- Asthma
- COPD
- Fraction of exhaled nitric oxide (FENO)
- Occupational exposure
- Smoking
- Socioeconomic status

ABSTRACT

Objective: To study occupational groups and occupational exposure in association with chronic obstructive respiratory diseases.

Methods: In early 2000s, structured interviews on chronic respiratory diseases and measurements of lung function as well as fractional expiratory nitric oxide (FENO) were performed in adult random population samples of Finland, Sweden and Estonia. Occupations were categorized according to three classification systems. Occupational exposure to vapours, gases, dusts and fumes (VGDF) was assessed by a Job-Exposure Matrix (JEM). The data from the countries were combined.

Results: COPD, smoking and occupational exposure were most common in Estonia, while asthma and occupations requiring higher educational levels in Sweden and Finland. In an adjusted regression model, non-manual workers had a three-fold risk for physician-diagnosed asthma (OR 3.18, 95%CI 1.07–9.47) compared to professionals and executives, and the risk was two-fold for healthcare & social workers (OR 2.28, 95%CI 1.14–4.59) compared to administration and sales. An increased risk for physician-diagnosed COPD was seen in manual workers, regardless of classification system, but in contrast to asthma, the risk was mostly explained by smoking and less by occupational exposure to VGDF. For FENO, no associations with occupation were observed.

Conclusions: In this multicenter study from Finland, Sweden and Estonia, COPD was consistently associated with manual occupations with high smoking prevalence, highlighting the need to control for tobacco smoking in studies on occupational associations. In contrast, asthma tended to associate with non-manual occupations requiring higher educational levels. The occupational associations with asthma were not driven by eosinophilic inflammation presented by increased FENO.

1. Introduction

Asthma and chronic obstructive pulmonary disease (COPD) cause significant burden to public healthcare. They are associated with many comorbidities, and especially COPD increases mortality [1]. They may also appear together, today commonly labelled asthma-COPD overlap. Occupational exposure may be important in the development of adult asthma or asthma symptoms [2–5]. Although smoking is the dominant cause of COPD, attention has also been given to occupational exposure to vapours, gases, dusts and fumes (VGDF) [4,6–10].

The Nordic EpiLung study, concerning the socioeconomic differences in Nordic countries, started in 2017. It gathered data from the previous Northern European epidemiological study (FinESs = Finland, Estonia and Sweden Study) on obstructive pulmonary disease [11]. In early 2000s, 1669 randomly selected subjects were interviewed and clinically examined with measurements of lung function and of fractional exhaled nitric oxide (ENO). For the present paper, the data was used to evaluate how occupation, socioeconomic status, and smoking relate to the occurrence of respiratory diseases and symptoms [12–15]. At the time of data collection, Estonia had just become independent and was socio-economically at a lower level than Finland (Helsinki) and Sweden (Orebro and Stockholm).

Assessment of occupational exposure has been diverse with postal questionnaire surveys, interviews on exposure at workplace [3] or using Job-Exposure Matrixes (JEM). The latter comprises lists of exposure to a variety of potentially harmful agents for selected occupational titles [16–18]. There is no consensus on the optimal way to evaluate occupational exposure in epidemiology [3,16]. Furthermore, the classification of occupations has also an effect on the observed associations of occupation with respiratory diagnoses and symptoms [4]. In Nordic countries, commonly used occupational classifications include Swedish Socioeconomic Classification (SEI, Socioeconomic Index), Nordic Classification of Occupations (NYK) based on the International Standard Classification of Occupations (ISCO) and Swedish Standard Classification of Occupations (SSYK).

2. Material and methods

The respiratory data originate from the FinESs Study of Finland, Estonia and Sweden with five participating research centres (Supplementary, Fig. 1). They performed similar questionnaire surveys and clinical examinations of random adult cohorts.

2.1. The study cohort (FinESs, Nordic EpiLung)

The FinESs Study was started in 1995 to study the prevalence and symptom of obstructive pulmonary disease in Finland, Estonia and Sweden [22–24]. The study began as a questionnaire survey posted to 8000 subjects in Stockholm, Orebro and Helsinki each, to 5519 subjects in Narva and to 5432 in Saaremaa. Cohorts in each research center were formed by randomization into 10-year-age cohorts. The postal questionnaire was based on the OLIN (Obstructive Lung Diseases in Northern Sweden) research project [11,25], which was developed mainly from the British Medical Research Council [26] and US Tucson [27] questionnaires.

The study continued in the early 2000s with structured interviews in 2658 randomly selected responders from the five centres. Of them 1669 were randomized for lung function testing including ENO measurements. Finally, 1498 subjects, aged 20–60 years with valid ENO measurements were included in the study cohort [21]. In 2017, the Nordic EpiLung study commenced in Nordic countries to find out how socioeconomic differences affect chronic obstructive pulmonary diseases.

2.2. Clinical examinations

Structured interview. The structured interview and clinical tests were conducted in 1997–2003. The interview included 162 questions about respiratory diseases, medication, and risk factors for asthma and COPD. The interview, based on the former postal questionnaire, with some modifications, has been used in several Nordic studies [28–31]. The questions used in the present study were the following.

Allergic rhinitis or conjunctivitis (ARC). “Have you had hay fever (allergic rhinitis) or allergic eye inflammation?”

Asthma diagnosed by a physician. “Have you been diagnosed with asthma by a physician?”

Asthma symptoms. “Have you had any symptoms of asthma during the last 12 months?”

Asthma medication. “Have you used any asthma medicines in the last 12 months?” Furthermore, those who answered “yes” were asked about certain asthma medications.

COPD diagnosed by a physician. “Have you been diagnosed with chronic bronchitis or emphysema by a physician?” Synonym for COPD at the time [32].

Chronic cough or sputum. “Have you had longstanding cough during the last year?” or “Do you usually have phlegm when coughing or do you have phlegm on your chest, which is difficult to bring up?”

Inhaled corticosteroids (ICS). “Have you used inhaled corticosteroids during the last 12 months?”

Smoking. “Do you smoke?” Subjects who answered “yes” were classified as current smokers and “no” as not current smokers.

Pack years were calculated from a question of “How many cigarettes
per day have you been smoking on an average since you started smoking?" with options of “1–4, 5–14, 14–24 or >24". Similar questions were asked about cigars and pipe smoking. Participants who were smokers or ex-smokers were also asked at what age they began or stopped smoking. The pack year values obtained from this were then divided into four categories. Further details can be found in the statistics section.

2.3. Other definitions

Occupational exposure to vapours, gases, dusts and fumes (VGDF) was used both as a value acquired by summation from 4 separate Job-Exposure Matrix (JEM) components which was used to calculate a mean value for each group (VGDF mean), and as a cut-off variable (any VGDF). When the sum of the 4 VGDF components was least 1, the participant was considered having any VGDF. The component values were obtained from the list of occupations and have been explained earlier [5,7]. Determinants of this variable are further detailed in the supplementary section (Supplementary, Fig. 2a and b).

Atopy is defined as a positive result (wheal diameter ≥ 3 mm) caused by any common allergen in the skin prick test (SPT).

FENO ≥ 25 is defined as the group having standardized FENO (ppb) value of 25 ppb or higher. This is recommended as a cut-off value for a mild inflammation in risk analyses [19].

FEV1% was acquired from the spirometry results [33].

2.4. Spirometry and FENO measurements

Different spirometers were used in the participating centres (in Helsinki SensorMedix Vmax22; in Stockholm, Ohio spirometer; in Örebro, Volugraph 2000 and Vitalograph; in Narva and Saaremaa,

Age, FEV1 (l), FEV1 (%) and FENO are median values with Interquartile range (IQR). The highest occurrence of each value is bolded.

BMI Body mass index; FEV1 Forced expiratory volume in 1 s (liters/percent); FENO Fraction of exhaled nitric oxide; MD Doctor of Medicine; VGDF Vapours, gas, dusts and fumes; COPD Chronic obstructive pulmonary disease.

* Lower amount skin prick test allergens were tested in Sweden.
Vicatest). We used only the values of forced expiratory volume in 1 s (FEV1) (Table 1), as the values of forced vital capacity (FVC) were not available from Estonia and Orebro in Sweden [34].

$F_{ENO}$ was measured according to the ERS guidelines [35]. All participating centres employed a chemiluminescent nitric oxide (NO) analyzer (Sievers 270B, Boulder, Co, USA). In each centre, a standardization method was used to obtain $F_{ENO}$ to correspond the same expiratory flow level. $F_{ENO}$ flow at 50 m/s was chosen as the standard flow [35, 36].

2.5. Skin prick tests

Skin prick tests (SPT) were used to determine atopic disposition, which was defined as having at least one positive test result (skin wheal $\geq$3 mm) caused by a common allergen (15 allergens were tested in Finland and Estonia, 10 in Sweden). The test method and allergens used have been described previously [21].

Classifications of occupation by the current title.

Three different classification systems were used and compared to the respiratory diseases and symptoms. These classifications were the Swedish Socio-economic Index (SEI) [37] Nordic Classification of Occupations (NYK) [38] and ISCO88 [39]. Their use and combinations are further explained in the Supplemental section (Supplementary, Fig. 3a–c).

2.6. Statistics

Multivariable logistic regression modelling was performed to calculate odds ratios (OR) with 95% confidence intervals (95%CI) for respiratory diseases and symptoms in association with the occupational categories according to the three classification systems (SEI, NYK and ISCO88). A separate model was estimated to calculate OR and 95%CI for any VGD. The regression models were adjusted for age, atopy, sex and pack years. Reference categories were as follows: Professionals and Executives (high) for SEI, Administration and Sales for NYK, Professionals for ISCO88 and no exposure for any VGD.

$F_{ENO}$ data consisted of both continuous and categorical variables. Kruskal–Wallis and Wilcoxon’s rank sum test were used to test the continuous variables (age, FEV1, $F_{ENO}$). For the categorical variables, the $\chi^2$ test was applied. Significance was set at $p < 0.05$ for all tests.

To calculate the pack years, a yearly smoking amount in cigarette packs was evaluated. 1–4 cigarettes per day was considered as 1/3 of a pack, 5–14 as 2/3 of pack, 15–24 as a single cigarette pack and $\geq$24 as 4/3 of a pack. One cigar was equivalent to four cigarettes and 25 g of pipe tobacco weekly 50 cigarettes per week. Smoking parameters were summed to get daily amount of cigarette packs for an average year. Smoking parameters were further explained in the Supplemental section (Supplementary, – Wallis and Wilcoxon $p < 0.001$).

To calculate the pack years, a yearly smoking amount in cigarette packs was evaluated. 1–4 cigarettes per day was considered as 1/3 of a pack, 5–14 as 2/3 of pack, 15–24 as a single cigarette pack and $\geq$24 as 4/3 of a pack. One cigar was equivalent to four cigarettes and 25 g of pipe tobacco weekly 50 cigarettes per week. Smoking parameters were summed to get daily amount of cigarette packs for an average year, which was multiplied by the years of smoking. The individual pack year values were then categorized within 4 categories: None, $< 10$ pack years, 10–$< 20$ pack years and $\geq 20$ pack years to be used in the multinomial regression analysis.

All analyses were carried out using IBM SPSS Statistics version 25 (IBM Corp, New York, NY, USA).

3. Results

Subject characteristics are given in Table 1. Allergic rhinitis, atopic disposition, asthma and asthma symptoms were much more common in Sweden and Finland than in Estonia, while COPD, smoking and occupational exposure were more common in Estonia. Allergic rhinitis was more prevalent in women.

Manual labor was more common in Estonia than in Sweden or Finland (Table 2). Finland had the highest prevalence of non-manual occupation titles.

The prevalence of current smoking in all subjects was 31% and peaked to 40–50% in manual workers in Industry (SEI), Transportation and Communications (NYK) and Plant and Machine Operators and Assembly Workers (ISCO88) (Supplementary Table 1). The amount of pack years was also higher in manual than in non-manual work. $F_{ENO}$ was significantly lower in the current smoking group. Prevalence of atopic disposition (positive SPT) did not differ between occupations.

Prevalence of asthma symptoms and asthma diagnosed by a physician were the highest in occupations classified as non-manual workers (SEI), healthcare & social work (NYK) and Legislation as well as in senior officials and managers (ISCO88) (Supplementary Table 2). COPD was most common in occupations classified as manual workers, the highest prevalence being in manual workers in Industry (SEI), Agriculture (NYK) and workers in Skilled Agricultural and Fishery (ISCO88).

Occupational exposure was more common in older age groups than in younger age groups (Supplementary Table 3). In addition, socioeconomic differences between age groups were more pronounced in men than in women (Supplementary Table 3).

In the adjusted multivariable logistic regression model (Table 3), there was a significant risk for asthma in the non-manual workers

In the adjusted multivariable logistic regression model (Table 3), there was a significant risk for asthma in the non-manual workers
4. Discussion

As several occupational classifications are used in Nordic countries, we chose to use three of them to get comprehensive analyses of the association between chronic lung diseases and occupational or socioeconomic status of the participants. The classifications differed from each other in some aspects. The Swedish Socioeconomic Index (SEI) and Nordic Yrkesklassificering (NYK) were superior for identifying associations between occupation and obstructive respiratory diseases and symptoms. The results showed that all the three classifications associated significantly with COPD in the manual workers. They also smoked more and were more exposed to vapours, gases, dusts and fumes (VGDF) at work. Smoking was by far the most important risk factor, but occupational exposure also increased slightly the risk for chronic cough and sputum production. In an earlier study of a Finnish population, COPD was associated with occupational exposure yielding an additive effect of smoking [5]. The present results are in line with that in terms of COPD and symptoms, but our study did not find any association between occupational exposure and asthma. In fact, the non-manual workers, not much exposed at work, had increased risk for asthma and asthma symptoms in two of the occupational classifications. Our results are similar with previous observations indicating the increased risk for asthma in healthcare & social workers [40]. Regarding age groups and differences in socioeconomic status between them and sexes, occupational exposure was more common in older than younger age groups and socioeconomic differences between the age groups were greater in men than in women. These both are reflective for COPD being more common in men than in women and changes in occupational structure in Nordic countries with the shift from manual occupations to non-manual during

the latter part of 20th century. Elevated \( F_{ENO} \) levels are signs of eosinophilic inflammation [19] and were associated with occupations requiring higher education and with little occupational exposure. The \( F_{ENO} \) levels, the prevalence of allergic rhinitis and of atopic disposition were the lowest in Estonia, where manual professions and occupations not requiring high education were most common. \( F_{ENO} \) levels were the lowest in Estonian noncurrent smokers. Smoking is well known to lower \( F_{ENO} \) levels [19–21], and this was seen also here in all three countries. Estonian current smokers had the lowest \( F_{ENO} \) levels but, surprisingly, the Estonians reported the lowest pack years.

In earlier studies, the east-west disparity has been apparent in increase of sensitization to common allergens and allergic diseases. Most of the reports are from children, but the difference has persisted in adult populations as well [21,41,42], and also the level and pattern of allergic sensitization among adults is different in Estonia compared with Finland and Sweden, storage sites and cockroach being the most common sensitizers in Estonia (43). In earlier studies, the east-west disparity has been apparent in more common sensitization to common allergens and allergic diseases, including asthma in westernized countries. The disparity has been associated with reduced exposure to biodiverse natural environment with rich microbiota in westernized countries [21,41,43–45]. The participants from Finland and Sweden had higher levels of \( F_{ENO} \) and had more often atopic disposition than those from Estonia. Estonians from Saaremaa and Narva were less likely to show mild eosinophilic inflammation, which here was suggested by lower \( F_{ENO} \) levels in both noncurrent and current smoking Estonians compared to Finns and Swedes. Ambient air pollution is a major global health risk, but its effect on the prevalence of allergies and asthma is controversial [46].

Our study did not indicate any association of occupational exposure to eosinophilic inflammation. Consequently, we suggest that differences in lifestyle and environmental changes (urbanization) are more important determinants than occupation explaining disposition to atopy, allergic diseases and asthma at population level. However, in specific working environments exposure to allergens or irritants may cause occupational or work-related asthma and rhinitis.

4.1. Strengths and limitations

The present material is large and includes data from three countries and five study centres. The participants represent variable socioeconomic status, lifestyle, environment and east-west location. The Estonians were recruited shortly after independency of the country. We also used the same structured interview for each center, and the cohorts were selected similarly randomized and stratified for age and sex. Therefore, the material is ideal for comparison of the risk factors of chronic respiratory diseases and symptoms.

One limitation was that the occupational exposure was not inquired from the subjects but assessed from the reported occupations with JEM. Exposure to vapours, gases, dusts or fumes was associated with occupations requiring higher education and with low \( F_{ENO} \) levels [19–21]. This was seen also here in all three countries. Estonian current smokers had the lowest \( F_{ENO} \) levels but, surprisingly, the Estonians reported the lowest pack years.

In earlier studies, the east-west disparity has been apparent in increase of sensitization to common allergens and allergic diseases. Most of the reports are from children, but the difference has persisted in adult populations as well [21,41,42], and also the level and pattern of allergic sensitization among adults is different in Estonia compared with Finland and Sweden, storage sites and cockroach being the most common sensitizers in Estonia (43). In earlier studies, the east-west disparity has been apparent in more common sensitization to common allergens and allergic diseases, including asthma in westernized countries. The disparity has been associated with reduced exposure to biodiverse natural environment with rich microbiota in westernized countries [21,41,43–45]. The participants from Finland and Sweden had higher levels of \( F_{ENO} \) and had more often atopic disposition than those from Estonia. Estonians from Saaremaa and Narva were less likely to show mild eosinophilic inflammation, which here was suggested by lower \( F_{ENO} \) levels in both noncurrent and current smoking Estonians compared to Finns and Swedes. Ambient air pollution is a major global health risk, but its effect on the prevalence of allergies and asthma is controversial [46].

Our study did not indicate any association of occupational exposure to eosinophilic inflammation. Consequently, we suggest that differences in lifestyle and environmental changes (urbanization) are more important determinants than occupation explaining disposition to atopy, allergic diseases and asthma at population level. However, in specific working environments exposure to allergens or irritants may cause occupational or work-related asthma and rhinitis.

5. Conclusions

In summary, the three occupational classifications gave similar results on associations with COPD but non-uniform ones with asthma. COPD was associated with manual labour where the smoking prevalence was high. This combination was especially seen in Estonia, where also COPD was more common. In contrast to this asthma was more common in non-manual occupations requiring higher educational levels which were more common in Finland and Sweden.

Occupational exposure to vapours, gases, dusts or fumes was associated with symptoms common in bronchitis, but not with asthma. The \( F_{ENO} \) levels were higher in Sweden and Finland than in Estonia, and tended to be higher in non-manual occupations requiring high education, but significant occupational associations were lacking. Thus, occupational associations with asthma seem at least not mainly driven by eosinophilic inflammation with elevated \( F_{ENO} \) levels, although lower \( F_{ENO} \) levels suggested on more favorable biodiversity in Estonia compared to Finland and Sweden. The results further highlight the importance of controlling for tobacco smoking in studies on occupational exposures and obstructive respiratory diseases, especially regarding COPD.

Ethics approval

The study was approved by the ethics committee of the Department of Medicine, Helsinki University Central Hospital and Tallinn Ethics Committee, Estonia and Swedish Ethical Review Authority. The subjects filled in a written informed consent form.

Consent for publication

Not applicable.

Data availability

The datasets used are not publicly available due to the laws of the study countries.

Funding

This work was supported by The Nordic Council of Ministers: NordForsk Foundation (Nordic EpiLung Study). Paul-Lassman-Klee received funding from the following sources; Foundation of the Finnish Anti-Tuberculosis Association, Finland; HES The Research Foundation of the Pulmonary Diseases, Finland; Tampere Tuberculosis Foundation, Finland; Väino and Laina Kivi Foundation, Finland. Päivi Piirilä received funding from Nummela Sanatorium Foundation. In addition the original FinEsS-project was funded by the Helsinki University Central Hospital special governmental subsidy for health sciences research project.
