Oceania. This seems very unusual correlation; however, for example Uitto, Juuti, Lavonen and Meisalo (2006) also reported that out-of-school experiences of nine-grade students in science and technology-related activities had surprisingly high correlation with an interest in basic processes in biology, such as cell biology. These findings have important implication for biology education. It gives support to regular experiences in nature which may enhance learners’ interest to study biology and biology related topics. Many studies suggest high importance of outdoor learning for students’ cognitive, affective, physical and social development (Rickinson, Dillon, Teamy, Morris, Choi, Sanders, & Benefield, 2004). Children need regular contact with the natural environment in school context, especially those children who do not have access to nature as part of their everyday lives (O’Brien, 2009).

Children thus have a considerable knowledge of the nature around them from personal first-hand observations, both real and virtual (Tunnicliffe, 2011). In the present study, majority of mentioned animals were mammals. This applies to all the continents except South and Central America, where the most mentioned group of animals were reptiles. In previous studies researchers also found significant differences in learners’ knowledge about various groups of animals (e.g. Palmer and Suggate, 2004; Genovart et al., 2013; Lindemann-Matthies, 1999; Yli-Panula, & Matikainen, 2014). Lindemann-Matthies (1999) stated that the children’s observations of the species reflect their preference to certain animals, which are mainly mammals. Yli-Panula and Matikainen (2014) investigated ability of secondary school students and student teachers to name animals to the four selected ecosystems. Authors reported that students knew animals living in the four ecosystems, especially mammals and birds.
One significant positive correlation between interest in biology and knowledge about bird species diversity was found, and no correlations for mammals, reptiles, amphibians, fish and invertebrates. In addition, more detailed analysis revealed that learners interested to go to natural environments to observe animals and plants named more bird species, and those who disliked plants named less bird species. Participants who visit farms and zoological gardens named more amphibians. And those who liked the most learning about animals and plants in (pre)school named more reptiles.

Our third research question was how gender affects studied variables. Boys and girls did not differ in their interest in biology or in total number of named species on different continents. Gender differences are the most commonly measured variable in relation to interest in biology. Most of the studies confirm that girls have higher interest in biology than boys. Uitto, Juuti, Lavonen and Meisalo (2008) emphasize that boys and girls may be interested in different content and contexts of biology, which should be considered when teaching biology.

In the last research question the age effect was examined. Some studies, like Prokop and Tunnicliffe (2010), found that as learners grow older their interest in animals decreases. In the present study age of participating learners was not significant variable, but the total number of named species from different continents was significantly higher among older learners. Similarly, Kellert (1985) and Randler (2008) showed that learners’ animal species knowledge increased with age. Study by Balmford et al. (2002) showed that after the age of 14 knowledge decreases.

The data obtained in the present study are important to consider when teaching topics about various biomes on Earth and the conservation of biodiversity. When planning lessons with biological topics, it is important to build on learners’ previous school and out-of-school experiences (i.e. formal and non-formal education) and nurture high interest in animals and biology learners have from their earliest years.

¹University of Cambridge, Cambridge, UK
²University College London, London, UK

The concept of matter is considered to be a fundamental concept for achieving scientific literacy, while students developing an understanding of its particulate nature is one of the prominent targets of chemistry curricula. The present study sought to examine how young children understand liquids (water) and solids (sugar) and their composition, and how these understandings progress through primary school. A sample of 108 children of four different year-groups (n = 27 5-year-olds, n = 27 7-year-olds, n = 27 9-year-olds, n = 27 11-year-olds) in the United Kingdom were interviewed using a structured interview protocol adopted from Nakhleh and Samarapungavan (1999). The findings suggest that young children start understanding materials in terms of their perceptual properties and their functions and properties in daily life, and as they grow older they attend to their composition and chemical properties. In terms of composition, children showed different conceptual progression patterns for sugar and water. They developed a better understanding of water, progressing from a continuous view of matter to the view that it is composed of invisible pieces of different shapes and sizes, while most of the children in all year-groups understood sugar as composed of visible pieces. A molecular understanding of matter did not emerge during the primary school years, something that is not surprising as primary school children in the UK are not formally instructed about the particle model. Even within the same year-group, there was significant variability in students' understandings of the materials and their progress did not appear to be a linear process.

Keywords: matter, understandings, qualitative

INTRODUCTION

This study seeks to explore primary school children's progress in understanding materials and their composition. Developing an understanding of the concept of matter and its particulate nature is considered to be one of the fundamental targets of chemistry curricula (Harrison & Treagust, 2002; Krnel, Watson & Glažar, 2005). However, a number of studies focusing on students’ understandings of matter indicate that students fail to acquire a deep understanding of its particulate nature and do not use it in a consistent way when they are asked to explain chemical phenomena (Liu & Lesniak, 2006; Nakhleh & Samarapungavan, 1999; Nakhleh, Samarapungavan, & Saglam, 2005; Talanquer, 2009). Consequently, research on how and when children start to develop an appreciation of the particulate nature of matter could lead to several recommendations for teaching practice and policy-making. Research during the last decade has moved from identifying and categorising learners’ conceptions and understandings about matter to examining their progression in understanding matter (Hadenfeldt, Liu & Neumann, 2014). Adding to this body of literature, this study aims to contribute to the
knowledge of how young children develop their understanding of matter using a much larger sample size than typically used and focusing on children as young as 5 years old.

LITERATURE REVIEW

Researching understandings

Although there are different terms used to describe them (e.g. ideas, beliefs, understandings, misconceptions, alternative frameworks), understandings can be seen as an inclusive term which includes, but is not limited to intuitive ideas and alternative conceptions. Students’ understandings of scientific concepts have been extensively studied in science education research, however the field still lacks a shared definition as understanding is a very complex construct (Taber, 2013; White and Gunstone, 1992). Most of the scholars seem to agree that it is multidimensional - as it depends on the quantity and kind of things a person knows, how the ideas/beliefs/experiences are connected with each other, etc., and it is a personal construct and thus not directly accessible to others (Barlett, 1932; Nickerson, 1985; Smith, 1991).

These aspects of understanding pose significant implications for how we study it. The researcher cannot merely depend on the person’s responses but rather tries to interpret their responses and behaviour in order to reach more valid conclusions (Newton, 2000). For the purpose of this study, understanding is considered to be a multidimensional and personal construct that can be captured on an individual level. This view of understanding adopted, aligns with our research goal, namely to explore the different ways children understand materials and their composition, as well the different meanings they attach to them.

Understandings of materials

Many researchers have examined how students initially understand or describe materials and how these descriptions change with time (e.g. Liu and Lesniac, 2006; Nakhleh & Samarapungavan, 1999, Solomonidou & Stavridou, 2000; Stavy & Stachel, 1985). The findings have shown that students develop initial understandings of materials that are inconsistent with scientific models, based on their personal experiences (Krnel, Watson, & Glazar, 1998; Stavridou & Solomonidou, 1998) and that these conceptions later impact the comprehension and learning of chemical concepts (Solomonidou & Stavridou, 2000).

Russell, Longden, and McGuigan, (1991) examined 5- to 11-year-old students classifying materials into groups and found that students used five main criteria (function, location, perception, composition and made by). Younger students used the composition criterion (what the material is made of) and perception criterion (perceptual characteristics) to classify the substances, while older students used the composition and function (how it is used) criteria more frequently.

Nakhle, Samarapungavan and Saglam, (2005) examined nine middle school students’ developing understandings of the nature of matter and found that students spontaneously described materials (sugar-presented as sugar cubes, wood-presented as toothpicks, copper-presented as wires, water and helium) in terms of macroscopic properties (function, visual properties, shape, texture) and microscopic properties (molecules, atoms). Most of the students (eight out of nine) used macroscopic properties to describe materials. Similarly, Liu and
Lesniak (2005) concluded that students’ spontaneous descriptions of the substances develop from overlapping categories of uses and benefits, physical properties and perceptual characteristics to chemical properties (a base, an acid, used in neutralizations) and finally to the particulate model of matter. The progression patterns for the three materials they used were unique (water, baking soda, vinegar), but given the small sample sizes it is difficult to separate differences between the materials from individual variability.

In summary, it seems that students of all ages describe materials in terms of their perceptible properties and uses/benefits drawing upon their personal experiences. Older students make use of some physical and chemical properties to describe them and in later years they use the composition of matter in their descriptions. However, due to the different terminology and coding schemes used in the studies reviewed it is hard to reach to a robust conclusion as to how their understandings progress and more systematic research is needed towards this direction.

**Understandings of the composition of matter**

Over the last decades there have been numerous studies in both the fields of cognitive science and science education that have reported on students’ conceptions of the physical world (Talanquer, 2009). One of the most researched concept areas in this enterprise is the particulate nature of matter because an understanding as well as the ability to utilise this model effectively in everyday situations and explanations of chemical phenomena is a primary goal of school science (Harrison & Treagust, 2002; Krnel, Watson & Glazar, 2005; Lofgren & Hellden, 2009). The particulate nature of matter is a suitable research domain for examining what young children of primary school age can understand of science, as it relates to phenomena that they will have observed in their everyday lives (e.g. states of matter and dissolving) (Nakhleh & Samarakunagavan, 1999). An on-going debate in the research community concerns the early introduction of the particulate nature of matter in schools and there are studies supporting both sides of the argument, either in favour (e.g. Novak & Musonda, 1991; Papageorgiou & Johnson, 2005) or against (e.g. Fensham, 1994; Harrison & Treagust, 2002). A detailed examination of what young children are capable of grasping and how they understand materials could offer valuable insight into this debate.

Various researchers have tried to explore how students, from primary school to university, progress in understanding the concept of matter (e.g. Crespo & Pozo, 2004; Ferk, Vrtacnik, Blejec & Gril, 2003; García Franco & Taber, 2009). Liu and Lesniak (2006) characterised children’s conceptual progression on matter as multifaceted, contextual and dynamic. They interviewed 6- to 16-year-old students (n = 9 Grade 1; n = 5 Grade 2, n = 8 Grade 3, n = 5 Grade 4, n = 5 Grade 5, n = 6 Grade 6, n = 6 Grade 7, n = 4 Grade 8, n = 6 Grade 10) on their understandings of water, baking soda and vinegar in three areas: description of substances, composition of substances and dissolving. They found that all three areas are interrelated and overlapping, while there is not a common conceptual path students follow. More specifically, they reported that students generally tend to progress from understanding the composition of materials/substances in macroscopic terms, to also understanding them in sub-microscopic terms but that they seem to have more developed conceptions of water than sugar and baking soda. Although Liu and Lesniak have provided a very detailed description of students’ understandings of matter and dissolving for a wide range of ages, it could be argued that in
order to reach robust conclusions in terms of how children progress in these categories, a larger sample would be necessary at each age, especially given that there may be differences between materials. With the small sample sizes used in previous studies one cannot be sure whether the difference found for different materials reflect idiosyncrasies of the few children studied, or whether they are true differences between the materials. With the large sample size used for the present study we can be a lot more definite about differences between these materials.

A similar study but on a still smaller scale is that of Nakhleh and Samarapungavan (1999) who examined children's conceptions about matter using materials/substances in all three states of matter (granular sugar, 'solid wood, copper wire, liquid water, and a helium-filled balloon) and across different processes (melting ice cube, phase change and dissolving). They interviewed 15 students from an urban primary school aged 7 to 10 years and they used a structured protocol containing both descriptive questions (description of substances and their composition) and explanatory questions (explanation of the phenomenon). They found that children's conceptions about matter are fragmented and they tend to have descriptive rather than explanatory belief systems. In terms of the spontaneous description, they reported that only a few children attended to microproperties (e.g. composition) while the vast majority described substances with macroproperties (e.g. shape, texture, taste, size). In terms of the composition of substances, nine children stated that they are made of little pieces in different pieces and sizes that are visible, three expressed a continuous view of matter (one big piece) and three expressed a molecular view of matter. The present study utilises the interview protocol of Nakhleh and Samarapungavan building on their findings and extending the research to a larger number of children and wider range of ages (5- to 12-year-olds). This age span is of particular interest as only a few studies have systematically focused on these year-groups (e.g. Krnel, Watson & Glažar, 2003; 2005)

Hadenfeldt, Liu and Neumann (2014), after a systematic review of the last decade's literature on progress in children's understandings of matter, suggested a five-level model that could describe students' progression in understanding the structure and composition of matter (Figure 1):

1) Students view matter as divisible but continuous and they do not use the particle concept in their descriptions of the structure of matter
2) Students understand particles as entities embedded in matter but they are not able to use this perception consistently in their explanations of matter.
3) Students understand particles as a 'building block of matter' and often attribute to them macroscopic properties, as they view them as the 'last divisible unit'.
4) Students can differentiate between molecules and atoms and describe particles utilising the differentiated atom model
5) Students are capable of explaining and describing the structure of complex molecules.
A similar model of how students progress in their learning of the structure of matter is described in Talanquer's (2009) study. Talanquer conducted an extensive review of studies within science education, cognitive science and developmental psychology in order to identify the implicit assumptions that constrain students’ thinking about the structure of matter. This model indicates that learners go through certain stages while developing their understanding. Novice learners view matter as *continuous* with no underlying structure and as they get introduced to the particle model they develop the assumption of *granularity* of matter (substances are made up of little pieces of the same material or they have atoms or particles *embedded*). The next stage is the corpuscularity assumption in which students conceive substances as a collection of same size and shape particles made of a distinctive type that are no more divisible. Only advanced learners assume that there is empty space between particles in a substance (*Vacuum* assumption).

Summarising, it seems that students' progression of understanding is not linear and it is unlikely to be the same for each student as it is dependent on the specific content and context of the task that students undertake (Hadenfeldt, Liu & Neumann, 2014). Thus, it is expected that there will be significant variability in students’ understandings of the composition of matter even within the same age group, something that makes the development of a learning progression model difficult (Talanquer, 2009). For this reason, it is important to conduct more research in this area and potentially develop any general conclusions about how students develop their understandings of the composition of materials. This research could be viewed as a response to Hadenfeldt, Liu and Neumann's (2014) open call for empirical evidence that could support or refine the aforementioned suggested model for investigating and potentially improving students' progression towards understanding matter. Based on the review of the literature focusing on 3- to 12-year-old students (e.g. Krnel, Watson & Glažar, 2005; Liu & Lesniak, 2005; Löfgren & Helldén, 2009) we would make the assumption that the vast majority of the participants in the present study would be categorised as Level 1 or 2.

**RESEARCH QUESTIONS**

The present study was framed by the following research questions:
- How do primary school children develop an understanding of materials over time?
- How does an appreciation of the particulate nature of matter emerge?

Although there are a large number of studies examining how students progress in understanding the composition of matter (e.g. Crespo & Pozo, 2004; Ferk, Vrtacnik, Blejec & Gril, 2003;
García Franco & Taber, 2009), few of them concern primary school children (Krnel, Watson & Glažar, 2005; Liu & Lesniak, 2005). Furthermore, as it is still an open question how children develop their understanding of the particulate nature of matter (Hadenfeldt, Liu & Neumann, 2014), more research is needed to support the existing models as to how children's understandings progress through time (e.g. Liu and Lesnak, 2006; Talanquer, 2009).

Considering that the development of an understanding of the particulate nature of matter is a primary goal in chemical curricula (Harrison & Treagust, 2002; Krnel, Watson & Glažar, 2005) and the research literature so far has mixed answers as to the age at which children can understand the particle model (e.g. Fensham, 1994; Harrison & Treagust, 2002; Novak & Musonda, 1991; Papageorgiou & Johnson, 2005) the second research question can provide meaningful insight in this direction.

**DESIGN AND PROCEDURES**

The research design of the present study was framed within an idiographic approach of research as the focus was on the unique individuals’ understandings of the concepts under study. Consequently, a cross-age qualitative survey research design was adopted using a structured interview protocol. The aim of qualitative survey is to determine the diversity of some topic, establish meaningful variation within a given population and provide depth and individual meaning to the topic of interest (Fink, 2003; Jansen, 2010).

The sample for this study consisted of 108 participants ($n = 27$ 5-year-olds, $n = 27$ 7-year-olds, $n = 27$ 9-year-olds, $n = 27$ 11-year-olds) from four primary schools in England. Students were of all achievement levels. The dataset was collected within the frame of Young Children's Reasoning about Everyday Chemistry project (Quinn, Ellefson, Schlottmann, & Taber, 2013). The project uses cognitive psychology paradigms and quantitative measures along with qualitative data to investigate young children’s chemistry reasoning. An overview of the qualitative results has been briefly reported in Quinn, Tsapali, Ellefson, Schlottmann, and Taber (2017). The project itself was approved by the University of Cambridge Psychology Ethics Committee in 2011 (Application No: 2011.48).

The interviews were one-to-one and took place in a quiet place in the schools. Children were showed a glass of water and a container with sugar. The interview protocol was adopted by Nakhleh and Samarapungavan, (1999) and included 12 questions on students' spontaneous description of sugar and water and on models of their composition. The first set of questions prompted children to spontaneously describe water and sugar (“This is water. Can you tell me about it? What is it like?”) while the second set aimed at capturing whether children view matter as one piece or made of little pieces and how they think these pieces are like (“What is water/sugar made of? Is it made of one piece or lots of little pieces? Think of the smallest pieces. Are they all the same or are they different? Can you see the smallest bits? What are the little bits like? What shape are they? Are they all the same shape?”).

In order to analyse the interview data, thematic analysis was used as introduced by Braun and Clark (2006). The analysis was conducted by author MT. The coding scheme was refined using an iterative procedure consisting of six stages and inter-rater reliability testing was conducted (90 per cent agreement). The two parts of the interview were coded separately: 1) spontaneous
description of materials 2) composition of materials. Eight and four main themes were identified, respectively, that fully captured the data-set. In order to increase the validity of the results, the findings were continuously tested, questioned and interpreted (Kvale & Brinkmann, 2009).

RESULTS AND DISCUSSION

Spontaneous description

Table 2 shows the themes and subthemes that derived from the thematic analysis supplemented by a summary description and examples. The themes are ordered hierarchically depending on the number of children who used one or more of the themes to describe the materials under question.

Overall, it seems that most children described materials based on what they can see and drawing upon their personal experiences with the substances. These findings are consistent with Stavy and Stachel (1985), who found that children of younger ages describe water in terms of its use and physical properties (e.g. falls, does not compress) and Solomonidou and Stavridou (2000), who reported that students initially describe substances drawing upon one or more of their perceptible properties. Also, a large number of children used their experiences from interacting with the substances to describe them (physical knowledge). Children of all grades described materials in terms of their perceptual characteristics, human use and physical properties a finding supported by Liu and Lesniak (2005).

Figure 2 shows how children's spontaneous description of materials progress through time. 5-year-olds mostly described substances in terms of their perceptual characteristics and human use. For 7-year-olds, there is not much difference compared to 5-year-olds but slightly more children talked about the composition of the substances. 9-year-olds started using some chemical knowledge to describe materials, while for 11-year-olds this number was increased both for chemical knowledge and for composition. Generally, the number of children attending to and describing the composition of materials increased with age, a finding consistent with the literature (Liu & Lesniak, 2006).

</table>

Overall, it seems that there are two completely different conceptual progression patterns for the composition of water and sugar (Figure 3). This finding is consistent with the literature (Liu & Lesnian, 2006; Nakhleh & Samarapungavan, 1999). Water is a very familiar substance for children and it seems that is easier for them to make the shift from macrolevel to microlevel views for liquids than solids (Nakhleh & Samarapungavan, 1999). As children grow older they gradually develop a microparticulate view of water while fewer children continue to attend to macroparticulate or macrocontinous views of water. It seems that most of the children in all year-groups understood the composition of sugar as macroparticulate (composed of visible pieces) and only some 11-year-olds had developed a microparticulate view of sugar.
Another finding is that students generally did not develop a molecular view of materials during the primary age range, apart from some exceptions for 9- and 11-year-olds. This finding is expected, however, as the particle theory of matter is not usually taught before secondary school in the English curriculum. A potential explanation is that those older children who expressed a molecular view did so because they had watched a relevant documentary or read a science book.

In summary, it seems that in terms of sugar, children progress from a macroparticulate view of matter to a microparticulate view of matter mainly after the age of nine. For water, children progress gradually throughout primary school from a macrocontinous and macroparticulate view of matter to a microparticulate and finally a few 9- and 11-year-olds hold a molecular view. Considering Hadenfeldt, Liu and Neumann's model (2014) (Figure 1) it seems that primary school children can reach level 3 for water as a good number of children attended to a microparticulate view of matter and often attributed macroporoperties to the invisible pieces. For sugar, however, most of the children reach up to the level 2 and only few 11-year-olds progress to Level 3.

As expected from the literature, children's progress in understanding the composition of matter is not linear but multifaceted and is different for each material (Liu & Lesniak, 2005; Talanquer, 2009). An illustrative example is that even 5-year-olds attended to a microparticulate view of matter. Although they might have not referred to particles but rather
to tiny drops that cannot be detected with the human eye, their responses showed signs that they can think at a more abstract level and not only attend to what they can see. Overall, it seems that primary school children show a greater progress in their understandings of the composition of water than of sugar.  

**CONCLUSION**

Considering the first research question, the findings of this study suggest that primary school children understand water and sugar in a different way, regarding both their spontaneous description and composition. Children initially identify materials in terms of their perceptual characteristics and everyday use and later describe them in terms of their physical and chemical properties and their composition. Considering children's progress in their understandings of the composition of matter, it seems that as children grow older they progress from a macroparticulate view to a microparticulate view of matter for water. For sugar, the progress is slower and most children have a macroparticulate view of its composition, probably because of its granular texture.

Considering the second research question, the findings suggest that children initially understand matter as composed of one piece or lots of visible pieces. For water, they refer to drops or bubbles, while for sugar they refer to grains. As they grow older, they start developing a microparticulate view of matter and state that it is composed of invisible pieces but in different shapes and sizes. Although this view does not mean that they refer to molecules, it shows an ability to think in a more abstract level and go beyond what they can see. For sugar, however, most of the children, even 11-year-olds, understand it as being composed of visible pieces, grains. A molecular understanding of matter does not emerge during the primary school years, which is not a surprising finding, as the particle model is not part of the English Science curriculum for primary school years. Overall, it seems that children start appreciating the particle nature of liquids sooner than solids.

Regarding primary school children's progress in understanding the composition of matter, the findings provide empirical support to Hadenfeldt, Liu and Neumann's (2014) theoretical model. We found that children generally progress from viewing matter as a continuous unit (Level 1) to understanding particles as building blocks of matter attributing to them macroproperties (Level 3). Primary school children can potentially reach level 3 of the model for water and mainly level 2 for sugar. Although the initial assumptions based on the literature (e.g. Krnel, Watson & Glažar, 2005; Liu & Lesniak, 2005; Löfgren & Helldén, 2009) was that the majority of the children would be categorised as Level 1 or 2, it seems that for water primary school children are capable of reaching Level 3. In general, the findings show that even within the same year-group, there is a significant variability in students' understandings of the composition of matter and their progress does not appear to be a linear process (Talanquer, 2009).

The insight on how primary school children progress in understanding materials and their composition can inform science teaching and curriculum development. A detailed description of children's understandings can help educators recognise potential barriers to and opportunities for facilitating children's learning of the concept of matter and provide them with
the means to design more effective courses that take into account children's early understandings of materials and mixing. In terms of curriculum development, the findings of this study seem to suggest that students are more familiar with water (liquid) than sugar (solid) and thus, students should potentially get introduced in the states of matter with an initial focus on the concept of liquid, as it has been found that students often use water as a prototype for liquids when they talk about liquids' properties (Krnel, Watson & Glazar, 1998).

Concerning the debate as to whether the particle theory should be introduced in primary school, the findings seem to suggest that most of the 11-year-olds have a microparticulate level of understanding the composition of matter and thus the introduction of the idea of molecules and atoms could potentially be within their conceptual reach. Papageorgiou and Johnston (2001) reported that the introduction of these ideas should be questionable if children have not developed a basic understanding of the states of matter. This study has shown that children develop a different understanding of water and sugar and use different physical properties to describe them, while after the age of nine they start using more technical terms as solids, liquids, substance etc. Thus, potentially a simple particle model could be introduced to 11-year-olds, probably using liquids as an entry point (Stavy & Stachel, 1985).

One limitation of this study is that there could not be established a direct comparison between sugar and water as the solid that was used was in powdery form and this could potentially have affected children's responses. As stated in the literature novice learners might develop different models of matter for rigid solids versus powdery solids (Talanquer, 2009). Thus, a suggestion for future research is the use of a solid with no apparent granularity in order to reach more robust conclusions for the differences between liquids and solids. What is more, a longitudinal design instead of a cross-age design would have provided better insight on how each child progress in their understandings of materials and what are some of the contextual factors affecting children’s development in understanding matter. Finally, this study could be extended with more materials (solids, liquids, gases) and students from more age groups. Although there have been many studies examining some of these aspects, a more comprehensive project examining students' progress, from kindergarten to high school, in understanding all three states of matter (solid, liquid and gas) and their composition could inform current policy decisions in terms of the contents of the curriculum in each year-group.

ACKNOWLEDGEMENT

The Young Children's Reasoning about Everyday Chemistry Project (Reference: RPG-115) is funded by The Leverhulme Trust. Polly Basak, Hyunji Kim, Julia Hill, Gina Plant Cabrita, Katja Rieger, Sarah Lauper and Matthew Cairnduff assisted in data collection.

TLS AS A TOOL FOR IN SERVICE PRIMARY SCHOOL TEACHERS TRAINING

Lenir Abreu¹, Valter Forastieri² and Nelson Bejarano²

² Universidade Federal da Bahia, Salvador, Brasil

Curriculum resources are one of the most important tools in learning about teaching. To understanding the influence of these resources on in-service primary school teachers training we analyze the development of a teaching and learning sequence (TLS) performed by a teacher of a class of ten year old children. We aim to answer the research question: What evidence does the application of the TLS 'energy transformation' by the teacher Suzana provide about her learning how to teach science in the investigative perspective? The analysis is performed using an analytical tool that characterizes the ways in which teachers interact with students to promote understanding, on the social plane of science classes. Before performing the TLS with her students she had the opportunity to become a student in a training program conducted by USP researches. We found that, in spite of not having had initial training in science, the teacher performed all the six interventions described in the analytical tool, which contributed to the students ability to develop their ‘scientific narrative’ for the subjects studied, as well as learning about approach to scientific methodology.

Keywords: in-service teacher training, primary school, teaching learning sequences.

INTRODUCTION

What kind of activities and what set of skills do teachers need to demonstrate? Teaching and teacher education is complicated, sophisticated and vital. In relation to primary school teachers (PST), it requires more attention, since research indicates that, as they have not mastered the complexities of science because they not have opportunity to learn it, they do not feel confident to teach it. Learning can be considered as a change in patterns of participation in social practices. For it the PST need to have an opportunity to participate in the learning community, to position themselves as apprentices and have access to TLS to be enabled to change their way of perceiving scientific content, thus changing their way of teaching science (Appleton, 2003; Loughran, 2004; Carvalho, 2010; Abreu, Forastieri, & Bejarano, 2013; Loughran, 2016).

Whereas PST are not experts in science content, in this work we will focus on teaching-learning sequences - TLS (Méheut & Psillos, 2004) as an important feature of the curriculum in the learning process of these professionals, both in regard to scientific content and how to teach it. The TLS developed in the work reviewed here is called "Transformation of energy."

To teach science so that students learn, it is important that teachers are prepared to lead the argumentation processes in class both among teacher/students and students/students (Carvalho, 2010). We used the analytical tool to investigate the quality of the interventions carried out by the teacher Suzana to develop the TLS 'energy transformation' in her class (Mortimer & Scott, 2002; Méheut, & Psillos, 2004). This tool allows review of the opportunities for interaction promoted by the teacher.
This study would like to improve understanding of the kind of interaction that the teacher can promote in the classroom from the TLS proposal, to: a) promote the use of scientific discourse by the students; b) change students’ participation patterns; and c) promote learning situations. To identify the interactions, we use the analytical tool developed by Mortimer & Scott (2002). We aim to answer the research question: What evidence does the application of the TLS ‘energy transformation’ by the teacher Suzana provide about her learning how to teach science in the investigative perspective? The analysis is performed using an analytical tool that characterizes the ways in which teachers interact with students to promote understanding, on the social plane of science classes.

**Rationale**

The nature of curriculum resources is considered as an important aspect of professional development programs. Without adequate resources it is impossible for the teacher to implement significant changes in their classes, even if they have opportunity to participate in training processes. Schulman & Schulman (2004) use the metaphor of ‘capital’ to define the resources that promotes the development of the teacher's understanding and ability to teach. They consider moral capital, venture capital, curricular capital and technical capital. These aspects are interrelated, and they appear imbricated in practice.

In this present work curriculum is defined:

Such as school experiences that unfold around knowledge, in the social relations, and that contribute to the construction of the identities of our students. Curriculum is thus associated with the set of pedagogical efforts developed with educational intentions. (Moreira & Candau, 2008, p.18).

Since the curriculum is associated with 'a set of pedagogical efforts' and teacher learning occurs through different forms of participation in teaching (reflection on practice, training meetings, among others), the curriculum also contributes to the teachers' identities. In this sense, it represents:

A set of practices that promote the production, circulation and consumption of meanings in the social space and that contribute, intensely, to the construction of social and cultural identities. The curriculum is, therefore, a device with significant effect in the process of constructing the student's identity. (Moreira & Candau, 2008, p.18)

Instead of using meanings, we prefer to use meaning-sharing (Wenger, 1998). In this sense, the curriculum is also a device for constructing teacher identity, which is formed and transformed as it makes decisions for the organization of teaching, that is, as it selects, classifies, shares and evaluates the knowledge that is part constituent of the curriculum. This is operationalized through the crossing of diverse practices and their meaning is given by the contexts in which it is inserted: class context, personal and social context, historical context and political context.

The view of the teacher as an actor, creator, interpreter, adapter and user of the curriculum is considered central to the changes that take place in the pedagogical practices of the teacher. The implementation of educational reforms depends on their capabilities and understandings about the teaching methodology that is intended to implement, as well as resources, indispensable elements. (Schulman & Schulman, 2004). The development of these capabilities and understandings should be the goal of ongoing training projects, which should create
opportunities for teachers to actively engage in the process. Considering the perspective of situated learning, they can be developed as teachers can participate in situations that promote their learning.

Instead of broad curricula to be developed in the long term, the planning and application of science-oriented topics or, in other words, teaching and learning sequence may be more effective in the teacher's learning process because they emphasize specific issues related to their daily lives, to their needs. However, we do not rule out the need to discuss the curriculum more broadly (Moreira & Candau, 2008, p.18). Investigating teaching and learning in science education at the micro level (specific activity, isolated) or medium (single topic sequence), rather than at the macro level, has become a tradition in science education research. This tendency began to stand out from the 1980s onwards (Mehéut & Psilons, 2004).

This type of work has been adopted both among Brazilian researchers and among educators in general. The authors of the projects analyzed in this paper elaborated specific TLS for Elementary School I and one of them was tested at the School of Application of USP before the elaboration of the projects that would be sent to CNPq (Carvalho et al., 2007). Currently this material has been published as a textbook. (Carvalho et al., 2011).

This movement originates from the concept of teaching and learning as constructive activities, which leads researchers to develop various kinds of instructional-based research activities and adopt approaches that promote students' understanding of scientific knowledge. These activities are usually organized in the investigative perspective and have as distinctive characteristic their dual character that:

(...) which involves both research and development targeting the close linking of the teaching and learning of a particular topic. Teaching sequences of this kind in effect draw on the tradition of action research, being used both the research tools and the innovations aiming at the handling of specific topic-related learning problems. (Mehéut & Psillos, 2004, P.515)

The teaching and learning sequences are both a research and an intervention activity. Included in these TLS structure are well-research teaching-learning activities empirically adapted to student reasoning. Sometimes teaching guidelines are included. (Mehéut & Psillos, 2004: 516). The authors highlight other aspects that seem to influence research: students' conceptions, characteristics of the specific scientific domain, epistemological assumptions, learning perspectives, current pedagogical approaches and characteristics of the educational context. This work proposal helps us to think about teacher training as an apprentice, since it articulates teaching and research, promoting the teacher's engagement with teaching.

In planning a sequence, it is important to consider the nature of the activities, the problems proposed, the contents to be worked, the epistemology that underpins it, the students' motivations and conceptions, and the teaching and learning conceptions. It can be structured from two axes, called epistemic dimension and pedagogical dimension. (Mehéut & Psillos, 2004, p. 517).

The two dimensions are relatively independent. However, the combination between them promotes the understanding of the interaction of pedagogical and epistemological components in the planning of a TLS. Some studies emphasize one or other dimension while others interweave the two. In the analysis, Mehéut & Psillos (2004) focus only on the pedagogical
and epistemological dimensions, and do not contemplate the contextual factors, although they do not discard their contribution. At the end of the analysis, these authors conclude that the epistemological considerations play a key role in the planning of these activities.

Regarding the validation process of a sequence, empirical regulation is closely related to its development. That is, as the TLS are applied by teachers in their classrooms, it is possible to evaluate which activities are appropriate and which need to be reorganized. In this sense, the planning of a TLS emerges both from the theoretical framework that underlies it and from the empirical study, that is, from the evaluation of the results of the application of this sequence in the classroom. As we show in the thesis (Abreu, 2013), the trainers always start the training meeting arguing: ‘we are with the theoretical part, you are with the hands-on’. The focus of the validation may be related to the comparison between several teaching-learning sequences or successive trials within the same sequence. (Mehéut & Psillos, 2004)

A posteriori analysis of TLS developed by the researcher himself or his colleagues from new theoretical perspectives is considered as a crucial step in the modelling of artisanal knowledge involved in the planning and development of several teaching and learning sequences because they can lead to more theory based on research.

Mehéut & Psillos (2004) highlight some of the focus of the research analysed: a) to verify the feasibility and efficacy of a sequence with relation to student performance; b) make two different ways of validating a sequence clear: the first, and perhaps the most common one, is to prove the effectiveness of a sequence in relation to the defined objectives; the other, less usual approach, observes and describes the student’s trajectory of learning through the activities that make up a sequence; c) validate the teaching experience as a means of investigating the teaching and learning processes in the field of chaotic systems.

**METHOD**

This work is part of a broader qualitative case study from the records produced by the partnership between University of São Paulo and Cândido Portinari Municipal Primary School, located in the outskirts of Sao Paulo - Brazil. The partnership was made possible through two research projects funded by the National Council of Technological and Scientific Development (Conselho Nacional de Desenvolvimento Científico e Tecnológico: CNPq): "Scientific literacy from the early years of primary school: in search of the viability for the proposal" and "Learning to teach and to teach students to learn". Although formally two projects have been developed, they constitute a continuum. There was no interruption between them and the actions taken in the second project were initiated in the first. The researchers having created TLS about several subjects, wished to test how it would work in schools. (Abreu, 2013)

We chose the TLS 'energy transformations', because it was not yet analysed by other researchers. Suzana was chosen because she had admitted she did not have any initial training in science, had poor scientific education and she had never taught ‘energy’ in her career.

The episodes analyzed were produced in the classes in which the teacher Suzana worked with a TLS "Energy Transformations" as following activities: 1 - Solve the problem: ball in the
basket; 2 - Understanding the problem: ball in the basket of the sequence; 3 - To know more.: As potential and kinetic energy served by work.

To analyze the data we use the tool by Mortimer & Scott (2002). It characterizes the ways in which teachers interact with students to promote understanding. It contains three aspects: **teaching focus** (teaching purpose and content), **approach** (communicative approach), and **action** (teacher interventions and patterns of interactions). We’ll try to identify if the teacher adopts a communicative approach in her class. For Carvalho (2010), it is important that teachers be prepared to conduct a class argument - between teacher/students and students/students. The tool will help us to look at opportunities for interaction promoted by the teacher Suzana, pointing out potentialities and weaknesses.

We will try to understand if TLS contributes to the teacher managing interactions in the classroom to: a) promote the appropriation of scientific discourse; b) change the participation patterns; c) reflect individually and collectively both in relation to scientific content and in the exercise of documentation in the research perspective; d) promote learning situations. We emphasize that greater emphasis will be given to teacher intervention, and that, as references for student learning, is done to evaluate the quality of her intervention.

The analytical framework of the tool developed by Mortimer & Scott (2002, 285) is based on interrelated aspects that focus on the role of the teacher and are grouped in terms of teaching, approach and action focuses (Table 1):

**Table 1: The analytic framework: a tool to analyze interactions and the production of meanings in science classrooms.** (Mortimer and Scott 2002: 285)

<td>3. Patterns of interactions</td>
<td>5. Teacher interventions</td>
</tr>
</tbody>
</table>

There are also other intentions of the teacher that should be considered: to create a problem; to explore the students' vision; to introduce the development of scientific narrative; to guide students in the application of scientific ideas and expansion; to guide students in applying scientific ideas and expanding their use; transferring to them the control and responsibility for this use; to maintain the narrative, supporting the development of scientific narrative.

About the content of the classroom discourse, we will focus on the construction of the scientific narrative and the procedural aspects that are part of the interactions between the teacher and the students in the sense of promoting an investigative teaching. For this, the analysis of the classroom discourse is based on the distinction between description, explanation and generalization, which Mortimer & Scott (2002, p.287) define as follows:

**Description:** involves statements that refer to a system, object or phenomenon, in terms of its constituents or the spatio-temporal displacements of these constituents.

**Explanation:** involves importing some theoretical model or mechanism to refer to a specific phenomenon or system.

**Generalization:** involves elaborating descriptions or explanations that are independent of a specific context.
In this analytical framework the concept of 'communicative approach' is central and provides the perspective on how the teacher works the intentions and content of teaching through different pedagogical interventions that result in different patterns of interaction. The authors point to four classes of communicative approach, which are defined through the characterization of discourse between teacher and students or between students, in terms of two dimensions: dialogical or authority discourse; interactive or non-interactive speech. (Mortimer & Scott 2002: 287, 288). We will use the authors' framework, but we chose to place the definition within the framework because we considered the presentation made that way more didactic (Table 2).

Table 2: Four class of communication approach

<table>
<thead>

</tr>
<tr>
<td>OF AUTHORITY</td>
<td>Consider what the student has to say just from the scientific point of view.</td>
<td>B) Interativo / de autoridade</td>
</tr>
</tbody>
</table>

Each of the four classes (Table 2), as presented below, are related in this study to the role of teacher Suzana in conducting the discourse in the class, as well as the interactions that occur in these spaces, for example, when the work to perform the experiment is done in small groups.

A. **Interactive /dialogical**: teacher and students explore ideas, ask authentic questions, consider and work on different points of view.

B. **Non-interactive /dialogical**: teacher reconsiders, in his speech, several points of view, highlighting similarities and differences.

C. **Interactive / Authority**: Teacher usually leads students through a sequence of questions and answers, with the goal of coming to a specific point of view.

D. **Non-interactive /authority**: teacher presents a specific point of view. (Mortimer and Scott 2002: 288)

Patterns of interaction emerge as students and teachers alternate speech shifts in the classroom. Mortimer & Scott (2002) consider the triads I-R-A (Teacher Initiation, Student Response, Teacher Assessment) to be more common, but suggests that other patterns can also be observed. Examples: The teacher only sustains the elaboration of a statement by the student, through short interventions that often repeat part of what the student has just said or provide feedback for the student to elaborate on that speech. These interactions generate chains of non-triadic shifts such as I-R-P-R-P, or I-R-F-R-F, where P means a discursive action to allow the student’s speech to continue and F, feedback for the student to elaborate a little more his speech.

With respect to the teacher’s intervention, the authors delimit six forms of pedagogical intervention: to shape meanings, to select meanings, to mark key meanings, to share meanings, to check students' understanding, to review the progress of scientific narrative.

**RESULT AND DISCUSSION**

The first class was divided into three episodes: in the first, the teacher focuses on the discussion about ‘how the students did’ - description of the phenomenon; in the second, it focuses on ‘why they have achieved such results’ - explanation of the phenomenon; and in the third, discusses
‘other phenomena related to the process of transformation of potential energy into kinetic energy, which are part of the students’ daily life-generalization’.

This was the first time that the teacher worked with this TLS. We would like to emphasize that this analysis is not intended to be a criticism of the teacher, who has the right to learn from her own experience, but serves as a way, from what we can observe in her class, to think about strategies and opportunities which may promote learning in science. If all elementary school teachers were willing to teach science to their students as this teacher did, we would certainly have a better-quality teaching in this segment.

Regarding the ‘teaching focus’ for the ‘content’ energy, the teacher's intentions were: to create a problem, to explore the vision of students, to introduce and develop the scientific narrative, to guide students in working with scientific ideas, to support the understanding process, to support the expansion of the use of the scientific ideas as well to maintain, sustain, and developing a scientific narrative.

Suzana – We're here in the lab because we will solve a problem, we have some materials on the tables: we have a basket and a ramp, right? And you will receive a ball ... and we will have to solve a problem. Pay attention! [Changes the tone of voice] 'Where do we need to put the ball on the ramp so it falls in the basket?' [Repeat]

She used the investigative teaching strategy to start her lesson by proposing a problem situation for her students. We realized that she values the enunciation of the problem situation as a way to lead a science class. She started the lesson enunciating the problem with objectivity. Her effort was perceived by the class that reduced its tone and conversations to watch the teacher’s speech, so in the second repetition of the problem all the class is silent.

The activity constitutes a problem situation and motivates the students. Everyone actively participates in the task, demonstrates joy, curiosity and willingness to experiment, manipulating the ball on the ramp, even when a teammate has already achieved the result. These are some of the characteristic attitudes promoted by 'activities that work'. As the students experimented, the teacher would go through the groups and check if everyone had understood and were participating. All were encouraged to participate actively, which meant that at that time there was joint venture and mutual engagement and that a favorable context for student participation was created (Wenger, 1998; Appleton, 2003; Abreu, 2013).

After it, the teacher promoted discussion about 'how' students have done and 'why' they have achieved those results. She started emphasizing the problem again:

1. Suzana - Look, hush, we had a challenge. [Raises her voice] where did we need to put the ball on the ramp so it fell ...?
2. All: In the basket!
3. Suzana - [...] How did you make it fall in the basket?
4. Gisele: When the basket was far like mine, we put the ball far away here [point out the ramp] to take momentum.
5. Suzana - To take the momentum and fall there. Speaks Murilo.
6. Murilo - When the basket was a little close to mine, we put the ball in the middle [point to the ramp]. And fall there.
7. Suzana - Fall in there.
8. Nara - [Who was filming the activity and coordinates the Science Laboratory, directs reflection on how they did it] But how was that, people? Did you suddenly find out? Go slow, all the steps to understand.

10. Mércia - We took the ball and put it like that! [Pointing to the ramp and gesticulating].

11. Suzana - But at first, already?

12. Marcos - When the basket was a little close we put the ball in the middle.

13. Nara - Look, the basket is fine, when you talk far and close we even understand, but when you talk about the ball on the ramp, talk loud and low so that we understand a little better.

14. (...) 

15. Cristiano - We put it right at the point here [shows the top of the ramp]. Then when she was up there she picked up speed.

16. Some - Impulse; Others - Speed! [At the same time]

17. Suzana - She got what? Look, someone said something important.

18. Suzana - Why?

19. Mark - The higher, the more speed.

20. [She asks everyone to repeat].

21. Suzana - When you put the basket farther, put the ball where?

22. Mark - Higher

23. Suzana - Higher. Because? To give impulse, she gets more of what?

24. All - More speed

25. Suzana - When you put the basket close ... put the ball more ...? 

26. All - Lower.

27. Suzana - More down to do what?

28. All - Less speed.

29. Luana - Jeferson started pushing away basket, but the ball went away ... [the students make a little confusion and she repeats.]

Relating to ‘teaching focus’, the intention of the teacher is to ‘explore the student’ view’, giving them freedom to express their ideas. She guided them in accordance with the TLS: in the first part of the discussion she focuses on the process of description, the idea of ‘how’ it was done to achieve the results. To start, organize the group and once again take up the challenge (quotation 3). Gisele was the first student to speak, but she did not use the expressions height and speed. The teacher repeats the speech of the student, valuing it.

Suzana spent 20 minutes to convince her students to not point out the ramp, rather they should express themselves using words. She made effort for them to deduce the best terms to describe (how) the experience. With Suzana leading them to think and debate, the students agreed to use ‘near’ and ‘far’ for the distance of the basket from the base of the ramp, they also concluded that was better to use ‘higher’ and ‘lower’ to talk about the point where they put the ball on the ramp.

The use of gestures, in the absence of words, in this initial phase is striking. The teacher's emphasis on using appropriate vocabulary can help students realize that they have had the opportunity to manipulate but were now arguing, so it was important to use appropriate words to express themselves. This strategy is important for students to build the ability to argue scientifically. The teacher's intervention aimed to 'mark the meanings', leading the students to relate the transformation of potential energy into kinetic energy by analyzing the height of a ball launch and the velocity acquired by it on a sloping track. (Carvalho, et. al., 1998).
The teacher invested time and effort to ensure they concluded that they were talking about two different variables. A student used the term ‘speed’ to describe what happened with the ball, so Suzana repeated the term and asked for the class to use it in their descriptions. Finally a student concluded that ‘The higher, the more speed’ (quotation 19). Suzana asked all to repeat it. She asked her class to help her to review the progress of the scientific narrative and the students described what happened evidencing variables and the relationship between them.

In quotation 18, after several groups state what they did, the students can share the causal relationship of the phenomenon - why - when Marcos states: the higher, the more speed. The teacher values his speech and asks everyone to repeat. In the following quotation she question using the students' initial vocabulary so that they use the appropriate terms. These interventions can help students in the construction of meanings.

In the speech transcribed below the teacher's intention, that is, the focus of teaching was 'to introduce and develop the scientific story', 'guiding students at work with scientific ideas' (Mortimer & Scott 2002) in the perspective of Carvalho, et. al. (1998), lead the students to explain why the phenomenon studied, which had already begun on quotation 18, set out above.

1. Suzana - A basket closer, one more ball, more ... You have been testing. So how about you so many testing? [The student goes on explaining and a teacher repeats.]
2. Suzana - But why did you do this, Jeferson?
3. I Love You
4. Suzana - When the basket was closer to you put the ball lower. Because?
5. Jeferson - Not to get Speed.
6. Suzana - If you put it on top, what would happen?
7. Jeferson - I would pick up Speed and pass the basket.
8. Suzana - Ia Pick up Speed and pass the basket. So what did you notice? Putting lower ...
9. Jeferson - There is not much speed and a ball falling into the basket.
10. Joaquim - Put it on the tip like this ...
11. Suzana - A bridge you mean from below or from above?
12. Joaquim - That was how she was going.
13. Suzana - The higher the speed, the slower the speed. [The students repeated along with it. Other groups are reporting].
14. Gisele - ... impact.
15. Suzana - Is it impact or speed?
17. Suzana - Speed.
18. Suzana - Did everyone realize that? Is there anything different that someone wants to talk about?
19. Luana - The ball fell in the basket was rolled, turning and fell inside.
20. Jeferson - The ball fell inside and jumped out.
21. Suzana - She came very fast she hit and ...
23. Suzana - Why will it be?
24. Everyone - Because of the impact!
25. Suzana - Is that why you have the role? So I think she has the little paper, when she comes with speed and if she hits the glass, what does she do?
26. Everyone - She jumps.
27. Suzana - And if she hits the paper ...
28. Everyone - Does not jump.
29. Carlos - My group put the ball up there. She went downstairs, fell into the basket, and jumped out.
30. Suzana - You almost lost the basket, right?
31. Suzana - Look at what everyone said and everyone agreed: the height of the ball and the distance from the basket is important. We noticed that when the basket is closer, closer, I have to put the ball ...

32. Glaucia - Lower.

In quotation 1, which gives continuity to the episode shown previously, the teacher makes a question that allows the student to advance in his reflection about the understanding of the phenomenon. However, on turn 4, she seems to be too attached to the relationship between height and speed and does not question the student about what he would like to test, missing the opportunity to continue the reflection. Instead, it brings the relationship between the distance of the basket and the place where he placed the ball, questioning ‘why’.

At that time, she could have stimulated the student's reflection and consequently the group's discussion of the important scientific procedure of hypothesis testing. In the quotation 4 to 11 she adopts the dialogical dimension; whose interaction pattern is Initiation - Response - Feedback - Response.

Even after all this discussion, Joaquim uses the words pointedly and slowly, indicating that students have different rhythms and forms of learning even when participating in a community. The teacher shows attention to the different learning rhythms and repeats several times the relation between height and speed, which is the focus of learning in this activity. Giselle brings a new concept: impact. And she questions whether it's impact or speed. Another student says that it is impulse, but she uses the authority discourse to affirm: speed.

A little further on, quotation 20, Jefferson presents an example of impact, reporting that the ball fell in and jumped out. The teacher does not take up Giselle's previous arguments and, instead of continuing to question, she adopts a type of intervention that, as we will see mainly in the second class, is frequent in the teacher's practice: she offers part of the answer so that the students simply complete the word or small sentences. This type of intervention reduces the need to reflect on the phenomenon and elaborate the response, not favoring learning. In turn 23 attempts to establish a discursive interaction to allow the continuation of Jefferson's speech, questioning why such a phenomenon happens. Everyone responds: because of the impact! His intervention on quotation 25 indicates that she did not know why, that is, she did not know the causal relationship of this phenomenon and merely discussed the ‘how’.

She considers the student's argument about the impact, but does not stimulate students' curiosity, as it does not propose a further investigation, which could be done through books, the internet or even the consultation of a physicist, who could be one of the trainers themselves. We conclude that in some moments the teacher adopts a proper way to apply the sequence, in others it follows the model that was offered in the formation.

In spite of the fact that some of the teacher's actions' could have stimulated students' reflection more if they were carried out in a different way, in focusing on their interventions, we can see in this episode that she: 'Forms the meanings', from the moment which introduces new terms and shows the difference between two meanings by exploiting students' ideas about using the terms high and low, contrasting them with the terms near and far. In this sense, the teacher is working the meanings in the development of the 'scientific story' (Mortimer & Scott, 2002).
Another intervention of the teacher consisted in 'selecting meanings'. This becomes evident when you value the students' response by repeating the word speed and ignoring the impulse response. She also intervenes 'marking key meanings' by repeating the expression: *The higher the speed* and ask the students to do the same.

At every moment of the episode the teacher is concerned with 'sharing meanings', making them available to all students in the class, by proposing that each group socialize the description (where they put the ball and what happened - How) and the explanation (the relationship between height and velocity - Why) (Carvalho et al., 1998).

It is also noticeable, in the teaching episode, that the teacher intervenes 'checking students' understanding by insisting that they adequately express the relationship between height and speed, verifying whether the class has reached consensus. At the end, quotation 31, through the authority discourse the teacher retakes and systematizes, asserting to students that there is an important relationship between height and speed. The students complete their speech, already using the terms, high, low and speed.

As the classroom discourses were moving from the description (how) to the explanation (why), the teacher gave to her class a text on potential and kinetic energy. She asked them to read and after that she requested that they explain what happened in the experimental activity using the new terms introduced by the text. Each student group explained using the terms, the teacher helped when they were confused or made mistakes. Finally, she put everybody to explain together:

1. Suzana - On the top of the ramp…what kind of energy had the ball?
2. Everybody – Potential
3. Suzana – Potential! So, I put the ball here [demonstrating on the ramp] it has potential energy… when I abandon it what happens?
4. Caio – Transformation
5. Suzana – yes…Turn into …what?
6. Many students – Kinetic energy
7. Suzana – What kind of energy?
8. All – Kinetic energy

The pattern of interaction that the teacher adopts in the above intervention is what Mortimer & Scott (2002) consider most common I-R-A. However, at times she also adopts I-R-P-R-P, as we can see below, when she asks her students to draw situations similar to what happens with the ball on the rail. She led them to apply the relation between height and speed and the use of the terms kinetic and potential energy. She showed concern to emphasize the idea of ‘energy transformation’.

1. Suzana - A T E N T I O N! You will think of some objects that have the same energy transformation: potential energy in kinetic energy, through velocity. Think about our daily lives, okay. [Repeat these forwarding multiple times]
2. Suzana - What are you doing, Thiago?
3. Thiago - A field.
4. Suzana - But how are you going to do it? Where do you have energy there?
5. Thiago - I use energy to run in the field. On the foot.
Through the analyzed data, we can make some inferences about what the use of the TLS 'transformation of energy' by the teacher Susana brings up about its learning to teach sciences in the investigative perspective. Although she presents ways of intervening that should be reviewed in its practice, the fact of being actively participating in a community indicates that it may develop increasingly sophisticated skills to teach. (Wenger, 1998)

Regarding pedagogical skills necessary to promote investigative teaching and scientific literacy, it is possible to see in this class that the teacher, in her practice, can perform actions that favor this teaching approach, promoting a wealth of interaction patterns with the class. It is not limited to triads I-R-A. At times it supports the elaboration of an argument enunciated by the student only repeating part of his speech. In others it provides feedback for the student to elaborate his or her speech a little more.

CONCLUSION

Although it was the first time that this teacher worked with the content of energy transformation, she performed all six types of interventions categorized in Mortimer & Scott (2002) tool: helped students to form and to select meanings; marked the key meanings to explore the idea of the students about how they had performed the experiment; development of the scientific story; shared meanings when she made them available for everyone when she allowed each student to speak, verified (checked) understanding of the students to see if they were understanding; reviewed the progress of scientific narrative when she recapitulates both at the end of the first or second class.

These sequences are located on the epistemic axis, since they are concerned with the teaching of scientific contents as well as with the procedures of doing science and its relationship with Technology, Society and the Environment. On the other hand, they also approach the pedagogical axis because they both present detailed pedagogical guidelines for teachers and their authors have proposed to train the teachers of EMEF Cândido Portinari so that they learn to use them.

With regard to scientific content, her interventions with students showed that she can use the concepts properly. The teacher was expressing herself as the scientific discourse and her practice denotes the effort for her students to also express themselves in this way.

Experiences of this nature are very important for teacher learning, but isolated are not capable of promoting an improvement in the overall quality of learning in science teaching. It is necessary to have public policies that promote the continuity of proposals such as the one discussed here and the implementation of new projects with these characteristics for a longer
period. Real changes in the teaching practice of teachers require ongoing training and support so that they can engage in their professional development process.

CHOICE⁰EXPLORE – A TEACHING CONCEPT FOR INCLUSIVE SCIENCE EDUCATION IN PRIMARY SCHOOLS

Lisa Rott and Annette Marohn
Westfälische Wilhelms-Universität, Münster, Germany

Inclusion is often understood to be a process to facilitate access to appropriate learning opportunities for all students. Since more and more children with a wide variety of needs have been entering mainstream schools, inter alia caused by the ratification of the UN Convention on Rights of Persons with Disabilities (2008), teachers are challenged to cope with this diversity. Recently, strategies have been explored on how to design differentiated materials so that every student can learn according to his or her own learning level. But teachers are still struggling to create classroom situations in which students are learning together through cooperation or collaboration. Over the last years, constructivist-oriented research shows the variety of perspectives and ideas that students have in different contexts and how to handle them in teaching (e.g. Marohn, 2008). According to Reich (2014), a constructivist view of teaching and learning is also based on the broad understanding of inclusion and consequent, inclusive teaching. This project combines concepts from science education and special needs as well as inclusive teaching strategies to create, test and evaluate the teaching concept “choice⁰explore” for inclusive science education in primary schools. Within the framework of design-based research, the aim of this study is, on the one hand, to focus on the concept, including its learning materials, which is designed to initiate conceptual development as well as collaborative learning situations. On the other hand, it’s aim is to display theories that describe how the teaching concept works. In this process of constructing, testing and reconstructing, the learning materials have become more and more adaptive to the requirements of highly heterogeneous learning groups. Therefore, third grade school groups from different locations were taught. Due to the ongoing revisions, accessible learning materials should be developed. Accompanying qualitative content analyses reveal conceptual developments, describe and characterize the learning situations regarding cooperation/collaboration and show how the learners work with particle models.

Keywords: collaborative learning, conceptual understanding, inclusive learning

INTRODUCTION

Science education in inclusive contexts aims at, both, enabling all students to participate as to promote students on the basis of their current skills as best as possible as well as initiating joint learning situations.

Participation for all means that everyone should be supported in his or her own individual learning process – Vygotsky describes this as the zone of the proximate development (Vygotsky, 1978). In the context of science education, learning could be designated as a conceptual development. Students should develop concepts that are transferrable to a secondary school context in order to enable scientific literacy (Bybee, 1997). Starting from the constructivist aim to promote conceptual development, you need to link your teaching to concepts that make students become aware of their ideas. To develop these concepts it is important to initiate cognitive conflicts, for example by showing an experiment which disproves their own idea (e. g. Duit, Reinders & Treagust, 2012).
In primary schools, teachers are aware of strategies on how students can learn individually on their own level (Shippen et al., 2011). Participation for all also means enabling access to teaching and the learning materials. An inclusive strategy does not differentiate materials or student groups from an outside perspective. Learning material should be developed in a way that allows every student to work with it (Florian & Spratt, 2013). From theories of special education, science education, and psychological concepts, the following principles to construct learning materials were derived:

- easy language
- symbols
- clear structure
- ritualized construction
- action-oriented activities
- various ways of expression and representation
- scaffolding measures (e. g. Abels, 2015; Degner & Burger, 1996; Kutzer, 1998; Therrien, Taylor, Hosp, Kaldenberg, & Gorsh, 2011; Therrien, Taylor, Watt, & Kaldenberg, 2014; Winter, 2014)

Additionally, the idea of joint learning defined by Feuser (1998) or Wocken (1998) is significant in an inclusive teaching approach. Joint learning aims to enable situations in which all members of a group support the learning of one another on the same subject. We know from studies that inclusive teaching in classrooms is often unplanned and the support of students with special educational needs often takes place outside the classroom. Furthermore, we know that external differentiation causes social tensions and that showing cooperative and helpful behaviour is crucial for social acceptance (Garrote, 2015; Vehkakoski, 2012; Zigmond & Baker, 1996). To consider this we need to create joint learning situations in which every student can contribute his or her competences so that he or she is being valued within the group: to enable joint learning means to enable collaborative learning.

Some studies focus on how cooperative learning works in inclusive groups or for special education and remedial students (f. e. Tateyama-Sniezek, 1990). Most studies merely focus on the achievement level, while social aspects or the description of the interaction that took place are unfortunately not taken into account at all. The main question of this project was: How can we construct teaching materials that are oriented towards students’ concepts and initiate collaborative learning in the inclusive context?

**PRELIMINARY STUDY**

Even if many studies describe students’ alternative concepts, students with special educational needs (SEN) or other diversity features were not taken into account. For this reason, a preliminary study was carried out to investigate the concepts of students with SEN on scientific phenomena. The focus was on dissolving salt or sugar in water as well as the change in the aggregate state of water. In the 20 individual guided interviews with third grade students with SEN, respondents conducted simple experiments and were asked to describe and to draw their observations and explanations. The interviews were evaluated using the qualitative content analysis (Kuckartz, 2016). Table 1 summarizes the characterized categories from the interviews with the students with SEN on the left hand side and regular students’ conceptions from the
literature regarding the solving process of salt in water on the right. It turned out that the students showed ideas and concepts that are comparable with the well-known concepts of regular schoolchildren. However, the heterogeneity of the concepts does not necessarily have to arise in an inclusive class. These findings made it advisable to take natural science phenomena as a starting point in inclusive science education in order to become aware of the individual idea of the students and to construct the teaching concept.

DESIGN OF THE TEACHING CONCEPT

In the framework of design-based research (Barab & Squire, 2004) the teaching concept choice2explore was constructed in an iterative process of designing, testing, analysing and optimizing. First of all, students from inclusive classes were interviewed to optimize the use of easy language and symbols. In the next step small groups of three students were taught to check whether the cognitive conflict was working. After that, five classes were taught to adjust the teaching concept and its procedures. The data collection was based on videography of the group work and interviews with teachers to get feedback out of practice. Out of these ongoing revisions the teaching concept has emerged.

The teaching concept combines the following elements: knowledge of conceptual-change research, design of teaching in heterogeneous learning groups, design of adaptive learning material, use of particle models (Carey, 2000; Florian & Black-Hawkins, 2011; see also Rott & Marohn, 2016). Based on the teaching concept choice2learn (Marohn, 2008), findings of the preliminary study and the influence of different theoretical concepts and research results, a first draft of the teaching concept “choice2explore” was prepared. The various ideas of the students on a natural science phenomenon form the starting point of the teaching concept. The aim is to build on the ideas of the students and to develop them further. Therefore, they are processing a diagnostic task that contains four of the most common concepts. With the help of simple experiments, the students can test in a hands-on way in small heterogeneous groups whether their own ideas withstand further experiments. Collaboration processes are to be initiated in these small groups.
The teaching concept “choice2explore”

The teaching concept choice2explore is divided into six phases which are named for the students and the teachers and also symbolized by an individual symbol. All those used symbols are part of a symbol system designed by Kitzinger (2016). Those symbols are used by children who use augmentative and alternative communication.

In the first phase “Let’s explore!” the students are introduced to the concept by two hand puppets “Milla and Lutz”. These two hand puppets accompany the students through all phases and give them a context. In the second phase “Watch closely!” the students observe a phenomenon in a small group of 3 students. Teachers are asked to group the students heterogeneously. For example, students observe the dissolving process of salt in water. After that, they are asked in a multiple choice task: What do you think? What happens to the salt? Figure 2 shows what this task looks like. The four answers are representing the most common concepts of the phenomenon as well as a transferrable explanation (compare Table 1).

In the next phase “Find out!” they prove their ideas in group work. They conduct small experiments that include cognitive conflicts. For example, in order to check if the salt has become water, they might compare water containing salt with tap water. They put a potato piece in each glass and observe that one sinks and one swims. Thereby they can deduce that...
the conditions are not the same. Figure 3 shows how the learning material is constructed: it is structured, uses easy language and symbols and also promotes different ways of expression. It also uses scaffolding measures, like focus questions that are structuring and promoting the learning process.

Figure 3. Learning material of the phase “Find out!” regarding the concept “The salt has become water.”
After all ideas are checked, the students explain the phenomenon with science language and represent it by using a particle model. This phase is named “Explain it!”. In the last phase they apply the acquired knowledge in a different context and deepen it. Right now materials for the solving process as well as the evaporation of water are constructed.

METHODS

Choice explore and its learning material was tested and reconstructed in the framework of design-based research in successive cycles. These took place in different kind of group sizes with third grade students. Firstly, it was tested in individual interviews with students from inclusive classes. After that, we tested it in group interviews (three students) before it was tested in classroom settings. During all these testings the data collection was based on videography of the group work, interviews and a follow-up test five weeks after the testing. Data analysis is carried out with support of the program MAXQDA and the majority of analyses based on the qualitative content analysis (Kuckart, 2016). To adapt the teaching concept to the requirements of heterogeneous learning groups, verbal support measures were found and incorporated into the revisions of the material - with the aim that small groups can work as independently as possible. The conceptual development is analyzed using the diagnostic task, the interviews directly after the test, as well as the follow-up test. While the answers of the diagnostic tasks could just be counted, the interviews and follow-up tests were subjected to a qualitative content analysis in an inductive way (Kuckartz, 2016).

The collected data also allows for an analysis focussed on how the students work with the particle model in the interviews as well as an analysis and descriptions of the group’s cooperative and collaborative conduct. For the latter, coding guides were constructed in a deductive-inductive way on the basis of categories by Naujok (2000). 13 different operations of cooperation were defined, coded and related to three different types of cooperation regarding its intensity (small intensity; helping (asymmetric); collaborating (symmetric)). In addition, it was marked which students are interacting. Every part of data coding was coded by two different coders to ensure intercoder reliability.

RESULTS

Regarding the student’s conceptual development, the analyses show that various answers are chosen in the diagnostic task. The analysis of the interviews one day after testing, reveal that 99 % students explain the solving process in a more scientific way. 80% out of them use the particle concept for their explanations. Similar results are shown in the follow-up tests. First results concerning the group interaction show that the groups are interacting in the three different types of cooperation and show various types of the cooperative operations. The groups differ in how their cooperation is designed: There are groups in which the types spread evenly among the group members. However, in other groups, there are certain students who give and receive help equally, while others are less integrated in the collaborative phases.
DISCUSSION

In conclusion, students have different alternative concepts to explain the same phenomena. But this heterogeneity does not increase in inclusive classes. These different concepts can be developed in inclusive classes by the teaching concept “choice2explore” and most of them evolve into a more scientific understanding. The analysis of the group interaction demonstrates that in inclusive classes cooperation and collaboration in hands-on group work are possible. The next step is to take a deeper look at the group interaction to analyze by type formation whether there are typical structures found how the interaction develops and if there are typical cooperative operations regarding cooperation types. Moreover, the analysis of the students’ use of the particle model is being carried out. Results from those next steps can give an indication of how the teaching concept works and may offer aspects to create joint learning situations not only in science education in primary schools.

ACKNOWLEDGEMENT

Special thanks to the students and teachers, without whom this project would not have been possible.

STRAND 17: INTRODUCTION

SCIENCE TEACHING AT THE UNIVERSITY LEVEL

The strand 17-science teaching at the university level is particularly relevant when university education models for science and technology are being analyzed and questioned throughout the world. University-level scientific-technological education should support a diverse student population where actually using knowledge, not just memorizing it, is becoming more important. Although the majority of scientists, mathematicians and engineers successfully managed to learn within a traditional teaching format, they are the exception and not the rule. In different countries, groups of experts report a science education focus on active learning and teaching. In this new approach of teaching science, the research in science education has developed a key role. It shows that, compared with traditional courses that transmit knowledge, active teaching and learning can improve the level of learning concepts and laws and the skills required to apply the knowledge in different contexts. The results of science education research are changing the university science education from the tradition and the intuition to proposals based on theories of learning and evaluated by reliable and validated instruments. The community of research in science education has worked hard to present solid teaching proposals, instruction materials and methods that have been repeatedly assessed. The strand 17 includes examples of these changes in the science education at higher education.

This strand comprises studies in a range of topics and with a rich diversity of aims and methods. The papers concern teaching environment and resources at university, assessment of implemented proposals, analysis of students’ learning and communication skills of undergraduate and graduate scientist and engineers. Further, within the range of papers, specific problems of science education at university, such as the attitudes of students who do volunteer work or are employed at the science faculty, are investigated. In summary, all eight papers provide data on the situation of university education in different countries and evidences of innovative ways of teaching and learning in classroom or laboratory contexts. Likewise, original topics on the collaboration of students in teaching are presented, and suggested actions aimed at improving the communication of researchers and professors with the Society.

The first two contributions are related to the analysis of various factors that can improve student learning. The conceptual understanding of models is an important competence in conceptual learning in Chemistry. The paper “Academic success and visual model comprehension – an (in)equal couple”, due to the great diversity of "visual models" in textbooks, investigates under which circumstances and conditions such models promote learning. The study focuses on predictors of visual model comprehension in chemistry and aims at comparing these with respective predictors in engineering. It shows that a medium correlation between the performance in the visual model comprehension test and students' cognitive abilities. Another empirical research on students' prior knowledge and their performance in the learning of Chemistry topics is presented by Daniel Averbeck, Eckart Hasselbrink and Elke Sumfleth. Their study analyzes the predictors of academic achievement in order to reduce these dropout rates in Chemistry. The study selects not only cognitive factors, but also, affective and motivational factors, and analyzes the impact on prior knowledge, content and on content knowledge acquisition of freshmen in chemistry study programs. The results indicate that prior
knowledge in general, chemistry and mathematical abilities are of the most important impact variables for content knowledge, content knowledge acquisition and academic achievement in the basic sub-disciplines within the entry phase of chemistry study programs.

There is an agreement in the science education research that laboratory work is a key characteristic of science education. However, in the science educator community, questions have been raised about its effectiveness as a teaching and learning strategy. Research on the benefits and shortcoming of the traditional laboratory work is important in order of improve teaching and learning in the laboratory. In the paper “Explore one tertiary chemistry laboratory course from CHAT perspective”, Xiaomei Yan and Justin Dillon conduct a study to explore the issues of the traditional laboratory in Higher Education. Cultural Historical Activity Theory, using individual interviews, observations and documentary analysis, guided the data collection. The findings identified the different orientations towards the objectives among the tutors, students and demonstrators (or research assistants). These differences also accounted for the mismatch between the students’ experience and the tutors’ design of the course. Another quantitative study in order to reflect the goals of curriculum in the experiments is presented by Birgitte Lund Nielsen and Rikke Frohlich Hougaard. They develop a proposal to stimulate students’ metacognition both before and during the experimental work. The study designs tasks for the prelab that are related to planning experimental work and explaining theory. The students were scaffold in guided inquiry, making definite choices related to calculations, representations, and assessing their data. This scaffolding successfully stimulated the dialogue among student-student and students-teacher assistant that revealed elements of exploratory talk including a dialogic approach with open questions and prompts.

Improving the learning in introductory physics at university is the topic of the contribution Evaluating the effectiveness of a tutorial intervention on students’ learning of the work-energy and Impulse-momentum Theorems developed by Mikko H. P. Kesonen, Risto Leinonen, Mervi A. Asikainen and Pekka E. Hirvonen. This study evaluates the effectiveness of an implementation of Tutorials in Introductory Physics curriculum in a student’s large number classroom. The results show that the improvement in students’ learning is better than that obtained in the traditional lectures. Furthermore, the learning improvement is comparable to those obtained in previous experience with small classroom implementations, which shows that the effectiveness of tutorial curriculum is transferable to different implementation formats.

The paper “Faculty teaching practices and perceptions: a cross-institutional study” aims to identify the educational practices that are used in institutions of higher education in Canada. The study starts by recognizing that many higher education institutions are largely unaware of what teaching practices are employed in the classroom. However, knowledge of teaching practices employed is crucial to promote the use of evidence to inform individual teaching practices in higher education. The paper concerns an international study involving eight research-intensive post-secondary institutions to gain a better understanding of faculty teaching practices and perceptions, conducted by The University of British Columbia.

Two studies deal with specific issues of higher education such as the attitudes of students employed by the university to participate in the education of other students and, the need for scientists to have communication skills so that they can inform Society about science and
technology. The research “Science students’ sense of belonging and university involvement” developed by Nadia Dyrberg focuses on student employment in relation to the concept of university belonging. The study constitutes one of the first European investigations of university belonging and calls for attention to this important and far-reaching concept. The paper presents investigations of the relation between science students’ sense of university belonging and their involvement in the study environment at the university’s science faculty. The paper by Sarah Hayes, Daniel Brandell and Felix Ho “RAW Communication and Engagement” addresses the importance that STEM students and researchers have to communicate to the Society science and technology topics. The paper explains the implementation and evaluation of some of the modules of the RAW Communication and Engagement project which aims to incorporate content, scientific communication and public communication skills. This international project has been aimed at students and faculty alike with the skills to understand the implications of their work on the wider global society and to communicate their work with wider societal audiences.

In summary, I would like to highlight the importance of the research into learning and teaching science presented in this strand, as developed from the science departments. The eight papers in this strand give important contributions within different educational problems and, provide different approaches to enhance our knowledge of learning processes at university. Science Education research has mainly been developed for primary and secondary levels and has had a low impact on post-compulsory secondary levels (16-18 years old) and on university courses. One example is the small number of contributions in this book dealing with of studies at Primary and Secondary level. However, the science education research is increasing at the level of university, in this proceedings, the number of the papers is double that of the number in the previous conference. Nevertheless, I do not believe that science education research at university area is feasible without a critical mass of faculty in science departments.

ACADEMIC SUCCESS AND VISUAL MODEL COMPREHENSION
– AN (IN)EQUAL COUPLE

Thomas Dickmann¹, Stefan Rumann¹ and Maria Opfermann²
¹ Institute of Chemistry Education, Duisburg-Essen, Germany
² Faculty of Philosophy and Educational Research, Bochum, Germany

The comprehension of models is seen as a crucial component for the development of conceptual knowledge in chemistry as well as engineering. In particular, the great diversity of visual models in respective textbooks raises the issue of whether, and under which circumstances, such models are beneficial for learning. In this regard, theories such as the Cognitive Load Theory (Van Merriënboer & Sweller, 2005) or the Cognitive Theory of Multimedia Learning (Mayer, 2014) emphasize the importance of instructional design as well as individual characteristics. Our study focuses on predictors of visual model comprehension in chemistry and aims at comparing these with respective predictors in engineering. Furthermore, we are interested to investigate, whether there is one general “visual model comprehension” ability or whether it is domain-specific. Based on a textbook analysis a test was developed, which should measure visual comprehension. In the pilot study, we tested 262 students with regard to their visual model comprehension ability at two different points of measurement. The results indicate that visual model comprehension can predict academic success. Moreover, we found that figural and verbal reasoning as well as spatial ability are able to predict visual model comprehension. Furthermore, our analyses show that a medium correlation between the performance in the visual model comprehension test and students’ cognitive abilities. The study contains three points of measurement (beginning of the first semester, end of the first semester and end of the second semester. First results of 527 students will be presented.

Keywords: multiple external representations, visual model comprehension, visualizations

INITIAL SITUATION

“Chemistry is a visual science” (Wu & Shah, 2004), or “Students learn better from words and pictures than from words alone” (Mayer, 2009). Statements such as these underline the importance of visualizations when it comes to science learning. For instance, the deeper understanding of chemical reactions cannot develop without insight into the structure of molecules, which, in turn, are often represented by means of structural formulas containing visual-spatial elements or three-dimensional visualizations. Quite similar, it’s almost impossible to imagine engineering courses without the countless textbook illustrations of all kinds of technical devices.

Visualizations are a popular means in science textbooks and materials. If one has a quick look into these, an abundance of different visualizations can be found. In an own textbook analysis (Dickmann et al, 2015) 85% of all chemistry textbook pages contained visualizations of multiple kinds. This, a closer look into the use and handling of visualizations seems to be necessary, because visualizations can only foster learning when they are designed according to insights into how we process and learn visual and verbal information (Mayer, 2009; Chandler & Sweller, 1991; Schnotz, 2005; Ainsworth, 2006). Moreover, we also do not yet know much
about the differential benefits of visualizations regarding individual learner characteristics and
the domain to be learned. Our study wants to take these gaps up and investigate the role of
visual model comprehension for study success in chemistry and engineering sciences.

THEORETICAL FRAMEWORK

A major problem for universities in many countries are the high drop-out rates for science
related studies (Chen, 2013; Heublein et al. 2012; OECD, 2011). For instance, the OECD-
report points out, that students, who start to study science related courses, often do not receive
an academic degree. Moreover, national reports such as the study of Chen (2013) and Heublein
et al. (2012) undermine the results of the OECD-report and show that drop-out rates for science
related courses in the US can be up to 48% and in Germany up to 43%. This problem was the
starting point for exploring reasons for students’ dropout and for developing ways to support
students’ academic performance.

In this regard, research on instructional design has recently emphasized multimedia learning
materials and has placed a special focus on visualizations (Ainsworth, 2006; Niegemann et al.
2008; Schnotz, 2005). This can be traced back to assumptions on dual coding to offload
working memory (e.g., CLT; Van Merriënboer & Sweller, 2005 or CTML; Mayer, 2009, 2014;
see also Paivio, 1986). To summarize how multimedia learning take place, the Cognitive
Theory of Multimedia Learning are discussed shortly. As you can see in Figure 1, that different
steps are necessary to develop a mental model respectively construct deeper comprehension.
First, ears and eyes includes words and pictures by an auditory and pictorial channel. In a next
step, the working memory selects relevant sounds and images. Then the working memory
organize the sounds to a verbal model and the images to a pictorial model. Finally, the verbal
model and pictorial model integrate prior knowledge from the long-term memory and this
integration constructs a new mental model.

![Figure 1: Cognitive Theory of Multimedia Learning](image)

The Cognitive Theory of Multimedia Learning describes, how learning with multimedia
material can take place. The benefit of multimedia learning is the using of different channels.
While using the auditory and pictorial channel, the cognitive load is lower and the construction
of deeper understanding is more likely proceeding (e.g. Van Merriënboer & Sweller, 2005 or
CTML; Mayer, 2009, 2014; Schnotz, 2005). Hereof, the comprehension of visual models is a
crucial component for the development of conceptual knowledge (Coll & Lajum, 2011;
Harrison & Treagust, 2000; Ramadas, 2009). In this regard, and since chemistry as well as engineering can be called “visual subjects” (Wu & Shah, 2004), it might be useful to support students in their visual model comprehension ability. As there is no clear definition for visual model comprehension yet, we conceptualize it in some kind of working definition as follows: Visual model comprehension is the ability of learners, taking into account domain-specific characteristics, to extract relevant information from visualizations, to „translate“ them and to relate them to each other and to their respective textual counterparts. That is, besides focusing on the effects of the visualizations themselves in terms of instructional design, it is also necessary to have a look at the interaction between individual learner characteristics and the kind of visualization that can be useful.

**METHOD AND MATERIALS**

An important first step of our long-term-study was the development of a test instrument, which assesses visual model comprehension reliably and validly. To do so, the item development took place based on the results of our own textbook analyses (see above) and the different kinds of visualizations we found. In order to assess domain-specific as well as general visual model comprehension, the test comprises three different scales:

- A chemistry-specific scale, in which the items are embedded in chemistry contexts (Figure 2 (1a)).
- An engineering-specific scale, in which the items are embedded in engineering contexts (Figure 2 (1b)).
- A general scale, which focuses on general competencies regarding the comprehension of visualizations and conventions to “read” and process them (Figure 2 (1c)).

A first version of the test was validated in a pilot study with 262 participants (Dickmann et al. 2016). The final version of the test contains 33 items, which are equally distributed across the three scales with a satisfying Cronbach’s Alpha of .853.

In a next step, we wanted to find out whether chemistry and engineering students differ in their visual model comprehension, which individual characteristics predict visual model comprehension and whether visual model comprehension is able to predict academic success. To do so, we accompanied 275 chemistry and 208 engineering students over the whole course of their first university year. 37.3% of the students were female, and their average age was 21.15 years. Students participated voluntarily and were rewarded with credit points as well as financial incentives if they completed all assessments.

The main study includes three times of measurement for our visual model comprehension test (start of first semester, end of first semester and end of second semester). All students have to solve all 33 items (that is, chemistry students also worked on the 11 engineering items and vice versa). Besides visual model comprehension, we also assessed the respective content knowledge (chemistry/engineering) of the students with standardized achievement tests and other individual learner characteristics such as cognitive abilities (verbal and figural reasoning; Heller & Perleth, 2000), spatial ability (Eckstrom et al. 1976), mathematical competencies and others. Furthermore, and in addition to the standardized achievement tests, we also assessed
the grades that students received in their lecture-based exams as an important indicator for academic success.

DATA ANALYSIS AND RESULTS

In a first step, we wanted to find out whether visual model comprehension indeed plays such a major role with regard to knowledge acquisition and study success. To shed more light on this, we first calculated scores for visual model comprehension with regard to the sum of the 33 test items as well as for the three scales individually. Next, we calculated regression analyses, in which we included the visual model comprehension scores as predictors and performance from the standardized knowledge tests as well as from the lecture exams as criterion variables.

As can be seen in Table 1, the overall score of visual model comprehension is able to predict domain-related content knowledge significantly for the standardized chemistry ($\beta = .586; p < .001$) and engineering ($\beta = .541; p < .001$) test. Analogously, performance in the lecture exams in chemistry ($\beta = .467; p < .001$) and engineering ($\beta = .305; p = .008$) could be predicted by the overall visual model comprehension score. A very similar pattern of results can also be found with regard to the predictive power of the three subscales of visual model
comprehension, which can predict content knowledge in chemistry as well as engineering (all $\beta \geq .333$; all $p < .001$) and, with one exception for engineering, also predict study success in terms of exam grades significantly.

In line with our expectations, visual model comprehension is an important predictor of knowledge gains and study success. It is thus interesting to know whether there are individual learner characteristics which, in turn, predict visual model comprehension, as this knowledge could help supporting learners with respective deficits as optimally as possible. To do so, we calculated multiple regression analyses, in which we included different learner characteristics as potential predictors and the respective visual model comprehension scores as criterion variables. These multiple regression analyses were calculated separately for chemistry students and for engineering students as we assumed domain-specific differences (Table 2).

</tbody>
</table>
For both student groups, domain-specific prior knowledge is the strongest predictor of visual model comprehension ($\beta = .339$ resp. $\beta = .391$; both $p < .001$). Not as strong, but still significantly, visual model comprehension of chemistry and engineering students is predicted by spatial ability ($\beta = .163$ resp. $\beta = .132$; both $p < .05$) and by mathematical abilities ($\beta = .156$ resp. $\beta = .125$; both $p < .001$). Furthermore, cognitive abilities in terms of figural reasoning significantly predict visual model comprehension for chemistry and engineering students ($\beta = .186$ resp. $\beta = .223$; both $p < .001$). In addition, cognitive abilities in terms of verbal reasoning also predict visual model comprehension for chemistry students ($\beta = .225$; $p < .001$), but not for engineering students ($p > .10$).

Moreover, we were interested in whether chemistry versus engineering students, although visual model comprehension seems to be an important part of studying abilities for both groups, differ in their visual model comprehension as well as in other learner characteristics. To do so, we calculated multivariate analyses of variance (MANOVAs). As dependent variables for the potential group differences in visual model comprehension, we included the scores of the three respective scales of the visual model comprehension test; and the factor was the study domain (chemistry versus engineering). Figure 3 depicts the results of this analysis. It can be seen that visual model comprehension in general seems to be higher for chemistry students. They outperform engineering students with regard to the chemistry items ($F(3,483) = 62.32$; $p < .001$), the general items ($F(3,483) = 9.86$; $p = .002$) as well as for the overall scale ($F(3,483) = 29.56$; $p < .001$). Only for the engineering items, chemistry students didn’t outperform the engineering students, but contrary to expectations, the latter weren’t significantly better on this scale either ($F(3,483) = 2.154$; $p = .143$).

In addition to these results, chemistry students performed better with regard to cognitive abilities in terms of verbal ($F(4,443) = 24.54$; $p < .001$) and figural reasoning ($F(4,443) = 13.32$; $p < .001$) and with regard to spatial ability ($F(4,443) = 6.69$; $p = .01$). With regard to mathematical abilities, we did not find any difference between chemistry and engineering students ($F(4,443) = 1.407$; $p = .236$). These results are summarized in Figure 4.
Finally, the results of the second point of measurement of our study shows, that visual model comprehension is able to predict lecture exams and the standardized knowledge test. Due to the presentation on the ESERA 2017, these results weren’t part of the presentation and will be presented and discuss on future conferences and articles.

Figure 4. Differences between chemistry and engineering students with regard to their individual learner characteristics.

CONCLUSION AND SIGNIFICANCE OF THE STUDY

Our results confirm that visual model comprehension seems to be an important individual learner prerequisite for academic success in chemistry and engineering studies. It is able to predict knowledge acquisition as well as study success in these domains and is in turn predicted by several other learner characteristics such as spatial ability, figural reasoning, mathematical ability and verbal reasoning. Furthermore, it seems that our visual model comprehension test can measure this ability validly and reliably and on a domain-specific as well on a general level.

Moreover, we discovered that chemistry students in general seem to have a higher visual model comprehension than engineering students. In this regard, the question remains whether this gap gets even larger throughout the university time because of the differences in study requirements for chemistry versus engineering students. This would be crucial, because as has been mentioned above, in both domains the acquisition of content knowledge as well as study success in general are strongly predicted by visual model comprehension. Thus, if we aim at supporting knowledge acquisition and study success in science-related studies, we should think about possibilities to increase either visual model comprehension or/and its predictors. The success of such trainings, on the other hand, also depends on the question whether visual model comprehension is a rather stable trait or whether it can change/improve over time and over the course of the different university subjects. This is one aspect that the future course of our long-term project will focus on. Furthermore, we will have a closer look at the domain-related differences and at the requirements that different knowledge areas place on different aspects of visual model comprehension.

ACADEMIC ACHIEVEMENT OF CHEMISTRY FRESHMEN – INTERRELATIONS BETWEEN PREREQUISITES AND CONTENT KNOWLEDGE ACQUISITION

Daniel Averbeck, Eckart Hasselbrink and Elke Sumfleth
University of Duisburg-Essen, Essen, Germany

The number of students who successfully complete their study programs has decreased during the last decades, especially with respect to chemistry. Accordingly, analyzing predictors of academic achievement becomes more important in order to reduce these dropout rates. Although a lot of studies examining predictors of study success exist, most of them do not focus particularly on chemistry, use different cohorts or investigate different variables. The few studies that examine subject-specific predictors mostly refer to general chemistry courses or examine freshmen in a cross-sectional study. Accordingly, the impact variables for the process of content knowledge acquisition cannot be clarified. In our study we selected different cognitive, affective and motivational factors and analyze the impact on prior knowledge (performance in a pre-test at the beginning of the term), content knowledge (performance in a post-test at the end of the term) and on content knowledge acquisition (difference between the amount of prior and content knowledge) of freshmen in chemistry study programs. Further, we investigated the interrelations between these types of knowledge in the basic chemical sub-disciplines. To do so, we surveyed 265 freshmen in chemistry at two universities in Germany using questionnaires and tests in a longitudinal study with three points of measurement during the first and second semester and analyzed the data using multivariate regression analysis. First results indicate that prior knowledge in general chemistry and mathematical abilities of freshmen are the most important impact variables for content knowledge, content knowledge acquisition and academic achievement in the basic sub-disciplines within the entry phase of chemistry study programs.

Keywords: academic achievement, chemistry

OBJECTIVES OF THE STUDY

On the one hand the demand for scientists is steadily growing, especially with respect to chemistry. On the other hand a study of the National Center for Education Statistics, for instance, published recently that only 3 % of American post-secondary students took up physical science studies including chemistry (Chen, 2014). According to a German study, only 2 % of all freshmen entered chemistry study programs (Society of German Chemists, 2016). This already low number of students decreases continually during years of study because of high dropout rates. In the United States up to 46 % of freshmen in physical sciences do not complete the program successfully (Chen, 2014). In Germany, up to 43 % of chemistry students leave the program without a bachelor degree or change their major within the STEM fields (Heublein, Richter, Schmelzer, & Sommer, 2012). Therefore, it is necessary to identify factors that contribute to study success in chemistry in order to develop supporting procedures for freshmen and reduce these dropout rates. In this regard, the focus of our research is to analyze the impact of various affective, motivational and cognitive factors on the level of chemistry content knowledge as well as on content knowledge acquisition of B. Sc. Chemistry students as central prerequisites for study success in the entry phase of chemistry study programs.
THEORETICAL FRAMEWORK

Up to now, a large number of studies has already examined predictors of academic achievement. Some focus on affective factors such as students’ interest (e.g. Shi, Drzymalski, & Guo, 2014) or satisfaction with the study program (e.g. Lourdes Machado, Brites, Magalhães, & Sá, 2011; Mavondo, Tsarenko, & Gabbott, 2004), others examine motivational predictors (e.g. Kosovich, Hulleman, Barron, & Getty, 2015) or are limited to cognitive factors like prior knowledge (e.g. Hailikari, Nevgi, & Komulainen, 2008) or students’ Grade Point Average (GPA) in high school (e.g. Power, Robertson, & Baker, 1987). However, most of these studies investigate different cohorts, use different operationalizations of study success, examine the influence of only a few isolated variables or focus on non-subject-specific factors. Accordingly, the results are difficult to compare and not transferable to academic achievement in the field of chemistry.

In contrast to this, only a few studies have already examined chemistry-specific predictors for achievement but predominantly focus on the introductory course of general chemistry because this “[…] first college chemistry course plays an important role in the academic trajectory of college students […]” (Tai, Ward, & Sadler, 2006, p. 1703). These studies established the Grade Point Average in high school (Carmichael, Bauer, Sevenair, Hunter, & Gambrell, 1986; Freyer, Epple, Brand, Schiebener, & Sumfleth, 2014; Tai, Sadler, & Loehr, 2005) as well as the high school grade in chemistry (Dougherty, Jian, & Mellor, 2006) as the most important impact variables. In addition, the prior knowledge (Hailikari et al., 2008) as well as students’ chemistry education background (Tai et al., 2006; Yager, Snider, & Krajcik, 1988) seem to predict study success in this introductory chemistry course. Furthermore, investigations indicate that students’ logical thinking skills (Lewis & Lewis, 2007; Tai et al., 2006), the intelligence (Freyer et al., 2014) and their mathematical abilities (Legg, Greenbowe, & Legg, 2001; McFate & Olmsted, 1999) show a remarkable impact on academic achievement in general chemistry.

In addition to general chemistry, chemical freshmen have to take courses in further chemical sub-disciplines like inorganic, organic and physical chemistry during the entry phase. Research investigating predictors for academic achievement in these chemistry sub-disciplines is rather scarce.

The most powerful predictor for study success in the sub-discipline of physical chemistry, for instance, are – according to Hahn & Polik (2004) - the mathematical as well as the problem-solving abilities (Derrick & Derrick, 2002) of the students. Furthermore, students’ physical content knowledge (Tsaparis, 2007) and their logical thinking skills (Bitner, 1991; Nicoll & Francisco, 2001) predict academic achievement.

As far as we know, only three studies on predictors for academic achievement in organic chemistry exist. Exclusively students’ prior knowledge in organic chemistry (Hailikari et al., 2008) and their spatial abilities (Pribyl & Bodner, 1987; Wu & Shah, 2004) can be considered as impact variables in this subject.

We could not identify any study assessing predictors for study success in analytical and inorganic chemistry at all.
To sum up, most of the aforementioned investigations show a certain gap in research because they focus on different variables influencing study success or use different definitions of academic achievement which leads to different relevant predictors. Furthermore, investigations focus non-subject-specific variables solely or mainly focus on the introductory course of general chemistry. Consequently, the influences of cognitive, affective and motivational variables on academic achievement in the other chemical sub-disciplines are not yet examined. Moreover, the different interrelations between these various chemical sub-disciplines as well as the dependencies of students’ content knowledge acquisition during the entry phase of the study program have not been clarified so far.

Hence, our research project aims at clarifying the impact of selected cognitive, affective and motivational factors on prior knowledge and content knowledge in each of the chemistry sub-disciplines. We also investigate the interrelations of prior knowledge (at the beginning of the term) and content knowledge (at the end of the term) between these sub-disciplines in order to identify impact variables for students’ content knowledge acquisition as a central factor for academic achievement during the entry phase of the program.

**METHOD & SAMPLE**

In order to achieve the aforementioned objectives, we carried out a longitudinal study at two different universities in Germany. The first one is the University of Duisburg-Essen (UDE) and the second on the Ruhr-University Bochum (RUB). The order of the various chemical sub-disciplines the students have to attend during the entry phase at both universities can be seen in Figure 1.

![Figure 1: Curriculum of the first and second semester of chemistry study programs](image)

As Figure 1 illustrates, the students at both universities have to attend an introductory course in general chemistry during the first semester. At the University of Duisburg-Essen, the students also have to attend a course in physical chemistry in this semester. In contrast to this, the students at the Ruhr-University Bochum take a course in analytical chemistry. In the second semester the introductory course of general chemistry ends at both universities. Additionally to an advanced physical respectively analytical chemistry course, the students have to attend specific courses in organic and inorganic chemistry. All courses consist of a typical lecture held by a professor, a tutorial where the students have to work on several tasks and a lab course.
To analyze predictors of academic achievement and potential interrelations between the several chemical sub-disciplines, we chose a longitudinal study design with points of measurement at the beginning (MSP1) and the end (MSP2) of the first semester and at the end of the second semester (MSP3). To assess the prior knowledge as well as content knowledge in the various chemical sub-disciplines, specific content knowledge tests in a multiple-choice single-select format for each sub-discipline were administered. All tests were developed based on the respective lectures to guarantee content validity.

At the point of measurement 1 we examined students’ content knowledge in the sub-disciplines of general, physical and analytical chemistry. The score sums reached in these performance-tests at the beginning of the term are defined as the students’ prior knowledge. Additionally, various students’ prerequisites shown below were captured at this point of measurement. At the end of the first semester we carried out the corresponding post-test in general, physical and analytical chemistry. The students’ level of university content knowledge at the end of the course was derived from these posttest scores. Additionally, we assessed the prior knowledge in the various sub-disciplines the students have to attend during the second semester. At the point of measurement 3 the corresponding post-test in organic, inorganic and in the advanced physical and analytical chemistry courses took place.

As possible predictors for prior knowledge, content knowledge and knowledge acquisition, we focused on factors which have already been proved as impact variables in other investigations. In our study these are the interest, the self-concept, self-efficacy, satisfaction with the program and motivation in terms of expectancy-value-cost (Kosovich et al., 2015), assessed with questionnaires based on 5-point Likert scales. Further, data on cognitive abilities, the GPA (A-Level), gender and chemistry course choice (advanced or basic) in high school were collected.

The aforementioned questionnaires and tests were completed by 118 freshmen in B.Sc. Chemistry at the University of Duisburg-Essen with an average age of 20.7 (SD = 2.6) years. 39 % of the students were female. At the Ruhr-University Bochum 157 Students with an average age of 20.5 (SD = 2.9) participated in the study. 36 % of them were female.

To shed light on the various dependencies we analyzed the data using multivariate regression analysis (Cohen, 2010). As we assessed students at two different universities with different orders of the chemical sub-disciplines, we calculated the parameters using multiple-group models. In these models the regression coefficients of the impact variables on the dependent variables were estimated simultaneously for the different groups of students. Differences of the path coefficients between the investigated groups were tested by imposing cross-group equality constraints on the path coefficients and compare the constrained and unconstrained models in terms of model fit (Byrne, 2012; Cheung & Rensvold, 2002).

Due to the not fully completed data analysis only results from the first two points of measurement will be presented in this paper.
RESULTS

In the first step of our analysis, the influences of the various cognitive, affective and motivational factors on prior knowledge in general, physical and analytical chemistry were estimated simultaneously. The results can be seen in Figure 2.

\[ \chi^2 = 117.21, df = 109, p = 0.320, CFI = 0.994, TLI = 0.992, RMSEA = 0.021 \]

Note: Only the significant standardized regression coefficients are shown. If the regression coefficients do not differ between the two universities, only one value is shown, otherwise: 1st (UDE) / 2nd (RUB).

Figure 3: Predictors for Prior Knowledge (MSP1)

As Figure 2 shows, the course selection in high school is the strongest predictor for prior knowledge in general chemistry with a high effect ($\beta = .321, p < .001$) at both universities. Additionally, the mathematical abilities of the students also show a remarkable impact on prior knowledge in this sub-discipline ($\beta = .310, p < .001$). Furthermore, students’ interest in chemistry, the cognitive abilities as well as their gender are also predictable for prior knowledge in general chemistry. Moreover, the influences of these predictors do not differ between the two universities.

With regard to the prior knowledge in analytical chemistry Figure 2 illustrates that the strongest predictor seems to be the course selection in high school again ($\beta = .330, p < .001$). This result seems to be plausible because the content between analytical and general chemistry largely overlap, which is also visible by the correlation between both sub-disciplines ($r = .466, p < .001$). Further, students’ interest as well as their mathematical abilities also show moderate influences on prior knowledge in analytical chemistry.

Finally, the strongest predictor for prior knowledge in physical chemistry seems to be the mathematical abilities of the students. This result seems to be plausible too, because the content of physical chemistry like quantum mechanics or thermodynamics requires significantly more
calculations as well as dealing with mathematical equations. Additionally, the interest of the students also show a moderate effect at both universities ($\beta = .180$, $p < .001$) as well as the cognitive abilities at the Ruhr-University Bochum. At the University of Duisburg-Essen the male students perform better in the prior knowledge test than the female ones. As other investigations like PISA have already shown, girls often underestimate their abilities predominantly in sciences. In this regard we assume that these differences between the regression coefficients presumably results from an interaction of gender and the cognitive abilities.

In summary, it can be stated that prior knowledge in the various sub-disciplines mainly depends on the selection of an advanced chemistry course in high school, students’ mathematical abilities as well as on interest in chemistry. All of the other cognitive, affective and motivational factors show no significant influences on prior knowledge at the beginning of the study programme.

In the second step of our analysis, we try to examine predictors for university content knowledge at the end of the term and deduced from that for content knowledge acquisition. To do so, we regressed the students’ prerequisites used before and the respective prior knowledge on the scores sums reached in the various posttest of general, physical and analytical chemistry carried out at point of measurement 2. Impact variables that influence content knowledge as long as the corresponding prior knowledge is controlled for can be seen as predictors for content knowledge acquisition in the respective sub-discipline. The results of the second step of our analysis are shown in Figure 3.

\[ \chi^2 = 168.05, df = 162, p = 0.356, CFI = 0.997, TLI = 0.996, RMSEA = 0.016 \]

*Note: Only the significant standardized regression coefficients are shown. If the regression coefficients do not differ between the two universities, only one value is shown, otherwise: 1st (UDE) / 2nd (RUB).*

**Figure 4: Predictors for Content Knowledge (MSP2)**
Figure 3 illustrates that the prior knowledge in general chemistry is the strongest predictor for the corresponding content knowledge with a very high effect at both universities (β = .377, p < .001). After that, gender (β = .188, p < .001) and the Grade Point Average in high school (β = .175, p < .001) also influence the content knowledge with a moderate regression coefficient. Finally, students’ mathematical abilities and their Grade Point Average in high school also predict content knowledge in general chemistry. Since these variables influence content knowledge in general chemistry while controlling for prior knowledge, they seem to increase content knowledge acquisition during the first semester.

Regarding content knowledge and content knowledge acquisition in analytical chemistry, Figure 3 shows that the strongest predictor for the amount of content knowledge in the post-test is the corresponding prior knowledge again. On the other hand it is also evident that this kind of prior knowledge decreases when the students get an opportunity to learn because there is a higher value of the regression coefficient at the University of Duisburg-Essen as at the Ruhr-University (β_{UDE} = .395, p < .001; β_{RUB} = .221, p < .001). Also, a very strong predictor for content knowledge in the sub-discipline of analytical chemistry seems to be the prior knowledge in general chemistry. For the reason that this kind of prior knowledge shows also a direct effect while controlling for prior knowledge in analytical chemistry, general chemistry seems to increase the content knowledge acquisition in analytical chemistry. This effect becomes more important, if the students have to attend a lecture in the first semester (β_{UDE} = .321, p < .001; β_{RUB} = .344, p < .001). We assume that the students at the Ruhr-University of Bochum are able to create more interrelations between the content of these two sub-discipline.

Finally, our analysis show that the GPA, the mathematical abilities as well as the gender of the students become significant for content knowledge and content knowledge acquisition in analytical chemistry.

For content knowledge in physical chemistry a similar trend can be observed. As can be seen in Figure 3, the prior knowledge in physical chemistry predicts its corresponding content knowledge with a different effect size depending on the opportunity to learn (β_{UDE} = .389, p < .001; β_{RUB} = .435, p < .001). Moreover, the prior knowledge in general chemistry also show an influence on the amount of content knowledge as well as on content knowledge acquisition in this chemical sub-discipline. This influence also becomes more important if the students have to attend a course in physical chemistry during the first semester (β_{UDE} = .201, p < .001; β_{RUB} = .140, p < .001). Finally, students’ mathematical and cognitive abilities as well as the gender show a direct impact on content knowledge respectively on content knowledge acquisition.

In the last step of our analysis, we regressed all of the students’ prerequisites used before as well as the prior knowledge and content knowledge in general, physical and analytical chemistry on students’ prior knowledge in organic and inorganic chemistry, also assessed at the point of measurement 2. For improved clarity, the results of this regression analysis are shown in Table 1.

Note: Only the significant standardized regression coefficients are shown. If the regression coefficients do not differ between the two universities, only one value is shown, otherwise: 1st (UDE) / 2nd (RUB).

With regard to prior knowledge in organic chemistry Table 1 shows the best predictors are prior knowledge ($\beta = .293, p < .001$) and the corresponding content knowledge in general chemistry ($\beta = .250, p < .001$). It can therefore be concluded that students who perform well in general chemistry also show a high score in the pre-test of organic chemistry. We assume that this relationship also results from the course selection in high school and the curriculum of upper secondary-schools. Students who have chosen an advanced chemistry course in Germany are working on the topics of organic and general chemistry much more intensively than other students. Accordingly, they perform better in the tests of both sub-disciplines. Beyond that, we conclude that a profound knowledge in general chemistry seems to be necessary to develop an elaborate understanding of chemical principles in organic chemistry.

Furthermore, the prior knowledge at the Ruhr-University Bochum as well as content knowledge in analytical chemistry at both universities influence prior knowledge in organic chemistry. We assume that the knowledge of the students who do not have to attend a course in analytical chemistry does not change during the first semester. Therefore, we assume that the influence of prior knowledge in analytical chemistry of students at the University of Duisburg-Essen is completely mediated by the amount of content knowledge at the end of the term.

With regard to prior knowledge in inorganic chemistry Table 1 illustrates that also content knowledge in general chemistry, students’ prior knowledge and the corresponding content knowledge in analytical as well as content knowledge in physical chemistry show a significant influence. The regression coefficients of analytical and physical chemistry also differs between the two universities for the reasons already mentioned. Nevertheless, students’ content knowledge in general, analytical and physical chemistry seems to be important for an elaborate understanding of the principles in inorganic chemistry.
DISCUSSION AND CONCLUSION

As can be deduced from the results of the first step of our multiple-group regression analysis, students’ prior knowledge in general, physical and analytical chemistry mainly depends on the course selection in high school, students’ mathematical abilities and their interest in chemistry. In the second part the results further underline that the corresponding prior knowledge is a very strong predictor for the amount of content knowledge in the basic sub-disciplines of general, analytical and physical chemistry during the first semester of B. Sc. Chemistry students. These results are in line with previous research showing effects of students’ cognitive prerequisites on study success in chemistry (e.g. Dochy, Rijdt, & Dyck, 2016; Freyer et al., 2014; Hailikari et al., 2008; Tai et al., 2006). Dochy et al. (2016), for instance, illustrates the importance of domain-specific prior knowledge on academic achievement. In addition, we are able to show that prior knowledge in general chemistry also shows a remarkable influence on the amount of content knowledge in analytical and physical chemistry and that a well-developed prior knowledge in general chemistry also increases the content knowledge acquisition in these two sub-disciplines at the end of the first semester. Finally, the last step of our analysis shows that a well-developed content knowledge in general chemistry seems to be a strong impact variable on prior knowledge in further specific chemistry courses like organic or inorganic chemistry. Therefore, we conclude that the introductory course of general chemistry seems to fulfill the purpose of enabling students to learn the fundamental principles of chemistry in order to develop a basis for the further study program.

Moreover, our results show that only students’ mathematical and cognitive abilities, the gender as well as the Grade Point Average in high school also show a significant influence on content knowledge and content knowledge acquisition during the entry phase of the program. The other motivational, affective and cognitive preconditions of the students such as the self-efficacy or motivation are predominantly mediated by the various kinds of prior knowledge and show no direct impact on content knowledge acquisition.

Regarding this, our conclusion is that prior knowledge in general chemistry seems to be the most important factor for content knowledge, content knowledge acquisition and, in consequence, for academic achievement in the entry phase of chemical study programs. Accordingly, we are convinced that universities can get clues for identification and the possibility to support at-risk students at an early stage of the study program by assessing the amount of prior knowledge in general chemistry. Following this, advanced training courses in general chemistry, for instance, can be implemented to improve prior knowledge of at-risk students, increase their content knowledge acquisition as well as academic achievement and decrease the enormous dropout rates of freshmen in chemistry study programs.

EXPLORE ONE TERTIARY CHEMISTRY LABORATORY COURSE FROM CHAT PERSPECTIVE

Xiaomei Yan¹ and Justin Dillon²
¹ Smart Learning Institute, Beijing Normal University, Beijing, China
² University of Exeter, Exeter, UK

The insufficient issues of the science laboratory course were well acknowledged across education levels. Believe in the importance of tertiary chemistry laboratory education (TCLE), this paper conducts an empirical study to explore the issues of the tertiary traditional laboratory. In particular, the issues of diverse learning objects and disengagement of students are explored. In order to obtain in-depth understandings regarding these issues, Cultural Historical Activity Theory (CHAT) is employed to examine the complex learning environment in TCLE. The empirical study took part over a period of three months in an undergraduate Chemistry course in a prestigious English university. Data collection was guided by CHAT, using individual interviews, observations and documentary analysis. The participants included 12 students working in three groups of four, 5 demonstrators and 4 course tutors in a second year chemistry laboratory course. The discussions guided by CHAT shed new lights into the issues of TCLE. The inconsistencies between ‘the objects’ and the learning context were highlighted. The finding identified the different orientations towards ‘the object’ among the tutors, students and demonstrators. This echoes to the research literature which pointed out the issue which the participants did not share the same object of learning in the TCLE. These differences also accounted for the mismatch between the students’ experience and the tutors’ design of the course. For example, the tutors made use of an ICT supported learning environment (DLM) and formative assessment schemes in order to improve the students’ learning experience in the laboratory. However, the findings identified the issues of students’ disengagement with DLM in pre-lab and the transferrable issues between information in DLM and the operations in the laboratory. Moreover, the findings also supported the research literature which claimed the important role of ‘demonstrators’ (or research assistants) on students’ learning experience in TCLE. It is suggested to include the pedagogical training on the preparation of the ‘demonstrators’ in TCLE.

Keywords: activity theory, tertiary chemistry education, chemistry laboratory education

INTRODUCTION

There are plenty of critiques on the ‘traditional laboratory’ and/or “the recipe-style laboratory activity” in the literature on science education (for example, Buntine, et al, 2007). The laboratory education is well acknowledged of its insufficiency across education levels (i.e. Domin, 2007; Johnstone & Al-Shuailli, 2001). This issue is critical for TCLE also (i.e. Kirschner&Meester, 1988; Read &Kable, 2007; Zoller& Pushkin, 2007). On one hand, the critical role of practical activities in chemistry and chemistry education is well accepted (Hawkes, 2004). For example, the Royal Society of Chemistry (RSC) requires the minimum 400 laboratory hours exclusive of a major research project during undergraduate studies at university (RSC, 2009: 7; McGarvery, 2004) in UK. On the other hand, the learning experiences in the laboratory are very expensive in terms of staff time, support, consumable materials and equipment (Hughes & Overton, 2009). In response to the tendency of a considerable reduction in time allocated to laboratory learning, “it is imperative that what time
is left is spent extremely effectively and efficiently” (Reid & Shah, 2007: 179). Therefore, some educators raised the questions of what should be learnt and how should one learn in the expensive laboratory (e.g., Bennett & O’Neale, 1998; Hawkes, 2004). This study carried out an empirical study to explore what is learnt and how it is learnt in TCLE.

LITERATURE REVIEW:

Based on a social constructivist perspective, educators have advocated a reconsideration of the nature of laboratory activities (Driver et al., 2000), including tertiary chemistry laboratory work. In particular, specific issues, including the diverse learning objectives of the tertiary chemistry laboratory education (what to learn) and inefficiencies of the traditional type of laboratory (how to learn), are reviewed in this section. Before the further review of the research literature, the terms of ‘practical’ and ‘laboratory’, which have been used interchangeably in some literature, is clarified. The term ‘laboratory’ education refers to ‘any activity relating to experimenting, such as demonstrations, real laboratories, pen and paper experiments, computer simulations, etc’ (Kirschner & Meester, 1988:83). ‘Laboratory’ work refers to ‘practical activities which students undertake using chemicals and equipment in a chemistry laboratory’ (Reid & Shah, 2007:177). This study is particularly focuses on the ‘laboratory’ work of ‘practical’ education at the university level.

Ineffective goals of science laboratory education

The aims of a laboratory course are important for teachers’ teaching (Johnstone & Al-Shuaili, 2001) and students’ learning (Tsaparlis & Gorezi, 2005). However, Reid and Shah (2007) argued that some instructors’ learning objectives of the practical course are either so detailed that they could not be applied to other contexts, or too general. Moreover, Talanquer and Pollard (2010:76) highlighted the shift of the focus from acquiring core chemical knowledge to mastering core ‘chemical ways of thinking’ in their summary of the new initiatives in the chemistry curriculum at the higher education level. Growing diversity of the science graduates’ career prospect, including chemistry disciplines, further promotes the shifting of the aim of tertiary education (Hughes & Overton, 2009; Reid & Shah, 2007). The diverse learning objectives lead to ambiguity of the laboratory course (Buntine et al., 2007), based on their study in university chemistry laboratory courses in Australia. In response, a number of initiatives have developed to address different learning goals of laboratory courses at tertiary level. There are also several projects developed to prepare the students with skills needed in future career, such as industrial work experience (Hughes & Overton, 2009), and research-based projects in the United States and other countries (Vallarino, Polo & Esperdy, 2001). Read and Kable (2007:270) developed the ACELL project to prepare the students with the specific skills required by their future scientific careers along with an ‘appreciation for and understanding of important scientific principles’. Although the reform initiatives took different forms and targeted various problems, most of them shared the features of giving the students more responsibility for designing the experimental procedures than the traditional format. However, some researchers (e.g., Harrison & Heslop, 2010; Winberg & Berg, 2007), who were interested in undergraduate science studies, often encountered the contradictions between expected educational aims of laboratory sessions and traditional laboratory experience.
Inefficiency of traditional laboratory education

A number of researchers (e.g., Buntine et al., 2007; Johnstone & Al-Shuaili, 2001; Kirschner & Meester, 1988; Reid & Shah, 2007) criticized the traditional laboratory activity in tertiary education as neither efficient nor effective in delivering learning. In particular, Hofstein and Lunetta (2004) summarized the problems in the traditional laboratory education in their study at secondary education level, as including 1) students’ preoccupation with manipulative procedures during the experiment session, 2) students’ lack of time and opportunities for reflective thinking and the inquiry process, and 3) insufficient assessment tools. Some researchers (e.g., Buntine et al., 2007; Carter, Ferzli & Wiebe, 2007) argue that these conclusions of Hofstein and Lunetta (1998; 2004) remain true today and are still relevant to tertiary chemistry laboratory education.

The most common problem in scientific laboratory is that students are occupied by manipulative tasks instead of being engaged in reflective thinking (e.g., Harrison & Heslop, 2010; Johnstone & Al-Shuaili, 2001; Winberg & Berg, 2007). In particular, Reid and Shah (2007: 177) pointed out the problem of ‘too much emphasis on the experiments to be performed and not enough emphasis on what the students should be gaining’. Moreover, McGarvery (2004:59) criticized the assessment tools, which require ‘generating ‘good’ reports with ‘correct’ data analysis and ‘correcting’ results from most students’ and did not reflect the students' understanding of the experiments. Furthermore, Hughes and Overton (2009) pointed out issues of overloading the curriculum in higher education, including the laboratory course. Nevertheless, some educators in tertiary science education (e.g., Domin, 2007; Hughes & Overton, 2009; Reid & Shah, 2007; Zoller & Pushkin, 2007) have claimed that simple reforms of traditional laboratories can offer the opportunities of achieving the expected educational aims. The suggested changes include implementing a new curriculum, new assessment schemes, more personalized and in-time feedback, a multimedia supported learning environment, as well as pre-laboratory and post-laboratory activities (e.g., McGarvery, 2004; Harrison & Heslop, 2010). The educators expect the students would be better prepared and more confident with the manipulations during the experiment sessions and would enables them to have some critical reflections upon the experimental procedures.

METHOD

The literature on science laboratory education (e.g., Marks & Eilks, 2009, Johnstone & Al-Shuaili, 2001) including TCLE (Farrell, Moog & Spencer, 1999), suggests the need to explore the issues in laboratory education from a social cultural perspective, which identifies these issues within their institutional, social and historical context (Reid & Shah, 2007). In response, Cultural Historical Activity Theory (CHAT) as an integrating and flexible social cultural theory, offers heuristic perspectives to explore the complex learning environment in TCLE. The implications of CHAT within science education research have inspired educators and researchers to rethink several traditional concepts (Roth et al., 2009). CHAT also serves as a methodological tool in this study, providing several models for guiding the empirical research design and data analysis.
Engeström's structure of activity system

Distinct from other social cultural theories, CHAT focuses on the social activities mediated by tools within the particular cultural-historical context (Langemeyer & Nissen 2005). Researchers using CHAT (e.g., Daniels, 2000; Kuttii, 1995) summarised its basic principles which include the integrated analysis unit, the tool mediation and the object orientation of the activity system, historical context situated-ness, the multi-voiced-ness and the inner contradictions. One of the core concepts of CHAT is to regard the whole activity system as the unit of analysis. This concept enables the study to explore the learning environment of the laboratory course in a holistic way.

Engeström (1987) developed a complex triangle model to illustrate the basic analysis unit, the activity system (Daniels 2001) (as illustrated in Figure 1). Within the triangle model, the activity system is composed of interacting components, including subject, tool, object, outcome, rule, community and division of labour. Both social and material resources, which are usually hidden in context, are illustrated in the triangle model (Roth & Lee 2007).

Figure 1. Illustration of the activity system of chemistry laboratory course

As Miettinen (2005: 53) stated, the activity system is bounded by object: *The activity does not have a direction and does not really start until the object of activity is defined.* Due to this object-oriented nature of activity (Kaptelinin & Miettinen, 2005), the identification of one activity system starts from the ‘object’. Engeström (2000b) elaborated on the interactions between ‘subject – object’: the subject is motivated to work towards the object, at the same time, the object transforms the subject through the activities, and then, a new object will be generated (Ruth & Lee, 2007). Therefore, the concept of ‘object’ enables the discussions on the relations between participants’ perceived aims and the object of the chemistry laboratory course in this study.
‘Community’ is defined by Roth and Lee (2007:199) as ‘within and for which some activity takes place’. The community of the activity system in this study involves the people in the course (the students, the tutors, the demonstrators and the technicians). ‘The rules’ in the activity system define what kinds of behaviour are acceptable or unacceptable. In this study, how teaching and learning are regulated in the laboratory course were explored. ‘The division of labour’ reveals the distribution of the responsibilities and practices among the subjects within the activity system. In this study, the responsibilities of teaching and learning in the laboratory course were investigated. Nevertheless, this study does not aim to identify entities under the moments of the activity system separately, but to focus on the interactions within and beyond the activity system.

Study context

The empirical study took part over a period of three months in an undergraduate Chemistry course in a prestigious English university. The chemistry laboratory course in this research was regarded as the activity system. Data collection was guided by CHAT, using individual interviews, observations and documentary analysis. The participants included 12 students working in three groups of four, five demonstrators (or Research assistants) and four course tutors. They were part of a larger cohort of 147 students, 26 demonstrators and 5 course tutors in a second year chemistry laboratory course. The learning environment was mapped out and illustrated by moments of the activity system with Engeström’s (1987) triangle model (as shown in Figure 1).

This activity system was part of UK Centres for Excellence in Teaching and Learning programme, which was funded to implement several changes to address the historical challenges of a traditional type of laboratory. The teaching laboratories in this centre were refurbished with upgraded safety features and better facilities. The facilities in the laboratories are described as ‘state-of-the-art, professional standard facilities for the teaching and learning of chemistry’s core practical elements’ on the centre’s website. Besides the upgraded laboratories with modern equipment, the tutors also re-designed and developed the laboratory courses to address the inefficiency problems in the traditional laboratory.

RESULTS

The analysis of the activity system with Engeström’s triangle model provides insights into TCLE, especially the issues of diverse learning objects and disengagement of students in traditional laboratory.

---

1The centres for excellence in teaching and learning (CETLs) programme was a funding initiative offered by the Higher Education Funding Council for England (HEFCE) from 2005. This initiative aimed to enhance the status of learning and teaching in higher education. http://www.hefce.ac.uk/pubs/rereports/Year/2011/cetlsummevaln/Title.92265.en.html (retrieved from the Internet on 30/06/2015)
Contradictions between subjects and objects

In this research, the subjects’ orientations towards the object of the activity system were explored through the interviews with students, demonstrators, and tutors. The finding identified the different orientations towards the object among the tutors, students, and demonstrators. The students’ and demonstrators’ views agreed with the shift in the literature on epistemological understanding of chemistry in scientific laboratory education, which is different to tutors. All students, demonstrators, and tutors regarded the laboratory course as an essential part of the chemistry education in their interviews.

All the students in the interviews agreed that they had learnt the essential practical skills through the experiments. These skills include the key chemistry practical techniques/skills (e.g., the re-crystallizations practiced in the experiments) and the operations of the important machines and equipment (i.e., the Schenkline and the liquid IR used in the experiments). For instance, when asked about what students had learnt in the laboratory, they replied:

To learn new skills, procedures, machines through the lab. (Group1, Emily/individual interview)

And also that is so much practical things I wouldn’t know, like the Schenkline, the IR, etc. (Group 2, Miho/individual interview)

The above quotes exemplified that students acknowledged the practical skills as an essential part of the object. Similarly, the demonstrators expected the students to acquire these practical skills through the experiments. Some of the students (five out of twelve) acknowledged that the laboratory course offered them an in-person experience of the laboratory-based chemistry inquiry. The students experienced the routines of doing the experiments in the laboratory, and got familiar with the environment of the laboratory. As one of the students described her experience in the laboratory:

When I first started in the lab, I didn’t feel comfortable. I didn’t know what I suppose to do, whether I supposed to touch this or [...] but by now, it has become natural: I get to know about safety [...] I don’t feel I’m lost anymore. (Group1, Debby/individual interview)

Three tutors (out of five tutors in total) stated that one of the objects was for students to know the norms and rules of working in the laboratory. Moreover, this view was agreed by most of the demonstrators as well (four out of five demonstrators in total explicitly mentioned this in their interviews). Nevertheless, there were different opinions expressed by the students, demonstrators, and tutors: the students and demonstrators also included ‘understanding about experiments and chemistry theories’ as the aims of this activity system. In particular, the aspects of ‘understanding of chemistry involved in experiments’ and ‘understanding of the design and procedures of the experiments’ were mentioned by students and demonstrators.

All the students claimed that by doing experiments they understood better about the theory they learnt in the lectures. For instance, the following quote extracted from one student’s interview represents similar views of her classmates:

The experience of laboratory is helpful in a way that you get more understanding; what you’ve been taught will be more relevant. You understand it [lecture] more when you see
the applications of it. [...] I see the day of lab as like a whole day of a revision session, it just re-teaches you what you’ve learnt from another aspect... then you actually get the whole picture. (Group 2, Miho/individual interview)

Miho thought the participation in experiments offered a context for her to understand the chemistry theories involved and reinforce these theories which they had learnt in other contexts. All demonstrators agreed with this view and further explained the two-way relationship between acquiring practical skills and understanding chemistry theories. For instance, demonstrator Isobel explained explicitly in her interview the interrelations between theory and practical skills:

*I think both knowledge and technique is important for labs, at the end of day, chemistry is a very practical subject, so you have to do the practicals. Because that’s a huge part of what chemistry means; but at the same time, you shouldn’t do procedures without understanding. I think they come with each other.* (Demonstrator, Isobel/ individual interview)

Moreover, most of the demonstrators and the students pointed out that the course should not only teach the students to conduct certain techniques, but also let the students understand these techniques and be able to apply the techniques in other conditions. For example, one group of students compared their experience in the physics laboratory with this chemistry course, as shown in Lisa’s quote below:

*In physics, they want you to understand, and they get you to design [the experiments] and then think about error. [...] I feel much more capable in a physics lab [...] to understand what’s going on and problem-solve myself. While in here [chemistry lab] I feel a bit like I have to constantly ask for help, if I don’t understand, kind of at my limit.* (Group 3, Lisa/individual interview)

The above quote shows that Lisa would like to understand the design of the chemistry experiments better and she thought that the insufficient understanding of the experiments resulted in her lack of confidence in the laboratory. Similarly, most demonstrators (four out of five) claimed that it was necessary for students to understand the processes of experiments. In particular, demonstrator Karen explicitly highlighted the importance for students to understand the procedure in her interview:

*To be able to fill a flask is not a skill, but to understand why you need to fill a flask, now, with these particular chemicals, that is a skill.* (Demonstrator, Karen/ individual interview)

As with Karen’s view above, the other three demonstrators also claimed that acquiring practical skills means the students would not only be able to conduct these techniques but also be able to know when and where to use them. For example, demonstrator Emily emphasized the understanding of experiments in her interview:

*I expect them to understand what the experiments illustrate or understanding how a particular effect works; for one experiment, for instance, we look at electrical charge on something, afterwards I expect them to understand what the charge does and to maybe apply this knowledge to another situation.* (Demonstrator, Emily/ individual interview)
Furthermore, all demonstrators emphasized that the students need to be able to interpret the data, including the unexpected data. For example, demonstrator Isobel explicitly raised the example of encountering unexpected data in laboratory as below:

_The students have been used to getting nice sets of data. However, there still will be some experiments that do not really work; even though they were well-designed undergrads laboratory experiments. So they [the students] will have some experience of encountering unexpected results or errors in experiments._ (Demonstrator, Isobel/individual interview)

Isobel’s colleagues similarly expressed the idea that students should be able to explain the empirical data obtained from experiments. Therefore, in both demonstrators’ and students’ perceptions, the objectives of this system should also be to include the understanding of chemistry theories involved in experiments, a critical review of the design and procedures of experiments, as well as interpreting the empirical data. However, students’ expectations of improving their understanding of chemistry theories were not addressed in tutors’ intentions and designs of experiments.

**Contradictions between the design of the course and the students’ experience**

Moreover, the laboratory course made use of an ICT supported learning environment (DLM) and formative assessment schemes in order to tackle the well documented problem of students’ pre-occupation with procedures in the laboratory. The assessment schemes were across the pre-lab, in-lab and post-lab stages of the laboratory course, assessing different aspects of students’ learning. However, the findings identified the issues of students’ disengagement with DLM in pre-lab and the transferrable issues of information in DLM to the operations in the laboratory.

DLM, the on-line learning environment, was developed by tutors in this laboratory course for students to complete the pre-laboratory activities, to be available as an on-line laboratory manual in the laboratory and for demonstrators and tutors to record the evaluation and feedback. In DLM, there was information about the background of the experiments, the procedures, and the key techniques. DLM also offered multi-media resources, including text-based information, video clips and also interactive simulations preparing students before the laboratory. Students mentioned that the information in DLM was a ‘good starting point’ for them to prepare for the experiment reports. All students also appreciated DLM in terms of preparing them for the experiments.

As for pre-lab experiences, all students thought DLM offered the basic information about the chemistry knowledge involved in the experiments, the processes of the experiments and the safety issues involved. For example, the following quote illustrates how DLM helped them to prepare for the experiments:

[…] doing it in this way [with pre-lab in DLM], you go to the lab and you see whatever results you get, but also you understand it as it goes along, you get lots more from it [doing the experiments]. (Group 1, Debby/individual interview).

The above quotes highlight the importance of prior preparations for enhancing students’ engagement in the laboratory. Moreover, the simulation and the video resources in DLM presented the key techniques more clearly than the written text in the students’ handbooks.
Among the multi-media information in the DLM, students particularly appreciated the video presentations of the key techniques, which prepared them for the hands-on operations in the laboratory. Students also mentioned the specific simulations with which they could do ‘trial-and-error’ in a safe environment. Therefore, before the students went in the laboratory, they had a better idea of key processes of the experiments and the expected results.

Students’ experience and perceived benefits of DLM were in accordance with the tutors’ design of the DLM. For example, tutor Charles explained explicitly that DLM was to prepare the students before they go into the lab:

\[
\text{[...]} \text{if the students go through DLM, they can start to do the experiment straight away in the laboratory \[...\] instead of wasting an hour of reading the instructions and figuring out the operations of the equipment \[...\] they [the students] know what to expect and they know what they are doing in the lab. (Tutor, Charles/individual interview)}
\]

The above quote indicates that tutors expected that, by using DLM, students would be prepared for the laboratory experience with regards to both knowledge and skills. Students were expected to be more focused and confident in performing the experiments. This was verified by demonstrators’ experience in the laboratory, for example, as shown in one of the demonstrators’ interview that:

\[
\text{Some conscientious students will go through all the theory stuff there and read all the instructions, and they know what to do once they get there, and it’ll save them a lot of time. (Demonstrator, Isobel/individual interview)}
\]

As with Isobel’s quote above, all demonstrators claimed that most students who went through the DLM prior to the experiments were well prepared and confident in conducting the experiments. Nevertheless, there were some gaps identified between the tutors’ design and the students’ experience regarding the information in DLM. For instance, there were also some students’ comments that specific instructions in DLM could be clearer and easier to understand. Moreover, there were disconnections between the presentations in DLM and the students’ operations in the laboratory.

The interview data highlighted the issue of some students’ lack of engagement with DLM. For instance, some demonstrators pointed out that, even with the video presentations in DLM, some students failed to connect the contents of the DLM/ handbook with the real settings in the laboratory. The following quote from demonstrator Jerry explained these disconnections between information in DLM and students’ performance in the laboratory, based on his observation:

\[
\text{DLM has the basic information there, but still there is a gap between what you see in DLM, either simulations, text, or video, and the real things they can carry out in the labs. (Demonstrator, Jerry/individual interview)}
\]

It seems that the students failed to recognize what was presented and explained in DLM, or it could be due to the students’ disengagement with DLM. For example, demonstrators complained that some students finished the tests in DLM without real understanding of the experiments:
[Some students] went through the DLM but failed to really take it in (Demonstrator, Karen).

All students admitted that the effectiveness of DLM on preparing them for laboratory depended on how much effort they put into it. For example, the following quote from students’ interviews showed the typical opinion:

 [...] actually no one really read through the instructions in DLM; unless it [the experiment] is really hard that you have to look up it [on DLM]. (Group 2, Steven/individual interview)

Therefore, students admitted their disengagement with DLM and attributed this to different reasons, such as their lack of motivation or the design of DLM. In response to this issue of disengagement with DLM, tutors requested students to pass pre-laboratory tests in DLM.

The important roles of demonstrators

Furthermore, the demonstrators’ roles were highlighted in this activity system. This finding supports the previous studies on roles of post-graduate teaching assistants (GAs or TAs) in teaching and learning in tertiary science education, including the chemistry laboratory context. However, the findings indicated that the subjects placed different a focus on the demonstrators’ roles, and the mismatch between the demonstrators’ receiving training and their responsibilities.

The subjects (include students, demonstrators, tutors and technicians) of the system shared the responsibilities of the course. The demonstrators assumed the major role of supporting students in the laboratory. The demonstrators worked in pairs and took turns to spend three hours a day in the laboratory. Each pair of demonstrators was assigned to look after 14-15 students for each session. All subjects (including the students, the demonstrators and the tutors) acknowledged the practical helps the demonstrators offered in the laboratory.

Tutors expected the demonstrators to ensure the students’ safe conduct of experiments, to answer the students’ questions, to demonstrate specific operations and also to represent the correct manner of conducting experiments. The tutors also expected the demonstrators to build good rapport with the students in order to improve the students’ understanding of what post-graduate chemistry studies and research involved. Moreover, the demonstrators were also responsible for the students’ assessment.

The demonstrators’ understanding of experiments was well appreciated by students, and expected from the tutors. In particular, students mentioned that the roles of demonstrators were complimentary to the information offered in DLM and manuals. The demonstrators’ highlighted and demonstrated some key techniques or procedures which reinforced what the students learnt from the DLM/manuals. The following quotes from students’ interviews reveals their appreciation of the support from demonstrators:

 [...] Demonstrating how to do it appropriately is very good, it reinforces what you see in the DLM, because in DLM you might not quite understand it. (Group 3, David/individual interview)
The above quotes show the demonstrators’ support on site was very useful, perhaps because of the disconnections between the resources in DLM and students’ performance in the laboratory. Students especially seemed to appreciate the demonstrators’ reassurance during the experiments. The students’ reliance on demonstrators’ reassurance in the laboratory raised the question of students’ confidence and concern of students’ pre-occupation in the laboratory.

Although the demonstrators assumed critical roles in the laboratory, the training for demonstrators was very limited. Consistent with tutors’ perceptions of the demonstrators’ major roles in laboratory, training they offered to the demonstrators focused on the safety issues. During the training, the tutors offered basic information about the laboratory course and emphasized the strict procedures of safety rules. As verified by demonstrators’ interviews, the safety issues were highlighted in their training prior, as shown in the following quote:

*We had a talk with [the tutor]. We need to make sure the safety of lab and run through the experiments before.* (Demonstrator, Isobel/individual interview)

The demonstrators were asked to shadow the previous demonstrators and get suggestions from them in an informal way. This informal way of training results from the tutors’ belief that the demonstrators were not teachers and they (the tutors) believe the routines of demonstrating tasks in laboratory were straightforward and could be learnt from observations. The tutors claimed that the demonstrators can pick up the roles intuitively, as exemplified in the following quote:

*You can get the routine of demonstrators’ tasks in laboratory by observing a couple of experiments. The most important is for them [the demonstrators] to make sure that students behave safely and they should [the demonstrators] know their experiments very well.* (Tutor, Tim/individual interview)

Moreover, the tutors claimed that the different styles of the demonstrators enriched the students’ experience. In particular, Tutor Charles explicitly explained the diversity styles of the demonstrators’ work were appreciated:

*They [the demonstrators] are not teachers […] and it would be beneficial for the students to experience the different styles.* (Tutor, Charles/individual interview)

Although the demonstrators’ diverse styles could be appreciated, their quality of delivering constructive support to students and inspiring students to reflect on experiments needed consistency.

**DISCUSSIONS AND CONCLUSIONS**

The implications of CHAT pictorially illustrated the complex relationships between argumentation and the learning environment. Guided by CHAT concept of contradictions, the findings of this study identified several contradictions embedded in the laboratory course. CHAT guided discussions shed new light on the inefficiency and ineffectiveness of the laboratory course. As discussed, echoing with the research literature on TCLE regarding diverse learning goals, this study also identified the different perceptions regarding the object of the laboratory course among the tutors, students and demonstrators. The differences between the tutors’ focus on the objects of the laboratory course and the national standard document of
QAA were also identified. Therefore, the discussions of contradictions brought opportunities for further development of the laboratory course.

ACKNOWLEDGEMENT

I would thank you all tutors, demonstrators, and students who participated in my study from Chemistry department (but can’t directly be named). My sincere appreciations also go to my patient and encouraging PhD supervisors.

SCAFFOLDING STUDENTS’ REFLECTIVE DIALOGUES IN THE CHEMISTRY LAB: CHALLENGING THE COOKBOOK

Birgitte Lund Nielsen¹ and Rikke Frøhlich Hougaard²
¹Science & Technology Learning Lab, Aarhus University and VIA University College, Aarhus, Denmark
²Science & Technology Learning Lab, Aarhus University, Aarhus, Denmark

The paper reports on a cross-case analysis comparing students’ activities and dialogue during BA level laboratory exercises, applying a mixed methods research design with video-data, student questionnaires and interviews. Our analysis identified specific affordances in relation to macro and micro-scaffolding of students’ activities and dialogues, in order to stimulate them to work at higher cognitive levels. A lab-exercise in the course Macroscopic Physical Chemistry was redesigned with the aim of stimulating students’ metacognition both before and during the experimental work. The redesign included a prelab task, related to planning experimental work and explaining theory, and a definite level of openness in relation to the choice of data points. The analysis of activities and dialogue during the laboratory work indicated that this rather simple redesign of a laboratory exercise successfully supported/stimulated student-student dialogue on course content. Furthermore, dialogue between students and teaching assistant revealed elements of exploratory talk including a dialogic approach with open questions and prompts. The students expressed that the preparatory assignments and the dialogue with the teaching assistant supported their understanding. The redesigned exercise cannot be labelled as a full inquiry-based laboratory exercise, but the students were scaffolded in guided inquiry, making definite choices related to calculations, representations, and assessing their data.

Keywords: chemistry education, laboratory activities, scaffolding

INTRODUCTION

Laboratory work is an established part of science education both at secondary level and in higher education (Reid & Shah, 2007). A range of challenges concerning student learning from laboratory activities have however been discussed in research. First of all, many laboratory activities are characterized by a lack of clearly defined purpose reflected in intended learning outcomes relating to both practical and generic skills, in addition to content understanding (Hofstein & Kind, 2012). Laboratory exercises are often instructed by the use of a cookbook-like manual, although it is well documented that this do not efficiently support students’ learning of higher cognitive skills (Domin,1999). In contrast, decades of research have highlighted the potential of (guided) inquiry-oriented laboratory activities to engage students in higher order thinking via the manipulation of both equipment and ideas (Hofstein & Kind, 2012). Millar, Tiberghien and Le Maréchal (2006) for example suggest to raise the degree of openness, offering students more complete laboratory tasks including planning and designing experiments and getting feedback from peers and teacher.

Evidently, there appears to be a gap between research results and the actual development in the teaching laboratories i.e. at the universities. Educational development of the laboratory teaching might best be implemented in close collaboration with the scientific staff, identifying the intended learning outcomes and discussing how challenges evidenced also by local data
can be targeted. Such a process must include both the teaching assistants (TAs) who are often responsible for the main part of the direct instruction in the lab, and the professors who have more influence on the instructional design (Addy & Blanchard, 2010).

This paper presents data collected in the frames of an educational development process with teaching assistants (TAs) and professors at the chemistry department at our university. The paper does not report on the cooperative process per se, but on the evidence of students’ activities and dialogues that was discussed in the process. These data inspired the collaborative redesign of a course, including specific initiatives to support students’ pre-lab preparation and follow-up activities (Millar et al., 2006; Reid & Shah, 2007; Winberg & Berg, 2007).

COMMUNICATION AND DIALOGUE IN THE LAB

Referring to a social constructivist theory of learning, dialogue among peers and with the teacher must be seen as essential for student learning outcomes in general, and in the laboratory in particular (Andersson & Enghag, 2017). Research has focused on how the teacher can support and scaffold student dialogue using a variation of communicative approaches (Scott, Mortimer, & Aguiar, 2006). A particular kind of student dialogue is the so-called exploratory talk where statements and suggestions are offered for joint consideration by the students, engaging critically and constructively with each other’s ideas and sharing thoughts about phenomena (Mercer & Dawes, 2014). Exploratory talk is often hesitant and incomplete, but comprehensive research, mainly from the secondary level, strongly suggests the learning opportunities when students are trying out their conceptual understanding through exploratory talk (Barnes, 2009). Mercer & Dawes (2014) opposes exploratory talk to disputational talk, typically based on disagreement with assertions and counter assertions where students are not searching for developing a shared understanding, and cumulative talk when students build positively but uncritically on fellow students’ ideas.

The teachers’ scaffolding can be executed both at macro- and micro-level (Prediger & Pohler, 2015; Pollias, 2016). Macro-scaffolding refers to the planned sequencing of activities whereas micro-scaffolding refers to the immediate strategies the teacher uses in-class e.g. in dialogue, engaging students’ perspectives and asking questions (Pollias, 2016, p. 98).

In relation to communication and dialogue specifically in the laboratory teaching at university level Andersson and Enghag (2017) have systematically analysed what students actually do and talk about during laboratory work in a university level physics course. They also among other theoretical references refer to exploratory talk, and call for more research looking into what is really going on during laboratory teaching at the university level.

This study provides such detailed evidence guided by the following research questions:

**Research questions**

RQ1: What can be condensed as typical features concerning students’ activities and dialogues during BA-chemistry laboratory exercises across courses at Aarhus University?

RQ2: What possibilities, challenges and specific affordances in relation to macro and micro-scaffolding students’ activities and dialogues can be identified?
RQ3: What characterizes students’ activities, dialogue and perceived outcomes working with the redesigned laboratory-exercise liquid-liquid phase diagram in the course Macroscopic Physical Chemistry?

METHOD

A sequentially mixed methods research design was applied (Creswell, & Clark, 2007).

RQ1 is answered by analysing video-data, student questionnaires and interviews from three different local laboratory courses: General chemistry, Environmental chemistry and Ecophysiology. Possibilities and challenges have been identified by cross-case analyses (RQ2), and based on these findings some laboratory courses are now being redesigned, i.e. a lab-course in Macroscopic Physical Chemistry redesigned in close collaboration with the professor and TAs.

RQ3 is answered by a questionnaire (n=61) with both open and closed categories, administered to students after the redesigned laboratory exercise liquid-liquid phase diagram, video-data and post interviews from two groups of students, each with three students. The redesign of this specific exercise included both specifying and sharing the learning goals with students and letting the students construct a flowchart describing the experiment (pre-lab) and choosing data points, followed by feedback from the TA at the start of the lab. During laboratory exercises the students had to make a range of calculations, assessing and evaluating own results and assembling their data into a phase-diagram used as the basis for in-situ feedback and in a post-laboratory report. The questionnaire focused on the students’ perception of the laboratory activities, and of their own preparation and learning process.

Interviews, video-data and open categories in the questionnaire have been analysed using data-based thematic analysis (Braun & Clarke, 2006). Open reflections from the questionnaire and video following two student groups in each laboratory exercise have been coded with the final categories, after an iterative process, and with a final quantitative coding with two coders, calculating inter-rater reliability. The closed categories in the questionnaire have been analysed by frequency and cross tabulations also including the coded open answers.

RESULTS

Students’ activities and dialogues analyzed in three laboratory courses

Cross-case video analysis of the three very different laboratory courses revealed rather large variations regarding how students spent their working time during (the same) laboratory exercise (Figure 1). Across courses it was however a general finding that relatively little time was spent talking about scientific concepts, theory and methods. The time spent in the laboratory for the groups of students in the three courses represented in Figure 1 varied between 2h 18 min and 5h 35 min, but the dialogue about science (theory and methods) was in all cases only 8-15 minutes (Figure 2).
Particular differences were identified on how students spent the waiting time, which is inherent to complex laboratory procedures (between 8% and 35% waiting time in the same laboratory exercise) (Figure 1). The analysis suggested that the teacher to a high degree affected students’ behaviour during the waiting time. Thus, for the group with most waiting time in the General Chemistry course, it was observed that the TA suggested the group members to take a break spent with coffee, cake and small-talk during the waiting time. In contrast, the other group had much less waiting time because the TA suggested them to work on the data analysis, so in Figure 1 this is coded as “data and report”.

The students themselves referred to the effect of the teacher scaffolding their work with the data immediately:

“We usually just sit and watch. But the reason ... we worked on data/report.. was because [the TA] suggested we could spend our waiting-time on the report”. (Interview)

“It has forced us to explore new ideas, which we would have postponed to the next day. There is no question about it”. (Interview)

It was as mentioned above a common finding across cases that only very little time, less than
10% of students’ time in the laboratory, was spent on dialogue with peers or TAs about the theoretical content of the exercises and/or data and results (Figure 2). Dialogues between the students and the TAs during the laboratory exercises typically concerned how to use the equipment, but not how to understand the procedures or the theory. The dialogue was characterized by the TA using closed questions resulting in a predominance of interactive-authoritative or non-interactive communicative approaches (Scott et al., 2006).

Many students expressed that they just followed the cookbook and postponed further understanding:

“I only focused on collecting the data ... that is primarily how exercises works for me. It has something to do with collecting data and then there’s the theory – that somehow comes afterwards”. (Interview)

When asked about their use of content specific knowledge during the laboratory work, between 12% and 50% of the students stated that they used their content specific knowledge. This suggest that the majority of the students complete the laboratory work without having talked or thought about the theory related to the experiment. This is reflected in the following student quotes from the interviews:

“..just do what you are told and take the numbers and put them into the given formula and then you get the precise results you are expected to get.,”

”..it is more about answering than understanding..”.

Summarizing the data from the cross-case analysis it is clear, that the students perceive their work in the laboratory as unconnected with the theory. The students both in survey and interviews expressed that they applied their scientific knowledge only to a very limited extent during their time in the laboratory. This was not explicitly problematized by the students, suggesting that they might be enculturated into an instructional approach where they are expected to follow a cook-book like recipe step-by-step.

This “doing without understanding” was however problematized when discussing the local data with scientific staff. Based on these discussions in the educational development process, a new laboratory exercise in the course “Microscopic physical chemistry” was developed with the purpose of stimulating students’ scientific thinking and subject specific dialogue.

The redesigned lab-exercise liquid-liquid phase diagram

The redesigned laboratory exercise is related to the concept of Phase Separation and involves the constructions of a liquid-liquid phase diagram based on students’ own measurements. The various elements in the redesign of the laboratory exercise liquid-liquid phase diagram are illustrated in Figure 3. The model used in Figure 3 to represent the redesigned course is presented and discussed in more generic terms in the perspectives below. This model was introduced as a tool in the educational development process.

The most prominent feature in the instructional design (Figure 3) is that students are provided with a laboratory manual, which contains only minimal information about the theory related to the experiment. Instead, students are guided towards acquiring and applying the relevant theory
by conceptual questions and experimental predictions to be answered before the laboratory class (pre-lab). In addition, it was required that the students completed a work-plan describing in details how they would carry out the experiment. This part contained a certain degree of openness (Millar et al., 2006), since the students should decide on their own which dilutions to make, and which points of measurements to take. Based on their initial measurements they were asked to repeat the experiment and adjust the conditions to obtain a better diagram (represented by a yellow arrow in Figure 3).

Figure 3. The instructional design in the redesigned course in physical chemistry. The model describes the teacher (blue) and student (black) tasks before the laboratory work (pre-lab), in the laboratory, and after the laboratory work. The yellow arrow represents a step where students are expected to adjust and repeat their measurements based on their first set of data.

Analyses of the video observations from the redesigned exercise showed no significant differences between time spent on the overall activities when comparing groups (Figure 4). This is opposite to the cross-case analysis above, where significant differences in the macro-structure of the work in the student groups were observed within the same course.

Figure 4. Students’ activities during the laboratory work in the redesigned experiment liquid-liquid phase diagram. Activities were quantified by coding video following two student groups. Each series represents one group. The data are represented as the percentage of the total amount of time the group spent in the laboratory.

In general, the observed students spent quite a lot of time talking about chemistry-related topics with each other and the TA. In average 33 % of the conversations during their time in the laboratory were related to higher order cognitive tasks, such as understanding chemistry theory and evaluation of data, and 50 % were related to more practical issues related to the experimental work. Several indications suggest that the macro-scaffolding of students’ pre-
laboratory work established the base for the qualified scientific dialogue. As one student expressed:

“The pre-lab questions are really good... then you know what you are doing as you go along. In other modules, you often just follow the manual and then afterwards you figure out what you did”.

In the interviews, the students expressed that they appreciated this type of instructional design, and that it affected their motivation and learning during the laboratory work, here exemplified with quotes from four students from the interviews:

“It is a useful way to do a report with these questions ... at least it’s a more fun way to do it”

“Yes, I also think you learn more, better.”

“I think this works better than just going for it and not think about anything until afterwards...”

“Yeah, then you’ll have an idea about what to expect from the experiment.”

It was also clear that the micro-scaffolding from the TA, posing open questions and providing prompts, was of significant importance for initiation of dialogue about chemical theory. Dialogue about theory and method was 34-52% of the student-TA dialogue versus 20-27% of the student-student dialogue.

A detailed analysis of the dialogue demonstrated that the majority of the student-TA dialogue was interactive-dialogic (Scott et al., 2006), and 20% could be classified as exploratory talk (Barnes, 2009). Several students in their open reflections specifically mentioned that the dialogue with the TA supported their learning:

“...the TA added new knowledge by asking questions and explaining”.

“Sometimes you’ll just stand there feeling uncomfortable having to decide something and know the answer beforehand. This time the TA helped us and that was really nice”.

In the questionnaire, nearly 80 % of the students stated that they found the pre-lab activities helpful to a “very high degree” or to a “high degree” (Figure 5). They also reported about using their subject knowledge during the laboratory work to a considerable higher degree than seen in the cross-case analysis.

Figure 5. Students’ application and learning of thermodynamics in the laboratory. A graphical representation of students’ answers related to the application and learning of thermodynamics in the laboratory (n= 58).
DISCUSSION AND CONCLUSIONS

It is evident that the students who attended the redesigned laboratory exercise “Liquid-liquid phase diagram,” spent more time on dialogue about the experiment with indications of higher order thinking, compared to the typical pattern seen across cases. The students’ pre-lab work with theory and planning of laboratory work and their work on plotting and adjusting a phase-diagram based on own data, can be seen as a macro-scaffolding structure (Pollias, 2016). This supported the students’ metacognition: planning how to approach the learning task, monitoring comprehension and evaluating progress (Hofstein & Kind, 2012, p.198). Furthermore, the macro-scaffolding helped to avoid the great differences in the macro-structure across student groups seen in the cross-case analysis. In our interpretation, these differences in how the time was spent in the laboratory in the same exercise could be due to some of the students “doing without understanding”. This is supported by the students’ utterances in the interviews (quotes above).

Opposite to this there were of course differences between groups at the micro-level also in the redesigned course, for example in the dialogue. This is mirroring the micro-scaffolding (Pollias, 2016), where the TA successfully targeted the challenges experienced by the individual student groups on the spot. Examples of dialogues between the students and the TA revealed elements of micro-scaffolding their exploratory talk (Barnes, 2009) by using open questions and prompts, and a more dialogic approach (Scott et al, 2006) than the average approach seen in the cross-case analysis.

In the questionnaire, the students expressed that talking with the TA influenced their learning. Furthermore, they expressed that the pre-lab work, supported their understanding during the laboratory work.

Concluding on this research it seems that a rather simple redesign of a lab exercise can successfully challenge the typical cookbook approach. The redesigned exercise cannot be labelled as a full inquiry-based lab exercise (Hofstein & Kind, 2012), but the students were scaffolded in guided inquiry, working at higher cognitive levels (Domin, 1999), making their own calculations, representations, and assessment of data both pre- and during lab.

PERSPECTIVES

The findings presented have implications both for laboratory teaching – how to support student learning in the laboratory – and for educational development at the university. The findings confirm what have been seen in several studies internationally, that a cookbook approach is still frequently used in lab courses at university despite years of research advocating inquiry and context based approaches (Hofstein & Kind, 2012; Reid & Shah, 2007). The good news is that a rather “simple”, but focused redesign thoroughly planned in collaboration between educational developer and academic staff from the science department seem to have rather large effects on some of the challenges identified in research in relation to this predominant cookbook approach. So, such small steps with degrees of openness (Millar et al., 2006) planned collaboratively might be the way to work on the gap between what is recommended based on research and the actual practice in the laboratory teaching at many universities.
Figure 6. A generic version of the model used in the educational development. The model represented in a generic version in Figure 6 was used above in Figure 3 to illustrate the concrete instructional design. The model describes the teacher (blue) and student (grey) tasks before the laboratory work (pre-lab), in the laboratory, and after the laboratory work. The yellow arrow represents a step where students adjust and repeat their measurements based on their first set of data and formative feedback. Looking forward, we are using the model in the continuing work on educational development i.e. in redesigning laboratory courses at our university.

EVALUATING THE EFFECTIVENESS OF A TUTORIAL INTERVENTION ON STUDENTS’ LEARNING OF THE WORK-ENERGY AND IMPULSE-MOMENTUM THEOREMS

Mikko H. P. Kesonen, Risto Leinonen, Mervi A. Asikainen and Pekka E. Hirvonen

Department of Physics and Mathematics, University of Eastern Finland, Joensuu, Finland

This study evaluates the effectiveness of an implementation of Tutorials in Introductory Physics curriculum. In this study, the use of tutorials was extended from a small classroom environment into a lecture hall setting with the aid of a 90 min tutorial intervention. A total of 77 introductory students participated in the intervention after relevant subject matter had been covered in a lecture-based physics course. Students’ learning was evaluated by using research-based test questions at the beginning and end of the intervention. According to the results, the proportion of students who successfully applied the work-energy and impulse-momentum theorems increased approximately 30 percentage points during the intervention. This improvement is comparable to those obtained in small classroom implementations, which shows that the effectiveness of tutorial curriculum is transferable to different implementation formats. This suggests that in the development of an effective and transferable instructional innovations rely more on tasks and activities students are engaged with, rather than its implementation format.

Keywords: higher education, evaluation, research informed teaching

INTRODUCTION

Research-based instructional innovations have proven more effective than traditional teaching methods (Handelsman et al., 2004). In recent years, a relevant question has been that what makes these innovations transferable and effective in different educational contexts (Kryjevskaia, Boudreaux, & Dustin, 2014; Henderson & Dancy, 2012). To shed some light to this question, the present study focuses on an alternative implementation of Tutorials in Introductory Physics curriculum (McDermott & Shaffer, 2002).

Tutorial curriculum is one of the most well-known research-based instructional innovations of physics in US (Henderson & Dancy, 2009) and elsewhere. The curriculum is designed to supplement lecture-based instruction at the introductory level of university studies. Its implementation is typically challenging since it requires commitment and exceptional teaching practices, such as small classroom sessions with 25 students guided by two instructors (Pollock & Finkelstein, 2008; Finkelstein & Pollack, 2005; McDermott & Shaffer, 2003). Due to these and other implementation challenges, certain institutes (e.g. Riegler et al., 2016) have stopped using the tutorials.

To ease the implementation, the tutorials can be used in a lecture format where the small classroom sessions are replaced with interactive lectures. In the course of these lectures, students answer quiz questions via classroom response system (Lasry, 2008; Walgren, 2011), work in pairs or small groups whilst answering the tutorial tasks, and are engaged with whole-class discussion lead by a lecturer (McDermott & Shaffer, 2003). Kryjevskaia et al., (2014)
have shown that this format can be as effective as the small classroom implementation of the tutorials. Their results have suggested that the effectiveness of tutorials results more from its content, such as tasks and activities students are guided to do, rather than the type of classroom setting where the tutorials are taken place.

Using the tutorials in the lecture format involve whole-class discussions where a lecturer is having a dialogue with students. This form of instruction is influenced by lecturer’s personality and charisma (Garcia, Kupczynski, & Hollond, 2011) which means that the lecture format likely provides an instructor-dependent indication of the effectiveness of the tutorials. To evaluate the effectiveness of tutorials more objectively, we have developed the tutorial intervention that does not involve the whole-class discussions. This tutorial intervention permits the use of the tutorials in a lecture hall, and it allows monitoring students’ learning occurred in the course of the intervention.

This study evaluates the effectiveness of tutorial intervention in the topics of the work-energy and impulse-momentum theorems. These theorems are important for students to grasp because they tie together essential of the concepts and quantities introduced in classical mechanics at various educational levels. Besides this, these theorems are powerful tools for solving a wide range of problems in mechanics (Singh & Rosengrant, 2003; Mungan, 2005), and they can be used to analyze many everyday phenomena, such as determining the vertical jump high with the aid of the force plate (Linthorne, 2001).

The work-energy theorem says that work $W$ done on an object equals to the change of its kinetic energy $K$. According to the impulse-momentum theorem, impulse $I$ exerted to an object equals to the change of its momentum $p$. With the aid of definitions of work $W = \vec{F}_{net} \cdot \Delta \vec{s}$, kinetic energy $K = \frac{1}{2}mv^2$, impulse $I = \vec{F}_{net} \Delta t$, and momentum $p = m\vec{v}$, the theorems can be written as below.

$$W = \vec{F}_{net} \cdot \Delta \vec{s} = \Delta K = \frac{1}{2}mv_f^2 - \frac{1}{2}mv_i^2 \quad (1)$$

$$I = \vec{F}_{net} \Delta t = \Delta p = m\vec{v}_f - m\vec{v}_i \quad (2)$$

Earlier studies in the field of physics education research have identified specific difficulties encountered by students in the process of learning these theorems (Singh & Rosengrant, 2003; Tang, Tan, & Yeo, 2011; Dega & Govender, 2016; Close & Heron, 2010; Pride, Vokos, & McDermott, 1998; Lawson & McDermott, 1987). For example, students have been found to reason in terms of the individual definitions of concepts work, kinetic energy, impulse, or momentum rather than applying the actual theorems per se (Pride et al., 1998). This has become evident when students have claimed that two blocks will have the same momentum, even if the net force, equal for both blocks, acts on the heavier block the longer period of time (Lawson & McDermott, 1987). These students have argued that the momentum of both of the blocks is equal because the heavier block moves slower and the lighter block moves faster, and the momentum is defined as a product of mass and velocity. In other words, a greater mass is thought to compensate slower speed, and vice versa, with the result that both of the blocks have equal momentum. This type of incorrect reasoning is known as a compensation argument.
(Lawson & McDermott, 1987), and it has proven to hinder students’ learning of the impulse-momentum theorem in various educational settings (Dega & Govender, 2016).

In the case of the work-energy theorem, students have been found to use the compensation argument in a more sophisticated manner related to the definition of the kinetic energy. Students have argued that speed determines which of the blocks’ kinetic energy is greater, because speed appears quadratically rather than linearly in the definition of the kinetic energy. (Pride et al., 1998) This has become evident when students have argued that the lighter object moves faster, and therefore it has greater kinetic energy than the heavier object, even if equal net force acts on both of the blocks at the same distance (Lawson & McDermott, 1987).

In the present study, the students’ difficulties described above have been taken into account in the evaluation of the effectiveness of the tutorial intervention that aims at supporting students’ learning of the work-energy and impulse-momentum theorems. The research question is stated as follows:

How well do students apply the work-energy and impulse-momentum theorems at the beginning and end of the tutorial intervention?

In answering it, we contribute to an existing understanding of how to support students’ learning of the important work-energy and impulse-momentum theorems.

TUTORIAL INTERVENTION AND DATA COLLECTION

The present study was conducted in a first year physics course Basic Physics I (5 ECTS) at the University of Eastern Finland in fall 2016. The course covers the basics of classical mechanics by following the textbook by Knight (2014). In every year approximately 100 students participate in the course, mainly majoring in physics, mathematics, or chemistry.

The course itself was rather conventional involving lecturing and the presentation of homework problems. In addition to the lectures and homework sessions, the tutorial intervention was held three times during the course covering the topics of force, the concept of work, and the work-energy and impulse-momentum theorems, respectively. Prior to the tutorial interventions, the topics addressed were presented in the lectures and further discussed in the homework sessions.

At the beginning of the intervention addressing the work-energy and impulse-momentum theorems, students answered individually to a pretest (10 min). During next 70 minutes, students worked collaboratively through the tutorial activities that were presented in the tutorial worksheet. During this stage, four teaching assistants aimed at supporting the students’ learning by questioning them rather than providing correct answers to the tutorial activities, as advised by the developers of the tutorial curriculum (McDermott & Shaffer, 2002). Finally, students answered individually to a posttest (10 min).

The tutorial worksheet was based on Changes in Energy and Momentum tutorial (McDermott & Shaffer, 2002, pp. 43-47). The questions used in the pretest and posttest were based on previous research on students’ understanding of the work-energy and impulse-momentum theorems (Pride et al., 1998). Prior to the intervention, the tutorial worksheet and pre- and

2 For more information on the tutorial activities, see reference (Pride et al., 1998).
posttest questions were translated in Finnish. The translations were check by the course lecturer and an experienced researcher (3rd author) to ensure that the material was properly translated and matched the terminology that was used during the course.

A total of 77 students participated in the intervention, out of which 69 gave a permission to use their answers for research purposes. The data consisted of these students’ pretest and posttest answers that were collected in a written form at the end of the tutorial intervention. In the analysis, the students’ answers were categorized based on to what extent they were consistent with the work-energy and impulse-momentum theorems or earlier reported difficulties. The descriptive statistics are used to present the proportions of students’ answers classified into the main categories. The analysis was performed by the 1st author.

RESULTS

At the beginning of tutorial intervention (in the pretest), the students were asked to compare kinetic energies and momenta of blocks A and B after they had glided through a fixed distance on the frictionless surface under the influence of the net constant force $F_0$ (see Figure 1). The students were also asked to explain their reasoning.

According to the work-energy theorem (equation 1), both of the blocks have the same kinetic energy after gliding from the starting line to the finish line, because the work done on the blocks are equal and both of them starts moving from the rest. Block B has, however, greater momentum than block A, because block B is heavier and therefore the net constant force $F_0$ acts on it longer period of time before it reaches the finish line. Due to this longer time period, block B has greater impulse than block A, and according to the impulse-momentum theorem (equation 2), this means that block B has greater final momentum than block A.

![Figure 1: Description of a task used in the pretest (modified from (Pride et al., 1998))](image)

At the end of the tutorial intervention (in the posttest), students were asked a similar set of questions with the exception of shorter distance travelled by block A. In the posttest item, block B obtained greater kinetic energy and momentum than block A.

The results regarding students’ learning of the work-energy theorem are presented in Figure 2. At the beginning of the tutorial intervention, 13% of students successfully applied the work-energy theorem. After working through the tutorial, 42% of students were able to apply the theorem as desired. Thus, the proportion of students who successfully applied the work-energy theorem increased with 29 percentage points during the tutorial intervention.

The majority of students (77%) were unable to apply the work-energy theorem at the beginning of the tutorial intervention. Typically, these students reasoned in terms of the definition of
kinetic energy by arguing that the blocks have unequal kinetic energies due to the difference between their masses or final velocities. Besides this, some students reasoned in terms of the compensation argument, where the difference in final velocities was thought to compensate the mass difference between the blocks. After the students had worked through the tutorial activities, the proportion of students who failed at applying the work-energy theorem decreased to 28%. The majority of students, who still failed at applying the theorem, reasoned in terms of the definition of kinetic energy or that of the compensation argument.

A total of 10% of students did not answer to the pretest at the beginning of the tutorial intervention. Surprisingly, the proportion of blank answer sheets increased to 30% in the posttest.

The results related to students’ learning of the impulse-momentum theorem are presented in Figure 3. At the beginning of the tutorial intervention, only one student out of 69 successfully applied the theorem. After students worked through the tutorial, 33% of them were able to apply the impulse-momentum theorem as desired. Thus, the proportion of students who successfully applied the impulse-momentum theorem increased with 32 percentage points during the tutorial intervention.

At the beginning of the intervention, a majority of students (71%) failed at applying the impulse-momentum theorem. Typically, these students reasoned in terms of the definition of the momentum by arguing that the blocks have different final momentum due to the difference between their masses or final velocities. Some students used the compensation argument by claiming that the final momentum of the blocks will be equal, because the lighter block A obtains greater final velocity but the heavier block B compensates it with greater mass. At the end of the tutorial intervention, the proportion of students who failed at applying the impulse-momentum theorem decreased from 71% to 47%. The majority of students, who failed at using the theorem, expressed reasoning that was consistent with the definition of momentum or the type of compensation argument described above.
When it comes to the comparison of the momentum of blocks A and B, 28% of students did not provide any answer in the pretest at the beginning of the tutorial intervention. The proportion of blank answers decreased to 20% in the posttest.

![Figure 3: Students’ answer distribution regarding the use of the work-energy theorem at the beginning and end of the tutorial intervention (N=69).](image)

**CONCLUSION AND DISCUSSION**

The moderate results obtained in the pretest indicate that applying the work-energy and impulse-momentum theorems is difficult for students to learn. The students tended to rely on the definition of momentum, kinetic energy, work, or impulse rather than applying the actual theorems themselves. This finding is consistent with previous studies (Lawson & McDermott, 1987; Pride et al., 1998). Our study supports the suggestion made by several experienced teachers and textbook authors, such as Jewett (2008) and Knight (2002): Additional instructional effort is needed to help students to obtain better understanding of these important theorems at the introductory level of the university studies.

Fortunately, the results showed that the tutorial intervention helped students to improve their abilities to apply the work-energy and impulse-momentum theorems. The improvement in the proportions of students who successfully applied the theorems increased between pretest and posttest approximately 30 percentage points. In the case of the work-energy theorem, this increase is about 15 percentage points higher than previously obtained with the aid of small classroom implementation of the tutorials (Pride et al., 1998). In the case of impulse-momentum theorem, the improvement was approximately 10 percentage points lower than reported from the small classroom implementation (Pride et al., 1998). Thus, in average, the tutorial intervention can be seen as effective as the small classroom implementation of the tutorials in supporting students’ learning of work-energy and impulse-momentum theorems. However, this conclusion is limited by the data obtained during one lecture course, and therefore, more studies are needed before this conclusion can be generalized.
The comparable learning results between the tutorial intervention and the small classroom implementation of the tutorial implies that the effectiveness of the tutorial curriculum relies more on the content of the instructional materials than its implementation format. This conclusion is consistent with the idea previously suggested by Kryjevskaia et al., (2014). This indicates that transferable instructional innovations in physics are based on physics education research that clearly contribute to the type of tasks and activities students are engaged with. In the case of tutorials, the design of tasks and activities is based on research that has uncovered problems that students often encounter in the process of learning physics (McDermott & Shaffer, 2003). Since these problems tend to be global in nature (McDermott & Redish, 1999), they offer a strong foundation for the development of transferable instructional innovations. From such foundation, as this study indicates, tasks and activities can be designed so that they engage students into productive thinking processes in various implementation formats.

FACULTY TEACHING PRACTICES AND PERCEPTIONS: A CROSS-INSTITUTIONAL STUDY

Gülnur Birol¹, Adriana Briseño-Garzón², Andrea Han² and Simon Bates²
¹Science Centre for Learning and Teaching, ²Centre for Teaching, Learning and Technology, The University of British Columbia, Vancouver, Canada

There has been a considerable interest in promoting the use of evidence to inform individual teaching practices in higher education. Despite this, many post-secondary institutions are largely unaware of what teaching practices are employed in the classroom. In partnership with Universitas 21, The University of British Columbia conducted an international study involving eight research-intensive post-secondary institutions to gain a better understanding of faculty teaching practices and perceptions. Individuals with teaching responsibilities from institutions representing East Asia, Europe, Oceania, and North America responded to a common teaching practices and perceptions questionnaire. In this paper, we share preliminary results, including widely-reported teaching practices; use of in-class time and expectations of students outside of class; perceptions of various pedagogies and the importance of teaching; and participation in professional development opportunities.

Keywords: teaching practices; perceptions of teaching; international study

INTRODUCTION

Documenting and understanding the relative effectiveness of the most widely used teaching practices in higher education has been a focus of scholarly activity over the past decade (Ambrose, Bridges, DiPietro, Lovett & Norman, 2010; Bain, 2004; Buskist & Groccia, 2011; Nilson, 2010). Researchers have also generated evidence of the impact on student learning of diverse teaching practices in various higher education contexts and disciplines. For example, while it has been widely documented that active learning teaching practices can positively impact the student learning experience (Freeman et al., 2014; Michael, 2006; Prince, 2004), it has been reported that lecture remains the prevailing instruction method in post-secondary institutions (Lammers & Murphy, 2002; Henderson, Beach, & Finkelstein, 2011; Smith, Vinson, Smith, Lewin & Stetzer, 2014). Despite the growing interest in this topic, many post-secondary institutions are largely unaware of which teaching practices are employed in the classroom as institutions rarely collect this information. In the cases where this information is available, there is a tendency to oversimplify the teaching practices employed by faculty and overlook the possibility that they commonly make use of a broad range of practices in the course of their teaching (e.g., Eagan, Stolzenberg, Berdan Lozano, Aragon, Suchard & Hurtado, 2014; Smith et al., 2014). Moreover, existing research on faculty teaching practices has been limited to either post-secondary institutions in the United States (Blackburn, Pellino, Boberg, & O’Connell, 1980; Lammers & Murphy, 2002; Smith et al., 2014; Thielen, 1987) or select disciplines (Smith et al., 2014). Such scattered information positions teaching and learning support units in a challenging situation, as effective support should ideally be tailored to fit the institutional teaching culture. With this in mind, research that sheds light on the teaching practices that take place in institutions beyond the United States and across disciplines...
could make significant contributions to our general understanding of teaching and learning in higher education.

This international study builds on our previous work at The University of British Columbia (UBC) in which faculty members’ teaching practices and perceptions were explored by means of a questionnaire (Briseño-Garzón et al., 2016). In an attempt to better understand the range of teaching practices employed in research-intensive institutions around the globe, we partnered with seven Universitas 21 (U21) institutions from East Asia, Europe, Oceania, and North America to collect self-reported data using an adapted version of the UBC questionnaire. In this paper we provide evidence on faculty teaching practices and perceptions by exploring data from across institutions and disciplines, employing a primarily quantitative approach. We seek to better understand which teaching practices are used in these institutions and what kind of similarities and differences there are across institutions. We discuss the breadth of teaching practices employed across the participating institutions as well as international trends and current institutional teaching and learning cultures.

**METHOD**

In the fall of 2015, UBC received a grant from the Universitas 21 Educational Innovation Cluster to offer an adapted version of UBC’s Teaching Practices Survey to interested U21 partners. We sought and received approval from the UBC Behavioural Ethics Review Board for this study (BREB # H15-203501) and in January 2016 we contacted U21 institutional partners via email regarding the questionnaire. While we received interest from 11 institutions, given challenges with timing and competing institutional priorities, eight institutions (Fudan University, Lund University, National University of Singapore, University College Dublin, University of Edinburgh, University of Glasgow, University of Melbourne, and UBC) participated in the study.

The questionnaire used in this study was developed and implemented at UBC in 2014 (BREB # H14-01879). For a detailed description of the original study and questionnaire development please see Briseño-Garzón et al. (2016). The questionnaire consisted of 30 questions, primarily multiple choice and/or Likert scale, and included three open-ended questions. The questions centered on teaching practices employed in the participants’ highest enrolment, lowest level course, allocation of time to in-class and outside of class activities, perceptions of teaching practices, and perceptions of institutional support for teaching. The three open-ended questions asked participants to describe what has improved their teaching, what has challenged their teaching, and what changes would help their teaching.

Because the questionnaire was initially designed for UBC and reflected institution-specific language and questions reflecting the structure of UBC, we worked with a representative from each participating institution to customize the questionnaire to the institution’s context. Customizations were limited and reflected institution-specific terminology for teaching appointments, academic units, and support roles. Despite these customizations in terminology, the questionnaire was not translated into local languages as all institutions chose to offer the questionnaire in English. We also consulted with each institution on deployment methods and committed to supporting a process that best met the individual needs and culture of the
institutions. Consequently, a variety of recruitment approaches were used across institutions, ranging from a recruitment email sent to all teaching staff to a generic link made available through teaching and learning centre communications. In all cases the questionnaire was made available for three weeks, and multiple institutions extended the questionnaire close date to recruit additional participants. Data collection was completed in late spring of 2016.

For each institutional dataset, descriptive statistics were generated for multiple choice and Likert scale questions. Any instances of self-disclosure in the open-ended questions were anonymized by one member of the UBC research team before analysis. Open-ended questions were analysed and coded through a process in which themes emerged from the comment data. Coding of responses was done independently by three researchers to ensure inter-rater reliability. Reports with institution-specific data were then produced and provided to the corresponding institution, and a summary report was made available to the Universitas 21 Educational Innovation Cluster (“U21 Teaching Practices Survey (TPS) Project”, 2016).

Across all institutions a total of 2063 participants with teaching responsibilities completed the questionnaire, with a high of 1131 responses and a low of 35 responses. Given that the number of responses received across institutions varied significantly, we weighted institutional responses equally by using the institutional averages and calculating an “average of averages” for each quantitative item. Throughout this paper, we will use the term “average” to refer to this average of averages, the term “institutional high” to refer to the highest average reported by any institution, and the term “institutional low” to refer to the lowest average reported by any institution. It was not possible to generate a study-wide report for some questions given institutional differences; these questions were mainly around participant rank and affiliation. For qualitative data, we looked at the relative rankings of most frequent themes across institutions.

Because STEM disciplines were often distributed across multiple upper-level university divisions (faculty, school, college, etc.), and we did not collect data on departments for confidentiality, we had no reliable way to distinguish responses from STEM disciplines. Consequently, we were unable to filter non-STEM disciplines from the data, and the findings contained in this paper include both STEM and non-STEM disciplines.

RESULTS

Demographics

We received responses from participants representing all ranks in every institution. Although we know the UBC data is representative of the UBC faculty population (Briseño-Garzón et. al., 2016), having no access to other institutional demographic data limits our ability to discern whether this is also true for other participating institutions. For consistency, participants were asked to provide information regarding their highest enrolment, lowest level course. This elicited data from a broad range of courses with 24% of courses reported as being first year, 21% second year, 16% third year, 17% fourth year, and 22% fifth year and up. There was considerable variation in course enrolment across institutions ranging from an institutional low of 54 students to an institutional high of 240 students. We received responses from participants...
with a wide range of teaching experience, with substantial participation from individuals with 20 or more years of experience teaching at the university level (Figure 1).

**In- and out of class practices and expectations**

There was a high level of consistency across institutions regarding select in-class teaching practices. The most commonly employed in-class teaching practices include: frequently encouraging students to ask questions during class (89%), connecting assessments to course learning goals/objectives/outcomes (78%), and connecting activities to course learning goals/objectives/outcomes (77%). Of the in-class teaching practices listed, the least frequently employed was “providing students choice in some aspect of their course such as how they will be assessed, what learning activities they complete, or what topics they will study” (22%). There was less consistency across institutions regarding participants’ expectations of their students outside of class. While an average of 63% of the participants expect their students to review material (readings, video, web resources) before class, only 28% expected students to do so and then complete an assessment of understanding before class. Many participants reported expecting students to work on problem sets/homework/worksheets outside of class meetings, with 48% assigning this work for a mark and 35% not assigning this work for a mark. Further, 34% of the participants expect their students to produce research papers or major projects outside of class meetings, while 39% expect them to write short papers or produce other minor work.

**Instructional time**

Looking at the distribution of instructional time, we see a wide variety of practices employed in classrooms across institutions (Figure 2). Participants were asked to indicate the approximate percentage of teaching time spent on various predefined practices during the course. While the use of lecture (presenting content) still remains the most widely employed teaching practice in classrooms, participants report spending less than half of classroom time (44%) on this passive learning approach. While there was considerable variability within institutions, with most institutions having both individuals who reported 0% and 100% of time spent on lecture, we
see more consistency across institutional averages with a low of 34% and a high of 56%. We also see a substantial amount of instructional time devoted to more active learning practices such as small group discussion, student-led teaching activities, students solving problems or producing work, and students engaging in peer review. An average of 36% of classroom time is spent on these activities, with institutional averages ranging from a low of 29% to a high of 51%.

![Pie chart showing percentage of instructional time dedicated to various activities.]

**Figure 2. Allocation of instructional time (average of institutional averages).**

**Workload**

Participants also report spending a substantial amount of time on course-related activities outside of instructional time: an average of 113 hours per course (Figure 3). The majority of this time is spent preparing for class, with an average of 49 hours devoted to this activity. This is closely followed by marking (average of 35 hours) and engaging with students either in person or online (average of 29 hours).

![Bar chart showing hours spent on various activities outside of instructional time.]

**Figure 3. Allocation of instructor time for course-related activities outside of classroom (average of institutional averages).**
However, we saw considerable variability across institutions in these responses. The greatest difference was found in marking, where we saw an institutional low of 18 hours and a high of 52 hours. It is worth noting that individual responses regarding time varied widely and institutional differences in what constitutes a course (number of student contact hours, length of term, etc.) make direct comparisons difficult. We did not find a statistically-significant relationship between the time spent marking and course enrolments, perhaps due to teaching assistants and other roles available to assist with this activity.

**Participation in professional development opportunities**

Participants were asked about their participation in and awareness of professional development opportunities based on a predefined set of activities (Figure 4). Across all institutions, participants were most likely to attend teaching development events such as talks, workshops, and seminars (69%), and very few reported not to be aware of these opportunities (7%). Across all institutions, approximately 50% of all participants indicated participating in the exchange of ideas/practices with their colleagues through peer evaluation of teaching, observing someone else’s teaching, or having a mentor to go to for advice about teaching. Slightly less than 50% of the participants indicated participating in teaching and learning conferences. Participants were least likely to report participation in a “cohort of scholars focused on teaching and learning” (40%), and 29% of the participants were not aware of how to access a mentor they could go to for advice about teaching.

![Figure 4. Participation in professional development activities.](image)

**Attitudes and perceptions**

Participants were also asked to share whether they felt teaching was a personal priority and their perception of the teaching climate at their institution. The majority of participants (78%) agreed with the statement “teaching is a priority to me” (Figure 5), with considerable variation across institutions illustrated through an institutional low of 53% and high of 89%. However, participants were more likely to agree with teaching being a priority than research (67%), perhaps due to teaching-focused roles in some institutions. We also saw considerable variation across institutions regarding research as a priority with an institutional low of 47% and high of 82%. Participants generally agreed that both their institutions and upper-level divisions
recognized the importance of teaching with only 20% and 19%, respectively, disagreeing with these statements (Figure 6). Generally, participants were more likely to report that their upper-level division recognized the importance of teaching than their institution, but these differences were minor and the two variables were closely related (r=0.82, p<0.01). There was also a small positive, but not significant, relationship between participants reporting that their upper-level division recognized the importance of teaching and reporting teaching as a personal priority (r=0.52, p=0.15).

Figure 5. Priorities: research and teaching.

University leadership at my institution recognizes the importance of teaching.

Leadership in my Faculty/School recognizes the importance of teaching.

Figure 6. Institutional support for learning.

In addition, participants were asked to share their perceptions of the efficacy of both lecture and active learning techniques. Previous research regarding teaching practices has found lecture to be the dominant teaching practice in post-secondary classrooms (Lammers & Murphy, 2002; Henderson, Beach, & Finkelstein, 2011; Smith, Vinson, Smith, Lewin & Stetzer, 2014), but there have been limited studies exploring faculty perceptions of the efficacy of lecture compared to active learning. In this study, participants were significantly more likely to agree that active learning techniques promoted student learning (90%) than agree that lecture promoted student learning (61%, Figure 7). Institutional averages for the question “active learning techniques are an effective way to promote student learning” were clustered near the high end of the scale with an institutional high of 98% and a low of 86%. In comparison, the question asking if participants agreed with the statement “lecture is an effective way to promote
student learning” saw an institutional high of 70% and low of 52%. Looking only at participants who strongly agreed with these statements, we see an even more dramatic difference with 55% strongly agreeing active learning is effective compared to only 16% indicating the same for lecture.

Lecturing is an effective way to promote student learning.

Active learning techniques are an effective way to promote student learning.

Figure 7. Promoting student learning: lecture and active learning.

Top themes from open-ended questions

Participants were asked to respond to open-ended questions that invited them to reflect on factors that have both challenged and improved their teaching. Across institutions the following themes, listed below in order of relative prevalence and with an illustrative response, were identified by participants as the main challenges to their teaching:

a. Balancing workload and time demands

“Having enough time to prepare and be truly engaged with students’ learning experiences, given other obligations such as research and administration.”

b. Low perceptions of institutional value for teaching

“General stress on faculty in a research-intensive university where there’s certainly lip service given to teaching, but where one knows that tenure and promotion decisions will ultimately be based on research.”

c. Lack of student engagement, enthusiasm, and preparedness

“Most students are final exam-oriented. They do not concern any other things which are not relevant to the final exam. This is a big challenge in making them to be active learners.”

d. Implementing student-centered pedagogies

“Changes take too long to implement (and get support for at the faculty), to remodel students from passive recipients to active participants is hard since too many courses do not involve the students in creating the course. Students’ personal and professional experiences are rarely made part of the course.”

e. Increasing class sizes

“Increasing class sizes - we can't run field schools or field labs, or even many discussion groups the way they need to be run for maximum experiential learning and for actual safety in
the field ones. The learning experience in many of our courses has diminished in the 20 years since I have been teaching here as a result of this.”

f. Limited funding, resources, and administrative support
“Constant erosion of funding while costs increase.”

Participants also identified the following as factors that have helped them improve their teaching. Listed in order of relative prevalence:

a. Engagement with colleagues
“Support from my own departmental faculty members who have encouraged me and helped me grow as a teacher.”

b. Experience and practice
“Trying things out. If it works, great. If it needs to be improved, that's perfect. If it doesn't work, recognising that this too had some value.”

c. Student feedback
“Listening carefully to student feedback and trying to change at least one thing on my modules each year in response to student feedback.”

d. Participation in formal professional development
“The [unit] course has provided a sound overview of teaching practices and has encouraged me to introduce new initiatives which have improved student engagement and performance.”

e. Implementing student-centered pedagogies
“Shifting away from more purely lecture-based instruction and incorporating more peer-to-peer interactive tasks during "lecture" time.”

f. Using technology
“Regular communications with the students via the [forum] and other instructional technologies.”

DISCUSSION AND CONCLUSIONS

This study provides an overview of teaching practices and perceptions of teaching at large research-intensive institutions. While few participants reported providing students with an aspect of choice in some aspect of their course, the majority indicated they deliberately connected course activities and assessments to course learning goals. We found a wide range of teaching practices employed across institutions, with less than half of classroom time, on average, being devoted to lecture or other passive learning activities. Participants also reported spending a substantial amount of time on teaching-related activities outside the classroom with preparing for class and marking demanding the majority of their time. Participants reported a strong commitment to teaching regardless of rank or tenure and most agreed that active learning was an effective way to promote learning.

Our findings form a starting point for conversations regarding teaching climate on the campuses that participated and provide data to inform institutional decision making regarding professional development. We found relatively consistent themes in the open-ended data across institutions regarding challenges participants faced in their teaching as well as factors that had
helped them improve teaching practice. Participants reported substantial concerns regarding their workload, increasing class sizes, and the lack of support for teaching. The relative importance of teaching compared to research also emerged as a concern. Our findings also suggest these concerns could be mitigated through more opportunities to engage with teaching colleagues and increased opportunities and support for professional development. Since participation in teaching development events was the most often reported form of engagement with professional development, teaching and learning centres are well-positioned to support this work. They may also be able to contribute by facilitating peer evaluations of teaching, organizing open observations of teaching, or connecting faculty with a teaching mentor or cohort of scholars focused on teaching and learning.

The methodological choices we employed pose limitations to this study. First, we recognize the limitations of questionnaires in capturing participant beliefs and perceptions (Kane, Sandretto & Heath, 2002; Richardson, 1996). While we have a good deal of data regarding what teaching practices individuals employ, we are unable to answer why they chose to employ these practices. Second, the way participants were recruited at sites other than UBC was beyond our control and ranged from posting a link to a commonly-visited website to sending email invitations to the participants. Consequently, we were unable to calculate response rates and these recruitment practices may have resulted in self-selection, which could skew the findings. Third, the accuracy of self-reported data may be questioned, although there is some research indicating this may be reliable (Smith, 2014). Due to the circumstances of this study, we were unable to triangulate the data we collected through classroom observations or other data sources. Additional work comparing classroom observations to self-reports would be useful to confirm the accuracy of self-reported behaviour and interviews to further understand the responses provided would paint a more complete picture. Fourth, our ability to engage in analysis beyond descriptive statistics was limited by differences in institutional contexts. Finally, we did not engage in broad content validation activities with participants from other institutions.

To mitigate these limitations, we are currently in the process of refining the questionnaire based on participant feedback and statistical analysis. We are also developing an improved methodology that includes closer collaboration with institutional partners to address the limitations mentioned above. Our plan is to run the questionnaire again at UBC in the spring of 2018 to explore change over time. Concurrently, we are developing a plan to collaborate with more institutions including, but not limited, to institutions in U21. This may allow us to make regional comparisons and to generalize findings with more confidence. We are also working on a method to group disciplines (e.g., STEM) in a way that is meaningful to institutions while allowing us to do a comparative analysis.

Further analysis may include exploring whether class size is a determining factor in the choices faculty make regarding teaching practices and whether choosing to implement particular teaching practices leads to increased workload. We are also looking at other data sources at our institution (e.g., an undergraduate experience survey) as a means of triangulating our findings. We recommend other institutions pursue similar approaches, and intend to follow up with partner institutions to determine how results are being used at their institutions.
ACKNOWLEDGEMENT

This work is supported by the funding of the Universitas 21 Educational Innovation Cluster. We would like to thank participating institutions and all faculty who either participated in the questionnaire or offered insights. We would also like to acknowledge Paulina Semenec for helping with comment data analysis and Erika Borys for providing editorial support.

SCIENCE STUDENTS’ SENSE OF BELONGING AND UNIVERSITY INVOLVEMENT

Nadia Dyrberg

1University of Southern Denmark, Odense, Denmark

Student employees are widely used at universities all over the world, e.g. as tutors, mentors and teaching assistants. The student employees are frequently mentioned in the literature as an important part of undergraduate teaching and mentoring initiatives towards younger students, but the employees themselves are more rarely the subject of research. This study focusses on student employment in relation to the concept of university belonging. Researchers indicate that university belonging is associated with a number of behavioral and emotional factors that are important to students’ success. The paper presents investigations of the relation between science students’ sense of university belonging and their involvement in the study environment at the university’s science faculty. This involvement can be either informal through volunteering activities and formal through student employment. Using Goodeknow’s ‘Psychological Sense of School Membership’ (PSSM) scale (α=0.944) this quantitative study (n=152) reveals a higher sense of university belonging among employed students than non-employed students (p<0.001, effect size=0.372) as well as among volunteering students compared to non-volunteering students (p=0.001, effect size=0.325). Findings also suggest that students employed in multiple positions possess even higher levels of university belonging (p=0.041, effect size=0.284). The study lays the ground for further research into the nature of benefits of student employments and volunteering activities - benefits which apply to both the students and the higher educational institutions. Furthermore, the study constitutes one of the first European investigations of university belonging and calls for attention to this important and far-reaching concept.

Keywords: higher education, emotion, motivation

INTRODUCTION

Sense of belonging is a central concept in the student life in higher education institutions. According to Strayhorn (2012) belonging can be ‘a key to educational success for all students’. He linked sense of belonging to achievement, intention to persist and involvement in both the social and the academic systems of colleges. Hurtado and Carter (1997) also found that students with a higher sense of belonging tended to involve themselves to a higher degree in student organisations and in discussions of course content with other students outside class. However, these activities were all informal and based on voluntary efforts. To extent this knowledge, this study includes the relation between sense of belonging and another, more formal type of involvement with the study environment; student employment.

Students are employed to undertake a number of jobs in higher education institutions throughout the world and are frequently mentioned as essential parts of initiatives towards younger students (e.g. Altus, 2015; Skaniakos, Penttinen, & Laira, 2014).
University belonging

The presumption in the paper is that student employees as well as students doing volunteer work constitute a group of students highly involved in the university community with regular contact to multiple persons (staff and students) at the institution. These are elements that could affect the students’ sense of belonging to their institution. Therefore, the study explores sense of belonging among students who are involved with the study environment and compares this to non-involved students. The importance of belonging is phrased by Osterman (2000): ‘belongingness is an extremely important concept. As a psychological phenomenon, it has far reaching impact on human motivation and behavior’. However, as noted by Pittman and Richmond (2008), a large body of research has been conducted on the construct of school belonging but only a limited (but growing) number of studies on the derived construct of university belonging.

The working definition of university belonging used here is closely related to the elements brought out by Pittman and Richmond (2008). Besides mere affiliation to an institution, university belonging also encompasses: i) a feeling of belonging to both the academic environment as well as among the other students; ii) a feeling of obligation towards the institution and towards doing of good job as well as feeling acknowledged and recognized for one’s abilities; and iii) a feeling of being connected to a larger community. The subject is important because studies indicate that students with a higher sense of university belonging are also more motivated and successful in their studies. Researchers have found that students’ feeling of attachment to their university is positively correlated with academic motivation, general adjustment, and perceived social support, and negatively correlated with depressive symptoms and attrition rates (e.g. Beyers & Goossens, 2002; Tao, Dong, Pratt, Hunsberger, & Pancer, 2000). The study adds new empirical evidence to theory in a context not investigated before: a European science faculty.

Hypotheses

Three hypotheses are formulated: 1) Students who do volunteer work and 2) students who are employed at the science faculty possess greater levels of university belonging than non-involved students, and 3) the number of employment positions is correlated with university belonging.

METHOD

Participants

Data were collected through a questionnaire which was distributed to 346 science students at University of Southern Denmark in the summer 2014, at the end of the academic year. The students were enrolled in 2009, 2010, 2011. Thus, the students would be finishing their third, fourth or fifth year of studies at time of distribution. These year groups were chosen because three years of studies is the minimum requirement for employment as a study group supervisor – one of the student jobs of interest to this study. Therefore, all the respondents had been eligible for all the three kinds of student jobs which employ a large quantity of students: social tutors, study group supervisors and teaching assistants. Students were enrolled in one of nine
study programmes ranging from computer science to biology. In total, 159 (46%) responded to the questionnaire. However, seven did not complete the questionnaire and were excluded from data analysis. A total of 79 students were not employed at the university and categorized as non-employed (although the students might have a student job outside the science faculty), and 76 students were or had been employed at the science faculty and were categorized as employed.

**Measure and statistical analyses**

The questionnaire consisted of demographic questions and a measure of university belonging; an adapted version of Goodenow’s 18 item ‘Psychological Sense of School Membership (PSSM) Scale’ (1993). PSSM has been used by multiple researchers (e.g. Anderman, 2003; Pittman & Richmond, 2007; Shochet et al., 2006). Items were formulated as statements and responses were given on a 7-point Likert scale (1: fully disagree – 7: fully agree). Examples of item statements were ‘Other students like me as I am’ and ‘People here know I can do good work’. The university belonging score was calculated by averaging all items (negatively phrased statements were reversed before calculation). The measurement showed good internal reliability (α=0.944), similar to other studies using the PSSM measure on college students (Pittman & Richmond, 2007, 2008; Freeman et al., 2007).

The questionnaire was managed with SurveyXact and statistical analyses were performed using the Statistical Package for Social Sciences (SPSS, IMB). The scale’s internal consistency were evaluated with Cronbach α and showed good internal consistency: α=0.944. The data were skewed towards higher values. However, the t-test is quite resistant to such skewness even with small sample sizes (Bortz, 2005). Therefore a normal distribution for the population was assumed and independent t-tests were applied to compare means between groups. A Chi-square test was used to test the distribution of employed versus non-employed and volunteering versus non-volunteering.

**RESULTS**

The overall level of university belonging among all respondent was M=5.19 (SD=1.23). Figure 1 shows the mean for the dichotomous variables concerning volunteer work, employment and number of employments. There were statistically significant differences (t=3.326, p=0.001) in the means between volunteering students (M=5.88) and non-volunteering students (M=4.96) as well as between employed (M=5.61) and non-employed (M=4.70) students (t=3.890, p<0.001). These differences had effect sizes of 0.325 and 0.372, respectively, corresponding to moderate associations. Hence, hypotheses 1 and 2, which proposed that employed and volunteering students possess greater levels of university belonging than non-involved students, were supported.

A statistically significant difference (t=-2.094, p=0.041) among students employed in one (M=5.32) versus multiple (M=5.90) positions was also confirmed with an effect size on 0.284 corresponding to a small association. Thus, the third hypothesis, proposing a correlation between the number of positions and level of university belonging, was also supported. Due to
a high degree of overlap among the students employed in the different positions, statistical comparisons of means among individual types of employment were not performed.

![Figure 1. Mean university belonging score for different groups of students. Comparison of means with independent t-test. *p<0.05. **p<0.01. Error bars represent standard division (SD).](image1)

Given that both volunteering students and employed students had an elevated sense of university belonging, one might also expect overlap of students between these two groups. Examining the distribution of students within the groups confirmed this. Within the group of employed students, 37.0% were involved in volunteer work, and within the non-employed student group only 5.1% were involved in these activities (see Figure 2).

![Figure 2. Association between being employment and volunteer work.](image2)

The association between being employed and doing volunteer work at the faculty was statistically significant ($\chi^2=23.82$, $p<0.001$).
DISCUSSION

Support of hypotheses

The proposed hypotheses were supported and the data support the conclusion that involved (both in-formal and formal) students possess higher levels of university belonging than non-involved students. Student employment represents a formal type of involvement in the campus community that (to my knowledge) has not been investigated in relation to university belonging before. The findings suggest that this formal form of involvement is associated with similar increased levels of university belonging as other more informal and voluntary types of involvement in the university community. The indication that similar associations between sense of belonging and involvement are present in both the US (Hurtado & Carter, 1997; Strayhorn, 2012) and in Denmark suggests that findings from this study are transferable to other countries. However, this claim is made with caution. Student employments differ in content and management among different universities throughout the world and all types of employment may not be associated with university belonging. Future studies should further investigate whether the some types of employment are associated more strongly with sense of belonging than others.

The multitude of the additional increase in sense of belonging associated with multiple employment positions also needs to be investigated further. Only a small association was found here and the present study did not take into account whether or not the students were employed at the time of questionnaire distribution nor the number of hours spent working. The latter could possess an upper threshold for the positive association. Strayhorn (2012) identified such a threshold at 20 hours spent on extracurricular activities (including work outside campus).

The measurement of university belonging showed good internal reliability ($\alpha = 0.944$), similar to other studies using the PSSM measure on college students (Pittman and Richmond, 2007, 2008). However, the Cronbach $\alpha$-coefficient is remarkably high. In the original development study Goodeknow (1993) reported $\alpha$-coefficients ranging between 0.771-0.875. One explanation to this may be that the older students in college and university studies rate the items more consistently. Perhaps, due to their age and them being more experienced in life, they may be more stable in their psychological state of mind with regards to the aspects measured here.

Causal relations?

The presented study is correlational; making the claim that student employment leads to elevated university belonging is not evident from the results. This causality is, albeit somewhat vaguely, indicated by Strayhorn (2012). One could speculate that students who already possess a high sense of belonging seek out or are singled out for opportunities for (both informal and formal) involvement. I suspect that sense of belonging and involvement in the campus community constitutes a positive feedback loop. As some of the elements of sense of belonging are being recognised for your abilities and experiencing positive relations with faculty members and other students, one could suspect that these elements also provide opportunities (and inclination) for additional involvement. The findings from this study also confirm a great overlap in the students involved in volunteer work and in formal employment. The importance and effect of student-faculty interactions has been a subject of research by e.g. Cotton and
Wilson (2006), Endo and Harpel (1982), and Groves, Sellars, Smith, and Barber (2015). The latter found the quality of students’ relationships with their teachers to be the single most important factor that encouraged student engagement. I propose that student employees naturally develop (positive) relationships to faculty members through their employment, and that part of their enhanced sense of belonging can be explained by the regular interaction between the student employees and the faculty members. Also, the act of offering the students employment might induce students’ feeling of being recognised for their abilities.

Need for further studies

The present study utilised a quantitative approach appropriate to explore patterns and reveal relationships. Follow-up qualitative studies may provide descriptive information as to the nature of the processes involved in the establishment of university belonging and turn evidence of correlation into theories of causality. Background variables that were not included in this study, but which would be interesting to explore in the future are: personality, minorities/ethnicity, living near the campus area, time spent at the campus, academic aspirations, etc. Hence, the study lays the ground for further studies of university belonging in the European context. Another apparent subject for exploration is the nature of the benefits that student employees gain from their job and to put the subject of student employments into an even wider perspective, gains from being a student employee may even be beneficial in terms of increasing the students’ employability.

There might be an inherent bias in who answered the questionnaire; students choosing to participate might constitute the group of students with the highest sense of duty towards the institution – a sense of duty that prompted them to answer the questionnaire. As such, not answering the questionnaire could be an indication of lack of university belonging. Being able to include these students in future studies might provide even clearer evidence to the conclusions made here.

Transferability of findings

The study was performed with science students exclusively, which may induce a question of transferability to other fields of sciences. Due to many weekly classes and practical work requiring students’ presence, it seems natural that science students have rich opportunities to interact with other students as well as faculty members. Therefore, science students could be expected to possess higher levels of university belonging than students from certain others fields. If this is true, it adds to the strength of this study that differences could be detected even in the field of natural science. In general, I argue that the findings apply to other fields as well, as the benefits of increased contact with faculty members and being acknowledged by employment are valid across disciplines.

CONCLUDING REMARKS

With the extensive use of student employees at higher education institutions worldwide in mind, the findings of this study are especially important to heads of study and coordinators of student affair initiatives. Although causal links are hard to establish, it is relevant to know more about university belonging and the relation to different aspects and activities in student life.
Actively seeking out ways to increase university belonging may help to reduce attrition, enhance performance and nurture students’ academic aspirations.

ACKNOWLEDGEMENT

The author thanks all students who participated in the study.

Science, Technology, Engineering, Mathematics and Medicine (STEMM) disciplines are increasingly shaping our lives and the world we live in. With this in mind, there is concern that skills shortages could impact on national and global economies. Addressing challenges across these areas requires engaged and informed citizens as well as a pool of STEMM professionals. There is an increasing demand from public bodies, research institutes and funding bodies for public engagement, believing it to provide a pathway towards research with impact, but many STEMM graduates and professionals lack the very skills required to communicate and engage with the public. To attempt to address some of these issues, the project RACE (RAw Communication and Engagement) was initiated as a joint project between universities and industrial partners across Europe. Through the design of a framework for developing adaptable training modules that incorporate content knowledge, scientific communication and public communication skills, this international project has aimed to equip students and researchers alike with the skills to understand the implications of their work on the wider global society and communicate their work with wider societal audiences. The implementation and evaluation of some of the modules resulting from this project is discussed in this paper.

Keywords: communication, higher education, raw materials

BACKGROUND, FRAMEWORK AND PURPOSE

In the current increasingly globalised as well as technology- and innovation-driven world, both economic and social development are increasingly reliant on research and development within science, technology, engineering, mathematics and medicine (STEMM) fields to both promote economic growth and to increase the quality and standard of living. Concomitant to this, policy-makers both nationally and internationally have become acutely aware of the need for professional within STEMM, and that skill shortages could ultimately be detrimental to the economic growth and welfare of their citizens.

However, it has also been recognised that, despite the crucial role that research and development in STEMM plays in society at both an everyday and long-term level, public awareness and understanding of the value and impact of research and development work can be low, and there can be a perception of a lack of accessibility to and engagement by those working these fields (National Academy of Science, Engineering, and Medicine [NAP], 2017). Therefore, not only is there a need for a sustainable pool of current and future STEMM profession, there is also a need for STEMM professionals who are able to communicate their work and who understand the broader implications of their work on society in order foster an engaged and informed citizenry. As a response to this, there is an increasing emphasis and requirement on public engagement activities from public bodies (European Commission [EC], 2013a), research institutes and funding bodies (Science Foundation of Ireland, 2015) who...
regard it as a pathway towards research with impact (UK Research Excellence Framework, 2014).

Another particularly relevant aspect in the current geopolitical climate, where the credibility of scientific theories and facts are called into question, is the importance of the public’s trust in scientific research. Effective, open, honest and understandable communication and engagement with the public are crucial in this regard, and should be an integral part of the work of the researcher (InterAcademy Council, 2012; NAP, 2017). This connects also directly with the concept of Responsible Research and Innovation (RRI), which describes an inclusive approach to the process of research and innovation with communication and dialogue between wide-ranging stakeholders throughout. This has been a significant focus for, for example, the European Commission, which has created a normative framework for RRI involving six policy agenda areas: ethics, open access, public engagement, gender equality, governance and science education (EC, 2012).

**The RACE project: RAw Communication and Engagement**

To attempt to address some of these issues, the project RACE (RAw Communication and Engagement) was initiated as a joint project between universities and industrial partners across Europe (University of Limerick, Ireland; Uppsala University, Sweden; University of Eastern Finland, Finland; Technical University of Madrid, Spain; Rusal Aughnish Alumina Ltd; Boliden Tara Mines Ltd). As a wider society engagement project under the EC European Institute of Innovation and Technology (EIT) Raw Materials, the key focus was on public engagement and communication about the broad field of raw materials, all the way from extraction to the final consumer products. Despite the importance of the extraction, exploitation and use of raw materials for the economic and social development in the EU, there is generally a lack of public awareness of this fact, and public perception of activities in the area of raw materials has traditionally been poor (EC, 2013b).

However, the very knowledge and skill sets that would allow professionals to effectively communicate with and engage the public are also the ones that have been identified as deficient among STEMM graduates. These include oral and written communication, ethics, global awareness, innovation and team work (Hanson and Overton, 2010; UK Commission for Employment and Skills, 2015; Hulme and De Wilde, 2014; European Centre for the Development of Vocational Training, 2015). Through the development and implementation of adaptable training modules aimed at graduate students (Masters and PhD) as well as industrial employees studying and working in areas relevant to the extraction and use of raw materials, a platform has been created in the RACE project for providing training in communication and public engagement, equipping participants with the skills to conduct outreach and public engagement activities to a variety of audiences and stakeholders in society. The design, implementation and results from selected parts of this project will be presented in this paper.
Framework for Module Design and Development

The overall sequence for the RACE project is summarised in Figure 1 below.

Figure 1. Overall sequence for the RACE project.

The first stage of the project involved the design of an adaptable training module, with different categories of participants in mind. In order to address both the current and future needs of STEMM professionals, both students in higher education training in areas relevant to raw materials as well as professions currently working in industry within the raw materials field were targeted. Furthermore, in order to ensure continuity of the project and wider skills dissemination, modules for higher education staff (“train-the-trainer”) were also designed. Against this background, adaptability was required in order for the module to be useful across the academic and industry sectors, both in terms of the educational/training context (higher education students vs. professionals in industry) and in specific content topics specific for the educational degrees or industries in question. In addition, to ensure that modules would lead to direct impact, the carrying out of outreach and public engagement activities was explicitly incorporated into various training modules (for example as part of assessment and examination), so that not only is there benefit for those undergoing the training modules, but the wider public is also benefitted in the process.

A first step in designing the training modules was identifying the key features in both skills and subject content that should be central themes. This is summarised in Figure 2 below. Two broad pillars were identified. The first pillar involves key skills that are required for effective STEMM communication, while the second pillar covers a broad range of topics, areas of application and products that the concept of “raw materials” can encompass. Importantly, underpinning both of these and functioning as a grouping for the modules as a whole are considerations of RRI, encompassing issues of ethics, impact for wider society, and sustainable development. Based on these foundations, the exact structure and content of the training modules were then tailored to the local conditions and requirements of the institution or organisation in question (e.g. degree level, the course content/research project in which the training would be incorporation, formal course requirements, time and resource constraints, available infrastructure and forums for public engagement etc.). As a project with scientific communication and public engagement as key focus areas, it should also be noted that this framework was conceived to allow the specific topic and subject context to be easily exchanged. In other words, while raw materials was the content focus for the RACE project, the design principles were such that this framework could also be used to design training modules for communication and public engagement with other topics (e.g. health, energy, nanotechnology) in mind.
Figure 2. Framework for the design of training modules.

Key considerations involving the pillar of STEMM communication were informed by research, illustrating issues with how researchers communicate to the ‘public’ (Bray et al., 2012). Particular issues arise as researchers frequently presume a public deficit in knowledge of, attitudes towards, and trust in science (Bauer et al., 2007). More recent studies (Royal Society of Chemistry, 2015) indicate that this presumption of public deficiency is quite widespread. These topics are all relevant to the underlying issues of the importance of enabling the wider public understand the impact of research and innovation to the broader society, as well as associated ethical and social issues. Regarding the pillar on content regarding raw materials, regard was paid to the poor public knowledge and perception of raw materials as referred to above, despite their ubiquity and importance for technological and other applications. The training modules therefore attempt to address this by highlighting the range of topics and applications that where raw materials are relevant, including not only mining and energy, but also areas such as advanced materials, machinery, pharmaceuticals, jewellery medical and electronic devices and information technology, as well as issues of recycling & materials substitution. With respect to the underlying theme of RRI, questions of personal and collective ethical responsibility of those engaged in research development for both society and the environment, regulation and governance, and sustainable development for future generations are addressed. As current and future STEMM professionals, there is a shared responsibility to engage in dialogue and inform the general public about the such issues of social responsibility and sustainability, to help equip citizens with the knowledge and skills necessary to make informed decisions.

IMPLEMENTATION AND EVALUATION

While different training modules and activities were developed and implemented at the various project partner sites, this paper will focus on the modules implemented at the Master’s level at Uppsala University (UU), as this was one the key pilot modules in the project. Also, a module at the PhD level will be briefly described and discussed as an example a module that was jointly designed and implemented internationally across the academic project partners.
Module at Master’s level at Uppsala University

A module was developed for implementation as a part of the Masters in Engineering course Materials of Sustainable Development at UU. The module was first piloted in 2016, modified based on the pilot results and delivered again in 2017, with 55 students enrolled in Master’s course each year. Keeping the module design considerations above in mind, the training module comprised of three seminars. The first seminar covered the concept of raw materials and the range of relevant issues and applications. Topics such as the availability of raw materials, environmental and sustainability aspects of extraction and refining and raw materials, as well as the range of applications where raw materials are essential were discussed. Secondly, a workshop was held where students conducted debates on given topics related to raw materials with an RRI focus. The debating topics were designed to cover both technical as well as socio-economic issues associated with raw materials (e.g. “That large subsidies should be used to simulate the introduction of battery-driven cars”; “That primary production of raw materials should be taxed while the tax on work be reduced”). These seminars gave students an orientation in the content area, and also brought in societal and environmental issues involved with RRI. Furthermore, through the use of the debating format, the students received training in oral communications and argumentation skills.

A third and major component of the module focused on communication and engagement of a wider range of audiences. Firstly, students took part in a seminar focusing on aspects of effective scientific communication: how to be engaging, how to be relevant, how to be understood, including theoretical models and practical techniques drawn from research in communication. This seminar was delivered jointly by an expert and researcher in scientific communication who was a consultant to the RACE project, as well as a content and chemistry education researcher. Students were then divided into groups of three, each charged with the task of preparing a three-minute presentation on an assigned topic a few weeks after the communications seminar. Each member of the group was to present to one of three different kinds of audience: school children aged 15, investor, or members of a research council. This exercise thus connected the raw materials subject matter to the skills and techniques that are required effectively engage and communicate with particular target audiences with varying backgrounds and interests. These three-minute pitches were presented for other students on the course, and each presenter received immediate individual feedback from the course instructors. Furthermore, the student presentations were video-recorded and these videos were shared within each group for review. Each student was required to write a brief reflection and self-evaluation about their own presentation, as well as give peer-feedback to the other members of the group. This reflection and peer-feedback phase was designed to be a critical step in helping the students learn and improve, as well as raise their metacognitive awareness of their learning process.

To investigate whether the implemented module affected the attitudes and understanding of the students, a pre- and a post-questionnaire was administered. An instrument used in the EC FP7 project Irresistible aimed at RRI education at the secondary level provided inspiration in the development of the questionnaire instrument in the RACE project. The initial instrument was piloted on the 2016 cohort of students, with the pre-course instrument comprising of 36
questions with responses on a 5-point Likert-scale questions, as well as a free response question regarding their views on relevant ethical issues in materials development. In the post-course instrument for this pilot module, an additional 11 questions on a 5-point Likert-scale as part of the continuous evaluation of the project in order to strengthen the focus on communication and public engagement about raw materials in more specific terms. After statistical analysis of the responses of the 2016 responses, further refinements were made for use with the 2017 cohort, with the final instrument containing 40 5-point Likert-scale times and free-text questions (one pre-course, three post-course)

Results from the Master’s course

Table 1 below shows some sample results which were carried out between the pre- and post-sample group on individual items during the 2016 pilot.

These items represent some of the statistically most significant changes that were observed pre- and post-course. Through statistical analysis of and reflection on the results, the wording of some items were further refined whereas others were omitted altogether from the final version used for the 2017 cohort. Analysis of responses to the items from the 2017 cohort questionnaire revealed a number of themes into which items could be grouped with reasonable reliability. These themes and example items are show in Table 2.

Based on these results, the mean values for each theme were calculated on the students’ pre- and post-course responses. The data for each theme was found to be normally distributed (based on the Shapiro-Wilk test) and paired-samples t-tests were performed to compare the data pre- and post-course (Table 3).
Table 2. Themes for item grouping, 2017 pilot (Cronbach’s alpha $\alpha$ calculated on post-course responses; $n_i$ = number of items grouped in the theme; no. of responses $N = 43$)

<table>
<thead>
<tr>
<th>Theme</th>
<th>Example items</th>
</tr>
</thead>
</table>
| **Understanding of raw materials** ($\alpha = 0.72; n_i = 12$) | I have a good understanding about what falls within the scope of raw materials.  
I am aware of what impact the use of raw material has on society.  
I have a good understanding about areas of applications involving raw materials. |
| **Scientific communication** ($\alpha = 0.62; n_i = 12$) | I am able to communicate science in such a way as to raise awareness in the community for current and relevant scientific issues.  
I am confident about how to communicate science in an engaging, informative and convincing way.  
When communicating science, I am able to appropriately take into account the purpose of the communication and the background of the audience. |
| **Individual responsibility** ($\alpha = 0.76; n_i = 4$) | Those like me with a higher education in science and technology have a responsibility to apply their skills and knowledge for the benefit of society.  
Those like me with a higher education in science and technology have a responsibility to communicate and engage in discussions with the wider community about the responsible use science and technology.  
Regardless of my future career, I will use my scientific skills and knowledge to contribute to the responsible and ethical use of science and technology in society. |
| **Ethics and governance** ($\alpha = 0.63; n_i = 8$) | If it becomes clear that the results of a particular line of research or innovation has negative implications or risks, those involved have the duty to stop conducting this line of work  
One of the roles of government is to prevent harmful or unethical practices in research and innovation.  
Both the academic sector and industry have an ethical and social responsibility to society with respect to the results of their research and innovation. |

From this data, it can be seen that there have been significant changes in the student’s self-reported knowledge and attitudes in these themes concerning raw material, scientific communication and RRI. In each of these, the results suggest that the students became more informed and aware of these areas and felt more equipped in engaging in communication and engagement activities. The observed effects on the themes concerning the understanding of raw material as well as ethics and governance were larger than for the other themes. It should
however be noted that the training module described here was part of the more extensive Master’s course the content of which also dealt with such issues. It is therefore not possible to totally isolate the effects of this module for these themes. Nevertheless, the modules did contribute to extra teaching and learning activities concerning raw materials and RRI issues, and can reasonably be argued to have contributed to the observed effects. As for the theme of scientific communication, the implemented module introduced training targeting skills that were not specifically covered in the rest of the course. The statistically significant increase in the students’ self-reported confidence and skills suggests therefore that the intervention has had a desired effect on the students. This also correlates well with initial findings emerging from the analysis of the students’ self-evaluation of their three-minute presentations, with many remarking that they came to realise that they were in fact better at presenting than they had previously thought.

**Joint PhD Summer School Scientific Communication and Public Engagement**

The academic project partners also developed PhD courses at their respective institutions focusing on scientific communication and public engagement. In line with the framework presented in Figure 2 above, the precise content of the courses were adapted to the local environment, while still preserving the connection to the two pillars. A common overall structure for these PhD courses was nevertheless adopted, consisting of an initial introduction phase and a final examination phase at the PhD students’ home university. The central feature these PhD courses was a joint, week-long residential PhD summer school at University of Limerick (UL) in August 2017 with participation from UL, UU and University of East Finland. The summer school covered a wide range of topics central to wider society engagement with the aim of enabling the PhD students to communicate their own research to different target audiences, as well as design, organize, implement and evaluate a range of public engagement activities to audiences of various age groups and educational backgrounds. The course content was designed and delivered by senior RACE project partners, guest speakers and other experts in scientific communication and engagement. Not only did students receive intensive training through activities such as seminars, workshops and excursions, they also had the opportunity to interact with international colleagues and exchange ideas and experiences from an international perspective. The schedule of the summer school is shown in Figure 3.

As can be seen from the schedule, a wide variety of contexts and different presentation formats were covered during the summer school (e.g. Thesis-in-three minutes, Pint-of-science outreach events, investor pitches, research funding presentation), a well as aspects such as the logistics of organizing public outreach events and audience management. Subsequently the participants returned to their home university for the final assessment tasks, which included the organization, delivery and evaluation of one or more public outreach events in each partner location (e.g. demonstrations at science fairs and shopping centres, participation in Researcher Nights, three-minute pitches to undergraduate students, “Beer and Science” event with popular science presentations at a local bar). This is directly in line with the sequence of the RACE project (Figure 1), where the training modules would not only benefit the course participants,
but also lead to actual engagement with the wider public, thereby increasing the value and impact of the training to beyond classroom.

Figure 3. Schedule of the joint PhD summer school at UL, Aug 2017.

Evaluation and analysis of the data gathered on effects of this training on the PhD students’ knowledge, skills and attitude is continuing. These have included formative feedback during the summer school, questionnaire instruments (based on the one use of the Master students described above) and semi-structured interviews at the different partner sites.

SUMMING UP

Through the RACE project, a framework for designing and implementing adaptable modules that focus on training in scientific communication and public engagement has been developed. While the content focus of the present project has been the area of raw materials, the framework lends itself to being easily adapted to other contexts and areas of research and development. Having the considerations of RRI as an underlying design foundation, the project has worked to address the perceived gap between STEMM professionals and the general public. The evaluations conducted so far suggest that positive effects have been achieved on the knowledge, skills and attitudes of those participating in the training modules designed through such a framework and approach. Furthermore, it has been possible to directly link the modules to actual public engagement activities for the benefit of the general public. Such training-cum-public engagement activities should be explored, developed and evaluated further in future projects.

ESERA Summer Schools have been a part of professional development within ESERA community since 1993. The number of colleagues, who have launched their research career with participation in an ESERA Summer School continues to grow. Formerly biannual summer schools became annual in 2017 as the interest of doctoral students grew and ESERA wanted to support early career members. ESERA Summer Schools are excellent opportunities to elaborate one’s research and network with colleagues from around the world. Though ESERA is a European community and participation of European science education PhD students stays high, there is also growing interest of students from around the world as the ESERA Summer Schools provide substantial assistance for further development of students’ research projects.

Students who participate in an ESERA Summer School are automatically invited to take part at the next ESERA Conference and present the progress of their research projects at special ESERA Summer School Poster Sessions. This was also the case at the ESERA 2017 Conference, for which 97 students participating in 2016 and 2017 ESERA Summer Schools received an invitation. Altogether 62 students took part in these specialized poster sessions and it was rewarding for their summer school mentors to see that some of them had finished their research and were preparing their results for publication. Thirteen percent of these students submitted their research reports as papers for e-proceedings.

The following section presents eight papers which are based on ESERA Summer School Poster Session presentations.

TEACHER TRAINING ON IMPLEMENTING MODULES ON CUTTING-EDGE RESEARCH TOPICS WITH SOCIOSCIENTIFIC ASPECTS

Emily Michailidi and Dimitris Stavrou
Department of Primary Education, University of Crete, Rethymno, Greece

The negotiation of socioscientific issues in science courses can be significantly assisted through teaching cutting-edge research scientific topics. Essential prerequisite to that is considered to be the proper teachers’ preparation in order to meet the challenges that emerge both in terms of teaching approaches and of scientific content. In this context, this work examines the way in which in-service teachers implement in their classrooms modules on cutting-edge research topics with socioscientific implications, with the support of mentor-teachers. In total 5 mentors and 32 in-service teachers participated in the research. The procedure took place within 5 Communities of Learners (CoL) and lasted for 8-9 months. Data were collected via recordings of the CoL meetings and interviews with the participants. To analyze the data methods of qualitative content analysis are applied. Data indicate that teachers proceeded in various adaptations of the teaching material.

Keywords: professional development, curriculum adaptations, communities of learners

INTRODUCTION

The importance of negotiating socioscientific issues (SSI) in science classrooms has been widely recognized by the scientific community, as in this way students’ interest is attracted and scientific literacy is promoted (Hofstein, Eilks & Bybee, 2011). Current scientific research serves as an appropriate field for the negotiation of such issues, as cutting-edge research topics usually represent a less clarified science, incorporating subjects that still are in debate between different scientific views and includes a dimension of uncertainty (Levinson, 2006). For the negotiation of SSI the use of the Responsible Research & Innovation (RRI) aspects has been investigated as a scaffolding for SSI specification (Blonder, Zemler & Rosenfeld, 2016). RRI represents a contemporary view of the intertwining between science and society which also tries to establish a common understanding of the role of different stakeholders (government, scientists, citizens, etc.) towards research and innovation processes (Sutcliffe, 2011).

However, any required change in education ultimately relies on teachers who act not just as “carriers” of the innovation in the classrooms but as active interpreters. Related research shows that teachers face significant constraints both in teaching current scientific topics effectively (Angell, Guttersrud, Henriksen & Isnes, 2004) and in including in their lessons SSI due to their multidisciplinary and ambiguous nature (Sadler, Amirshokoohi, Kazempour & Allspaw, 2006; Forbes & Davis, 2008).

Curriculum materials – which usually include instructional resources as complete teaching modules, lesson plans, worksheets etc – are considered as an important means through which to operationalize and infuse educational innovations and to improve instruction and teaching practices in science classrooms (Rogan, 2007; Forbes & Davis 2010; Davis & Krajcik, 2005). Therefore, the dissemination of innovative TLSs and curriculum materials and the expansion
of their impact to larger numbers of teachers in a variety of school contexts consists a major concern of the research community in science education in order to bring about educational change (Pintó, Hernández & Constantinou, 2014; Fishman & Krajcik, 2003).

However, regarding the adoption of any educational innovation by teachers, research shows that it is not always smoothly achieved (Pintó, Couso & Gutierrez, 2005) and depends on (i) teachers’ characteristics, (ii) materials’ characteristics and (iii) the context of implementation (Brown, 2009; Remillard, 2005). Specifically, the process of large-scale implementation of teaching-learning sequences (TLS, Meheut & Psillos, 2004) inherently involves teacher’s adaptations to the specific context that his/ her students, teaching style and other local circumstances formulate (Brown & Edelson, 2003). During this procedure, very often major aspects of an educational innovation’s design are not being enacted as intended by its developers. Consequently, spreading innovations in a wide range of educational contexts requires an ongoing supportive training procedure that would guide teachers throughout the implementation as well that would ensure a fruitful interaction among researchers/developers and teachers. (Bitan-Friedlander, Dreyfus & Milgrom, 2004).

One of the approaches proposed to achieve this is teachers’ participation in Communities of Learners (CoL) where teachers interact equally, exchange experiences, knowledge and practices developing in this way their professional teaching identity (Akerson, Cullen & Hanson, 2009). Additionally, Geeraerts et al. (2015) proposed the design of “peer group mentoring”, according to which education takes place within learning communities under the guidance of experienced mentors. In this way, the training teachers benefit from the mentor's specialization as well as from their interaction with the practice of colleagues, evolving professionally in terms of knowledge and practice. According to Rogan (2007) these communities of practice may act as a scaffolding to support teachers in taking ownership of the innovation.

Our research intends to make a further step in this direction, by inviting teachers to implement modules on cutting-edge research topics enriched with SSI. Throughout this process teachers are provided with educational material and support from a network of expert teachers, research centres and science education researchers. The main purpose of our study is to outline how teachers implement teaching modules on current research and RRI topics under the supervision of expert science teachers within Communities of Learners. The detailed research questions are:

a) Where are the mentors' interventions focused on when supporting teachers in the implementation of modules on cutting-edge research topics including socio-scientific issues in their classrooms?

b) What kind of adaptations do in-service teachers make to modules on cutting-edge research topics including socio-scientific issues when implementing them in their classrooms?

**METHODOLOGY AND RESEARCH DESIGN**

The research framework is the Model of Educational Reconstruction (MER; Duit, Gropengießer, Kattmann, Komorek & Parchmann, 2012), a model that aims to bring science content structure and educational concerns into a balance when developing teaching and learning environments. Specifically, we use a variation of the MER, the model of Educational Reconstruction for
Teacher Education (ERTE) as introduced by Van Dijk and Kattmann (2007) which serves as a model for designing guidelines for the education of pre-service and in-service teachers. The model consists of three components closely interrelated. Component (1) in this model, concerns the clarification of ideas of educational structuring from literature. The investigation of teachers’ views and their role in initiating and supporting learning processes (component 2) is another prerequisite in the recursive process of developing the guidelines for teacher education (component 3).

Figure 1. The model of Educational Reconstruction for Teacher Education (Van Dijk and Kattmann, 2007).

In total 37 in-service teachers participated in the research: 5 mentors (who in a previous phase developed and implemented a module on Nanotechnology and aspects of RRI in collaboration with researchers in the field of science, science education researchers and science communication experts) and 32 trainees from various school types and regions of Greece. In the context of our research, each mentor trained 5-10 teachers, within a CoL, in implementing in their classrooms (i) the aforementioned nanotechnology module, (ii) a module about the effect of microplastic in the oceans and (iii) a module about the carbohydrates of breast milk. The commonality of the three modules, (all developed in the framework of the IRRESISTIBLE project, www.irresistible-project.eu) lied in the negotiation of current research topics through the prism of their socioscientific implications and the high level of interaction they promoted with research centres and science museums.

The training procedure, presented briefly in figure 1, lasted for 8-9 months and can be divided in three periods, common for all 5 CoLs. The first period, which constituted the main body of the training process, began with a kick-off meeting where the main axes of the modules were presented. Thenceforth, the CoLs met, either face-to-face or on-line. During the next 4-5 CoL meetings, teachers along with their mentors examined thoroughly the modules, discussing apart from the fundamental concepts of each module’s topic, aspects of inquiry-based science education (IBSE) and the involved RRI dimensions. In that period teachers with the support of their mentors also conducted necessary adaptations to the module in order to be implemented in their classrooms.

During the module’s implementation phase which included 4-5 meetings of the CoLs, mentors provided their on-going support discussing with the trainees the difficulties that arose, providing feedback and consults on the handling of certain activities and refining the modifications.

The third period covers the development of interactive exhibits by the students and the guidance their teachers provided in doing so. For that purpose, despite the continuing CoL meetings, an
exhibit-development workshop held by science communication experts took place, in order to equip and orient teachers towards supporting their students. As a corollary of the whole process, students presented their exhibits during the opening of two exhibitions hosted in the Eugenides Foundation and the Natural History Museum of the University of Crete.

By the end of the project, a final plenary meeting was held, where teachers were asked to reflect on their experiences implementing the curriculum. During the meeting teachers presented their experiences of the training program, the modifications they made to the curriculum and their view on the support they had received from the other members of the CoLs.

**Figure 2. Overview of teacher training process.**

For the data collection we used three main sources: open-ended questionnaires on teachers’ adaptations on the TLS, the recordings of CoL meetings, and the worksheets developed by teachers. While the open ended questionnaire, which was filled in by both teachers and mentors of each CoL gave us a capture of the performed transformations, the recordings of the CoL meetings where all these decisions were discussed in details, shed light on teachers’ intentions and the overall negotiation that preceded the adaptation.

**Data Analysis**

Due to the explorative nature of the study methods of qualitative content analysis are applied (Mayring, 2015). Specifically, concerning both mentors’ interventions and the teachers’ adaptations to the modules, the coding keys were developed on the basis of the relevant literature and were enriched or differentiated based on the new empirical data.

Regarding mentors’ interventions, we based our coding upon Hudson’s (2005) five factor mentoring model. According to that literature-based model – which was originally proposed as a means for specifying the mentoring practices that assist primary teachers in developing their science teaching – mentoring practices can be discerned in five main categories: (i) dealing with pedagogical knowledge, (ii) discussing about system requirements, (iii) providing feedback, (iv) modelling activities and (v) mentors’ personal attributes.

For the characterization of the conducted adaptations we used the Design Capacity for Enactment (DCE) framework (Brown, 2009). Deriving from the perspectives that conceive the
teacher – material relationship as synergistic the DCE framework tries to operationalize this relationship by identifying the factors that can influence how a teacher interacts (adapts, offloads or improvises) with curriculum resources. According to Brown and Edelson (2003) the teacher’s use of teaching materials can be explained as an interplay between his/her own personal resources (scientific knowledge, PCK, goals and beliefs) and the curricular resources (subject matter, tasks/activities, physical objects and/or their representations) within a certain context and the affordances and constraints that entails.

Based on the above models and the empirical data the coding keys used for our analysis are presented in Table 1.

Table 1. Coding keys for mentoring practices and for the modules’ aspects that had been submitted to transformation.

RESULTS

In the context of this study we examined firstly the types of mentoring interventions that emerged during a teacher training process which had as objective the implementation of three modules on cutting-edge scientific topics and secondly the adaptations these modules were subjected to by mentors and teachers.

Mentors’ Interventions

Mentors, in order to support training teachers throughout the demanding task had to mobilize a wide range of practices that would fit teachers’ needs. The employed mentoring practices are presented in Table 2.

According to Table 2, there exists a divergence between the mentoring interventions that were brought into practice during teachers’ training for the three different modules. These differentiations are mostly apparent in the degree of mentors’ modelling of the modules’ activities, in the provided assistance in redesigning the modules and secondarily in the amount of knowledge they share with the teachers. Specifically, the significant percentage regarding
the practice of modelling in the module of nanotechnology can be interpreted by the design and previous implementation of that module by the mentors themselves.

Mentors’ increased engagement with the nanotechnology topic may also be the underlying reason for the slightly augmented frequency of sharing topic-related knowledge with the teachers in this module. Finally, the notable difference in the time spent in assisting teachers with adapting the modules in each classroom context may be attributed to the fact that the nanotechnology module was originally designed taking into account the Greek educational context and was addressed to 6-11 classes incorporating alternative activities for all ages. The other two modules needed apart from the adaptation to the particularities of each class, more fundamental transformations to normalize the differences between the two countries’ educational contexts.

Modules’ Adaptations

As a result of the described training process, teachers, with their mentors’ support, proceeded to modifications regarding specific aspects of the modules. The elements of the modules that were subjected to adaptations with the initiative of mentors and training teachers are presented in Table 3.

In the above table a notable difference is depicted in the degree of mentors’ active role in suggesting modifications in the three different modules. Specifically, it is apparent that while in the nanotechnology module teachers incorporated many transformations originally proposed by the mentors, in the other two modules mentors gave the initiative of the adaptations to the teachers. Regarding the nanotechnology module, as described before, in a previous phase the 5 mentors had designed five distinct modules on nanotechnology applications which were thereafter synthesized into one single module that was provided to the training teachers. As a result when mentoring the teachers in implementing the final module in their class, each mentor
suggested the activities he/she had previously used for approaching the nano-related concepts, fact that resulted in an increased number of mentors’ transformations in table 3.

Subsequently, it bears mentioning that according to the particular characteristics of each module and of each classroom context it was applied in, teachers proceeded in transformations regarding different aspects of each module. In this way, in the nanotechnology and the microplastic module most of the modifications concerned additions or alterations in their activities rather than their content dimensions or the physical objects used. The aforementioned transformations were mostly related to different ways of approaching the core ideas of each module in a way that would fit the students’ capabilities and interests and to the incorporation of various out-of-school learning settings (beyond those originally recommended). In the breast milk module the majority of the modifications were related to the module’s content, as the module originally approached the differences between breast milk and baby formulas both by micro-biological and chemical aspect in a highly sophisticated way. Therefore, teachers had to omit certain features of the module and to render the module’s content more accessible to high school students.

DISCUSSION AND CONCLUSIONS

The implementation of three modules on cutting edge scientific topics and RRI issues reinforces the findings of a series of previous studies that underline the active, interpretive role of teachers in the process of curriculum enactment (e.g. Barab & Luehmann, 2003; Remillard, 2005; Squire, MaKinster, Barnett, Luehmann & Barab, 2003). According to these studies, curriculum is rarely enacted exactly as planned by their designers, as during the transfer process from one learning setting to another they get re-constituted and re-structured (Zappia et al., 2017). Furthermore, our results underline the participatory relationship and the importance of both teacher’s background and the curriculum’s features when conducting adaptations to teaching materials. Thus, following Brown’s (2009) Design Capacity for Enactment framework, we can conclude that the conducted modifications of the modules’ elements were dictated by the teachers’ content knowledge, pedagogical content knowledge and their teaching goals as well as by the module’s features.

Subsequently, from the results it can be concluded that a degree of adaptation of the modules is always needed, as each classroom constitutes a different context with its own particular characteristics. According to Testa et al. (2012) and the modified Adaptation and Re-Invention model (ARI model, Rogers, 1983), the process of transferring a TLS from one context to another includes: (i) a de-contextualization of the original implementation procedure, (ii) the identification and adaptation of the “core” ideas of the TLS and (iii) the re-contextualization in the new setting. This process was omnipresent throughout the whole training procedure but it was more apparent in the case of the breast milk module. In that case, because of the extent of the original module’s content, teachers consciously tried to re-define the ideas they judged as fundamental to be taught and re-contextualized them with the necessary activities and teaching materials in order to do so.

Regarding the mentoring interventions, they were mostly guided by the teachers’ needs in each stage of the training procedure. Thus, the extent of the needed modifications in each module
also defined the amount of time mentors devoted in assisting teachers with re-designing. Likewise, the slightly increased percentage of mentors sharing knowledge in the case of the nanotechnology module apart from mentors’ familiarity with the topic also reflects the teachers’ augmented needs when having to deal with such an innovative topic.

Finally, attempting an overall evaluation of the Communities of Learners as a context for training and supporting teachers throughout the implementation of the modules, they can be judged as effective and the mentors’ role as determinant for the completion of that demanding endeavour. Within the CoLs and under the guidance of experienced mentors, the innovation seemed less threatening to the teachers. The CoLs also worked as a safety net for the teachers who were encouraged to try out innovative content and teaching practices and to reinvent the modules following their own ideas for modifications and adopting others suggested by the mentors.

ACKNOWLEDGEMENT
The modules described in this paper were developed within the project IRRESISTIBLE, funded by the EU as FP-7 project number 612367.

This research work was implemented with a scholarship from IKY (Greek State Scholarships Foundation) funded by the “Enhancing human research potential through doctoral research” act from the funds of the Operational Program “Human Resources Development, Education and Lifelong Learning” 2014-2020 with the co-financing of the European social fund and the Greek State.

PREDICTING COURSE SUCCESS IN THE UNDERGRADUATE GENERAL CHEMISTRY LAB

Thomas Elert and Maik Walpuski
University of Duisburg-Essen, Germany

Increasing criticism regarding the effectiveness of laboratory courses at university level requires educators to find convincing evidence for their inclusion in the science curriculum. In addition, there are hints that laboratory courses as “gateway” courses might contribute to the high dropout rate of chemistry students in Germany. Based on a model on the effectiveness of practical work, prior knowledge and learning goal alignment as two factors possibly influencing lab course success are investigated in this study in order to gain a better understanding about laboratory-centred instruction. Within the context of a general chemistry lab course for undergraduates in teacher training, prior chemistry content knowledge emerges as a predictive factor, while learning goal alignment is not relevant. This investigation is also able to relate lab course success to performance in the general chemistry final exam.

Keywords: undergraduates, practical work, course success

PURPOSE OF THE STUDY

Literature suggests that the investigation of laboratory courses at university level is long overdue. Laboratory-centred instruction has always been a core component in the science curriculum (Hofstein & Lunetta; Reid & Shah, 2007) and teaching science without it appears to be unthinkable. However, nowadays educators rarely give specific reasons for that. Most often they only highlight its nostalgic value or the logical conclusion that educating skilled practitioners works best through hands-on experience (Cooper & Kerns, 2006; Elliot, Stewart, & Lagowski, 2008; Reid & Shah, 2007). As a reaction, Hofstein and Lunetta (2004) have challenged the 21st century to conduct more focused research. Similarly, educators in Germany have raised the issue of a strong need for methodological innovations in higher education chemistry, including laboratory-supported instruction (Eilks & Byers, 2010). Critics from science education circles only fuel this ongoing debate. Not only are laboratory courses very cost-intensive in terms of facilities, resources and time for both faculty and students compared to lectures (Hawkes, 2004; Reid & Shah, 2007; van den Berg, 2013). Hawkes (2004), for instance, doubts that these expenses cannot justify the poor return in learning chemistry. It is very likely that this is because the aims of practical work appear to be very vague or are not even defined at all (Reid & Shah, 2007).

Criticism towards the usefulness of laboratory courses becomes particularly relevant considering that over 40% of chemistry students in Germany drop out of their program without a degree (Heublein et al., 2017). Apart from overall difficulties with performance during the first semester of studying chemistry (Heublein et al., 2017), the literature also suggests that undergraduates are specifically overburdened with coursework in the introductory general chemistry laboratory (Schwedler, 2017). It therefore is possible that some of these dropouts are the result of low success in introductory laboratory courses designed for undergraduate
chemistry students as “gateway” courses. However, research has yet to identify preconditions of students that predict whether they are successful in them or not.

This study tries to contribute to two core issues using the example of a typical traditional laboratory course in general chemistry. First, it examines two theory-deduced factors that possibly predict lab course success. Second, it investigates its significance for learning chemistry throughout students’ first year of studying and its relationship to overall study success. These findings can be useful to adequately evaluate the cost-benefit ratio of laboratory courses in the undergraduate curriculum and inform chemistry educators about ways for improving or even reconstructing it. As a long-term goal these measures are possibly able to remedy the high dropout rates in chemistry.

THEORETICAL FRAMEWORK

The foundation for this study is a theoretical framework for laboratory-centred instruction (Bussey, Orgill & Crippen, 2013), as well as a model for the effectiveness of laboratory work (Abrahams & Millar, 2008). From those, two factors potentially influencing lab course success, prior knowledge and learning goal alignment, can be extracted. First, we assume prior knowledge to be relevant in our predictive model due to the role it plays in the construction of meaning and meaningful learning from a constructivist viewpoint (Novak, 1993). In the context of laboratory-centred instruction, prior knowledge determines the kinds of observations learners make during experimentation and how they make sense of it (Hodson, 2005; Johnstone & Al-Shuaili, 2001). Similarly, Bussey et al. (2013) argue in their framework that learners’ construction of meaning in laboratory settings is dependent on the kinds of experiences they make in and with the learning environment. This in turn is influenced by their prior knowledge. Learners try to recall similar situations when interacting with the lab material or performing specific experiments and thus adjust their behaviour accordingly. However, when their prior knowledge is either faulty due to distinct misconceptions or they cannot recall an appropriate similar situation due to low prior knowledge they might encounter problems with solving the tasks in the lab and are endangered to perform poorly. A study conducted by Rice, Thomas and O’Toole (2009) throughout Australian universities attests that chemistry undergraduates’ prior knowledge levels are very different, this is also true for the German context, where school background primarily dictates the amount of prior knowledge for chemistry undergraduates (Freyer, 2013). As such, it is possible that these differing levels of prior knowledge can explain variance in the students’ performance in the lab.

Second, we assume learning goal alignment to be a predictive variable due to the underlying design principles of laboratory courses. Laboratory courses, as any other form of instruction, are always designed with certain intentions in mind, which manifest themselves in a set of learning goals. They have the function to structure learning activities and serve as a framework for choosing and designing assessments. In addition, they help learners understand the intentions behind a specific activity (Hofstein & Lunetta, 2004). Several newer studies could establish that faculty is able to formulate these learning goals when asked about the intentions of an undergraduate chemistry lab (Bretz, Fay, Bruck & Towns, 2013). These intended learning goals of faculty can be communicated to the learners, e.g. they are explicitly written down in the lab manuals or discussed in pre-lab sessions. However, this is only rarely the case (Meester
& Maskill, 1995). In consequence, learners resort back to what they think they are supposed to learn and anticipate and perceive other goals than intended (DeKorver & Towns, 2015; Wilkinson & Ward, 1997). Bussey et al. (2013) argue that in that case learners adjust their actions and behaviour in the laboratory and focus on varying aspects according to their own expectations and perceptions towards the lab course’s learning goals. This can be problematic, as it might happen that the learners miss the conceptual idea behind a certain task and fail to solve it to the lab assistant’s satisfaction. In Abrahams and Millar’s (2008) terms this is a sign of an ineffective laboratory. Thus, low alignment of intended learning goals of faculty and perceived learning goals of the learners might negatively influence student performance.

Based on this framework we see a lot of potential in the investigation of prior knowledge and learning goal alignment as two factors, particularly as empirical predictive models on laboratory course success are rare. Figure 1 summarizes the relationship between these potential influencing factors and actions in the lab.

**PROCEDURE**

**Study Context**

This study was performed at the University of Duisburg-Essen, a large, public university located to the West of Germany, which offers a study program for chemistry students in teacher training. Apart from enrolling in a general chemistry lecture and a tutorial course, these students are required to enrol in a laboratory course during their first semester. Using the terminology of Abraham et al. (1997), the syllabi among those three show no formal coordination, meaning that while the content covered in each course is more or less the same, the chronological order of the topics differs substantially. There are two reasons why this study program, in particular, was chosen for the investigation. First, as the chemistry education department is in charge of organising and teaching most of the general chemistry courses for these students, the sample is readily available and the study can be integrated with the curriculum easily. Second, the students are free to choose between two different enrolment options for the general chemistry laboratory course, which allows for drawing convenient subsamples: Students may either choose to enrol in a weekly 5-hour laboratory course during the semester or a daily 7-hour laboratory course at the end of the semester. With this freedom...
of choice for the students, it is possible to contrast students who choose to enrol in the lecture, the tutorial and the laboratory course simultaneously during the semester and students who save the laboratory course for later.

Regardless of choice, both options are identical in overall length (70 hours in total) and content. The topics of this course are comparable to other introductory lab courses and include acid-base chemistry, redox reactions, photometric analyses and qualitative analyses of mixed substances among others. These are typical concepts from general chemistry that are also taught in introductory chemistry courses at other institutions (e.g. Matz, Krajcik, Rothmann & Holl, 2012). Judging from the way the experiments are presented in its home-grown lab manual and its strong focus on precise execution of procedures, this course can be classified as a traditional introductory chemistry lab, where manipulation of apparatus and gathering and processing of data are more important than inquiry thinking. The first hour of each lab session is allotted to a pre-lab discussion, which primarily focuses on the theoretical background of the experiments, as well as the lab techniques and safety precautions. After lab time, there is no post-lab discussion scheduled to wrap up the findings. References towards learning goals for this general chemistry laboratory course are very scarce, which resonates with a study conducted by Meester and Maskill (1995) who observe numerous lab manuals across universities in England and Wales devoid of any learning goal descriptions. As such, it is completely up to the students to understand the lab course’s didactic concept.

Test Instruments and variables

For each course option, data on the students’ prior knowledge was gathered during the course groups’ respective first lab session. We differentiate between prior content knowledge relevant to the first semester and prior knowledge about typical experimental procedures of this introductory lab, which we label prior lab skills. Prior content knowledge is assessed via a multiple-choice single-select paper-pencil test with 35 items, which has been developed for the German context (Freyer, 2013) and revised and reused since (Elert & Walpuski, 2016). Of those, 24 address chemical concepts and ideas ranging from upper secondary school to undergraduate university and 11 primarily address content specific to the general chemistry laboratory course. Prior lab skills are assessed via two different test instruments. The reason behind this is that paper-pencil-based tests alone are not valid enough to measure practical skills (Schreiber, Theyßen & Schecker, 2009). Instead, investigations measuring practical skills should consider test instruments that are closer to the real experience, such as computer simulations or actual real experimentation. If possible, assessing practical skills both directly and indirectly is recommended to produce valid data (Abrahams, Reiss & Sharpe, 2016). The direct assessment is realized via a hands-on lab skills test, where students are asked to demonstrate their manipulating skills in five hands-on tasks, each one addressing a core lab technique for this introductory chemistry lab. The indirect assessment allows inferring the students’ abilities from another paper-pencil test consisting of 21 items addressing knowledge about typical procedures in the lab. Both lab skills instruments have been developed (Platova, 2017), revised and piloted before. The pilot study could also establish satisfying test parameters for all prior knowledge test instruments and separate prior content knowledge and prior lab skills as two significantly different constructs based on data of paper-pencil tests (Elert &
Walpuski, 2016). The same instruments were also administered at the end of the semester in order to obtain information about the students’ knowledge in the according knowledge domains prior to the general chemistry finals. Test scores of all test instruments and points of measurement are fit in a Rasch model, from which person ability measures are drawn via means of item response theory. It should be noted, however, that at this point data from the hands-on lab skills test is not yet considered for the following analyses because scoring conversion is not yet finalized.

In order to obtain a measure representing learning goal alignment for the general chemistry lab, all lab assistants and students were asked to successively rate the relevance of learning goals specifically addressing the lab’s experiments via five-point rating scales uploaded to an online tool as they progressed through the lab course. These are a compilation of learning goals from the literature (e.g. Kirschner & Meester,1988; DeKorver & Towns, 2015), the lab manual, interviews with students and faculty and were cross-validated with faculty, as well as piloted with previous lab course participants. With 11 experiments in total, the participants of this study rated 180 experiment-specific learning goals throughout the whole course. Each student’s responses are paired up with the ones of their according lab assistant and weighted Cohen’s κ coefficients are calculated as a measure for learning goal alignment between learner and lab instructor.

Student performance in the lab course is assessed on two different levels. First, the quality of the students’ experimentation is assessed via the accuracy of their experimental results. The students have to report the correct result within a predefined range of tolerance in order to pass the experiment and continue with the next one. If they do not succeed, they have to repeat the experiment. After a maximum of three trials they must have passed the experiment, otherwise they fail the course. Second, when they passed all the experiments they have to write two lab reports, each one focussing on a set of the experiments they performed. These lab reports primarily require the students to explain the procedures and results using content knowledge. The lab instructor grades the lab reports with a grading rubric and averages the final course grade from both lab report grades. The final lab course grade is the main indicator for course success in this investigation. Both, students who perform poorly during experimentation or those, who hand in inadequate lab reports, are considered as “fail” in the data.

In order to address the question of overall study success, we were granted access to the scores and grades of the general chemistry module exam at the end of the first semester. This allows us to relate student performance in the exam with the other assessed variables.

In addition to the independent and outcome variables, we assessed cognitive abilities via two scales, the V2-scale representing verbal abilities and N1-scale representing spatial abilities, from the German Cognitive ability test (Heller & Perleth, 2000). Cognitive abilities, as well as basic demographic data, school/university background and three self-concept scales (chemistry self-concept, manual abilities self-concept and laboratory-related ability self-concept) serve as control variables and help characterising the sample in more detail.
Sample Description

During winter term 2016/2017, 76 students (53% female, $M_{\text{age}} = 20.24$, $SD = 2.50$) enrolled in the lab course and participated in the study. Two-fifths (43.4%) report that they had the opportunity to perform at least one experiment the same year they began their chemistry study program. Approximately half of those (55.3%) also tend to agree that they were given many opportunities to perform experiments during their school career in general. This can also explain why the sample appears to be rather confident in learning chemistry, as well as being manually skilful, but also specifically in handling the laboratory inventory, as evidenced by the according mean ability self-concept values (see Table 1).

1 scales range from 1 to 6

Regarding cognitive abilities, the sample’s Rasch-scaled person-centric mean scores are above average ($M = .44$, $SD = 1.08$) for the $N1$-scale (spatial abilities) and slightly below average ($M = -.28$, $SD = .87$) for the $V2$-scale (verbal abilities).

As space in the laboratory is limited to a maximum of 24 students, the overall sample is split into five lab course groups while trying to keep the number of students per group more or less even. This resulted in three groups working during the semester ($n = 49$) and two after the semester ($n = 27$). In addition, five doctoral candidates from the chemistry education department enter the sample as the course groups’ lab instructors.

For statistically clean comparisons between course participants of both lab course enrolment options, we had to ensure that they are comparable with regard to the control variables and levels of prior knowledge. We therefore assigned the different lab course groups based on the pre-test instrument results and carefully observed the sample the following week. Significant differences among these measures due to dropouts would have required reassigned the students to rebalance the means. Table 2 lists the results of this balancing process and indicates significant mean differences between course participants during the semester and course participants after the semester via according $t$-test statistics marked in bold.

We have to acknowledge that we were not able to keep equal levels of prior lab skills between both groups as measured by the paper-pencil test. In addition, course participants after the semester have a higher self-concept about learning chemistry. The according $t$-tests show significant differences with a middle-sized effect each.

RESULTS AND DISCUSSION

Influence of Prior Knowledge and Learning Goal Alignment on Lab Course Success

In order to test for overall effects of the students’ prior knowledge and learning goal alignment on the final lab course grades as a measure of lab course success we first inspected the bivariate correlations between those (see Table 3).

Table 3. Bivariate Pearson correlations between the predictor variables and final lab course grades.

</tbody>
</table>

Note: Pearson correlations between prior knowledge domains and final lab course grades are negative because the German grading system is reversed, with 1 as the best grade and 5 as the worst

The results show that only the two prior knowledge domains significantly correlate with course success, while learning goal alignment has to be rejected as predictor variable due to missing correlations. This result contradicts the theoretical assumption made before. We assume this is because we defined learning goal alignment as fit between the lab assistants’ learning goal expectations and the students’ according perceptions. However, we did not consider how well the assistants’ expectations aligned with the course’s pre-set grading rubrics. It might be that although the assistants answered truthfully in the ratings, some of their expectations were not considered in these rubrics and therefore had no significance for the grading. Although the
theoretical framework on laboratory-centred instruction acknowledges instructional material to create noise while assessing intended learning goals, we propose that this could also be the case for external course restrictions, such as grading rubrics. It is also important to remember that lab course success solely refers to lab report grades here. Checking for correlations between the predictor variables above and experimental accuracy as another measure for course success could reveal other relations between these variables.

In the following, we applied a stepwise regression model to explain variance in the final course grades with the remaining predictor variables. The order, in which each predictor variable was entered into the model, is based on their respective bivariate correlation with the outcome variable. The resulting regression model only accepts prior chemistry content knowledge as factor explaining a total of 10.6 % of the variance in the lab course grades, $F(1,74) = 8.805, p = .004$, whereas the influence of prior lab skills is not significant (see Table 4).

The dominance of prior content knowledge over prior lab skills in this model can be explained by the way lab course success is operationalized in this study. It makes sense that content knowledge is more important for a well-written lab report than hands-on abilities due to its strong focus on explaining core concepts and ideas relevant to the experiments. In addition, these two prior knowledge measures show a highly significant moderate to high correlation to one another ($r = .576, p < .001$). It appears that this correlation is high enough for the lab skills test results to become insignificant in the presence of prior content knowledge as predictor.

A high proportion of the variance remains unexplained, though. As writing a good lab report is also a matter of effort, in addition to high knowledge or capabilities, we recommend to account for that by implementing scales measuring conscientiousness and mental effort and explore their influence on the predictive power of the model, as well. Other investigations could also reconsider how lab course success is defined in this context. It might be worth exploring additional factors for course success, such as total lab time needed to pass the course or accuracy during experimentation.

Effect of Lab Course Enrolment on Learning Chemistry

As we assessed the students’ prior content knowledge at the beginning of the semester, as well as their content knowledge at the end of the semester, we are able to make statements about their knowledge development over time. For this purpose, students who enrolled in all mandatory courses for the first semester simultaneously ($n = 46$) are contrasted against those who chose to enrol in the lab course separately from the other courses after the semester ($n = 27$). Note here that we had to exclude a few cases that did not deliver complete data sets due to missing the post-test, which explains the reduced sub-sample sizes. The according repeated measurement ANOVA reveals that first, all students regardless of lab course choice highly significantly learn chemistry content over time, $F(1,71) = 68.919, p < .001, \eta^2 = .493$, 2301
reassuring that a learning effect takes place at all. However, it appears that concurrent enrolment in all general chemistry courses does not have any additional effect as indicated by the insignificant interaction between enrolment option and knowledge gains, $F(1,71) = 1.330$, $p = .253$. Both sub-samples start with statistically equal prior content knowledge levels and end with statistically equal content knowledge levels.

**Effects of Lab Course Success on Study Success**

For students, who enrolled in and completed the lab course before the general chemistry module exam ($n = 42$), it is also possible to investigate in how far lab course success relates to study success in the first semester based on performance during the general chemistry module exam. Here, we can model a partial mediation of the effect of content knowledge on general chemistry module exam scores via final lab course grades (see Figure 2).

![Figure 2. Partial mediation of the effect of content knowledge on general chemistry module exam scores via final lab course grades.](image)

One possible interpretation is that the students reflect content before the exam that the content knowledge test does not address explicitly. For instance, they have to do calculations and present them in the lab reports, which is also often required in the final exam. It might also be that writing coherent texts while integrating the content knowledge is closer to the format of the exam than a paper-pencil test.

**IMPLICATIONS FOR RESEARCH AND TEACHING**

This study tried to derive predictor variables for lab course success based on a theoretical framework on laboratory-centred instruction and found prior knowledge, specifically prior chemistry content knowledge, to be predictive. However, as most of the variance remains unexplained and learning goal alignment is not relevant, more thought has to be put into what other factors might predict lab course success. As this explorative investigation mainly focused on cognitive factors, we believe that research including the investigation of affective and social factors could lead to a more rounded model. We also chose to investigate a traditional lab course, which, from a student perspective, is rather non-transparent with regard to its learning goals, so that comparative studies with varying types of labs, e.g. the inquiry-centred lab could provide more evidence of the validity of the theoretical framework.
More importantly, however, is the question of which function the traditional lab fulfills here. Although it does not foster learning chemistry content per se, it nevertheless appears to be beneficial for exam performance at the end of the first semester. This is surprising, given the strong hands-on nature of laboratory courses. Admittedly, this result is a matter of by how lab course success is operationalized in this study, which is lab report grades. However, it is an operationalization also held by faculty and communicated accordingly. This raises the question of how well aligned learning goals and assessments for this laboratory course are. It might be that its didactic concept needs to be revised in order to achieve its full potential.

SYSTEMIZING AND EMPATHIZING IN EARLY YEARS SCIENCE – A VIDEOBASED STUDY WITH PRESCHOOL CHILDREN

Nina Skorsetz 1,2 and Manuela Welzel-Breuer¹
¹University of Education, Heidelberg, Germany
²Goethe University Frankfurt/Main, Germany

Children are very different in their motivation to do science. An approach for explaining these differences in the motivation for science could be the Empathizing-Systemizing (E-S)-Theory (cf. Baron-Cohen, 2009). It says that every person’s brain has two dimensions, the systemizing and the empathizing. Both dimensions can be measured with a questionnaire and represented in an EQ- and a SQ-value. People with a high SQ-value were called “systemizer” and tend to search for systems behind things. Empathizers orientate themselves to other person’s feelings. Systemizers are generally more engaged in science and motivated to do science than people with a high EQ-value who are stronger in empathizing (cf. Zeyer et al., 2013). Main goal of the study is to find out if pre-school children with various EQ- and SQ-values act differently in scientific learning environments. Tested children will be observed within two didactically methodically different arranged learning environments to investigate potential diverse behavior. In this study the brain types resp. the EQ- and SQ-values of 4 to 6 year old pre-school children were determined with a 55 item EQ-SQ-questionnaire (Auyeung et al., 2009) that we translated into German. In terms of a design-based research approach (cf. Collective, 2003) the tested children were video-observed while acting within two different scientific learning environments in spring 2015 and 2016. Results seem to show that children with high SQ-value, according to literature, tend to be more motivated to do science than children with a high EQ-value. Children with a high SQ-value were motivated in both learning environments which could lead to the interpretation that these children are motivated to do science undependable from the didactical-methodically arrangement of the learning environment. For children with a high EQ-value no such correlations for their motivation to do science were found. They seem to be less motivated in both learning environments than children with high SQ-value. More research will be needed.

Keywords: early years science, video based research, design based research

INTRODUCTION

Starting Point: Diversity

Children in kindergarten are often very motivated to do science but this motivation distinguishes from child to child and fades away within age (cf. Patrick & Mantzicopoulos, 2015). One usual explanation for the different motivation to do science is the gender difference between boys and girls. A slightly different approach for explaining differences in the motivation for science is the Empathizing-Systemizing (E-S)-Theory from Baron-Cohen (2002). The idea of his theory is that every human brain has two dimensions. On the one hand there is the “empathizing” which is defined by the drive to identify another’s mental states and to respond to these with an appropriate emotion, in order to predict and to respond to the behavior of another person” (Baron-Cohen et al., 2005). On the other hand there is the “systemizing” which is defined as the drive to analyze or construct systems” (Baron-Cohen,
2009, p. 71). With questionnaires the measure of the peculiarity of the both dimensions – called EQ and SQ – can be determined (cf. Billington et al., 2007).

People with a high SQ-value are called “systemizer” who are generally more engaged in science than people who are stronger in empathizing (cf. Zeyer et. al., 2013, p. 1047). In Baron-Cohen’s studies it seemed that the two dimension are dependable from each other. Baron-Cohen and his colleagues calculated the difference between the EQ- and the SQ-Value and build statistically five so called brain types: Extreme Empathizers, Empathizers, Balanced, Systemizers, Extreme Systemizers.

Further studies showed that the two dimensions do not depend on each other and the concept of brain types sometimes mislead because a person can have a balanced brain type with either both similarly high EQ- and SQ-values or both similar minor values (cf. Svedholm-Häkkinen & Lindeman, 2015, p. 366).

Zeyer et al. (2013) showed that only the SQ-value has an impact on the motivation to do science. So far the relation between the SQ-value and motivation for science has not been tested with the young children – only with high school students. But the EQ- and SQ-values can be collected for 4 to 11 year old children with a combined 55 item EQ-SQ-Child-Questionnaire that was validated in a large study with over 1500 applications (Auyeung et al., 2009). In this case the parents filled out the questionnaire for their children.

In this current study the goal is to find out whether there are differences between systemizers and empathizers in motivation attending scientific learning environments at the kindergarten (cf. Skorsetz & Welzel, 2015). Maybe the different brain types need different forms of access to science (cf. Zeyer et. al., 2013, p. 1047).

**What is Motivation?**

Before we can find out how motivated preschool children are in scientific learning environments we have to define what motivation is. A useful definition is: “Motivation is an internal condition that elicits, leads and maintains the children’s behavior” (Glynn & Koballa, 2006). Motivation is here been seen as to be motivated to learn something or the desire to gather knowledge (cf. Artelt, 2005). Motivation can be seen as a “time on task” (Artelt, 2005, p. 233) spend with focusing on the subject. If somebody is motivated to learn something he or she will probably spend more time with it. There are several constructs concerning motivation. Following Glynn & Koballa (2006) those are for instance intrinsic/ extrinsic motivation, goal orientation, self-confidence, self-determination and anxiety (cf. Glynn & Koballa, 2006). Thus, the challenge is to observe different aspects of motivation knowing that “motivation cannot be observed directly” (Barth, 2010). Some kind of instruments measure the amount of motivation like the Leuven’s scale of involvement/engagement including (cf. Laevers, 2007). With this, Laevers specified different signs of motivation. These are bodily posture, attentiveness, endurance, accuracy, responsiveness and contentment. If we assume that someone is motivated when he or she follows attentively in a situation, we can observe the different viewing foci the children chose in the scientific learning situations and the duration of it.

2306
Early Years Science in German Kindergartens

In German kindergartens it is common practice to use basically two different approaches to do science. Main difference of these two approaches is the degree off structuring of the used didactical and methodic arrangement. Both ways have in common that they are organized in a so called learning environment that often starts the exploring of a natural phenomenon.

The first applied approach could be called “rather structured” because the idea is that the child co-constructed new knowledge with others, for example, in an experiment structured by an instruction followed by an interpretation and guided by questions and interventions of the teaching person (cf. Lück, 2009). In this way, the learning environment is leaded and structured by the preschool teacher. The preschool teacher and the children are often sitting around a table. The used materials are displayed by the preschool teacher on a dark pad and labeled together with the children. A manual is displayed which is followed by in a step by step procedure. The experimentation phase is followed by an interpretation phase where the children try to find an explanation for the phenomenon.

For the other approach the idea is that the child playfully makes holistic (nature-) experiences together with others in a communicative setting. Hence, it has the possibility to identify itself with somebody else or a situation in a social setting - for example trough a fictional framing story (cf. Schäfer, 2008, 2015). The children and the preschool teacher are often sitting on the floor in a circle. The materials are also displayed. A framing story is e.g. “told” by a puppet and the story ends with a problem of that puppet that has to be solved by the children. After the story the children have time to explore the materials or the phenomenon and solve the problem in their own way in order to help.

RESEARCH QUESTIONS

Main goal of the study is to go find out how pre-school children with different EQ-/SQ-Values act and react in different didactical and methodical learning environments on the same topic. Respectively, we are observing tested children within two different learning environments in order to investigate potential different behavior.

Our hypotheses in this context are:

H1: Systemizers could be more motivated to do science in more structured learning environments because of their higher SQ-value which leads them to search for systems.

H2: According to Zeyer et al. (2013), we assume that fictional stories and the possible identification with protagonists should especially motivate empathizers to do science. An additional idea is that maybe learning environments who include time to explore the materials could be motivating for empathizers.

Based on these hypotheses we developed the following research questions in order to find differences between the children in two contrastive learning environments. At first we have to find out whether different EQ- and SQ-values can be found within preschool children:

RQ1 To what extend do preschool children show empathizing or systemizing characteristics?
At first all tested children of the first project year and of both brain types participated in a more structured setting. In the following year other tested children (next “generation”), again of both brain types, entered the rather exploring learning environment. So our research question is specified for the two settings:

RQ2: To what extend is the influence of brain type or of the EQ- and SQ-value shown by differences in children’s actions in a rather structured (RQ 2.1) or a rather open (RQ 2.2) learning environment based on the criterion of chosen viewing directions and its duration?

METHOD

In order to answer the research questions our study was organized in three steps: (1) application of the EQ-SQ-Child-Questionnaire (developed by Auyeung et al., 2009), (2) application of the more structured learning setting, and of the rather exploring type of learning environment, (3) analysis of correlations between the brain type of the children and their actions within the different learning settings.

(1) At first we had to translate and validate the EQ-SQ-Child-Questionnaire (Auyeung et al., 2009) in order to determine the EQ- and SQ-values of every child in a communicative validation process (Lamnek et al., 2010). The questionnaire is to be applied to children’s parents because of the low age of the children analyzed. The tested children should be 5 to 6 years old and spending in kindergarten in their last year before entering the primary school.

(2) In order to see different actions concerning their motivation and to investigate if that is independent from the didactical and methodological arrangement of the learning environment in step two, children participated in one of two contrastive organized scientific learning environments. Both learning environments are based on the same phenomenon “absorbency of different materials” (Krahn, 2005). The learning environments were developed theory based and evaluated with the Design Based Research approach (cf. DBR Collective, 2007).

One part of the mixed groups with tested children participated in the “rather structured” approach; the other part participated in the “rather open” approach. The children’s behavior (n=50) has been observed (video-recording) carefully. The same procedure was performed with the “rather open” approach in the following year. The videotapes are the basis for the following empirical analysis with inductively developed categories putting the focus on the children’s viewing directions (c.f. Mayring, 2008).

(3) The third and last step was to calculate statistically the correlation between the compiled EQ- resp. SQ-values and the data from the video analysis in order to find the expected significant differences between the two groups of children (Bortz & Döring, 2006).

RESULTS

The EQ-SQ-Questionnaire

The translation process of the questionnaire was organized with different researches from different faculties in order to validate it communicatively (cf. Lamnek et al., 2010). About 17 scientists usually meeting regularly in a seminar participated in that two-step procedure. For the subsequent pre-test the first version of the questionnaire in German was applied to a mother
with a child in that age. From that we got answers to the questions as well as comments concerning the understandability of the items. After another communicative validation process in with the above mentioned research group build on the mothers’ comments, the next and improved version of the questionnaire was finalized. The pilot study followed, though the questionnaire was applied to 25 parents of preschool children. The internal consistency of the results has been tested statistically. Cronbach’s alpha coefficients were calculated and showed acceptable coefficients for empathy items ($\alpha=0.81$) as well as for systemizing items ($\alpha=0.61$). This result is in accordance to the literature data of Auyeung et al. (2009). Thus, we can conclude that the translated questionnaire should be valid and reliable. Overall 112 children were tested by the questionnaire during data collection in spring 2015 and spring 2016.

**Development, Implementation and Analysis of Learning Environment**

Both learning environments are based on the phenomenon of absorbency. We expected the children to recognize this phenomenon from situations at home and in the kindergarten when fluids were spilled.

For the study, children with tested brain type/EQ- and SQ-value participated the learning environment in groups of four. All activities were video recorded using two video cameras filming the sequences from different angles. During summer 2015 and 2016 the number of 99 pre-school children of seven different kindergartens in the area of Heidelberg, Germany, and from age 5 to 6 were filmed.

The data collection of the rather structured learning environment took place in spring/summer 2015 in 15 settings with 52 children. The data collection of the rather exploring learning environment comprised 14 settings with 47 children and followed in spring/summer 2016. Hence, the total number of video material sums up to about 10 hours.

The two videotapes of each setting were inset in the evaluation software program “Videograph” (Rimmele, 2012) and synchronized. Inductively we developed eight observation categories with the focus on the children’s viewing directions:

1. Towards Preschool Teacher
2. Towards other Children
3. At the Experimentation Material
4. Towards the Observer/into the Camera
5. Around
6. Material, that is not relevant right now
7. Indistinguishable
8. Any other business

In the following step we summarized the fourth, fifth and sixth code to a new category “Distraction/Attentiveness”. The 6th category involves material that the children bring in their pockets, experimentation material that has been used before but is not relevant any more. The 8th category has not been used. A manual has been produced.
The videotapes of both learning environments were then analyzed in detail according to the manual. Two coder analyzed all videos. In the rather structured learning environment the children’s viewing directions in the whole setting were gathered. With the software programme “Videograph” the duration was measured in percentage for a comparison dependable from the duration of the setting. Different codes were identified and discussed in a communicative validation process (Lamnek et al., 2010). The same procedure followed with the rather exploring learning environment. The coding of the viewing directions of the whole setting started here after the end of the framing story.

Correlations

In order to answer the second research question the EQ- and SQ-values of each child were correlated with the video analyzed data. In Table 1 the results of the correlations of the date from the rather structured learning environment and the children’s EQ- and SQ-value are shown. Two significant values were identified in this one-tailed Spearman correlation: r=−.31* (Correlation between SQ and “View to material that is not relevant right now”, row 3, column 9) and r=−.28* (Correlation between SQ and “Distraction, row 3, column 10). That means that children with higher SQ-value tend to be more focused on the scientific related foci.

Notes: Difference = Difference EQ/SQ = Brain Type, EQ = relative EQ-value (2); SQ = relative SQ-value (3), Teacher = View towards Preschool Teacher (4), Children = View towards other Children (5), Exp.mat. = View towards the Experimentation Material (6), Cam. = View toward the Observer/into the Camera (7), Around = View around (8), Mat. n. r. = View t. Material that is not relevant right now (9), Distraction (10)* p < .05, ** p < .01. (one-tailed)

In Table 2 the results of the correlation in the rather exploring learning environment with the children’s EQ- and SQ-values were displayed. One for our study relevant correlation shows a significant value (r=.28*, row 2, column 9) between the EQ-value and the “view towards material that is not relevant right now”. That means that children with a higher EQ-value tend to focus this non-relevant material. So they seem to be more distracted than children with higher SQ-value. Another significant value is r=−.34** (variable difference, row 1, column 9) between the children’s brain type and the “view towards material that is not relevant right now”. This
result could be interpreted that children with higher SQ-value (in the difference accumulated) focus less on distracting material. This could be interpreted that again children with high SQ-value are more motivated to do science.

Limitations

In this study only the parents value their children with the questionnaire. Some of their answers could be socially desirable. Other characteristics than the EQ- and SQ-values were not collected with the questionnaire (e. g. socio-economical background, intelligence, previous knowledge) and there is no longitudinal data of the children. Additionally the influence of the small group the children participated during the learning environments could not be investigated.

In this study only selected aspects, like the focus, of motivation based on the duration of the children views could be observed.

Additionally the comparability of the groups in the sample 2015 and 2016 is not really given because of random composition of pre-school children.

DISCUSSION AND CONCLUSIONS

First conclusion that we found from the results was that children with high SQ-value seem to be motivated in both learning environments. So children with high SQ-value seem to be motivated to do science undependable from the learning environment. This result matched our first hypotheses that children with high SQ-value have to be motivated to do science in
structured learning environments. The results complemented it because these children always seem to be motivated to do science.

But the second hypotheses can neither be confirmed nor falsified because there is no hint that children with high EQ-value seem to be motivated to do science in the learning environments. Maybe these children like to focus the non-used material to add it to the learning environment.

So the significant correlations lead to the following hypotheses that need to be investigated further:

- Children with high SQ-values tend to be motivated to do science independent from the learning environment.
- The rather open learning environment motivates children with high EQ-values due to the possibility of choosing additional material.

In the further analysis the quantity and choice of the touched and labelled materials could be an interesting focus.

ACKNOWLEDGEMENT

The study is financially supported by the Klaus Tschira Foundation and the Forscherstation, the Klaus Tschira Competence Center for Early Years Science Education, which aims at arousing enthusiasm for natural sciences in children at a very young age by training kindergarten and primary school teachers. The Competence Center is an affiliation of the Klaus Tschira Foundation and is associated with the Heidelberg University of Education.

USING DIGITAL STORYTELLING IN BIOLOGY TEACHING

Maria Dokopoulou and Evangelia Pavlatou
National Technical University of Athens, Athens, Greece

Our study focuses on exploring the effectiveness of Digital Storytelling (DS) in teaching Biology in Secondary Education. Despite the growing popularity of digital storytelling technology, there are technological and pedagogical challenges about using DS for educational purposes such as the necessary time students need to spend on creating digital stories, training in using software and the connection with the curriculum. The effects of integrating DS on students' engagement and learning achievements have not been fully investigated in the area of Sciences and specifically in Biology. Thus our research aims to explore the impact of DS on students' learning in Science and subsequently to contribute to the discussion on how and why DS facilitates deep learning. The sample is consisted of 54 students that is divided in two groups. In both groups an educational process took place in thematic sections of Human Anatomy and Physiology during the school year. At the end of each thematic section students are assigned with individuals tasks; they develop either a digital story or a presentation about a specific health problem and explore possible causes and solutions. The first group (DS group) produced digital stories. The second group (PPT group) created digital presentations using Microsoft PowerPoint. Data collection began in November of 2015 and was completed in September of 2016. The research tools that are going to be used in are a) Questionnaires. b) Knowledge Tests c) Students' Digital Products and d) Students' interviews. The preliminary findings have shown that DS learning tasks have influenced students' engagement and promoted deep learning. In specific, the students of DS group make more enriched descriptions than the students of PPT group; they search for several alternatives ways of therapy. DS group also uses different studying strategies concerning the number of revisions and the time they spend on creating their products.

Keywords: digital storytelling, biology

THEORETICAL FRAMEWORK

Digital storytelling (DS) is a technology application that “takes the ancient art of oral storytelling and engages a palette of technical tools to weave personal tales using images, graphics, music and sound mixed together with the author’s own story voice” (Porter, 2005). In education DS grows in popularity in the last years. Educators use DS very often (Lowenthal, 2009) as digital stories creation facilitates the convergence of four student-centered learning strategies: engagement, reflection for deep learning, project based learning and the effective integration of technology into instruction (Barret, 2006).

Despite the growing popularity of using DS technology, there is a number of technological and pedagogical challenges about using DS for educational purposes (Hofer & Swan, 2006) such as the necessary time students need to spend on creating digital stories, training in using software and the connection with the curriculum (Ohler, 2005/2006). Furthermore, DS is most often associated with the arts and humanities (Sadik, 2008); Tsou et al (2006) found that integrating DS into the language curriculum can improve students’ level of learning in reading,
writing, speaking and listening. Although there is a special type of digital story which is used in content areas such as science that Robin (2008) calls “Stories that inform or instruct” there is a lack of research in this area. There are few relevant studies that suggested that DS can be used to teach computer science and programming or algorithms to a wider and more diverse audience (Papadimitriou, 2003 and Schiro, 2004). The effects of integrating DS on students’ engagement and learning achievements have not been fully investigated in the area of Sciences. Thus our research aims to understand the impact of DS on students’ learning in Science and especially in Biology and subsequently to contribute to the discussion on how and why DS facilitates deep learning.

Engagement and motivation are key factors in successful learning (Hung, 2012). The application of technology improves students learning motivation and performances in technology-rich classrooms (Jonassen, 2000). However instructors need to design meaningful activities for enhancing students’ interest and promoting active learning (Chang, 2005) in order to actively interpret and comprehend the knowledge (McLellan, 1993). Creating a digital story could be a meaningful activity for students as it provides them the chance to express their personal opinion on a subject or explore in their own way a physical phenomenon or procedure (Blocher, 2008). Taking into consideration these remarks in our study we developed and applied educational material that has two basic characteristics; first the use of several multimedia resources (e.g images, video) and second the connection of the educational content with everyday life problems.

Research Questions

This study aims to provide answers to the following questions:

1. Whether and how DS promotes students’ engagement in Biology learning tasks?
2. Whether and how DS promotes students’ understanding in basic Biology concepts?
3. Whether and how DS promotes students’ deep learning in Biology?

RESEARCH DESIGN

Data collection began in November of 2015 and completed in September 2016. The sample consisted of 54, 15 year old Greek students of Upper Secondary Education and is divided in two groups of 27 students each; Digital storytelling (DS) and Power Point (PPT) group. Both groups worked on the same thematic sections in Human Biology: Nervous, Sensory, Circulatory, Reproductive Systems, and Glands and Hormones. According to the Greek curriculum Biology is a two – hour weekly lesson. Thus our study covered 40 teaching hours during the school year 2015-2016. At the end of each thematic section students assigned with individuals tasks; they developed either a digital story (DS group) or a presentation (PPT group) on a specific health problem that addressed by exploring possible causes and solutions. For example students worked on the symptoms and causes of meningitis or Parkinson disease when they studied the Nervous System.

In our study we use both qualitative and quantitative research methods. In our study we use them in analyzing students’ interviews and digital products. Descriptive quantitative research
methods are used i) to establish associations between DS teaching and students’ performances and ii) to look for educational challenges concerning DS in the teaching – learning procedure.

Research tools

In order to investigate the impact of DS in the learning process we use the following research tools:

a) Questionnaires. At the end of each section students completed a self-assessment questionnaire that contained questions on the way they worked and the problems they faced during the development of either digital story or presentation. Students’ attitudes towards study and learning in each section were studied using the Revised Two Study Process Questionnaire (R-SPQ-2F) (Biggs et al, 2001).

b) Knowledge test. At the end of each section students completed an assessment test that contained both closed and open questions to check students’ reflection on the content. A late post test on September of 2016 assessed students’ capability to recall knowledge and to explain and synthesize basic Biology concepts.

c) Students’ Digital products. Both groups’ digital products are going to be analyzed in order to study: i) students’ knowledge (relevance to the task, specificity of answers, correct answers), ii) deep learning (students synthesize information to develop their own solutions, express novel ideas, pose new questions, express personal opinions) and iii) engagement (multimedia resources students use, searching of information, students’ references, combinations they make using resources)

d) Students interviews for the evaluation of digital storytelling impact in engagement. Interviews conducted at the end of school year both in person and in group discussions to investigate how students comment their learning process.

Preliminary Findings and Discussion

DS students created 72 digital stories and PPT students created 82 presentations (Table 1) during the school year. Students of DS group mostly use Microsoft Power Point software to create their digital products (Table 2) and they also spend more time creating their digital stories (3-4 hours) than students of PPT group (1-2 hours) (Table 3).

Table 1. Number of digital products per group

</thead>
<tbody>
<tr>
<td>82</td>
<td>72</td>
<td></td>
</tr>
</tbody>
</table>

Students prefer using Microsoft Power Point software to create a digital story to any other video producing software (e.g. Movie Maker, Photo Story). They usually answer during their interviews that they were familiar using this software or they felt more comfortable using it.

<th>3-4 hours</th>
</tr>
</thead>
<tbody>
<tr>
<td>PPT group</td>
<td>1-2 hours</td>
<td></td>
</tr>
</tbody>
</table>

DS group spent double the time to develop their digital stories. This is because they need to repeat an oral narration many times to synchronize it with the images, they search for the appropriate images, they often embed sound (e.g. music) and they usually need to study the whole section before start working on their project. PPT group students spent less time as they used given educational material (e.g. set texts) to answer questions.

As it concerns the content of the digital products students in the PPT group usually repeat the part of the story that is already given and they continue by answering all the questions making lists of bullets. In Figure 1 it is shown the Power Point Presentation of a student on the project in the Sensory System. The initial story that was already given was that during a music concert one of your friends suddenly crumbled. Students had to describe the anatomy (e.g. sense organs, receptor cells) and the function of the sensory system (e.g. describing how senses works) and answer on the possible reasons that caused their friend problem.

In this digital product the student repeats the subject of the story (slides ppt 1-ppt 2–ppt 3), names the five senses adding balance (ppt 4), matches the type of the receptor cells with each of the sense (ppt 5) and searching for possible causes connecting each of the sense with the circumstances (e.g. smoke, light, sound) of the concert (ppt 6- ppt 7). Finally this student propose safe measurements that are necessary in crowded places to avoid similar accidents (ppt 8 – ppt 9).

One of our concerns in these products is whether students on PPT group change the initial educational material or not. They usually copy – paste texts and images without editing them which is connected to surface learning approaches. These students also refer during their interviews that this way of study helped them in memorizing basic concepts.

Some of the most common characteristic of the ppt presentations are:

- Students use the pictures they already have on their text books or on the extra educational material that is given;
- They avoid editing images;
- They usually use school book text without making any changes;
- They answer all the questions one by one;
- They don’t make any further comments on the subject.
DS group on the other hand had to develop a new story based on the same initial idea and answer the same questions on the anatomy and physiology of human body. Figure 2 shows snapshots of one story about the same project in the Sensory System that is called “A page from my diary”.

The student added oral narration and music as background in the produced video and begins “telling” the story by giving information on the day of the concert (ds 1 - ds 3), the name of the friend that was invited to that concert (ds 4), and how she/he felt about it (ds 5 – ds 6). Ds 7 and ds 8 describe the place of the concert and ds 9 describe the accident. Ds 10 is used to connect the story with the Biology seeking for answers on the accident in the Human Sensory System. The student describes all the necessary senses (adding balance) connecting each sensor with the relevant type of receptor cell (ds 12 – ds 13 – ds 14 – ds 15 – ds 16- ds 17). Finally, the student makes some suggestions on the way somebody should react when in danger (ds 18 – ds 19) and finishes the video by also expressing personal feelings (ds 20).

One of our concerns in this type of digital products is that although students get engaged with major biological concepts -as the function of an organ system- they emphasize on information that seems to be irrelevant (e.g. how enthusiastic they feel because they would go to the music concert). They also spent time on searching on internet for images or videos and editing them. Searching for more information could be helpful especially for 15+ students as long as they are going to be used in meaningful activities. During their personal interviews students refer that their project was interesting and challenging but sometimes they had to study their text book to be prepared for their tests.
Some of the most common characteristics of the DS group digital products are:

- The students make enriched descriptions of the anatomy of human body and the way each system works;
- The students give emphasis to the symptoms of the diseases which they usually discuss in details and they search for alternatives ways of therapy;
- The students edit images to embed them to the software;
- The students edit school book texts to make connections with the given scenario;
- The students don’t answer all the questions they are asked;
- They use new images and information from the internet.

Concerning oral narration only 12 out of 27 students of DS group used it on their videos expressing difficulties in embedding recorded sound; repeating the same text many times to synchronize with the images and dislikes about the sound of their voice.

DS students’ on their self assessment questionnaires and interviews (Table 4) refer that developing digital stories makes the lesson “less boring” while working with real-world problems shows that Biology is a “useful” school subject. Students on the PPT group also refer that developing their presentations made them understand the connection with real world problems but they don’t make any comments if they find it more interesting or not. There arises one of our concerns about the way learning tasks influence students’ engagement.
Table. 4 DS group – quotes of personal interviews

<table>
<thead>
<tr>
<th>DS group interviews’ quotes</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>DS 10:</strong> “It was the first time I worked on a real life problem and it was difficult because I also had to make a story.”</td>
</tr>
<tr>
<td><strong>DS 22:</strong> “Making my project (digital story) helped me organize my study and revise.”</td>
</tr>
<tr>
<td><strong>DS 7:</strong> “I am very proud for my work in Biology and I will study my stories again just because I paid too much effort for making them.”</td>
</tr>
<tr>
<td><strong>DS 3:</strong> “I didn’t have the time to make all the digital stories you asked me.”</td>
</tr>
<tr>
<td><strong>DS 15:</strong> “It took me four hours to complete my digital story on nervous system but it worth it.”</td>
</tr>
<tr>
<td><strong>DS 6:</strong> “I had to say some of the boring school book details – that I didn’t like – but after that I had the chance to make it the way I like”.</td>
</tr>
<tr>
<td><strong>DS 2:</strong> “I would like to work only on the sections I like most.”</td>
</tr>
<tr>
<td><strong>DS 1:</strong> “It is the story that makes me looking for the causes of a disease.”</td>
</tr>
<tr>
<td><strong>DS 2:</strong> “I wouldn’t study anything in Biology if I didn’t like making the digital stories”, “At the beginning I thought that I knew all about the health problem I had to make the story but during my work I understood that I didn’t have all the necessary information and I had to search it further.”</td>
</tr>
</tbody>
</table>

Finally, some of the data from interviews show that students in DS group worked in a different way of the students in PPT group to complete their task. The main difference is that they studied the whole section before start working on their digital story while students of PPT group develop their presentations just by answering questions during their study meaning that they hadn’t studied the whole section before start working on it.

**CONCLUSION**

In this study Digital Storytelling was employed to develop learning activities on Human Anatomy and Physiology in order to explore students’ learning in that context. Preliminary findings indicate that Digital Storytelling could be a useful tool for engaging students in studying Biology and for understanding several difficult and abstract topics in Human Anatomy and Physiology but further analysis of students’ performances and perceptions must be conducted.

ASSESSING NATURE OF SCIENCE CONCEPTS IN INCLUSIVE CHEMISTRY CLASSES USING UNIVERSAL DESIGN FOR ASSESSMENT

Malte Walkowiak and Andreas Nehring
Leibniz Universität Hannover, Hannover, Germany

Science education should give all students the opportunity to become responsible citizens. For this purpose, scientific literacy and an understanding of the nature of science (NOS) play a key role. However, students often show multilateral, alternative, or naïve NOS concepts. A lot of research was done to promote NOS concepts. Quantitative studies show that students’ background variables are relevant to NOS. At the same time, the Universal Design for Assessment provides a framework for reducing the construct irrelevant variance in assessment. The present study examines the impact of applying the concept of Universal Design for Assessment (UDA) on a Likert tool for capturing the NOS concepts with regard to students’ background variables. While the original assessment was already used once in Germany, the other was newly adapted according UDA. The analyses show that UDA is able to reduce the influence of background variables. However, this cannot be applied to all NOS scales.

Keywords: nature of science, assessment methods

POLITICAL SITUATION

In 2009, the German government ratified the “Convention on Rights to Persons with Disabilities” (CRPD). Due to this ratification, inclusive instruction became crucial for the German educational system. This led to the establishment of inclusive schools in every Federal State. The Federal State Lower Saxony implemented inclusive instruction in the summer of 2013, posing new challenges for chemistry teachers. Correspondingly, there is little evidence about designing learning environments for German special-needs learners. Additionally, we have a lack of knowledge about designing and assessing learning processes in these inclusive environments.

SCIENTIFIC LITERACY AND THE CHALLENGE OF DIVERSITY

Scientific literacy is supposed to prepare all students for participating in social life (European Commission, 2015). At the same time, concepts about the NOS play a key role for developing scientific literacy. The “nature of science education is needed to prepare students for the kind of scientific literacy necessary for responsible citizenship” (Holbrook & Rannikmae, 2007, p. 1348). These concepts include “developing social values”, “being able to function within the world of work” and having a “conceptual background or skills of learning to learn” concerning relevant knowledge and public understanding about science and technology in a changing society (Holbrook & Rannikmae, 2007, p. 1353). With regard to students who have and who do not have disabilities and special needs, learning inclusively together fosters these concepts in an inclusive setting which is an important and challenging goal for chemistry education. However, approaches that focus on how to foster NOS concepts inclusively are rare to this day (McGinnis & Kahn, 2014).
Positioning between Special-Needs and Inclusive Education

At least in German in educational research and pedagogical discourse, the most commonly studied or discussed concept of “inclusion” is the joint teaching of students with and without special-needs or disabilities. This type of teaching refers to the term "special-need" and pursues the idea of instructional adaptations to specific audiences. It constitutes a narrow concept of inclusion, which aims at facilitating science education for people with disabilities and special-needs. This procedure becomes problematic if the instructional adaptation is interpreted only as lowering the level for individual pupils. This circumstance is critical and can dominate the perception of inclusion of many science teachers in such a way that it is rejected by many people. However, teachers' attitudes toward “inclusion” influence the design of instructional materials as well as lesson planning and student performance (Savage & Erten, 2015).

Although an understanding of "inclusion" as “special-needs education” may not seem wrong, prima facie, it is politically motivated and shows shortcomings with regard to empirical evidence about educational success (Ainscow, 2007; Göransson & Nilholm, 2014). As a result, an understanding of “inclusion” as an “inclusive education” makes sense. This step does not represent a radical change for science education. In the context of inclusion however, individual prerequisites for learning processes need to be discussed more strongly than before. Science education needs to think about multi-dimensionally individual prerequisites, taking into account individual dimensions of difference and inequality, as well as examine their interplay. According to a literature review, Nehring, Nowak, Upmeier, & Tiemann, (2015) identified prior or conceptual knowledge, intelligence, cognitive load, reading skills, interest and motivation, self-concept, language spoken at home and social background as relevant to learning success. This multidimensional perspective is achieved by including students’ background traits to determine their interdependence for learning success. At the same time, there is the question of which of the background traits were decisive for the learning success in the specific study. In addition, conceptual provisions of science education have a tendency towards "learning and teaching for all". A shortened science education for learners with special educational needs or disabilities is not intended because all learners should be able to communicate and reflect on scientific knowledge and information in order to be able to make decisions about it. Thus, the idea “teaching and learning for all” is given a more prominent place in the conceptual orientation of science education because it aims at the term "citizenship" (European Commission, 2015). Ultimately, this corresponds in a deeper sense to the CRPD and the Human Right to Education (Abels, 2015).

Universally designed assessments

From a research perspective, an assessment for investigating the impact of inclusive teaching, should also be made as barrier-free as possible as it is important to think about assessing students’ outcomes to meet requirements of inclusive environments. Many factors may influence the validity of inference made from test scores. In the context of inclusion however, it is particularly important to think about test accessibility. Thus, the question remains open: What influence do modes of assessment representation have on the data collection and on the influence of students’ background variables on test scores in the context on NOS?
Test accessibility is “defined as the extent to which a test and its constituent item set permit the test-taker to demonstrate his or her knowledge of the target construct” (Beddow, 2011, p. 381). Access is defined as “the interaction between construct irrelevant item features and persons characteristics that either permits or inhibits students response to the target measurement content of the item” (Winter, Kopriva, Chen, & Emick, 2006, p. 268). The smaller the construct irrelevant variance, the higher the test accessibility. The test value can only be meaningfully interpreted, when the test-taker interacts exclusively with the target construct (Figure 1).

Figure 1. Test accessibility in a test event (Beddow, 2011).

In order to deal with this problem of construct irrelevant variance, Thompson, Johnstone, & Thurlow (2002) applied Universal Design on large scale assessments. The objective of universally designed assessments is to assess each child test score without being affected for example by language, disability, gender or ethnicity. “Universally designed assessments are not intended to eliminate individualization, but they may reduce the need for accommodations and various alternative assessments by eliminating access barriers associated with the tests themselves” (Thompson et al., 2002, p. 5). The design guidelines of UDA aim to ensure the highest possible test accessibility (Beddow, 2011).

STUDY

The UDA principles were applied on a Likert-based NOS-questionnaire in the context of an experimental study. This research was about fostering NOS-concepts in the context of inclusive teaching using an iPad-based learning environment (Walkowiak & Nehring, 2017a, 2017b). In order to meet the multi-dimensionally of individual prerequisites, multiple background variables were selected in the context of this study. These variables were shown to have an impact on test performance. They include, above all, gender but also readability and motivation in the natural sciences. As a basic cognitive variable, intelligence was assessed. And with regard to diversity, the socio-economic status and the migration background were added. If a student had a special-need status, this was also recorded. The aim of the study was to review
the theoretical framework of UDA in the field of NOS. The various background variables serve this purpose. With regard to the idea of test accessibility, typical background variables should not, or only slightly, predict the performance of the UDA-based assessment.

In order to collect data about the NOS concepts, we have resorted to published tools to focus on the test adaptation, not the test design itself. Recently, Kampa, Neumann, Heitmann, & Kremer (2016) used this in a large-scale assessment across Germany. This test instrument includes the classic nature of science conceptions with the four scales of “certainty”, “development”, “source” and “justification” of scientific knowledge. “Certainty” of scientific knowledge includes concepts for the tentative nature of knowledge. “Justification” of knowledge addresses the role of empirical evidence as well as the theoretical obsolescence of scientific knowledge. The scale "development of knowledge" describes the process of knowledge production, while "source" concepts encompass who can contribute to knowledge production. While the "justification" and "development" items are exceptionally positively pooled, the reverse applies to the negatively poled "certainty" and "source" scales.

To apply UDA, we simplified the language (“Easy German”) of the original test instrument. In a second step, the adaption was evaluated in various rounds by experts in German, special-needs and science education. On the one hand, the goal of the translation was to carry out a simplification according to the Inclusion Europe Pathways rules (Inclusion Europe, 2016). On the other hand, the core of the item should be preserved so that the original and UDA-based assessments are comparable. For better comparability between the assessment versions, the polarity of the items was retained, although evidence suggests that negatively poled items may be detrimental (Salas-Wright, Olate, & Vaughn, 2013). According to Carifio & Perla, (2007) and Rhemtulla, Brosseau-Liard, & Savalei (2012), the items were provided with five possible answers (1 = strongly disagree; 5 = completely agree). The assessment was carried out on iPads. This allowed students to arbitrarily magnify pictures on the screen. Moreover, students were able to use the read-aloud function of the devices. We limited the number of items per page and added a page organization showing how many of the test had already been completed. The response format was a star rating based on the assumption that this is known to the students from the internet. In comparison, the original assessment was also completed on iPads. However, the standard Likert design was used without an adaptation.

**Research questions**

An essential goal of the project is to examine the interplay of the questionnaire with the background variables. The following research questions have guided the project: 1) What internal consistency do UDA-based NOS-scales have compared to the original NOS-scales? 2) Is there any influence of the students’ background variables on the response behaviour in the two NOS questionnaire versions (original and UDA-based)?

**Methods**

To answer the research questions, 322 students from regular schools (age mean = 12,2 (0,78), ♂ = 154, ♀= 150, NA = 18) took part in the study. Every student was randomly assigned to one of the test versions. The study took place in pre-post design. 13 pupils had special-needs.
All statistical calculations were done in R (R Core Team, 2017). To address the research question 2, all outliers from the reading ability, the intelligence, and the socioeconomic status were removed. Missing values were determined by multiple imputation under the missing at random assumption (MAR).

Results

To answer research question one, which aims at the reliability of both questionnaires, the internal consistencies of each NOS scale and the entire questionnaire are determined (Tab. 1). Instead of Cronbach's α, McDonald’s ω does not assume tau equivalency or uncorrelated error variances are needed. However, item homogeneity is needed and this applies to the data. Table 2 the McDonald’s ω with 95%-confidence intervals (CI).

Table 2 Internal consistencies (McDonald's ω) with CIs

<tr>
<td>Development 0.83[0.76-0.89]</td>
<td>0.87[0.82-0.91]</td>
</tr>
</tbody>
</table>

Note: Negatively poled items are marked with (-).

With regard to the scales certainty and development the values are in an acceptable range. Two outliers can be observed per assessment. While the source scale shows good values in the original assessment, the UDA assessment is lower here. However, the CI are overlapping. Accordingly, the values are not significantly different. The same applies to the justification scale in the original assessment. But the CI does not overlap here. Thus, this scale shows
significantly higher internal consistencies. The overall analyses however, show comparable reliabilities between original and UDA-based assessment.

With regard to research question two, Figure 2 shows, in a first step, the distribution per NOS scale with respect to the test version (original assessment and UDA-based assessment). It reveals that the medians in the original assessment according to the scales *development* and *justification* are each slightly higher, interquartile ranges are broader (development: 3.73[3.40-4.11] and 3.44[2.95-4.07]; justification: 3.83[3.54-4.10] and 3.67[3.16-4.11]). What is striking about Figure 2 is that even after changing the negative poled items, the medians of the NOS dimensions’ certainty and source are much lower than in the NOS dimension justification and development. In addition, the whiskers of the boxplots continue to expand, which speaks a broader and thus more variable response behaviour of the students in the UDA version (source: 2.27 [1.82-2.76] and 2.54 [2.10-2.90]; certainty: 2.48 [2.03-2.86] and 2.88 [2.32-3.33]).

**Figure 2. Boxplots for each NOS dimension and test version**

Overall, it seems that the participants in the study also have rather adequate ideas about the *justification* and the *development* of scientific knowledge. With reference to the preliminary nature of scientific knowledge, there is also more agreement to the idea of knowledge being changed or being constructed by the scientist. According to *source* of scientific knowledge, students are more likely to agree that scientists, and not the students themselves, are the starting point for knowledge of the natural sciences. Next, multiple regressions and analyses of covariance’s (ANCOVA) were calculated. In each case, the mean of the four NOS scales was set as independent variables and predicted by reading ability, socioeconomic background, intelligence, motivation and the migration background, gender and special-need. With reference to the NOS scale "development" (Tab. 3.a) it can be seen that mean values are
significantly related to the reading ability and to the migration background. The mean values in the original assessment are additionally predicted by the motivation. For better comparability between the regressions, the CI of the unstandardized regression coefficients are given.

Almost the same pattern can be observed for the NOS scale “source” (Table 3.c): There are no significant predictors. Remarkable here is that the unexplained variance (residuals) is almost identical for both scales. Therefore, it can be said that the NOS scale source in both versions is almost identical on a statistical level.

The biggest differences are revealed in the NOS scale *certainty* (Table 3.d). While no significant predictors can be found in the UDA-based version, the reading ability significantly and with a high effect size predicts the performance on the scale. Notable is the difference between the values of the residuals.

Discussion, limitations and future directions

The analyses show that both motivation and the reading ability are significant predictors for the assessment of NOS-concepts. However, no systematic pattern can be observed across all scales. Thus, it is only possible to analyse each scale individually with regard to how different influences are justified. The background variables have little influence on the source’s scores. Here, each item has an average of 6.4 words in both assessment versions. At this length, the item poling seems to have no influence anymore. The situation is different with scale certainty. Again, the items are negatively poled. However, they are much longer (original assessment: 12 words, UDA assessment: 10.3 words). But the reasons for the results may not be exclusively in the polarity of the items or item length. On average, the development scale has 10.6 or 9.3 words in the original UDA-based questionnaire. But while the models assign readability and motivation to have significant and average effects, this does not apply to the justification scale (original assessment: 12.9 words, UDA assessment: 10.8 words). Overall, it can be stated that the models explain little of the observed variance, which is shown on the one hand by the theoretical values for $R^2$ and the high values for the residual term (Tab. 4). Each model for the original rating has the higher $R^2$ values. The NOS scales of development and certainty are particularly noticeable here. Here, clearer differences in the evaluation of each version can be observed than in source and justification scale.

The analyses for the internal consistencies show values range from good to acceptable, if the CI are included. It is therefore clear that the low variance explanation is cannot only be based on the reliabilities of the NOS scales. After that, the question arises of an explanation for the observed variance. The measurement error certainly does not represent mere data noise, because then internal consistencies would have to be worse (Table 4). Yet, two conclusions can be drawn. On the one hand, it can be assumed that relevant predictors and group distinctions are missing in the models. As a result, the $R^2$ decreases from a pure statistical point of view. On the other hand, it can be assumed that the scales already have a comparatively high accessibility. First, this is due to the fact that they are Likert scales, which per se make less demands on the individual characteristics of the learners. Second, concepts are captured. There is no real performance test in the true sense. In addition, there are no convincing arguments that suggest that a test participant who can read better, rather rejects or approves statements of the questionnaire in the desired manner. Rather, such test participants would locate their own NOS-concept more clearly on the NOS-scale. Third, the NOS dimensions may be considered as distinct. Following this idea, one could also assume that there are dimensions that are more sophisticated in their concepts (“development”) than others (“justification”). As a result, background variables have different effects. Here think-aloud studies would provide more information.

In order to make the items of the UDA-based version as equivalent as possible to the original, not all rules of the Easy German were implemented. This had the advantage that the sentence structure was largely as well as the items’ content could be preserved. In German, however, this results in unfamiliar speech rhythms that can disturb the flow of reading. So, the question arises of detailed item examinations. In addition to the sentence length, the number of sub-
clauses, passive constructions or indirect speech and much more can also influence intelligibility. And again, think-aloud studies would add more detailed information.

ACKNOWLEDGEMENT

We would like to thank all students, all teachers and all parents who have made their contribution with their confidence in this study. We also would like to thank the doctoral college "Educational Research" ("Promotionskolleg Didaktische Forschung") of the Leibniz University Hannover.

HOW TO ENHANCE THE STRIVING FOR KNOWLEDGE AND SELF-RELIANCE OF HIGHLY ABLED AND GIFTED PRIMARY SCHOOL CHILDREN IN A SCIENTIFIC OUT-OF-SCHOOL LEARNING-CONTEXT?

Marcus Bohn and Manuela Welzel-Breuer
University of Education, Heidelberg, Germany

Motivation is one of the factors with the most impact on the evolving of giftedness. Knowing that, we want to know, what makes a child, already motivated within a scientific learning-context, keeping its motivation, when it comes to an interaction. To find answers to that, we focused in a video-study on interaction processes within scientific courses for highly abled and gifted primary school children, to see which modes of behavior of the teaching persons or of the other children keeps the motivation on. Analyzing the data in a deductive as well as an inductive qualitative approach, we found, that some modes of behavior can be identified, that enhances the motivation of a gifted child obviously in an ongoing striving for knowledge and self-reliance.

Keywords: giftedness, primary-school, video-analyses

AIM OF THE STUDY

The aim of this research-project is to figure out factors of a learning-context that enhance the striving for knowledge and self-reliance of highly abled and gifted primary school children in out-of-school science courses.

To get a look into those courses, the presented research study is allocated to a co-operation-project between the University of Education Heidelberg and the Kinderakademie Mannheim - an academy for highly abled and gifted primary school children. All children participating in the academy are tested and identified as highly abled or gifted, what means they achieved an IQ of 130 or higher in an official intelligence test. The academy’s aim is to support these special children in different ways out of school by satisfying their special needs. To do so, the Kinderakademie offers a manifold programme of gratis courses within different disciplines. The duration of these thematic courses expands from October to May. The children can choose a specific course for participation – matching their interests. The results of this research-study will be connected to an evaluation of the courses addressing some criteria of the individual needs of the children (striving for knowledge and self-reliance).

THEORETICAL FRAMEWORK

We identify striving for knowledge and self-reliance as the “Erkenntnis- und Selbstständigkeitsstreben” described by Lehwald. In his opinion the quest for knowledge (Erkenntnisstreben) as the motivational aspect of the striving for cognitive self-reliance (kognitives Selbstständigkeitsstreben) is a remarkable aspect of highly abled and gifted children (see Lehwald, 1981, 1985, 2009, 2010, 2017). In his work these aspects are not only an important factor for the identification of abled children but also for the preparation of
learning-contexts to enhance the giftedness (ibid). Lehwald defines the “Erkenntnisstreben” as a type of habitual motivation (Lehwald, 1985, p. 38) and insofar as a personality trait, that shows a remarkable behaviour in the transaction with other variables within the situation (see ibid, p. 19), understood as a mutual influence (ibid, S. 19). In that way, the striving for knowledge becomes the basic motivation for learning as well as a personality trait (see ibid).

One can find the situated motivation in almost all psychological dynamic models of giftedness. Gagné calls it “intrapersonal catalyst” (see Feger & Prado, 1998, p. 39), Mönks defines it as a “factor” (vgl. Mönks & Ypenburg, 2000, p. 23) and in the model of Heller the situated motivation is introduced as a non-cognitive personality trait, a so-called moderator (see Heller, 2001, p. 24).

Lehwald argues that the quest for knowledge and so for cognitive self-reliance as a personality trait can be seen in the following behaviours:

- preferring self-reliant and cognitive work,
- affective and emotional working on problems,
- tendency not to give up and overcome difficulties,
- a never ending interest in information,
- interest in complicated work that needs flexible thinking (see Lehwald, 2009, p.11, 2017).

Those aspects also can be found in variations in the works of Deci and Ryan about the intrinsic and extrinsic motivation especially within learning-situations (see Deci & Ryan 2000). Lehwald itself talks about the quest for knowledge and so the striving for cognitive self-reliance as intrinsic motivated actions (see Lehwald 2009, 2017).

In a further step, we understand that a personality trait divides itself in different aspects of the person and so into “elements of being” (see Trautmann 2008). If these elements fit together with an extraordinary predisposition (giftedness as a cognitive disposition), an effect taking environment and the evolving self in a positive combination and surrounding (family, school, peer group, media), the internal giftedness can be an external one and can be lived by the child. This model of giftedness, the so called “Mikadomodell“ (Trautmann, 2008) is not only a dynamic but also a pedagogical and interventional one, focusing the individual aspects of giftedness, and because of this, it is our preferred model for the research project. Our study focuses on the situational possibilities to enhance the striving for knowledge and self-reliance in the science courses of the Kinderakademie by the learning-context. Furthermore, this model includes the basic thinking of interaction between the child and its situated context, which is also fundamental for Lehwald’s work, defining behaviour as a result of a transaction between the child’s personality traits and the situated variables (see Lehwald, 1985, p. 19).

---

1 In 2007 Lehwald’s questionnaire „Fragebogen Erkenntnisstreben“ had become a part of the testing within the „Münchner Hochbegabungstestbatterie für die Sekundarstufe“ (see Lehwald, 2017, S. 123).
RESEARCH QUESTIONS

According to the outlined theory above, we are investigating interaction-processes between the gifted children and their learning-contexts while acting in the science courses in order to find factors that enhance the striving for knowledge and self-reliance. In this context, the enhancing shall not be understood as a remarkable development within the course-time but as the opportunity and the freedom for the children to develop their giftedness. The learning-context we define as the sample of the learning-material offered to the children, the room with its opportunities and the interactions with the course-instructor. So we are looking for interaction-processes with the following three-step approach:

1. Behaviour of the child that shows a striving for knowledge and self-reliance,
2. Reaction of the teaching person/other children to that behaviour,
3. Reaction of the child to the reaction of the teaching person/other children.

By finding, analysing and interpreting those three-step-interactions, we want to give answers to our research question: What are the factors of a learning-context that enhance the striving of highly abled and gifted children for knowledge and self-reliance?

To answer this question we have to go three steps:

First, we locate sequences, in which we can see behaviour/actions of highly abled children representing their striving for knowledge and self-reliance.

Secondly, we describe, what kind of reactions the teaching person and/or the other children show to that striving of the children.

Thirdly, we decide, whether or not the children hold on the striving or end up with it as a reaction of the reaction of the teaching person/the other children before.

RESEARCH DESIGN AND METHODS

According to the steps described above, we started a qualitative analysis of interactions based on video data, a so called video-based field study, which is the most established way to get video based data within the social sciences (see Jewitt, 2010, S.4). Using Saldanas “streamlined codes-to-theory model for qualitative inquiry” (2016) we were able to figure out the reactions of the striving child and summarize them in categories, but we would not be able to line out, what kind of behaviour as a reaction by the teaching person/other children to the child´s striving was reasonable for that. So we copied and mirrored the scheme as shown below (Figure 1).

With this scheme it is now possible to use the theory of Lehwald as mentioned above, searching for the situations of striving and connecting them with the reaction of the teaching person/other children as well as with the reaction of the striving child. Only then it is possible, to get a comparable and analysable overview from the first to the last step, which enables us to decide whether or not the reaction of the teaching person/other children was enhancing. Transferring this scheme to the special conditions of our study, we finally got the following design (Figure 2).
We took video recordings of different science courses and analysed them in two steps: At first, within the macro analyses, we searched the video data for the striving behaviour of the children applying the CBAV method (see Niedderer et. al., 1998). To do so, we transformed the behaviours described by Lehwald (e.g. the Items of the FES-questionnaire, Lehwald 1985) into codes and identified operators and examples for them; so we ended up with a manual for this first step of analysis by a category based event-sampling (see Fischer & Neumann, 2012). That means, that we searched the data for situations, where a striving was obvious and coded that sequence with the appearing code. We tested our analysing tool on two videos, made in forehand of the study. To get reliable results we did this step with two more decoders.

Because some of the codes were very low-inferent, (see Fischer & Neumann, 2012) we did an argumentative validation (see Terhart, 1981). That means, that every single code was discussed by all three coders and only those codes were selected for further analysis, that were accepted
by all coders. Those argumentative discussions led to reformulations and changes to some of the codes. At the end of this pre-test phase, we ended up with two categories (see Lehwald, 2016) and 40 different codes. Using that new catalogue of codes, the three coders analysed the twelve videos, videographed in scientific courses for gifted children. Every coder watched and coded four of the videos separately. After that, all coder met and validated the found sequences in the already mentioned argumentative discussions. In those discussions the coder presented the sequence and the coding with the data, so that the two other coders were able to see the situation and to decide if they can apply to the coding or not. The code “exchange of knowledge” was treated not completely in that way, because of it’s overwhelming number of appearance. We decided not to validate every single coding in an argumentative way. Firstly we did so, because of the high number of codings, that would have brought us to an exhausting amount of time. Secondly, this code was within the testing phase one, that showed nearly no differences in the understanding and finding by all coders. So we decided to do only some picking ups during the analyses of the following videos to see, if that understanding and identifying kept on.

Having identified the situations of striving, we went to the second step, the micro analyses and analysed these filtered data in a much more detailed way: Understanding interactions in the way of Jordan and Henderson (1995), we adapted the video-interaction analysis as explained by Knoblauch (2009). We want to figure out, what obvious behaviour of the teaching person/other children is reasonable for an ongoing or ending of a striving. So we used the sequence analysing method of the video-interaction analysis, in which three-step-interactions (as described above) are separated into single sequence elements (see Dinkelaker & Herrle, 2009) to find the following up sequence elements to the striving, meaning the reaction of the teaching person/the other children and the reaction of the striving child. To find those sequence elements, we looked for turn-taking-situations, like they are described by Sacks, Schegloff & Jefferson (1974), to find those interactions, that were build up by a three-step and to separate the three steps, to get the single sequence elements for the further analyses.

After the finding and selection of the three-step-interactions, all of their three sequence elements were paraphrased and coded by a descriptive coding (see Saldana, 2016), to get a more comparable and analysable frame of what is going on within the interactions.

Now, having complete and detailed lines of three-step-interactions, we looked for the last step, the reaction of the striving child. For each sequence detected, we decided whether the behaviour shows an ongoing striving, or a giving up of the striving. If there was a giving up, we differentiated it into a giving up of striving but a hold on to the working process and a total giving up without participating anymore in any way. Having this selection in mind and looking back now to the second step of the interaction, the reaction of the teaching person/other children, we are able to label such behaviour as an enhancing one, when it led to an ongoing striving or to an ending one, when it led to giving up the striving.
RESULTS AND FINDINGS

The rigorous video data analyses show abundant results throughout the above described three-step procedure. On the one hand, modes of behaviour which indicate a striving for knowledge or for cognitive self-reliance of children can be identified. Those modes of behaviour can serve as markers for pedagogical decisions in situ. On the other hand, typical interaction patterns after those striving modes result in also typical re-actions of the children observed. From this, it is possible to determine fruitful and not fruitful interactions with respect to the support of striving activities of children.

In the following paragraphs we will summarize these results:

According to step 1. Identification of behaviour of the child that shows a striving for knowledge and self-reliance.

We are able to figure out modes of behaviour of primary school children, that fit to the items of Lehwald and embody their quest for knowledge and so the striving for cognitive self-reliance in scientific learning-contexts. Those are for example:

- **Variation of a given experiment** (The children want to do different investigations with the given material. They want to proceed with their own investigations in contrast to the experiment suggested by the instructor.)

- **Focusing the work** (The children keep on working, even if the other children make noise around them. The children keep on working to finish it, even if the teaching person already changed it.)

- **Matching with others** (The children scream out the answer also it is not permitted. The children go into contests, to see who knows more or can do something better.)

According to step 2. Reactions of the teaching person/other children to that behaviour.

Looking at the reactions of the teaching persons/other children, we can also list modes of behaviour that follow the striving of a child, as the second step of the interaction. Those are for instance:

- The instructor is giving the opportunity to follow own ideas (The teaching person allows the children to do some researches on their own. The teaching person handed more material to the children, when they ask for it. The other children follow the ideas of a striving child, not insisting on the given work.)

- Allowing to do work in parallel (The teaching person allows the children to finish their experiment, while he or she steps on.)

- Stopping the work (The teaching person insists in the given group work and stops the children’s activities. The teaching person tells the children how to work and doesn’t accept their individual ways.)

According to step 3. Reaction of the child to the reaction of the teaching person/other children.

Also for the third step of the interactions we found modes of behaviour remarkable for the reaction of the striving child, such as:
- Finishing work and resume to the group (The children, ended up with their own experiments and take part in the already started group discussion.)

- Working in parallel (The children keep on working on their not yet finished experiment, while answering questions in parallel, which are asked by the teaching person to some different content.)

- Keep on with arguments (The children insist in their arguments, when the teaching person does not give a satisfying answer or does not go into the discussion.)

According to the aim of this research-project, to figure out factors of a learning-context that enhance the striving for knowledge and self-reliance of highly abled and gifted primary school children in out-of-school science courses.

By analysing the three-step-interactions we looked for patterns to be able to figure out specific factors. Within our data set we found a variety of influences to the striving of the children caused by the reactions of the teaching persons/other children. In the following, we want to present two examples: one enhancing as well as one stopping the reactions. These are typical ones which we could identify several times:

Enhancing: The striving child wants to do some own research with the given material.

↓

The teaching person gives the child the opportunity to do its own research and pushes it forward by handing over more and new material.

↓

The child keeps on working on his own research, until his/her questions are answered to a personal grade of satisfaction.

Stopping: The child wants to find out the name of a plant and starts looking into a book about flowers.

↓

The teaching person stops the child to hold it back till the whole group has talked about, how to use the book.

↓

The child stops his/her working process immediately and does not take part in the following group situation.

Looking at the two examples above, it becomes obvious, that one of the main factors for an enhancing of the striving for knowledge and self-reliance focusing primary school children in an out-of-school scientific learning context, seems to be the opportunity for the children to work autonomously on their ideas. Corresponding with other results of our study, that autonomy seems to be necessary not only in the freedom to work on ideas but also in the time, given for that work and the possibility to talk about the working process and the results of them.
The conclusion of our findings is at the moment, to give as much space and time as possible to those gifted children in those learning-contexts to investigate their own questions to the world and to talk about that, in a trustworthy and helpful atmosphere, that encourages their striving.

DISCUSSION

The findings, mentioned above, according to the reaction of the teaching person/other children enhancing or stopping the striving of a gifted children are only the most obvious ones. We found also indicators about enhancing reactions towards “asking questions”, “asking for help” and some more. Some of the other factors do not present such clear relationship between the behaviour of the teaching person/other children and the following behaviour of the striving child. Those have to be described very carefully and within its situated contexts. But we are able to line out, that “the instructor is giving the opportunity to follow own ideas” is an enhancing behaviour as a reaction to a striving, while” stopping the work” is definitely a stopping one, within the conditions of our study. More details are results of a doctoral thesis by Marcus Bohn, which will be published presently.

IMPLEMENTING ASPECTS OF INQUIRY-BASED LEARNING IN SECONDARY CHEMISTRY CLASSES: A CASE STUDY

Elisabeth Hofer and Anja Lembens
Austrian Educational Competence Centre for Chemistry, University of Vienna, Austria

Although inquiry-based learning (IBL) has been a component of the Austrian curricula for chemistry for several years, it is implemented only rarely in schools. Even after attending a workshop-series regarding IBL teachers stated to not feel confident to implement IBL in their own classes. The professional development programme presented in this article aims to support teachers in gaining both experience and expertise in planning, applying and reflecting IBL in the framework of a Lesson Study. In collaboration with three chemistry teachers, a case study was conducted to identify useful structural elements as well as scaffolding strategies when implementing IBL in secondary chemistry classes. In addition, it is investigated in how far the professional development programme influences the teachers’ concept of IBL, their professional knowledge and skills, as well as their attitude towards IBL. In this article, the IBL units as well as the Lesson Study process are described in detail. The participating chemistry classes are characterised briefly and methods of data collection and data analysis are presented. Moreover, insights into first results are provided.

Keywords: inquiry-based learning, teacher professional development, chemistry education

INTRODUCTION

In the last decades, the focus of science education has moved away from learning and reproducing content knowledge towards acquiring and applying skills to adequately deal with knowledge. The National Science Education Standards (NSES) (National Research Council, 1996) intended more emphasis on “student understanding” and the “use of scientific knowledge, ideas, and inquiry processes” (p. 52). This idea was further developed in the Next Generation Science Standards (NGSS), where expectations for students’ performance are listed in three areas: ‘Science and Engineering Practices’, ‘Disciplinary Core Ideas’ and ‘Crosscutting Concepts’ (NGSS Lead States, 2013). In Austria, an orientation towards skills (‘competencies’) has been statutory since 2008: curricula have changed and standards, as well as competency models have been developed. However, the progress made so far is unsatisfactory which is demonstrated by the PISA 2015 data. There was no other participating country in which the gap between declarative and procedural/epistemic knowledge was as large as in Austria. These results are in line with students’ statements concerning the activities in science lessons. In Austria, science lessons are mainly teacher-led – the main activity of the students is to receive and reproduce content. Students rarely seem to be involved in investigative tasks (Suchań & Breit, 2016).

Inquiry-based learning (IBL) is seen as an appropriate approach to include such investigative tasks in science lessons. Moreover, learning content knowledge can be combined with the acquisition of skills, leading to students developing the competence of problem solving (Abrams, Southerland & Evans, 2008; Hmelo-Silver, Duncan & Chinn, 2007). However, to
implement IBL beneficially in science lessons, it requires experience as well as expertise. In this article, we present a case study designed for this purpose: teachers collaborate with researchers in the framework of a professional development programme (PDP) to investigate the implementation of IBL in Austrian secondary chemistry classes.

THEORETICAL BACKGROUND

IBL is a teaching approach which is characterised by students’ activities within the scope of planning, conducting and analysing investigations. By dealing with scientifically oriented questions, students “develop knowledge and understanding of scientific ideas as well as an understanding of how scientists study the natural world” (NRC, 2000, p. 23). Depending on its form, the level of openness (e.g. Blanchard et al., 2010; Colburn, 2000) and the role of the teacher, IBL achieves different effects and pursues three different aims: “learning about inquiry”, “learning to inquire” and “constructing learner’s scientific knowledge” (Abrams et al., 2008). Well prepared and suitably applied, IBL induces positive effects on students’ content learning, procedural skills and attitude towards science (e.g. Blanchard et al., 2010; Fang et al., 2016; Furtak, Seidel, Iversion & Briggs, 2012; Jiang & Mc Comas, 2015; Minner et al., 2010). Moreover, IBL is regarded as an indispensable component of science education which aims to educate scientifically literate people (Barron & Darling-Hammond, 2010; Roberts & Bybee, 2014).

Within the Austrian curriculum for chemistry in upper secondary schools, IBL is included in the form of inquiry activities, which are explicitly mentioned in the action-related dimension of the incorporated competency model (BMB, 2016). Nevertheless, IBL is implemented only rarely in Austrian schools too (BIFIE, 2016; Crawford, 2014; Wallace & Kang, 2004). According to international studies, prominent reasons are inadequate knowledge and abilities both on the students’ and the teachers’ side, a lack of material and organisational resources as well as the teachers’ beliefs and values regarding teaching and learning in general (Anderson, 2002; DiBiase & McDonald, 2015; Wallace & Kang, 2004). Even after attending a workshop-series regarding IBL, Austrian teachers stated to not feel confident to implement IBL in their own teaching. Based their own statements, it seems that they would have needed a longer-term mentoring with activities better tailored to their particular needs. Moreover, it was shown that the teachers’ concept of IBL was lacking in structure and theoretical foundation, as well as in connection to the curriculum (Hofer, Abels & Lembens, 2016). Hence, it would be prudent and necessary to design long-term PDPs which include theoretical, as well as practical parts, provide opportunities to implement IBL under “real” conditions and support teachers considering their specific needs in addition to the curricular regulations.

One approach to combine the above mentioned aspects with essential features of effective PDP is the model of Lesson Study (LS). In LSs, teachers form teams (professional learning communities) in order to work on specific aspects of classroom practice with the aim to improve teaching practice. In a cyclic process, teachers collaboratively plan, apply, reflect and revise particular lessons in their own classes to systematically investigate strategies of implementation (e.g. Cerbin, 2011; Stepanek, Appel, Leong, Mangan, & Mitchell, 2007). Stepanek et al. (2007) characterise the core elements of LSs at different levels: the ‘Process’ of LS, the ‘Big Ideas’ of LS and the ‘Habits of Mind’ when applying LS (see Figure 1). For the
latter, they name three components which support teachers in gaining professional growth: taking up a research stance, being willing to learn together and being convinced that their actions matter (see inner circle of Figure 1). The aforementioned ‘Big Ideas’ – Instruction, Students, Goals and Content (see centre circle of Figure 1) – are key elements of teaching and learning which are explored by the teachers in the course of a LS. During the whole process of LS (see outer circle of Figure 1), teachers focus on the students and their learning. First of all, they assess the status quo of their students’ knowledge and skills and define appropriate aims (‘Setting Goals’). Based on this, the teachers work on the topic (content) of the lesson (elaborating key concepts and connections to other concepts) and consider the students’ perceptions and prior knowledge. Finally, they develop instructional approaches, discuss expected reactions and develop possibilities to deal with challenges which might arise (‘Planning the Lesson’). Because of substantial adaptions, the further steps of LS are not discussed at this point, but are described with regard to the present study later in this article.

As pictured in Figure 1, LS is a multi-faceted approach in which teachers adopt a researchers’ role. Undergoing this iterative cycle in a professional learning community is regarded as highly effective. Several studies show positive effects on teachers’ professional growth as well as on students’ learning. LS is suitable for implementing reform curricula as well as to link theory and practice in teacher professional development (cf. Cheung & Wong, 2014; Huang & Shimizu, 2016).

**PURPOSE AND AIMS OF THE STUDY**

The present study aims to foster the implementation of IBL in secondary chemistry education. For this purpose, a PDP was designed to support teachers in planning, applying and reflecting on IBL units to finally gain the ability to implement IBL autonomously. In the framework of
the PDP, we aim to acquire knowledge about useful structural elements and scaffolding strategies. Emerging challenges are identified and characterised in order to develop appropriate strategies to deal with them. Additionally, we want to evaluate the designed PDP regarding the (further) development of the participating teachers’ professional knowledge, skills and their attitudes towards IBL. Lastly, the findings from the study are used to deduce implications for designing gainful programmes for teacher pre- and in-service education.

The study is guided by the following main research questions:

1. How can teachers implement aspects of IBL in their own secondary chemistry classes? What are useful structural elements and scaffolding strategies? What are challenges teachers are confronted with and how can they deal with them?

2. How far does the PDP influence the teachers’ concept of IBL, their professional knowledge and skills – especially regarding IBL – as well as their attitude towards IBL?

DESIGN AND METHOD

To answer the aforementioned research questions, we carried out a case study following Yin (2009) with three chemistry teachers at secondary schools in Vienna. The selection of the cases was guided by the idea to gain insight into classes as diverse as possible. The teachers of all three classes were female, had about five years teaching experience in schools and participated in a PDP regarding IBL in the year preceding this study (see Hofer, Abels & Lembens, 2016). All three teachers had experience in both research in the natural sciences and laboratory work, but only Teacher C (teacher of Class C) completed her studies in teacher education. Teacher A obtained her diploma degree in pharmacy and Teacher B finished her diploma degree in chemistry. During the period of the study, the selected classes were in grade 11 (beginning of the study) and grade 12 (end of the study). In the following, the three classes are described briefly.

Class A is part of a secondary school which is known for students with a high socioeconomic status. Schooling extends from grade 5 to grade 12 and focus on language learning (students successively learn three foreign languages, beginning with grade 5). On average, there are 19 students (50% of them are female) in Class A.

Class B is part of a secondary school which extends from grade 9 to grade 12 and is known for students with a low socioeconomic status and first languages other than German. In this class, the focus is on scientific laboratory work, i.e. students participate in biology, chemistry and physics laboratory, beginning with grade 10. On average, there are 12 students (half of them are female) in the class.

Class C is part of a secondary school which extends from grade 5 to grade 12. In this class, there is particular emphasis on sciences (higher amount of lessons in biology, chemistry and physics including laboratory work). There are no particularities regarding the socioeconomic

1 In Austria, almost three quarters of teachers are female (BMBF, 2015).
background of the students of Class C. On average, there are 23 students\(^2\) (approximately 40% of them are female) in the class.

As already mentioned in the introduction, implementing IBL requires both experience and expertise. To support teachers in gaining both, we decided to accompany the implementation of three IBL units in the framework of a LS. In the following section, we will briefly outline the three IBL units and the adapted process of LS as well. Moreover, the methods of data collection and data analysis are described.

**The IBL units**

To talk about the teachers’ expectations regarding the study, a preliminary meeting took place in February 2017. In the course of this meeting, the teachers expressed four specific demands they put on the IBL units. Supplementing these demands with aspects from relevant literature resulted in Table 1.

**Table 1. Demands on the planned IBL units**

</tbody>
</table>

Considering these aspects, we decided to implement IBL units at Level 1. In collaboration with the teachers, three topics of the curriculum were selected to be subject of the LS (see Table 2). The units took place in the period from March to November 2017 in the aforementioned secondary chemistry classes. To realise the units in a resource saving manner, well-known and proven experiments provided the basis for planning the units. The 5E model (Bybee, 2006) – a constructivist instructional model – was already known by the teachers and served to structure the units. To address both hands-on and minds-on activities, the students had to work on various investigation tasks in small groups. Table 3 schematically shows the structural framework of the units.

The Lesson Study (LS)

The three IBL units were investigated in the framework of a LS. Following Stepanek et al. (2007), the process of LS was divided in several steps. To meet the specific conditions of the present study, some adaptions of their procedure seemed to be appropriate (see Figure 2).

In step 1, the objectives for the unit were defined and the question the students had to work on was formulated collaboratively (see Table 2). Then, the unit was planned and structured (step 2) and appropriate material was designed and prepared (step 3). At this point, the teachers had the chance to slightly adapt both the structure and the material to the prevailing conditions in their own classes. In the next step, the pre-structured units were implemented by the teachers accordingly and observed by the researcher (step 4). After each teacher had applied the unit in her own class, they met with the researcher (most of time jointly, rarely individually\(^3\)) to debrief and reflect on the unit (step 5). In this meeting, individual impressions and experiences were shared. The teachers reflected on the used structure and strategies and discussed how far the defined objectives were reached. Results from this step were considered when planning the next unit. Overall, this cycle was realised for three times.

\(^3\) Occasionally, it was not possible to organise a joint meeting shortly after the teachers had implemented the unit. In these cases, the absent teacher met individually with the researcher to debrief and reflect on the unit.
Figure 2. The Lesson Study process (based on Stepanek et al., 2007)

Compared with the process given by Stepanek et al. (2007, see also Figure 1), the process of the present LS differs substantially in the following three aspects:

1. All units were implemented only once by each teacher. The findings were used to revise the units, however “re-teaching” of the units was not possible. Nevertheless, experiences and findings from already implemented units were considered when planning unit 2 and unit 3, respectively.

2. The implemented units were observed exclusively by the researcher. Hence, the meetings primarily served to share individual impressions and experiences. To inspire a collective reflection, questions, as well as specific observations were introduced by the researcher.

3. Because of the teachers’ limited time resources, they were not able to write comprehensive reflections on the units. Summaries of the results and findings were thus written by the researcher.

Clearly, the teachers’ responsibilities as researchers are reduced through these adaptions and the efficacy of the Lesson Study might be reduced consequently. Unfortunately, there is a lack of organisational framework conditions for in-service teacher education in Austria. Although the teachers participated in this LS, they neither had the possibility to reduce their teaching responsibilities nor the chance to get any support from the school administration. For these reasons, limitations regarding the effort for the LS (common observations, extensive written documentation …) were necessary.

Methods of data collection and data analysis

Within the framework of this study, data was collected in various settings and different formats. There are written records (e.g. field notes, observational protocols, instructional sheets) for all steps of the LS (see Figure 2). Additionally, all conversations during the meetings (planning and reflection of the units), as well as the teachers’ statements during the IBL units were...
audiotaped. Data from the implemented units are supplemented by video recordings as well. Moreover, audio data from a group discussion previous to the PDP are available and individual interviews subsequent to the PDP with each of the participating teachers are planned.

To answer the research questions, we strive for triangulating data from different settings. To answer research question 1 (How can teachers implement aspects of IBL in their secondary chemistry classes?), we aim to mainly use data collected during the IBL units. These data shall be supplemented by the teachers’ statements during the joint meetings as well as during the individual interviews after the PDP. To evaluate the PDP regarding the teachers’ professional growth (research question 2), a combination of data from the group discussion (pre) and from the individual interviews (post) seems appropriate. Additionally, the data from the joint meetings will be used to work on different aspects of research question 2. To analyse the data, we will use the method of qualitative content analysis following Mayring (2010). In doing so, a combination of deductive and inductive strategy is planned. Already existing models, tools and coding manuals (e.g. Bae, Hayes, Seitz, O'Connor & DiStefano, 2016; Clark & Hollingworth, 2002; Gess-Newsome, 2015; Gutierez, 2015; Puddu, 2017; Widjaja, Vale, Groves & Doig, 2017) shall be used as basis to develop appropriate coding manuals. In addition to the qualitative content analysis, the IBL units, as well as experiences in the course of the LS will be described in detail.

INSIGHTS INTO FIRST RESULTS

Experiences from the units have shown that the procedure presented in Table 3 seems to be useful to structure the IBL units. However, students need support especially in formulating a hypothesis, gathering data and drawing conclusion. The following scaffolding strategies have been proved to be helpful: offering options students can choose as their hypothesis, providing prestructured possibilities to document the data (e.g. tables, diagrams, graphs), as well as applying step-by-step instruction to analyse and interpret the data in order to finally draw conclusions. Referring to research question 2, there are several aspects which indicate some kind of professional growth. The teachers used increasingly structured approaches when planning the units. Moreover, the reflections were characterised by growing depth. To verify these impressions, the data will be analysed systematically by applying the above-mentioned methods in a next step.

ACKNOWLEDGEMENT

We are very thankful for the teachers and students cooperating in this study.

DEVELOPMENT OF A TRAINING TO PROMOTE THE ACADEMIC CONCEPT OF STRUCTURE OF MATTER

Andreas Jackowski and Stefan Rumann
University of Duisburg-Essen, Germany

Within this work, the impact of different competences on the conceptual understanding of various models of the structure of matter is evaluated. The objective of the investigation is to develop a training to promote the academic concept of structure of matter. Images are a fundamental part in chemistry education, especially in the field of structure of matter. Illustrations can be characterized according to various factors, e.g. by means of their information content. Within our project, we focus on instructional visualizations. These illustrations contain relevant information for the learning of content knowledge. Instructional visualizations can be distinguished with regard to their degree of abstraction and can be varied by the use of iconic and symbolic representation forms. Within this work, the influence of the learners’ competences in mathematic abilities and spatial sense on the conceptual understanding of models in the two representational forms is analysed. Moreover, a potential chronological order in the development of the conceptual understanding of illustrations in these two forms of representations is investigated. For this purposes, a pre-post-test with N=122 first-year chemistry undergraduates in teacher training is carried out. An additional qualitative study with a reduced number of test persons with characteristic skills is conducted to complement the quantitative data. A training to promote the understanding of the academic concept of structure of matter will be developed based on the results of these tests.

Keywords: structure of matter, instructional visualizations, undergraduates training

AIM OF THE PROJECT

The aim of this project is to develop a training to improve the conceptual understanding of structure of matter. It will be designed on basis of the learners’ requirements and preconditions, which will be captured and analysed in various tests. The main target group for the application of the training are first-year chemistry undergraduates in teacher training.

The project is divided in two phases. In the first phase, the influence of different competences of learners on the handling of illustrations with varying levels of abstraction is evaluated. Particular attention is paid on the relation between the subjects’ mathematical ability and spatial sense to their conceptual understanding of different abstraction forms.

Another aspect of the first phase is the examination whether a basic understanding of symbolic models is required to increase knowledge in an iconic domain or if both fields develop independently.

In the second phase, a training for the learners will be designed on basis of the results of the first phase. The aim of this training is to increase the conceptual understanding of models of the structure of matter in the iconic field and in the symbolic field.
THEORETICAL FRAMEWORK

The application of images plays a crucial role in education of scientific-related contents in chemistry. An adequate teaching of scientific contents is not practicable without the use of illustrations (Gilbert & Boulter, 2000).

Additionally, learning processes can be supported considerably by the combination of images and text (Mayer, 2009). According to the integrative model of text and picture comprehension by Schnitz, information from images and text can be absorbed by means of different cognitive channels (Schnitz, 2005). These cognitive paths can be used simultaneously, which further fosters the comprehension.

Therefore, students learn better from images and text than from plain text (Mayer, 2009). As a consequence, illustrations are very common within chemistry textbooks. Their form of representation varies depending on the intended use (Dickmann, et al., 2015). It is important for learners to be aware of the presented forms as well as to know how to deal properly with them. The learners must be able to identify the information of different parts of an image to capture the higher-level context (Weidenmann, 1994).

However, it is possible that illustrations are misinterpreted due to confusion with alternative types of representation. To avoid misinterpretation, a great number of competitive types of representation, each with a specific vocabulary and different features, have to be known by the learners (Schnitz, Baadte, Müller, & Rasch, 2010).

Another problem for learners working with different types of representation is the dependence of the benefits of different multimedia learning materials on the individual skills (Hoeffler, Opfermann, & Schmeck, 2013). So different types of learners need different types of multimedia learning material. The individual characteristics of learners directly influence the work with different types of visualisation.

Especially in the field of structure of matter, a variety of different forms of representation is used. The term “structure of matter” deals with the basic characteristics of structures and the origin of matter and therefore is a basic concept in chemistry.

Every chemical content knowledge is considered at three different levels, designated as the chemical triangle (Johnstone, 2000). The macroscopic level is the stage of description. It contains experiences, which are perceivable with human senses, for example the colour and the shape of an object. The submicroscopic level is the stage of explaining. It includes information about modifications on an atomic scale. This stage is used to explain the observable changes in chemical reactions and the underlying structure of matter.

It is impossible to switch directly between the macroscopic and the submicroscopic level. The contents of these levels are linked via the representational level.

The representational level stands for the different possible representations of chemical contents in form of illustrations.
Illustrations can be characterized depending on the amount of information implied, as decorative visualizations or as instructional visualizations (Niegemann, et al., 2008). Decorative visualizations only serve the purpose to be visually appealing and thus are not meant to foster the acquisition of content knowledge. In contrast, instructional visualizations contain relevant information for learning content knowledge and therefore they can support learning processes. Instructional visualizations themselves can be differentiated by their level of abstraction. A distinction can be made between purely iconic representations, purely symbolic representations, as well as hybrid forms of both (Dickmann, et al., 2015).

Iconic visualizations show a structural similarity to the real object. They are depictive representations of the reference object (Schnotz, 2005).

In comparison, symbolic representations are descriptive representations. They present their information in a condensed and conceptional way and have no similarity to the real object (Schnotz, 2005).

Additionally, there are hybrid types, containing symbolic as well as iconic attributes in various combinations.

RESEARCH QUESTIONS AND HYPOTHESES

Against the described background, the following research questions (RQ) and hypotheses (H) will be addressed in the first phase of the study:
RQ 1: Which influence has the mathematical ability to the conceptual understanding of models of structure of matter in the symbolic field?

H1: The mathematical ability is predictive for the conceptual understanding of models of structure of matter in the symbolic field.

RQ 2: Which influence has the spatial sense to the conceptual understanding of models of structure of matter in the iconic field?

H2: The spatial sense is predictive for the conceptual understanding of models of structure of matter in the iconic field.

RQ 3: Is there a chronological order in the development of different fields of understanding of models of structure of matter?

The examination of these research questions and hypotheses form the basis for the second project phase. The content of the second phase is the development, implementation and evaluation of a training to increase the conceptual understanding of models of structure of matter in the iconic and symbolic domains.

**RESEARCH DESIGN AND METHODS**

The presented study is realized in a pre-post-design with a test-sample of N = 122 first-year undergraduates in chemistry teacher training at the University of Duisburg-Essen. The subjects’ average age is 20.9 years (SD = 3.1). The sample nearly consists of an equal distribution of female and male students (♀ = 51% / ♂ = 49%).

Data is collected at the start and at the end of the first term. The pre-test has been carried out before the first lecture in order to record the prior knowledge at the beginning of the course. The post-test has been performed at the end of the lecture period in order to determine the increase of knowledge over the first term by comparing the pre and post data.

Typical forms of representation to teach contents in the field of general chemistry are identified to develop an extensive questionnaire for the evaluation of the academic understanding of models in the field of structure of matter. The tasks vary in their level of complexity and the demand of different cognitive processes. The students have to reproduce, select, organise or integrate the given information to complete the tasks. The chemical content within the single tasks is illustrated either in iconic form or in symbolic form.

In addition to the developed test, a variety of further test instruments is used. The mathematical ability is evaluated with a math test (Kimpel & Sumfleth, 2015). A card rotation and a paper-folding-test (Ekstrom, French, Harman, & Dermen, 1976) are used to specify the subjects’ spatial imagination.

The content knowledge is determined with a chemistry knowledge test (Freyer, 2013). Moreover, a cognitive ability test (Heller & Perleth, 2000) is performed to assess the cognitive capability of the students. Additionally information about individual learner characteristics is collected as control variables. This person related data contains beside test persons’ demographic data, such as age and sex, also the self-assessment of mathematical and chemical
knowledge, as well as the students’ educational background, especially concerning chemistry education in school.

An additional qualitative study is carried out to investigate the impact of different competences on the work with different types of representation. Extreme groups in terms of spatial sense and mathematic abilities are identified from the results of the pre-test. On the one hand, subjects with a high knowledge in math, as well as a high ability of visual thinking were selected for the first extreme group. On the other hand, the subjects of the second extreme group had a low mathematical knowledge and a poor spatial imagination. These two extreme groups were chosen to ensure a maximum difference between the groups. A number of N=15 subjects from these extreme groups are selected and take part in the additional qualitative study. Their age ranged from 18 to 30 years (M = 21.27, SD = 4.2). 60% of the subjects were female, 40% were male. The students perform different tasks in the field of structure of matter by application of the thinking aloud method. The subjects are encouraged to express all their thoughts and the intentions loudly. A smart pen is used to capture the progress of task completion in form of spoken and written words. The smart pen records the written assignment as well as the subjects’ statements, which can be linked and shown, even if part of the written words were crossed out at a later time.

**INITIAL RESULTS**

The reliability of the study results is investigated for all performed tests. This examination points out a satisfactory to very good reliability for all test instruments. The test instruments and the results of the reliability analysis are shown in Table 5.

The dimensional analysis illustrates that a two-dimensional model has to be preferred. The difference between the one-dimensional and the two-dimensional model is highly significant ($\chi^2 = 9.50, p < 0.001$). Hence, the academic understanding of structure of matter can be separated into an iconic and a symbolic part.

During the first term, the students’ knowledge in the field structure of matter increases significantly in the iconic part as well as in the symbolic part.

The growth of iconic understanding during the first term was significant ($p=.016$) with a medium effect ($d = 0.37$). The increase of knowledge in the symbolic field pointed out a high significance ($p=.001$) with a large effect ($d= 0.64$).

The initial results of the pre-test suggest an influence of specific learner competences on the understanding of illustrations with different levels of abstraction.

Students with a high mathematical knowledge tend to achieve better results in the symbolic understanding tasks, while students with a good ability of spatial imagination show better results in the iconic part.

**OUTLOOK**

An additional qualitative study has been performed to point out whether the learners’ abilities have an influence on the way they handle different illustrations. Therefore, a reduced sample of students in extreme groups in terms of spatial sense and mathematic abilities have been selected from the results of the pre-test. The subjects performed different tasks in the field of structure of matter using a smart pen to capture the process of task completion.

The collected data will be analysed to point out differences in task execution of students with varying skills in math and spatial imagination.

Moreover, the analysis of the post-test data will be completed, so the results of all study results are available as basis to develop an intervention training for the students.
All study results from pre- and post-test, as well as from the additional qualitative study will be considered in the design of the training, to provide an optimal support for students in the academic understanding of models in the symbolic and iconic field of structure of matter.

Within the training, different multimedia elements, such as animations and three-dimensional interactive illustrations will be provided to give the students the best possible access to the chemical contents in the field of structure of matter. The influence of usage of the training on the academic understanding of structure of matter will be evaluated.
