4 **15 Abstract**

5  
6 16 *Arabidopsis thaliana* cyclic nucleotide-gated ion channel gene 4 (*AtCNGC4*) loss-of-function  
7  
8  
9 17 mutant *dnd2* exhibits elevated accumulation of salicylic acid (SA), dwarfed morphology,  
10  
11 18 reduced hypersensitive response (HR), altered disease resistance and spontaneous lesions on  
12  
13  
14 19 plant leaves. An orthologous barley mutant, *nec1*, has been reported to over-accumulate indole-  
15  
16 20 3-acetic acid (IAA) and to exhibit changes in stomatal regulation in response to exogenous  
17  
18  
19 21 auxin. Here we show that the *Arabidopsis dnd2* over-accumulates both IAA and abscisic acid  
20  
21 22 (ABA) and displays related phenotypic and physiological changes, such as, reduced stomatal  
22  
23 23 size, higher stomatal density and stomatal index. *dnd2* showed increased salt tolerance in root  
24  
25  
26 24 growth assay and significantly reduced stomatal conductance, while maintaining near wt reaction  
27  
28  
29 25 in stomatal conductance upon external application of ABA, and probably consequently increased  
30  
31 26 drought stress tolerance. Introduction of both *sid2-1* and *fmo1* into *dnd2* background resulting in  
32  
33 27 removal of SA did not alter stomatal conductance. Hence, the closed stomata of *dnd2* is probably  
34  
35  
36 28 a result of increased ABA levels and not increased SA levels. The triple *dnd2sid2abi1-1* mutant  
37  
38 29 exhibited intermediate stomatal conductance compared to *dnd2* and *abi1-1* (ABA insensitive,  
39  
40  
41 30 open stomata), while the response to external ABA was as in *abi1-1* suggesting that reduced  
42  
43 31 stomatal conductance in *dnd2* is not due to impaired ABA signalling. In conclusion, *Arabidopsis*  
44  
45 32 *dnd2* mutant exhibited ABA overaccumulation and stomatal phenotypes, which may contribute  
46  
47  
48 33 to the observed improvement in drought stress resistance. Thus, *Arabidopsis dnd2* mutant may  
49  
50  
51 34 serve as a model for studying crosstalk between biotic and abiotic stress and hormonal response  
52  
53 35 in plants.

1  
2  
3  
4 **39 1. Introduction**

5  
6 40 Plant lesion mimic mutants (LMM) are essential tools for understanding mechanisms of  
7  
8  
9 41 the hypersensitive response (HR) and plant disease resistance (Bruggeman et al., 2015; Lorrain  
10  
11 42 et al., 2003). The link between plant disease resistance and hormonal response and abiotic stress  
12  
13 43 tolerance is becoming increasingly established (Andersen et al., 2018; Kazan and Manners,  
14  
15 44 2009; Moeder et al., 2010). Arabidopsis *dnd2* and *hlm1* mutants have mutations in the *AtCNGC4*  
16  
17 45 gene leading to the disruption of *cyclic nucleotide-gated ion channel 4* gene, which causes  
18  
19 46 multiple phenotypes including elevated accumulation of salicylic acid (SA), defective seed  
20  
21 47 development, dwarfed plant size, delayed growth and time of flowering, defective reproduction,  
22  
23 48 changed leaf shape, reduced hypersensitive response, altered disease resistance, spontaneous  
24  
25 49 lesions on plant leaves and defective programmed cell death (PCD) during pathogen attack,  
26  
27 50 while maintaining effective gene-for-gene resistance and elevated thermal tolerance (Balague et  
28  
29 51 al., 2003; Finka et al., 2012; Genger et al., 2008; Jurkowski et al., 2004; Mercier et al., 2004).  
30  
31 52 While the phenotypes of the *dnd2* mutant have been well characterized, the molecular  
32  
33 53 mechanisms that lead to them are not entirely clear, and, in addition to the already identified SA  
34  
35 54 and reactive oxygen species (ROS) pathways and suspected Ca<sup>2+</sup> signaling (Chin et al., 2013),  
36  
37 55 may include other unknown signals. Different members of CNGC gene family may have  
38  
39 56 different roles in Ca<sup>2+</sup> signaling, e.g., *CNGC5* and *CNGC6* genes apparently encode cGMP-  
40  
41 57 activated nonselective Ca<sup>2+</sup>-permeable cation channels in the plasma membrane of Arabidopsis  
42  
43 58 guard cells (Wang et al., 2013), while the Arabidopsis CNGC2 was demonstrated to mediate  
44  
45 59 Ca<sup>2+</sup> influx in mammalian HEK293T cells and in Arabidopsis leaf cells (Leng et al., 1999; Wang  
46  
47 60 et al., 2017). Recently, Arabidopsis *dnd1* was reported to have reduced auxin sensitivity,  
48  
49 61 impaired auxin signaling and reduced increase in Ca<sup>2+</sup> after treatment with exogenous auxin,  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1  
2  
3  
4 62 suggesting that CNGC2 may be involved in auxin-mediated Ca<sup>2+</sup> signaling (Chakraborty et al.,  
5  
6 63 2018). Considering that Arabidopsis CNGC2 and CNGC4 are involved in the same signaling  
7  
8 64 pathways and have been shown to form homomeric and heteromeric ion channels in plants (Chin  
9  
10 et al., 2013), similar Ca<sup>2+</sup> response in the *dnd2* mutant can be expected compared to *dnd1*.  
11  
12 65  
13  
14 66 Previously, a possible auxin phenotype of *dnd2* mutant was hypothesized (Sherman and Fromm,  
15  
16 67 2009); however, no information is available on auxin content and responses in *dnd2*. *dnd2* plants  
17  
18 68 have elevated plant disease resistance, but the mechanisms have not been discovered in detail.  
19  
20 69 Thus, it is possible that phytohormones other than SA participate in *dnd2* disease resistance.  
21  
22 70 Auxin and/or its signaling pathways may regulate plant disease resistance directly (Kazan and  
23  
24 71 Manners, 2009). Auxin could also play an indirect role by inducing changes in plant  
25  
26 72 development and altering plant and stomatal size and preventing plants from pathogen  
27  
28 73 penetration via stomata (Melotto et al., 2008; Melotto et al., 2006).  
29  
30

31  
32  
33 74 ABA is mediating many aspects of plant growth and development (Leung and Giraudat,  
34  
35 75 1998), as well as responses to variety of abiotic stresses including salt and drought stress (Cutler  
36  
37 76 et al., 2010; Finkelstein, 2013). *CNGC* genes have been shown to be induced under salinity stress  
38  
39 77 in chrysanthemum leaves and roots (Cheng et al., 2018). Recently, the wheat *TaCNGC14* gene,  
40  
41 78 which is an ortholog of the *AtCNGC2* gene, was found to be significantly upregulated during  
42  
43 79 ABA treatment (Guo et al., 2018); however, no relation between *dnd2* mutant and ABA has been  
44  
45 80 shown until now. Regulation of stomatal closure to optimize transpiration is a key step in  
46  
47 81 preventing plants from water loss. Transpiration is mediated by a turgor-driven change in volume  
48  
49 82 of the two surrounding guard cells (Yu et al., 2008). Many factors can influence the guard cell  
50  
51 83 turgor change including light, phytohormones, potassium and calcium ions, malate, NO, and  
52  
53 84 H<sub>2</sub>O<sub>2</sub> (Assmann, 2003; Nilson and Assmann, 2007; Schroeder et al., 2001; Shimazaki et al.,  
54  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1  
2  
3  
4 85 2007). Additionally, overaccumulation of ABA has been demonstrated in Arabidopsis lesion  
5  
6 86 mimic mutant *cpr22* that contains a fusion of *CNGC11* and *CNGC12* genes (Mosher et al.,  
7  
8  
9 87 2010). ABA is also known as one of the regulators of drought stress tolerance in plants (Sauter et  
10  
11 88 al., 2001). The role of ABA in pathogen defense is poorly understood, although there are some  
12  
13  
14 89 reports revealing correlation between ABA levels and resistance to pathogens (Mauch-Mani and  
15  
16 90 Mauch, 2005). ABA is also one of the players in the regulation of stomatal closure, which is part  
17  
18  
19 91 of the innate immune system against bacterial infection. In view of this, it would be of interest to  
20  
21 92 determinate auxin and ABA content of *dnd2* plants and measure stomatal characteristics, which  
22  
23  
24 93 could indirectly affect *dnd2* resistance to *Pseudomonas syringae*.

25  
26 94 The orthologous mutant in barley, *nec1* (Rostoks et al., 2006), has been shown to possess  
27  
28  
29 95 essentially the same “defense–no–death” phenotype as *dnd2/hlm1* (Keisa et al., 2011) and  
30  
31 96 provides significantly reduced disease development caused by fungal pathogens *Ramularia*  
32  
33 97 *collo-cygni* and *Fusarium culmorum* (McGrann et al., 2015). However, *nec1* also exhibits  
34  
35  
36 98 reduced stomatal conductance and aperture, altered response to exogenous auxin and increased  
37  
38 99 level of endogenous indole-3-acetic acid (Keisa et al., 2013). In this study we characterized IAA  
39  
40  
41 100 and ABA content and expression of relevant genes in Arabidopsis *dnd2* mutant, as well as  
42  
43 101 changes in its physiological responses and its drought tolerance.

## 44 45 46 102 47 48 103 **2. Material and methods**

### 49 50 104 *2.1. Arabidopsis mutants*

51  
52  
53 105 Arabidopsis mutants used in the study are described in the Table 1. Arabidopsis accession  
54  
55 106 Col-0, as well as mutants *dnd2-1* and *aba2-1* were obtained from the European Arabidopsis  
56  
57  
58 107 Stock Centre (<http://arabidopsis.info/>). Arabidopsis *fmo1*, *sid2* and *abi1-1* mutants were gifts

1  
2  
3  
4 108 from Dr. Hans Thordal-Christensen, Dr. Jean-Pierre Métraux and Dr Julian Schroeder,  
5  
6 109 respectively. Double and triple mutants were generated through crossings. Mutations were  
7  
8  
9 110 confirmed in F<sub>2</sub> and F<sub>3</sub> generations by using cleaved amplified polymorphic sequences (CAPS)  
10  
11 111 primer-based PCR for *dnd2-1*, *sid2-1*, *abi1-1*, and *aba2-1*, and PCR genotyping for *fmo1*. Primer  
12  
13  
14 112 sequences for genotyping are provided in Table 2.

## 16 113 2.2. Measurements of IAA and ABA

18  
19 114 Non-conjugated forms of IAA and ABA were extracted and determined by HPLC-UV-FLD as  
20  
21 115 described previously (Nakurte et al., 2012). Briefly, the plant material was ground in liquid  
22  
23 116 nitrogen and the samples were weighted and extracted with 100% methanol (2.5 mL g<sup>-1</sup> of fresh  
24  
25  
26 117 weight (FW)). The extract was cleared by centrifugation at 4,000 g for 10 min at room  
27  
28  
29 118 temperature. The resulting supernatant was transferred to a new tube and evaporated until the  
30  
31 119 volume decreased to less than one-tenth of the initial. The evaporated residue was dissolved in a  
32  
33 120 1% acetic acid solution (2.5 mL g<sup>-1</sup> FW) and filtered with 0.20 µm filters (Nonpyrogenic Sterile-  
34  
35  
36 121 R, Sarstedt) to remove particulate and other suspended solid matter. The filtered samples were  
37  
38 122 immediately preconcentrated by SPE using AccuBOND II ODSC18 200 mg 3 mL SPE (Agilent  
39  
40  
41 123 Technologies, Santa Clara, CA, USA). C18 SPE columns were pretreated with 2.5 mL of  
42  
43 124 methanol followed by 2.5 mL of 1M acetic acid. Samples (approximately 2.5 mL) were loaded  
44  
45  
46 125 on the cartridge, the column was washed with 2.5 mL of 1M acetic acid and methanol (2.5 mL)  
47  
48 126 was used to elute the analytes from the extraction column. The extract was evaporated till  
49  
50  
51 127 dryness and redissolved in 300 µL of the mobile phase (60% methanol and 40% of 1% acetic  
52  
53 128 acid v/v). Standards of indole- 3-acetic acid (>99%), and ABA (99%) were purchased from  
54  
55 129 Sigma-Aldrich (St. Louis, MO, USA).

1  
2  
3  
4 130 Chromatographic analysis was performed on a modular HPLC system, Agilent 1100 series  
5  
6 131 consisting of quaternary pump, autosampler, column thermostat, UV and fluorescence detectors  
7  
8  
9 132 (Agilent Technologies, Santa Clara, CA, USA). HPLC separations were achieved by using a  
10  
11 133 reverse-phase Zorbax Eclipse XDB-C8 (Agilent Technologies, Santa Clara, CA, USA) column  
12  
13  
14 134  $4.6 \times 150$  mm,  $5 \mu\text{m}$ . Column temperature was controlled at  $30^\circ\text{C}$ . Mobile phase was composed of  
15  
16 135 methanol and 1% acetic acid (60:40, v/v) in isocratic mode at a flow rate of  $1 \text{ mL min}^{-1}$ . The  
17  
18  
19 136 detection of ABA was monitored using UV detection at 270 nm and the detection of IAA was  
20  
21 137 monitored using FLD detection at 282 nm (Ex) 360 nm (Em). Injection volume was  $50 \mu\text{L}$ .  
22  
23  
24 138 Results were evaluated by a ChemStation Plus (Agilent, Santa Clara, CA, USA).

25  
26 139 Plants for the experiment were germinated in pots (Arasystem, Betatech bvba, Ghent,  
27  
28  
29 140 Belgium) filled with a mixture of half soil and half vermiculite. After seven days seedlings were  
30  
31 141 transplanted in new pots and grown for one month. For ABA content measurements during  
32  
33 142 drought stress leaf samples were collected two days after withholding water (drought stress) or  
34  
35  
36 143 from routinely watered control plants. Plants were grown in a growth chamber under long-day  
37  
38 144 (16 h day, 8 h night),  $22^\circ\text{C}$  and medium light (ca.  $150 \mu\text{mol m}^{-2} \text{ s}^{-1}$ ) growing conditions.  
39  
40  
41 145 Histochemical visualization of endogenous IAA level in Col-0 and *dnd2* plants was done using  
42  
43 146 pIAA2-GFP-GUS reporter gene system crossed into *dnd2* background according to a published  
44  
45  
46 147 protocol (Bishopp et al., 2011).

47  
48 148

### 49 50 149 *2.3. Effects of IAA, ABA and NaCl on root elongation*

51  
52  
53 150 Seeds were surface sterilized in 2.5% bleach solution and incubated at  $4^\circ\text{C}$  for three days  
54  
55 151 to synchronize the germination. Seedlings were grown on Murashige and Skoog (MS basal  
56  
57  
58 152 medium) supplemented with 0.8% agar (Murashige and Skoog, 1962). Plants were grown on  
59  
60  
61

1  
2  
3  
4 153 Petri plates in a growth chamber under long-day (16 h day, 8 h night), 22°C and medium light  
5  
6 154 (ca. 150  $\mu\text{mol m}^{-2} \text{s}^{-1}$ ). After growth in MS medium for seven days, plants were transferred to  
7  
8  
9 155 Petri plates with fresh medium containing different concentrations of IAA and ABA or 100 mM  
10  
11 156 NaCl. During the transfer dots were marked on Petri plates showing the tip of primary root. Petri  
12  
13  
14 157 plates were incubated vertically, and the increase in length of primary roots from dots  
15  
16 158 (elongation) was measured after seven days from digital images using Image J software  
17  
18  
19 159 (Schneider et al., 2012). Results are average measurements of at least 10 seedlings per treatment  
20  
21 160 from three independent experiments. Results were expressed as a percentage from untreated  
22  
23  
24 161 plant root elongation.  
25  
26 162

#### 28 163 *2.4. RNA extraction and quantitative real-time PCR*

30  
31 164 Total RNA extraction from Col-0 and *dnd2* rosette leaves, cDNA synthesis, and  
32  
33 165 quantitative real-time PCR were performed as described by (Keisa et al., 2011). A set of genes  
34  
35  
36 166 for quantitative real-time PCR was selected based on 1) involvement in indole-3-acetic acid  
37  
38 167 biosynthesis and signaling (*YUC1*, *YUC2*, *YUC6*, *TIR1*, *TAA1*, *AMII*, *CSN5*) and 2) ABA  
39  
40  
41 168 signaling (*ABII*, *ABI4*). *TIR1*-encoded protein is a receptor of auxin (Dharmasiri et al., 2005;  
42  
43 169 Kepinski and Leyser, 2005), as well as a member of SCF TIR1 ubiquitin-ligase complex  
44  
45  
46 170 involved in degradation of Aux/IAA proteins (Tan et al. 2007), while CSN5 has been shown to  
47  
48 171 modulate auxin response in COP9 signalosome (CSN) complex with SCFTIR1 (Dohmann et al.,  
49  
50 172 2008). YUCCA flavin monooxygenases encoded by different *YUC* genes are implicated in auxin  
51  
52  
53 173 biosynthesis via indole-3-pyruvic acid (IPyA) pathway (Di et al., 2016), while TRYPTOPHAN  
54  
55 174 AMINOTRANSFERASE OF ARABIDOPSIS1 (*TAA1*) has been shown to convert L-  
56  
57  
58 175 tryptophan to IPyA and AMII is involved in conversion of indole-3-acetamide (IAM) to IAA  
59

65

176 (Mano and Nemoto, 2012). *ABA INSENSITIVE1* encoding protein phosphatase 2C is a known  
177 negative regulator of ABA signaling (Gosti et al., 1999) and is itself upregulated by external  
178 ABA applications (Hoth et al., 2002). *ABI4* gene encodes an AP2 domain transcription factor  
179 (Söderman et al., 2000) which functions as a positive regulator of ABA signaling.

180 Primers used for qPCR analysis are listed in Table 2. Relative gene expression in *dnd2*  
181 was calculated using  $2^{-\Delta\Delta Ct}$  method (Livak and Schmittgen, 2001) and gene expression was  
182 normalized to the *AtACTIN2* gene, which is commonly used for normalization of gene  
183 expression data in Arabidopsis and its expression is not affected by external application of ABA  
184 (Hoth et al., 2002). Gene expression in *dnd2* was shown relative to the expression in Col-0  
185 plants. Plants for the experiment were grown as described above for quantification of IAA and  
186 ABA (section 2.2).

### 188 *2.5. Drought stress treatment*

189 Plants for the drought stress treatment were germinated in pots (Arasystem, Betatech bvba,  
190 Ghent, Belgium) filled with a mixture of half soil and half vermiculite and watered three times a  
191 week, ensuring soil saturation. After seven days seedlings were individually transplanted in new  
192 pots and irrigated with 5 ml water on day one, four and seven after transplantation. On day 14  
193 after germination drought stress was induced by withholding water for 12 days and removing  
194 baskets from plastic tray for increased water evaporation. Plants were grown in a growth  
195 chamber under long-day (16 h day, 8 h night), 22°C and medium light (ca.  $150 \mu\text{mol m}^{-2} \text{s}^{-1}$ )  
196 conditions with constant ventilation. Majority of Col-0 plants showed clear symptoms of wilting  
197 that were considered as severe drought stress. The survival rates were evaluated after five days of

1  
2  
3  
4 198 resuming watering (5 ml water per day). Two independent experiments were performed using in  
5  
6 199 total 56 *dnd2* and 56 Col-0 plants per treatment.  
7  
8

9 200

## 10 11 201 *2.6. Measurements of stomatal density, index and sizes*

12  
13  
14 202 Plants for the experiment were grown as described in section 2.5. in Arasystem pots  
15  
16 203 (Betatech bvba, Ghent, Belgium) filled with a mixture of soil and vermiculite (1:1) under normal  
17  
18 204 watering regime. Leaves from one-month old *dnd2* and Col-0 plants were used for stomatal  
19  
20 205 measurements. Stomatal sizes were determined by light microscopy. Nail polish images from  
21  
22 206 silicone rubber imprints of abaxial surfaces of rosette leaves were photographed and measured  
23  
24 207 according to Casson et al., 2009. Stomatal density and stomatal index were calculated as  
25  
26 208 described by Royer, 2001.  
27  
28  
29

30  
31 209

## 32 33 210 *2.7. Measurement of stomatal conductance*

34  
35  
36 211 *Arabidopsis* seeds were planted in soil containing 2:1 (v:v) peat : vermiculite and grown  
37  
38 212 as described by (Kollist et al., 2007). Briefly, the plants were grown in growth chambers (AR-  
39  
40 213 66LX, Percival Scientific, IA, USA and Snijders Scientific, Drogenbos, Belgium) with 12 h  
41  
42 214 photoperiod, 23 °C day, 18 °C night temperature, 150  $\mu\text{mol m}^{-2} \text{s}^{-1}$  light and 70% relative  
43  
44 215 humidity. Plants were 24-32 days old during gas exchange experiments.  
45  
46  
47

48 216 Whole-plant stomatal conductance response to exogenous ABA was measured as  
49  
50 217 described by Merilo et al. (2015) with a custom made rapid-response gas exchange measurement  
51  
52 218 device (Kollist et al., 2007). Intact plants were sprayed with 5  $\mu\text{M}$  ABA solution (distilled water,  
53  
54 219 0.012% Silwet L-77 (Duchefa), 0.05% ethanol). After spraying stomatal conductance was  
55  
56  
57 220 measured for 40 min. Due to the small size of rosette leaves stomatal conductance of *dnd2aba2-1*  
58

221 plants was not measured (Supplemental figure 1). ANOVA with Tukey unequal N HSD *post hoc*  
222 test was used to identify significant differences among Col-0 and all the mutants at  $P < 0.05$ .

### 224 3. Results and discussion

225 Plant LMMs that exhibit spontaneous cell death, changes in the hypersensitive response  
226 and disease resistance in the absence of pathogen have proved useful to unravel the mechanisms  
227 of plant disease resistance (Lorrain et al., 2003; Moeder et al., 2011). Recently, the interplay  
228 between plant hormonal signaling and disease resistance involving salicylic acid, auxin and  
229 abscisic acid (ABA) has been established in some detail (Kazan and Manners, 2009; Moeder et  
230 al., 2010). The barley mutant *nec1*, which is an orthologue of Arabidopsis *dnd2* (Rostoks et al.,  
231 2006), was found to exhibit similar disease resistance response as *dnd2* (Keisa et al., 2011),  
232 while also containing increased level of indole-3-acetic acid (IAA) and showing altered auxin  
233 response and reduced stomatal conductance (Keisa et al., 2013). In this study, the levels of free  
234 IAA and ABA in Arabidopsis *dnd2* were studied using HPLC-UV-FLD. Approximately 2.5-fold  
235 increase of IAA in shoots and 1.4-fold increase in roots was found in *dnd2* compared to Col-0  
236 (Fig. 1A). The 2.5-fold increase of IAA content in *dnd2* shoots was somewhat smaller than that  
237 found in barley *nec1*, which showed 4-fold increase of IAA in both shoots and roots. In terms of  
238 absolute quantity, IAA content in the Arabidopsis Col-0 shoots and roots was 49 and 30 ng g<sup>-1</sup>  
239 fresh weight (FW), respectively, which was comparably higher than in wt barley shoots and roots  
240 – 14 and 2.4 ng g<sup>-1</sup> FW. *dnd2* shoots and roots contained 123 and 44 ng g<sup>-1</sup> FW IAA,  
241 respectively, while barley *nec1* shoots and roots contained 60 and 10 ng g<sup>-1</sup> FW IAA,  
242 respectively (Keisa et al., 2013). Thus, orthologous *dnd2* and *nec1* mutants both showed

65

243 significant increase in auxin content compared to their respective wt plants, although the IAA  
244 content in wt plants from both species was different.

245 Under normal growth conditions *dnd2* leaves accumulated about 80-fold more ABA than  
246 Col-0 plants (98.6 vs. 1.2 ng g<sup>-1</sup> FW) (Fig. 1B). Under drought stress conditions Col-0 plants  
247 exhibited approximately 27-fold ABA induction in leaves (34 ng g<sup>-1</sup> FW), while *dnd2* plants  
248 showed smaller 1.4-fold induction of ABA in leaves (134 ng g<sup>-1</sup> FW). Nevertheless, level of  
249 ABA in *dnd2* plants under drought stress was 4-fold higher than in Col-0 (Fig. 1B). The ABA  
250 content in barley was below limit of detection in both wt and barley *nec1* mutant (Nakurte et al.,  
251 2012); therefore no comparison with *dnd2* was possible.

252 The Arabidopsis line carrying the pIAA2-GUS reporter gene was crossed with *dnd2*  
253 mutant and the resulting F<sub>2</sub> homozygous progeny was used to assay the auxin distribution in  
254 *dnd2* plants in comparison with Col-0. The pattern of auxin-inducible GUS expression indicated  
255 that the location of auxin and auxin signaling in *dnd2* was similar to Col-0, while the somewhat  
256 stronger reporter gene signal was consistent with the observed IAA increase in *dnd2* (Fig. 2).

257 To study potential causes for the observed increase in IAA and ABA content, the  
258 expression of several IAA and ABA response-linked genes were studied in *dnd2* leaves (Fig. 3).  
259 Significantly increased expression was observed for *AMI1* and *CSN5* genes, which are involved  
260 in conversion of indole-3-acetamide (IAM) to IAA (Mano and Nemoto, 2012) and in regulation  
261 of auxin responses via interaction of COP9 signalosome (CSN) complex with SCF<sup>TIR1</sup>  
262 (Dohmann et al., 2008), respectively. Thus, increased auxin content in *dnd2* may be caused by  
263 increased IAA biosynthesis through IAM pathway, while differences in auxin response may  
264 relate to activity of CSN complex or slightly decreased expression of auxin receptor *TIR1*. Of the  
265 three YUCCA flavin monooxygenase genes which have been implicated in auxin biosynthesis

1  
2  
3  
4 266 via indole-3-pyruvic acid (IPyA) pathway (Di et al., 2016), only the *YUC2* gene showed slightly  
5  
6 267 decreased expression. Increased expression of *ABI1* and *ABI4* genes, encoding protein  
7  
8  
9 268 phosphatase 2C and AP2 domain transcription factor, respectively, that are involved in ABA  
10  
11 269 signal transduction may explain the observed changes in response to exogenous ABA  
12  
13  
14 270 application. *ABI1* expression was shown to be increased by exogenous ABA treatment in  
15  
16 271 Arabidopsis by massively parallel signature sequencing (Hoth et al., 2002), while it has been  
17  
18  
19 272 shown that *ABI1* is a negative regulator of ABA signaling (Gosti et al., 1999). Thus, increased  
20  
21 273 expression of *ABI1* in *dnd2* plants may be a compensatory mechanism to reduce ABA signaling  
22  
23  
24 274 caused by higher levels of endogenous ABA. Increase of *ABI1* expression has also been  
25  
26 275 observed in another lesion mimic mutant, *cpr22* with defective cyclic nucleotide-gated ion  
27  
28  
29 276 channel genes, although, unlike *dnd2*, reduced responsiveness to ABA was observed in *cpr22*  
30  
31 277 (Mosher et al., 2010).

32  
33 278         The physiological effects of altered IAA and ABA content were studied in *dnd2* using  
34  
35  
36 279 root elongation assay and under the drought stress. ABA is a mediator for several plant adaptive  
37  
38 280 responses to abiotic stresses including drought and salinity stress (Fernando and Schroeder,  
39  
40  
41 281 2016). Arabidopsis usually shows inhibited root growth, when treated with NaCl (Xu et al.,  
42  
43 282 2008). Salt stress involves rapid and massive accumulation of ABA, which acts on endodermis  
44  
45  
46 283 and prevents root growth (Duan et al., 2013; Jia et al., 2002). The effects of exogenously applied  
47  
48 284 IAA, ABA and NaCl were studied by measuring by how much the root growth (elongation) was  
49  
50  
51 285 reduced in treated plants (Fig. 4A-C). Increasing concentrations of exogenous IAA reduced the  
52  
53 286 root growth in the *dnd2* significantly more than in Col-0 (Fig. 4A), which may be linked to  
54  
55  
56 287 already elevated level of IAA in *dnd2*. At the same time *dnd2* root growth appeared to be more  
57  
58 288 insensitive to ABA and NaCl treatment than Col-0 (Fig. 4B, C). While the simplest explanation  
59  
60  
61  
62  
63  
64  
65

1  
2  
3  
4 289 is that increase in endogenous IAA concentration in combination with exogenous application  
5  
6 290 contributes to reduced root growth in *dnd2* mutant, the crosstalk between IAA and ABA in root  
7  
8  
9 291 growth regulation may be involved (Wang et al., 2011; Xu et al., 2013). Even though different  
10  
11 292 concentrations are usually used for root growth (elongation) assays for barley and Arabidopsis,  
12  
13  
14 293 the same trend in root growth was observed in both barley and Arabidopsis by applying  
15  
16 294 increasing IAA concentration (Keisa, 2013). However, under relatively high IAA concentration  
17  
18  
19 295 Arabidopsis *dnd2* maintained sensitivity and showed increasing root shortening, while the barley  
20  
21 296 *nec1* lost sensitivity and exhibited longer roots than wt plants (Keisa, 2013). This observation  
22  
23  
24 297 may be due to the fact that increase of IAA in Arabidopsis *dnd2* was smaller than in barley *nec1*  
25  
26 298 compared to respective wt plants. In order to reach auxin homeostasis, IAA levels may need to  
27  
28  
29 299 be reduced in *nec1*; however, the process of reducing IAA levels in plants is not clearly defined.  
30  
31 300 Some of the known IAA catabolism pathways involve IAA oxidation to 2-oxindole-3-acetic acid  
32  
33 301 (oxIAA) and conjugation to amino acids or sugars (Normanly, 2010). Further studies on IAA  
34  
35  
36 302 conjugate content in barley *nec1* and Arabidopsis *dnd2* would be necessary to cover this issue, as  
37  
38 303 increased IAA level may be due to increased biosynthesis or altered catabolism which may also  
39  
40  
41 304 be affected by abiotic stress conditions (Feng et al., 2015).

42  
43 305         A common defense response to several abiotic stresses including drought, cold and salt  
44  
45 306 stress is activation of ABA signaling (Fernando and Schroeder, 2016). Considering the elevated  
46  
47  
48 307 amount of ABA in *dnd2* and differences in response to external ABA and 100 mM NaCl  
49  
50 308 between *dnd2* and Col-0 in root elongation assay (Fig. 4B, C), it was relevant to study the *dnd2*  
51  
52  
53 309 response to drought stress. The drought stress test showed that *dnd2* mutant plants survived the  
54  
55 310 drought period much better than Col-0 plants (Fig. 5). Severe drought stress using water  
56  
57  
58 311 withdrawal for 12 days resulted in wilting and drying of most of the Col-0 plants (Fig. 5A), but

312 did not significantly affect *dnd2* plants (Fig. 5B). Once the watering was resumed, over 80% of  
313 *dnd2* plants survived, while most of the Col-0 plants did not recover (recovery rate 6.5%; Fig.  
314 5C). The increased ABA content and reduced stomatal size (Fig. 6A) may explain the increased  
315 drought resistance of *dnd2* plants, although *dnd2* and Col-0 plants differ in development, which  
316 can also influence the response to drought stress. In addition, mutations in *CNGC2* and *CNGC4*  
317 genes have been shown to increase thermotolerance in Arabidopsis through accumulation of heat  
318 shock proteins (HSP) (Finka et al., 2012), which are often involved in responses to other abiotic  
319 stresses (dos Reis et al., 2012).

320         Since the level of ABA was increased in *dnd2* and the study on barley *nec1* showed  
321 reduced stomatal conductance and aperture (Keisa et al., 2013), the stomatal characteristics of  
322 *dnd2* were studied. Measurements of stomatal length and width indicated that *dnd2* has smaller  
323 stomata than Col-0 (Fig. 6A) similarly to barley *nec1* that showed reduced stomatal aperture  
324 (Keisa, 2013; Keisa et al., 2013). In addition, *dnd2* exhibited increased stomatal density per unit  
325 leaf area and increased stomatal index (Fig. 6B, C), which may represent a plant strategy to  
326 compensate for reduced stomatal size as supported by Franks and Beerling (2009). Similarly to  
327 barley *nec1*, Arabidopsis *dnd2* exhibited constitutively lower stomatal conductance (Fig. 7A),  
328 while the application of exogenous ABA resulted in even further reduction of conductance (Fig.  
329 7B). Since the stomatal conductance was already very low in *dnd2*, the relative values were used  
330 to visualize the decrease in stomatal conductance upon ABA treatment. The ABA treatment  
331 resulted in even further decrease in stomatal conductance in *dnd2*, indicating that ABA response  
332 was not impaired in *dnd2*, although the decrease in stomatal conductance was somewhat slower  
333 than in Col-0 (Fig. 7B). To determine whether *dnd2* have more closed stomata due to increased  
334 ABA levels (Fig. 1B) or due to increased SA levels (Jurkowski et al., 2004), a genetics approach

1  
2  
3  
4 335 was used to remove SA from *dnd2*. The *sid2-1* mutant is defective in the main SA biosynthesis  
5  
6 336 enzyme ISOCHORISMATE SYNTHASE1 (Nawrath and Métraux, 1999) and *fmo1* encoding  
7  
8  
9 337 FLAVIN MONOOXYGENASE1 is defective in systemic acquired resistance (SAR) and  
10  
11 338 exhibits lower level of SA (Hartmann et al., 2018; Mishina and Zeier, 2006). Removal of SA  
12  
13  
14 339 acid resulted in significantly increased rosette sizes in *dnd2sid2fmo1* plants compared to *dnd2*  
15  
16 340 plants, although they were still smaller than *sid2fmo1* plants implying deficiency in other  
17  
18  
19 341 functions (Fig. 8, Supplemental figure 1). Introduction of both *sid2-1* and *fmo1* into *dnd2* did not  
20  
21 342 alter the stomatal conductance (Fig. 7). Hence, the closed stomata of *dnd2* was likely a result of  
22  
23  
24 343 increased ABA levels and not increased SA levels. To study the interaction between ABA and  
25  
26 344 *dnd2*, independent from SA, a combination mutant was constructed: *dnd2sid2-1* (to remove SA)  
27  
28  
29 345 and *abi1-1* (a strong ABA insensitive mutant). As strong ABA insensitive mutants have very  
30  
31 346 high stomatal conductance (Merilo et al., 2013), this combination of mutations would allow to  
32  
33 347 determine, if the low stomatal conductance of *dnd2* could suppress the high stomatal  
34  
35  
36 348 conductance of *abi1-1*. Furthermore, to exclude a role for SA, the *sid2* mutation was included.  
37  
38 349 The triple *dnd2sid2-1abi1-1* mutant exhibited intermediate stomatal conductance compared to  
39  
40  
41 350 the *dnd2* and the ABA insensitive *abi1-1*, while its response to external ABA was similar to  
42  
43 351 *abi1-1* (Fig. 7). Overall the phenotype of *dnd2* is likely the result of several interacting signaling  
44  
45  
46 352 pathways including responses to auxin, ABA and SA.  
47

#### 48 353 49 50 354 **4. Conclusions**

51  
52  
53 355 In conclusion, Arabidopsis *dnd2* mutant exhibited significantly increased IAA content in  
54  
55 356 leaves and roots and ABA content in leaves. In addition to constitutively increased ABA content,  
56  
57  
58 357 *dnd2* showed increased tolerance to salinity, near wt-like reaction to exogenous application of

358 ABA, reduced stomatal conductance and probably consequently increased drought stress  
359 tolerance. Thus, *Arabidopsis dnd2* mutant may provide a useful model for studying crosstalk  
360 between biotic and abiotic stress and IAA and ABA response in plants. Further work on *dnd2* is  
361 required to substantiate the link between abiotic stress response, disease resistance and hormone  
362 signaling.

363

581 drought tolerance with improved root system and reduced stomatal density. Plant Cell 20,  
582 1134-1151.

583 Table 1. Description of Arabidopsis mutants used in the study.

Mutant	Genetic		Gene	Relevant phenotype	Reference
	background	Type of mutation			
<i>aba2-1</i>	Col-0	EMS, G to A substitution at Ser262Asn	<i>ABA2</i>	ABA deficient 2	Leon-Kloosterziel et al., 1996
<i>abi1-1</i>	Col-0 <sup>a</sup>	EMS, substitution at Gly180Asp	<i>ABI1</i>	ABA insensitive 1	Koornneef et al., 1984
<i>dnd2-1</i>	Col-0	Ethylmethane-sulfonate (EMS), G to A substitution at Trp89, premature stop codon	<i>DND2</i> or <i>HLM1</i> or <i>AtCGNC4</i>	Defense no death	Jurkowski et al., 2004
<i>fmo1</i>	Col-0	T-DNA insertion line SALK_026163	<i>FMO1</i>	Deficient in systemic acquired resistance (SAR)	Mishina and Zeier, 2006
<i>sid2-1</i>	Col-0	EMS, C to T substitution in exon 9 at Glu449, premature stop codon	<i>SID2</i>	Deficient in isochorismate synthase (salicylic acid (SA) biosynthesis)	Nawrath and Métraux, 1999

<sup>a</sup> The original *abi1-1* mutant (Koornneef et al., 1984) was in Ler background, while in this study an equivalent mutant in Col-0 background was used.

586 Table 2. Primers used for genotyping and qPCR.

## \*Contribution

LK – performed the experiments and drafted the manuscript

IN – performed HPLC analysis and drafted the appropriate section of the manuscript

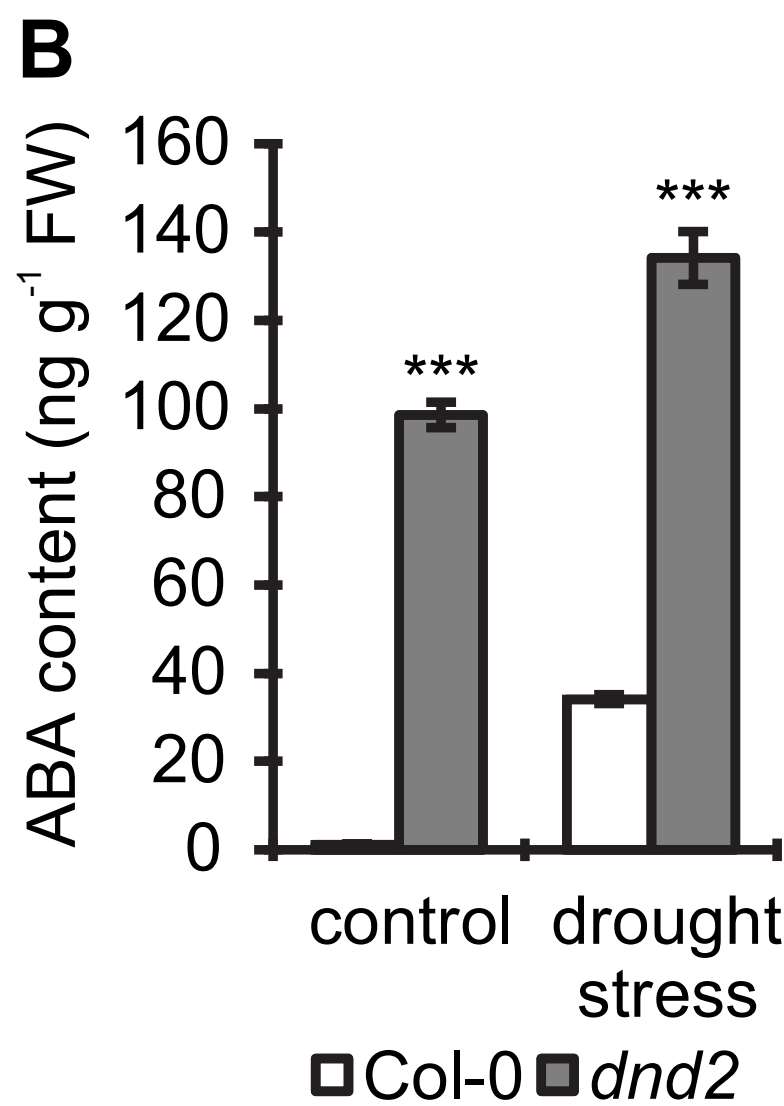

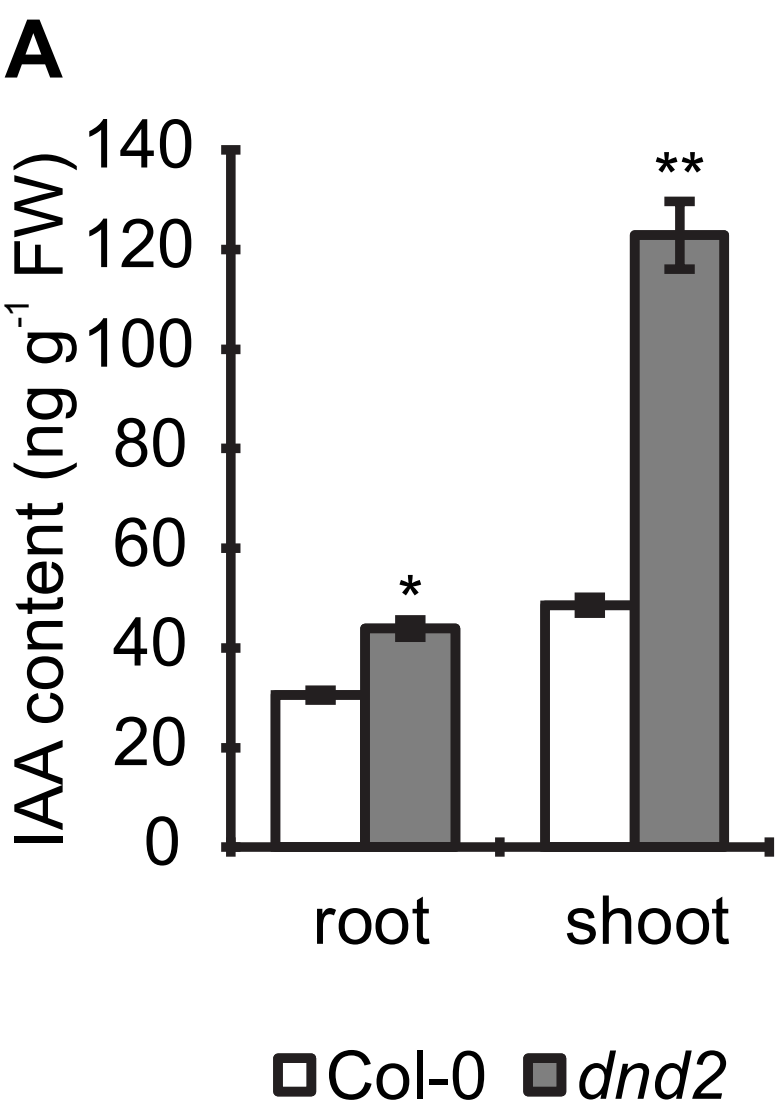

PJ – measured stomatal conductance and drafted the appropriate section of the manuscript

LKJ – performed the experiments

MB – designed the study, performed the experiments and drafted the manuscript

NR – designed the study and wrote the manuscript

All authors have reviewed the final version of the manuscript submitted for publication.

## \*Highlights

- Arabidopsis *dnd2* mutant shows increased IAA and ABA content
- Hormonal changes in *dnd2* are linked to reduced stomatal size and conductance
- Arabidopsis *dnd2* is useful to study cross-talk between abiotic and biotic stress
