Quasiminimal structures and excellence

Martin Bays, Bradd Hart, Tapani Hyttinen, Meeri Kesälä and Jonathan Kirby

Abstract

We show that the excellence axiom in the definition of Zilber’s quasiminimal excellent classes is redundant, in that it follows from the other axioms. This substantially simplifies a number of categoricity proofs.

1. Introduction

The notion of a quasiminimal excellent class was introduced by Zilber [12] in order to prove categoricity of his non-elementary theories of covers of the multiplicative group of a field (group covers) [13] and of pseudoexponential fields [11]. The excellence axiom is the most technical part, and is adapted from Shelah’s work on excellent sentences of $L_{\omega_1,\omega}$ (see [8]). Both Shelah’s and Zilber’s work on excellence is described in Baldwin’s monograph [1]. Zilber’s original proof of categoricity of group covers contained a gap, which was corrected in [3] by strengthening a hypothesis in one of the statements relating to excellence and giving a new proof. However, the proof of the categoricity of pseudoexponential fields relied on the original stronger and now unproved statement from [13]. A patch for the categoricity proof for pseudoexponential fields was recently circulated by the first and fifth authors [2].

In this paper, we show that the excellence axiom of quasiminimal excellence classes is actually redundant, in that it follows from the other axioms. This substantially simplifies the proof of categoricity of Zilber’s group covers and pseudoexponential fields, and avoids the troublesome part of the proofs where the gaps were.

In the case of first-order theories, part of Shelah’s Main Gap theorem involves reducing a condition on $n$-systems of models, akin to excellence, to the case $n = 2$, where it becomes the condition (prime models over pairs) that primary models exist over independent pairs of models [4, 9]. The main insight behind the current paper is that these arguments, suitably modified, apply also to the (non-elementary) classes of structures considered here, and moreover that the reduction can be pushed even further, to $n = 1$, where the condition becomes one of $\aleph_0$-stability over models. This reduction is performed in Proposition 6.2. In Propositions 4.2 and 5.2, we find that this $\aleph_0$-stability condition does follow from the $\aleph_0$-homogeneity over models assumed of quasiminimal excellent classes. This argument is based on a classical argument from stability theory, but the version in this paper is a modification of a corresponding argument in the non-elementary framework of finitary abstract elementary classes [5].

An uncountable structure $M$ is quasiminimal if every first-order $M$-definable subset of $M$ is countable or co-countable. In Section 7, we consider in the light of our main results the question of when a quasiminimal structure belongs to a quasiminimal excellent class.

Our main results directly answer Question 1 in [6, Section 6]. They also render Question 2 there redundant: it asks for equivalence of the excellence axiom and the conclusion of [6, Lemma 3.2], which we show both to be consequences of the other axioms, hence trivially

equivalent modulo them. The remaining questions, 3–5, concern finite-dimensional models; our techniques say little about these, and in fact it is key to the proof of our main result that we deal only with infinite-dimensional models.

2. Statement of main result

Throughout this paper, the notion of type will be quantifier-free $L$-type, denoted by $\text{tp}$.

(QM1) The pregeometry is determined by the language. That is, if $\text{tp}(\bar{a}, \bar{b}) = \text{tp}(\bar{a}', \bar{b}')$, then $a \in \text{cl}(\bar{b})$ if and only if $a' \in \text{cl}(\bar{b}')$.

(QM2) The structure $M$ is infinite-dimensional with respect to $\text{cl}$.

(QM3) (Countable closure property). If $A \subseteq M$ is finite, then $\text{cl}(A)$ is countable.

(QM4) (Uniqueness of the generic type). Suppose that $H, H' \subseteq M$ are countable closed subsets, enumerated such that $\text{tp}(H) = \text{tp}(H')$. If $a \in M \smallsetminus H$ and $a' \in M \smallsetminus H'$, then $\text{tp}(H, a) = \text{tp}(H', a')$ (with respect to the same enumerations for $H$ and $H'$).

(QM5) ($\aleph_0$-homogeneity over closed sets and the empty set). Let $H, H' \subseteq M$ be countable closed subsets or empty, enumerated such that $\text{tp}(H) = \text{tp}(H')$, and let $\bar{b}, \bar{b}'$ be finite tuples from $M$ such that $\text{tp}(H, \bar{b}) = \text{tp}(H', \bar{b}')$, and let $a \in \text{cl}(H, \bar{b})$. Then there is $a' \in M$ such that $\text{tp}(H, \bar{b}, a) = \text{tp}(H', \bar{b}', a')$.

We say $M$ is a weakly quasiminimal pregeometry structure if it satisfies all the axioms except possibly (QM2).

Note that, while in (QM5) there is a restriction that $a \in \text{cl}(H\bar{b})$, in the presence of the other axioms this restriction can be removed. In particular, we have the usual notion of $\aleph_0$-homogeneity of a structure.

Lemma 2.2. Let $M$ be a weakly quasiminimal pregeometry structure, let $\bar{b}, \bar{b}'$ be finite tuples from $M$ such that $\text{tp}(\bar{b}) = \text{tp}(\bar{b}')$, and let $\bar{a}$ be a finite tuple from $M$. Then there is $\bar{a}'$ in $M$ such that $\text{tp}(\bar{a}\bar{b}) = \text{tp}(\bar{a}'\bar{b}')$.

Proof. We may assume that $\bar{a}$ is a singleton, $a$. If $a \in \text{cl}(\bar{b})$, then apply (QM5). If not, since $\text{cl}$ is a pregeometry and using (QM1) we have $\dim M \geq \dim(\bar{a}\bar{b}) = \dim(\bar{b}) + 1 = \dim(\bar{b}') + 1$. So there is $c \in M \smallsetminus \text{cl}(\bar{b})$, and by (QM4) we can take $a'$ to be any such $c$. \qed

Given $M_1$ and $M_2$ both weakly quasiminimal pregeometry $L$-structures, we say that an $L$-embedding $\theta : M_1 \hookrightarrow M_2$ is a closed embedding if for each $A \subseteq M_1$ we have $\theta(\text{cl}_{M_1}(A)) = \text{cl}_{M_2}(\theta(A))$. In particular, $\theta(M_1)$ is closed in $M_2$ with respect to $\text{cl}_{M_2}$. We write $M_1 \subseteq_{\text{cl}} M_2$ for a closed embedding.
Given a quasiminimal pregeometry structure \( M \), let \( K^{-}(M) \) be the smallest class of \( L \)-structures that contains \( M \) and all its closed substructures and is closed under isomorphism, and let \( K(M) \) be the smallest class containing \( K^{-}(M) \) that is also closed under taking unions of chains of closed embeddings. Then both \( K^{-}(M) \) and \( K(M) \) satisfy axioms 0, I, and II of quasiminimal excellent classes from [6], and \( K(M) \) also satisfies axiom IV and, together with closed embeddings, forms an abstract elementary class. We call any class of the form \( K(M) \) a quasiminimal class.

Our main result is the following theorem.

**Theorem 2.3.** If \( K \) is a quasiminimal class, then every structure \( A \in K \) is a weakly quasiminimal pregeometry structure, and up to isomorphism there is exactly one structure in \( K \) of each cardinal dimension. In particular, \( K \) is uncountably categorical. Furthermore, \( K \) is the class of models of an \( L_{\omega_1,\omega}(Q) \) sentence.

When \( M \) satisfies an additional property called excellence, Theorem 2.3 is Zilber’s main categoricity theorem, specifically in the form from [6, Theorem 4.2 and Corollary 5.7], along with the \( L_{\omega_1,\omega}(Q) \)-definability result [6, Theorem 5.5]. We will prove Theorem 2.3 by showing in Proposition 6.2 that the specific form of the excellence property used in the categoricity proof always holds.

Assuming that proposition, we prove the main theorem.

**Proof of Theorem 2.3.** Let \( \mathfrak{M} \) be a quasiminimal pregeometry structure and \( K = K(\mathfrak{M}) \). As in [6, Theorem 2.2], all closed subsets of \( \mathfrak{M} \) of dimension \( \aleph_0 \) are isomorphic to each other, and are also quasiminimal pregeometry structures. Let \( M \) be one. Then, by Proposition 6.2, \( M \) satisfies the excellence property. Thus, by Kirby [6, Corollary 5.7 and Theorem 4.2], \( K(M) \) is a quasiminimal excellent class and has exactly one model of each cardinal dimension, and by Kirby [6, Theorem 5.5] it is the class of models of an \( L_{\omega_1,\omega}(Q) \) sentence. It remains to show that \( K = K(M) \). Let \( B \) be a basis for \( \mathfrak{M} \), and note that \( \mathfrak{M} = \bigcup \{ \text{cl}(B') \mid B' \subseteq B, |B'| = \aleph_0 \} \). Since \( K(M) \) is closed under unions of chains, it is also closed under unions of directed systems, and hence \( \mathfrak{M} \in K(M) \). Thus, \( K(\mathfrak{M}) = K(M) \).

\[ \square \]

3. **Models and types**

Let \( K \) be a quasiminimal class. We call the structures in \( K \) models. Then, by Kirby [6, Theorem 2.1], the models of dimension up to \( \aleph_1 \) are determined up to isomorphism by their dimension. Furthermore, back-and-forth arguments as in the proof of that theorem immediately give us the following characterization of types.

**Lemma 3.1.** Let \( \mathfrak{M} \) be a model of dimension at most \( \aleph_1 \), let \( M \preceq_{cl} \mathfrak{M} \) with \( M \) countable, let \( H = \emptyset \) or \( H \preceq_{cl} M \), and let \( \bar{a}, \bar{b} \) be \( n \)-tuples from \( M \). Then the following are equivalent:

(i) \( \text{tp}(\bar{a}/H) = \text{tp}(\bar{b}/H) \);
(ii) there exists \( f \in \text{Aut}(M/H) \) with \( f(\bar{a}) = \bar{b} \);
(iii) there exists \( f \in \text{Aut}(\mathfrak{M}/H) \) with \( f(\bar{a}) = \bar{b} \);
(iv) there exists \( f \in \text{Aut}(\mathfrak{M}/H) \) with \( f(\bar{a}) = \bar{b} \) and \( f(M) = M \).

Thus, Galois types coincide with syntactic types for types over the empty set and over models, and furthermore Galois types do not depend on the model in which they are calculated (we have shown this for models of dimension at most \( \aleph_1 \), but it will follow from our main result that it holds for arbitrary models).
4. Splitting of types

Definition 4.1. Let \( M \) be a model, and let \( B \subseteq M \) and \( \bar{a} \in M \). We say that \( \text{tp}(\bar{a}/B) \) splits over a finite \( A \subseteq B \) if there are finite tuples \( \bar{c} \) and \( \bar{d} \) in \( B \) with

\[
\text{tp}(\bar{c}/A) = \text{tp}(\bar{d}/A) \quad \text{but} \\
\text{tp}(\bar{c}/A \cup \bar{a}) \neq \text{tp}(\bar{d}/A \cup \bar{a}).
\]

Proposition 4.2. Let \( M \) be a model and \( M \preceq_{cl} M \) be a countable closed submodel. For each finite tuple \( \bar{a} \in M \), there is a finite \( A \subseteq M \) such that \( \text{tp}(\bar{a}/M) \) does not split over \( A \).

Proof. Replacing \( M \) with \( \text{cl}(M \bar{a}) \), we may assume \( M \) to be countable. If \( M \) has finite cardinality, then we may take \( A = M \). So assume \( |M| = 8_0 \).

We suppose that no such finite \( A \) exists and construct uncountably many types over \( M \), all realized in \( M \). This contradicts the countability of \( M \).

Enumerate \( M = \{e_n : n < \omega\} \). For each \( k < \omega \) and \( \eta : k \to 2 \), we denote by \( \eta^0 \) and \( \eta^1 \) the functions with domain \( k + 1 \) extending \( \eta \) and mapping \( k \) to 0 and 1, respectively. Given any function \( f \) and a subset \( A \) of the domain of \( f \), we write \( f|A \) for the restricted function.

We recursively construct finite sets \( A_\eta \) and automorphisms \( \sigma_\eta \in \text{Aut}(M) \) such that:

(i) \( \sigma_\eta(M) = M \);
(ii) \( \eta \subseteq \tau \) implies \( \sigma_\tau|A_\eta = \sigma_\eta|A_\eta \);
(iii) for any \( \mu : \omega \to 2 \), we have that

\[
M = \bigcup_{k<\omega} A_\mu|k,
\]

and that

\[
M = \bigcup_{k<\omega} \sigma_{\mu|k}(A_{\mu|k}).
\]

(iv) \( \text{tp}(\sigma_{\eta^0}(\bar{a})/B_\eta) \neq \text{tp}(\sigma_{\eta^1}(\bar{a})/B_\eta) \) where

\[
B_\eta = \sigma_{\eta^0}(A_{\eta^0}) \cap \sigma_{\eta^1}(A_{\eta^1}) \subseteq M.
\]

First let \( A_\emptyset = \emptyset \) and \( \sigma_\emptyset = \text{Id}_M \). Then assume that we have defined these for all \( \eta \) with domain \( \leq k \).

Since \( \text{tp}(\bar{a}/M) \) splits over \( A_\eta \) by assumption, there are finite \( \bar{c}, \bar{d} \in M \) with

\[
\text{tp}(\bar{c}/A_\eta) = \text{tp}(\bar{d}/A_\eta) \quad \text{but} \\
\text{tp}(\bar{c}/A_\eta \cup \bar{a}) \neq \text{tp}(\bar{d}/A_\eta \cup \bar{a}).
\]

Hence, there is \( f \in \text{Aut}(M/A_\eta) \) mapping \( \bar{c} \) to \( \bar{d} \) and by Lemma 3.1 we may assume that \( f(M) = M \).

Let \( \sigma_{\eta^0} = \sigma_\eta \) and \( \sigma_{\eta^1} = \sigma_\eta \circ f \). Furthermore, for \( i = 0, 1 \) let

\[
A_{\eta^{-i}} = A_\eta \cup \{e_{k+1}, \sigma_{\eta^{-i}}^{-1}(e_{k+1}), \bar{d}, \bar{c}\}.
\]

We have that

\[
\sigma_{\eta^{-1}}|A_\eta = \sigma_{\eta^{-1}}|A_\eta = \sigma_\eta|A_\eta,
\]

and that

\[
\sigma_{\eta^{-1}}(\bar{c}) = \sigma_\eta(\bar{d}) = \sigma_{\eta^{-1}}(\bar{d}).
\]

Hence, \( \sigma_\eta(A_\eta) \) and \( \sigma_\eta(\bar{d}) \) are in the set \( B_\eta \) of item (iv).
Now item (iv) must hold, since if there were \( g \in \text{Aut}(\mathfrak{M}/\sigma_\eta(A_\eta) \cup \sigma_\eta(d)) \) mapping \( \sigma_{\eta-0}(\bar{a}) \) to \( \sigma_{\eta-1}(\bar{a}) \), then the automorphism \( \sigma_{\eta-1}^{-1} \circ g \circ \sigma_{\eta-0} \) would map \( \bar{d} \) to \( \bar{c} \) and fix \( \bar{a} \) and \( A_\eta \), contradicting splitting.

Finally, we define for each \( \mu : \omega \to 2 \) a map \( f_\mu \) as the union of the restricted maps \( \sigma_{\mu|k} \) on \( A_{\mu|k} \) for \( k < \omega \). By item (ii), the map is well defined and by item (iii) it is an automorphism of \( \mathfrak{M} \). By Lemma 3.1, each \( f_\mu \) extends to an automorphism \( \pi_\mu \) of \( \mathfrak{M} \).

Now suppose that \( \mu, \nu : \omega \to 2 \) are distinct, let \( k \) be greatest such that \( \mu|k = \nu|k \), and let \( \eta = \mu|k\). Then without loss of generality, \( \mu|k+1 = \eta^{-0} \) and \( \nu|k+1 = \eta^{-1} \). Thus, \( \pi_\mu|A_{\eta^{-0}} = \sigma_{\eta^{-0}}|A_{\eta^{-0}} \), so

\[
\text{tp}(\pi_\mu(\bar{a})/\sigma_{\eta^{-0}}(A_{\eta^{-0}})) = \text{tp}(\pi_\mu(\bar{a})/\pi_\mu(A_{\eta^{-0}})) = \text{tp}(\sigma_{\eta^{-0}}(\bar{a})/\sigma_{\eta^{-0}}(A_{\eta^{-0}})).
\]

Since \( B_\eta \subseteq \sigma_{\eta^{-0}}(A_{\eta^{-0}}) \), we have \( \text{tp}(\pi_\nu(\bar{a})/B_\eta) = \text{tp}(\sigma_{\eta^{-0}}(\bar{a})/B_\eta) \).

The same argument shows that \( \text{tp}(\pi_\nu(\bar{a})/B_\eta) = \text{tp}(\sigma_{\eta^{-1}}(\bar{a})/B_\eta) \).

Thus, by item (iv), \( \text{tp}(\pi_\mu(\bar{a})/B_\eta) \neq \text{tp}(\pi_\nu(\bar{a})/B_\eta) \) and hence \( \text{tp}(\pi_\mu(\bar{a})/M) \neq \text{tp}(\pi_\nu(\bar{a})/M) \).

Thus, we have \( 2^{\aleph_0} \) different types over \( M \), all realized in \( \mathfrak{M} \), which is a contradiction. □

5. Isolation of types

**Definition 5.1.** Let \( A \) be a subset of a model \( \mathfrak{M} \) and let \( \bar{a} \in \text{cl}(A) \). We say that the \( \text{tp}(\bar{a}/A) \) is \( s \)-isolated if there is a finite subset \( A_0 \subseteq A \) such that if \( \bar{b} \in \text{cl}(A) \) and \( \text{tp}(\bar{b}/A_0) = \text{tp}(\bar{a}/A_0) \), then \( \text{tp}(\bar{b}/A) = \text{tp}(\bar{a}/A) \). In this case, we also say \( \text{tp}(\bar{a}/A) \) is \( s \)-isolated over \( A_0 \).

In Shelah’s notation, this is \( F^*_{\aleph_0} \)-isolation [9, p. 157]. In general, it does not imply isolation of a type by a single formula, at least not without expanding the language.

We show that types of tuples inside the closure of a model union a finite set are \( s \)-isolated.

**Proposition 5.2.** Let \( \mathfrak{M} \) be a model, and let \( M \preceq_{\text{cl}} \mathfrak{M} \) be a countable closed submodel. Let \( \bar{a}, \bar{b} \in \mathfrak{M} \) be finite tuples with \( \bar{b} \in \text{cl}(M\bar{a}) \). Then \( \text{tp}(\bar{b}/M \cup \bar{a}) \) is \( s \)-isolated.

To show that the hypotheses cannot be significantly weakened, consider a quasiminimal pregeometry structure \( \mathfrak{M} \) where the language contains a single equivalence relation, and \( \mathfrak{M} \) has \( \aleph_0 \) equivalence classes, all of size \( \aleph_0 \). For \( A \subseteq \mathfrak{M} \), \( \text{cl}(A) \) is the union of the equivalence classes that meet \( A \). Then if \( M \subseteq \mathfrak{M} \) is infinite but not closed, then the conclusion fails.

**Proof of Proposition 5.2.** By Proposition 4.2, there exists a finite \( A \subset M \) such that \( \text{tp}(\bar{a}\bar{b}/M) \) does not split over \( A \). We may suppose (extending \( A \)) that \( \bar{a} \) is cl-independent from \( M \) over \( A \), and that \( \bar{b} \in \text{cl}(M\bar{a}) \). We will show that \( \text{tp}(\bar{b}/M\bar{a}) \) is \( s \)-isolated over \( A\bar{a} \).

Let \( \bar{b}' \in \mathfrak{M} \) with \( \text{tp}(\bar{b}'/A\bar{a}) = \text{tp}(\bar{b}/A\bar{a}) \). Let \( \bar{d} \in M \).

**Claim 1.** There exists \( \bar{d}' \in M \) such that \( \text{tp}(\bar{b}'\bar{d}/A\bar{a}) = \text{tp}(\bar{b}\bar{d}'/A\bar{a}) \).

Assume the claim. Then \( \text{tp}(\bar{d}/A) = \text{tp}(\bar{d}'/A) \), so by non-splitting \( \text{tp}(\bar{d}/A\bar{b}) = \text{tp}(\bar{d}'/A\bar{b}) \).

Hence, \( \text{tp}(\bar{b}\bar{d}/A\bar{a}) = \text{tp}(\bar{b}\bar{d}'/A\bar{a}) = \text{tp}(\bar{b}'\bar{d}/A\bar{a}) \), and so \( \text{tp}(\bar{b}/A\bar{d}\bar{a}) = \text{tp}(\bar{b}'/A\bar{d}\bar{a}) \).

So \( \text{tp}(\bar{b}/M\bar{a}) = \text{tp}(\bar{b}'/M\bar{a}) \).

It remains to prove the claim. Say \( \bar{d} = \bar{d}_1\bar{d}_2 \) with \( \bar{d}_1 \) an independent tuple over \( \text{cl}(A\bar{a}) \) and \( \bar{d}_2 \in \text{cl}(A\bar{d}_1\bar{a}) \). By the independence of \( \bar{a} \) from \( M \) over \( A \), in fact \( \bar{d}_2 \in \text{cl}(A\bar{d}_1) \). Since \( \bar{b} \in \text{cl}(A\bar{a}) \), by (QM4) we have \( \text{tp}(\bar{b}'/A\bar{a}\bar{d}_1) = \text{tp}(\bar{b}/A\bar{d}_1\bar{a}) \).

So, by Lemma 2.2, there exists \( \bar{d}'_2 \in \mathfrak{M} \) such that \( \text{tp}(\bar{b}'\bar{d}_2'/A\bar{a}\bar{d}_1) = \text{tp}(\bar{b}\bar{d}_2'/A\bar{a}\bar{d}_1) \).

But then \( \bar{d}'_2 \in \text{cl}(A\bar{d}_1) \subseteq M \), so we conclude by setting \( \bar{d}' = \bar{d}_1\bar{d}'_2 \). □
We remark that the conclusion of Proposition 5.2, or that of Proposition 4.2, could replace $\aleph_0$-homogeneity over models in the definition of a quasiminimal pregeometry structure.

**Corollary 5.3.** Let $\mathfrak{M}$ be an $L$-structure for a countable language $L$, equipped with a pregeometry $\cl$. Suppose that $\mathfrak{M}$ satisfies (QM1)–(QM4) and is $\aleph_0$-homogeneous over $\emptyset$, that is, the conclusion of Lemma 2.2 holds.

Then the following are equivalent.

(a) The structure $\mathfrak{M}$ satisfies (QM5).

(b) If $M \preceq_{\cl} \mathfrak{M}$ is countable and $\bar{a} \in \mathfrak{M}$, then there is a finite set over which $\tp(\bar{a}/M)$ does not split.

(c) If $M \preceq_{\cl} \mathfrak{M}$ is countable and $\bar{a}, \bar{b} \in \mathfrak{M}$ with $\bar{b} \in \cl(M\bar{a})$, then $\tp(\bar{b}/M\bar{a})$ is $s$-isolated.

**Proof.** Proposition 4.2 gives (a) $\Rightarrow$ (b), and the proof of Proposition 5.2 gives (b) $\Rightarrow$ (c).

We show (c) $\Rightarrow$ (a). Let $H, \bar{b}, H', \bar{b}', a$ be as in (QM5), with $H$ and $H'$ closed in $\mathfrak{M}$ of dimension at most $\aleph_0$. Write $\sigma : H\bar{b} \to H'\bar{b}'$ for the given isomorphism. By (c) applied to $\sigma$, there exists $\bar{c} \in H$ such that $\tp(a/H\bar{b})$ is isolated by $\tp(a/\bar{c}\bar{b})$; let $\bar{c}' := \sigma(\bar{c})$. By $\aleph_0$-homogeneity over $\emptyset$, there exists $\bar{a}'$ such that $\tp(c\bar{b}a) = \tp(c'\bar{b}'a')$. Now suppose $\bar{d} \in H$, and let $\bar{d}' := \sigma(\bar{d})$. By $\aleph_0$-homogeneity over $\emptyset$, there exists $\bar{a}''$ such that $\tp(d''\bar{c}'\bar{b}'a') = \tp(d\bar{c}'\bar{b}'a')$, and by the isolation $\tp(d\bar{c}'\bar{b}'a') = \tp(d\bar{c}'\bar{b}'a')$ as required.

6. **Excellence**

Shelah’s notion of excellence says that types over certain configurations we call crowns are determined over finite sets, that is, $s$-isolated. It will be convenient to use notation for crowns that is borrowed from the notation used in simplicial complexes, in particular with the use of a boundary operator $\partial$.

Let $M$ be an infinite-dimensional model, let $B \subseteq M$ be an independent subset of cardinality $\aleph_0$, write $M_B = \cl(B)$, and let $b_1, \ldots, b_n \in B$ be distinct. We define $\partial_i M_B = \cl(B \setminus \{b_i\})$ and the $n$-crown $\partial M_B = \bigcup_{i=1}^n \partial_i M_B$. Note that $\partial M_B$ depends on $n$ and the choice of $b_1, \ldots, b_n$, but we suppress that from the notation.

**Definition 6.1.** The model $M$ is excellent if for every $n \in \mathbb{N}$ with $n \geq 2$ and every $n$-crown $\partial M_B$ in $M$, and every finite tuple $\bar{a} \in M_B$, then the type $\tp(\bar{a}/\partial M_B)$ is $s$-isolated.

Note that the definition of crown here, and consequently the definition of excellence, is a special case of the definition in [6]. However, it is exactly the special case that is used in the proofs in that paper.

**Proposition 6.2.** For each $n \geq 2$, each $n$-crown $\partial M_B$ and $\bar{a} \in M_B$ we have

(i) $\tp(\bar{a}/\partial M_B)$ is $s$-isolated and

(ii) if $\tp(\bar{c}/\partial M_B) = \tp(\bar{a}/\partial M_B)$, then there is $\pi \in \Aut(M_B/\partial M_B)$ such that $\pi(\bar{a}) = \bar{c}$.

In particular, $M$ is excellent.

**Proof.** Any two $n$-crowns in $M$ are isomorphic, so we may fix $B$ and assume $M = M_B$. We proceed by induction on $n$. The proofs for the base case $n = 2$ and the inductive step are very similar, so we do them together. Thus, we suppose that the result holds up to $n - 1$ for some $n \geq 2$. 

Fix $b_1, \ldots, b_n \in B$, and let $\bar{a} \in M$ be a finite tuple. Choose $b_0 \in B \setminus \{b_1, \ldots, b_n\}$ such that $\bar{a} \in \cl(B \setminus \{b_0\})$ and let $M' = \cl(B \setminus \{b_0\})$. Choose $\pi \in \Aut(M/\cl(B \setminus \{b_0, b_n\}))$ such that $\pi(b_n) = b_0$ and $\pi(b_0) = b_n$.

First, suppose $n = 2$. Then $\bar{a}, \pi(\bar{a}) \in \cl(\partial_1 M, b_1)$ so, by Proposition 5.2, $\tp(\bar{a}, \pi(\bar{a})/\partial_1 M, b_1)$ is $s$-isolated.

Now suppose $n > 2$. Then $\Lambda := \bigcup_{i=1}^{n-1} \partial_i M$ is an $(n-1)$-crown and $\cl(\Lambda) = M$ so, by part (i) of the induction hypothesis, $\tp(\bar{a}, \pi(\bar{a})/\Lambda)$ is $s$-isolated. Note that in this case $b_1 \in \Lambda$, so $\tp(\bar{a}, \pi(\bar{a})/b_1, A)$ is $s$-isolated. Thus (whatever $n$ is) $\tp(\bar{a}/b_1, \pi(\bar{a}), \bigcup_{i=1}^{n-1} \partial_i M)$ is $s$-isolated, say over $A_0$. Since $\pi(\bar{a}) \subseteq \partial_i M$, we have $A_0 \subseteq \partial M$.

We proceed to show that $\tp(\bar{a}/\partial M)$ is $s$-isolated over $A_0$. So suppose $\bar{c} \in M$ and $\tp(\bar{c}/A_0) = \tp(\bar{a}/A_0)$. Then we have $\tp(\bar{c}/b_1, \pi(\bar{a}), \bigcup_{i=1}^{n-1} \partial_i M) = \tp(\bar{a}/b_1, \pi(\bar{a}), \bigcup_{i=1}^{n-1} \partial_i M)$, so by Lemma 3.1 (if $n = 2$) or by part (ii) of the inductive hypothesis (if $n > 2$) there is $\sigma \in \Aut(M/b_1, \pi(\bar{a}), \bigcup_{i=1}^{n-1} \partial_i M)$ such that $\sigma(\bar{a}) = \bar{c}$. Let $\eta$ be the commutator $\eta = \sigma^{-1} \sigma^{-1} \pi$. Then $\pi(\bar{a})$ is fixed by $\sigma^{-1}$, we have $\eta(\bar{a}) = \sigma(\bar{a}) = \bar{c}$. Now $\eta$ fixes $\bigcup_{i=1}^{n-1} \cl(B \setminus \{b_0, b_i\}) = \partial M'$ pointwise; indeed, for $i = 1, \ldots, n-1$ we have $\cl(B \setminus \{b_0, b_i\}) \subseteq \cl(B \setminus \{b_i\})$, and the latter is fixed setwise by $\pi$ and pointwise by $\sigma$, while $\cl(B \setminus \{b_0, b_n\})$ is fixed pointwise by $\pi$ and setwise by $\sigma$. So $\tp(\bar{c}/\partial M') = \tp(\bar{a}/\partial M')$.

Let $B_0$ be a finite subset of $B \setminus \{b_0, b_1, \ldots, b_n\}$ such that $\bar{a} \in \cl(B_0 \cup \{b_1, \ldots, b_n\})$. Then also $\bar{c} \in \cl(B_0 \cup \{b_1, \ldots, b_n\})$, since $B_0 \cup \{b_1, \ldots, b_n\} \subseteq \bigcup_{i=1}^{n-1} \partial_i M \cup \{b_1\}$.

Since $B$ is infinite, there is a bijection $B \setminus (B_0 \cup \{b_1, \ldots, b_n\}) \to B \setminus (B_0 \cup \{b_1, \ldots, b_n\})$ extending to an isomorphism $\phi : M' \to M$ that fixes $\cl(B_0 \cup \{b_1, \ldots, b_n\})$ pointwise.

Now $\tp(\bar{c}/\partial M') = \tp(\bar{a}/\partial M')$, so $\tp(\phi(\bar{c})/\partial M') = \tp(\phi(\bar{a})/\partial M')$, but $\phi(\bar{a}) = \bar{a}$ and $\phi(\bar{c}) = \bar{c}$, and $\phi(\partial M') = \partial M$, so $\tp(\phi(\bar{c})/\partial M') = \tp(\phi(\bar{a})/\partial M')$. Thus, part (i) is proved.

For (ii), suppose that $\tp(\bar{c}/\partial M) = \tp(\bar{a}/\partial M)$, and so in particular $\tp(\bar{c}/A_0) = \tp(\bar{a}/A_0)$. Let $\eta \in \Aut(M/\partial M')$ and $\phi : M' \to M$ be as above. Since $\eta$ fixes $B$ pointwise, $\eta M' \in \Aut(M'/\partial M')$. Defining $\theta = \phi \circ (\eta | M') \circ \phi^{-1}$, we have $\theta \in \Aut(M/\partial M)$ with $\theta(\bar{a}) = \bar{c}$, which proves (ii).

7. Quasiminimal structures

An uncountable structure $M$ is quasiminimal if every first-order $M$-definable subset of $M$ is countable or co-countable. In this section, we treat the question of when a quasiminimal structure is a quasiminimal pregeometry structure. Certainly some conditions are required, for example, $\omega_1 \times \mathbb{Q}$ equipped with the lexicographic order has quantifier elimination and is quasiminimal, but the quasiminimal closure ($\cl$ defined below) does not satisfy exchange.

Based on the analyses of Zilber [10] and Pillay–Tanović [7], we are able to give simple ‘natural’ criteria that, under the assumption of quasiminimality, substitute for all the conditions of quasiminimal pregeometry structures other than (QM5). For (QM5), we have no alternative formulation in this context beyond those given in Corollary 5.3.

So let $M$ be an uncountable quasiminimal structure in a countable language. Suppose, extending the language if necessary, quantifier elimination for types realized in $M$: if $\bar{a} \in M$ and $\bar{b} \in M$ have the same quantifier-free type, then $\bar{a}$ and $\bar{b}$ have the same first-order type.

Let $p \in S_1(M)$ be the generic type, the type consisting precisely of the co-countable formulas. For $A \subseteq M$, define $\cl_p(A) := \{x \in M \mid x \not\models p_A\}$. A weak Morley sequence in $p$ over $A \subseteq M$ is a sequence $(a_1, \ldots)$ such that $a_i \in M$ and $\tp(\bar{a}_i/\cl_p(A \cup a_\leq i)) = p_{\cl_p(A \cup a_\leq i)}$, where $a_\leq i := \{a_j \mid j < i\}$.

**Proposition 7.1.** (A) The structure $(M, \cl_p)$ is a quasiminimal pregeometry structure if

(i) $p$ does not split over $\emptyset$; that is, if $\tp(\bar{b}/\emptyset) = \tp(\bar{b}'/\emptyset)$, then for all $\phi$ we have $\phi(x, \bar{b}) \in p$ if and only if $\phi(x, \bar{b}') \in p$, that is, $|\phi(M, \bar{b})| = |\phi(M, \bar{b}')|$;
(ii) there is no $M$-definable partial order on $M$, defined over finite $A \subseteq M$ say, for which weak Morley sequences in $p$ over $A$ are increasing;
(iii) $(M, \text{cl}_p)$ satisfies (QM5).

(B) Conversely, if $(M, \text{cl})$ is an uncountable quasiminimal pregeometry structure, then $M$ is a quasiminimal structure, $\text{cl} = \text{cl}_p$, and (i)–(iii) hold.

Proof. (A) By Pillay and Tanović [7, Theorem 4], (i) and (ii) imply that $\text{cl}_p$ is indeed a pregeometry. Axioms (QM1–3) are clear. Axiom (QM4) follows directly from (i).

By (QM1) and (QM4), there exists a complete type $q \in S_1(M)$ such that for $B \subseteq M$ finite and $a \in M$, we have $a \models q_B$ if and only if $a \notin \text{cl}(B)$. By (QM3) and uncountability of $M$, a formula $\phi(x, \bar{b}) \notin q$ if and only if $\phi(M, \bar{b})$ is countable. So $M$ is quasiminimal, $q = p$, and hence $\text{cl} = \text{cl}_p$.

To prove (i), suppose $\phi(M, \bar{b}) \in p$ and $\text{tp}(\bar{b}/\emptyset) = \text{tp}(\bar{b}'/\emptyset)$. Then say $a \in \phi(M, \bar{b}) \setminus \text{cl}(\bar{b})$. By (QM5), there exists $a' \in M$ such that $\text{tp}(a, \bar{b}) = \text{tp}(a', \bar{b}')$. By (QM1), $a' \notin \text{cl}(\bar{b}')$. Hence, $\phi(M, \bar{b}') \in p$.

To prove (ii), note that permutations of weak Morley sequences are weak Morley sequences, since $\text{cl}_p = \text{cl}$ is a pregeometry.

Remark 7.2. Conditions (i) and (ii) in the preceding proposition could be replaced with the following conditions of a more elementary flavour, which appear in [10]:

(i') $\aleph_0$-homogeneity over $\emptyset$;
(ii') ‘Countability is weakly definable in $M$’: if $a \in \text{cl}_p(\bar{b})$, then there exists a formula $\phi(x, \bar{y})$ over $\emptyset$ such that $M \models \phi(a, \bar{b})$ and $|\phi(M, \bar{b})| \leq \aleph_0$ for all $\bar{b}' \in M$;
(iii') $|M| > \aleph_1$ or there is no definable partial order on $M$ with a chain in $M$ of order type $\omega_1$.

Indeed, (i') and (ii') imply (i), since if $\psi(M, \bar{b})$ is countable, it is then covered by countably many $\phi_i(M, \bar{b})$ as in (ii'); by (i'), if $\text{tp}(\bar{b}') = \text{tp}(\bar{b})$, then $\psi(M, \bar{b}')$ is countable since it is covered by the countably many countable $\phi_i(M, \bar{b}')$. By Zilber [10, Lemma 3.0.3], (ii') and (iii') imply that $\text{cl}_p$ is a pregeometry and hence that weak Morley sequences in $p$ are indiscernible, and hence that (ii) holds by Pillay and Tanović [7, Theorem 4]; conversely, [7, Theorem 4] shows under the assumption of (i) and (ii) that $p$ is $\emptyset$-definable, which implies (ii'), and that $\text{cl}_p$ satisfies exchange, which implies (iii').
